

Wednesday April 11, 2018 8:30 AM-11:15 AM

Seminar 1 8:30 AM-11:15 AM

ANALYSIS OF AMBULATORY ASSESSMENT DATA IN BEHAVIORAL MEDICINE

Stephanie T. Lanza, Ph.D., Michael A. Russell, Ph.D.

The Pennsylvania State University, University Park, PA

Ambulatory assessment strategies, including daily diary designs, ecological momentary assessment and experience sampling studies, and wearable biosensors, are gaining increasing prominence in the field of behavioral medicine. The goal of this half-day workshop is to describe two extensions to the linear regression model that are particularly relevant to the analysis of ambulatory assessment data. First, multilevel models will be discussed, with a focus on their application to innovative research questions (e.g., longitudinal burst, where momentary effects are allowed to vary across days, months, or years) in behavioral medicine. Second, time-varying effect modeling, a novel statistical technique for estimating regression coefficients as complex, non-linear functions of time, will be introduced. Estimation of all models described at the workshop models will be demonstrated in SAS. Participants will be provided with a copy of all lecture notes, select computer output, and suggested reading lists for future reference.

CORRESPONDING AUTHOR: Stephanie T. Lanza, Ph.D., The Pennsylvania State University, University Park, PA; slanza@psu.edu

Seminar 2 8:30 AM-11:15 AM

MAKING DIGITAL HEALTH PARTNERSHIPS WORK 'ACROSS THE AISLE': LESSONS FROM INDUSTRY AND ACADEMIC SCIENTISTS

Melanie D. Hingle, PhD, MPH, RDN¹, Heather Patrick, PhD², Paul Sacher, RD, PhD³, Donna Spruijt-Metz, MFA, PhD⁴, Kate Wolin, ScD⁵

¹University of Arizona, Tucson, AZ; ²Carrot Inc, Redwood City, CA; ³Slimming World, London, England, United Kingdom; ⁴University of Southern California, Los Angeles, CA; ⁵Coeus Health, Chicago, IL

Partnerships between industry and academic researchers have been touted as the path leading to the production of efficacious digital health products. This type of partnership can facilitate significant uptake and sustained user engagement, provide a sturdy vehicle for dissemination, minimize duplication of efforts and possibly increase impact on health. However, barriers to these partnerships persist. Examples of these barriers include: differences in approaches to product development and improvement, commercial sensitivity to open source and release of proprietary “ingredients” vs academics’ focus on extramural funding, open source products and publishing peer-reviewed articles; and, the tension between almost daily updates in technology vs researchers’ need to “freeze” software or hardware versions to maintain study integrity; and, time and resource constraints.

The purpose of this seminar is to advance participant understanding of the science and practice of digital health from the perspectives of industry and academic experts who are engaged in development of commercial digital health products designed to change health behaviors. Participants will learn how several digital health companies use the evidence base to inform product design and testing, and how researchers can collaborate with companies to develop and test scalable and cost-effective solutions.

This seminar is divided into three parts, all of which include interactive elements: Part I, a question and answer session to introduce the concept of digital partnerships and to understand participants’ prior experiences and their questions and concerns; Part II, three brief case studies, representing common challenges to productive digital health partnerships (e.g., timelines and deliverables, evaluation and outcomes, practical considerations to forming academic-industry partnerships), and Part III, a thought experiment, in which participants will engage in small group discussions focused on ways in which academia and industry can learn from one another and align to advance the field of digital health. The seminar will conclude with a panel discussion with all workshop faculty, providing participants with an opportunity to contribute to the conversation about the future of digital health science and practice including the role of academic-industry partnerships in achieving next steps.

CORRESPONDING AUTHOR: Melanie D. Hingle, PhD, MPH, RDN, University of Arizona, Tucson, AZ; hinglem@email.arizona.edu

Seminar 3 8:30 AM-11:15 AM

R FOR BEHAVIORAL SCIENCE

Ernesto R. Ramirez, PhD, MS¹, Gina Merchant, PhD²

¹Fitabase, San Diego, CA; ²UC San Diego, La Jolla, CA

Behavioral science has been keen to use technology for data capture (e.g., social media, smartphones, and wearable devices) as well as integrate multiple streams of data to measure exposures and outcomes. However, as a whole, the field has been slow to adopt sophisticated methods to manage, process, analyze, and share the data and analyses afforded by said tools and approaches. This is in spite of the fact that open-source and collaborative tools are widely available. R, and its user-friendly workspace application RStudio (and its toolset), can help behavioral scientists become better stewards of their data, and produce more reproducible research.

This workshop will introduce the power of using R for managing, visualizing, and analyzing data with an explicit focus on reproducible research. In this workshop, we will introduce how R, RStudio, and RMarkdown can be leveraged to meet the ongoing and upcoming needs of researchers at all career levels. The workshop is designed for novice to intermediate R users. There is no expectation that attendees are currently using R to manage/analyze their data but we do expect that users come prepared to “live code” and follow along with the instructors during in-class activities.

A short introduction to R, RStudio, and RMarkdown will be given by the instructors. The remainder of the workshop will focus on example-driven instruction that will help attendees learn how to get started with R through using the RStudio application. Example data and analysis code will be made available, and attendees will be introduced to “tidy” data principles for importing, transforming, visualizing, and modeling data. Attendees will be also show how to use the RMarkdown document format and RStudio to create easily shareable and accessible documentation and analytical outputs. Attendees will have access to all workshop materials online for further review after completion of the workshop.

CORRESPONDING AUTHOR: Ernesto R. Ramirez, PhD, MS, Fitabase, San Diego, CA; ernesto@fitabase.com

Seminar 4 8:30 AM-11:15 AM

MB-EAT (MINDFULNESS-BASED EATING AWARENESS THERAPY): TREATING BINGE EATING AND OBESITY

Jean L. Kristeller, Ph.D.

Indiana State University, Terre Haute, IN

Mindfulness approaches to treating binge eating and improving weight regulation offer substantial promise. This seminar will introduce the conceptual background, research evidence from multiple NIH-funded clinical trials, and treatment components of a mindfulness meditation-based intervention used effectively with individuals with compulsive eating problems and significant weight problems. It will also frame this approach within a multi-domain model of meditation effects. Our research to date suggests that these individuals can bring compulsive over-eating under control, and that weight loss is associated directly with degree of mindfulness meditation practice. An overview of our manualized NIH-RCT will be presented, along with experiential material related to increasing patients’ experiences of improved self-regulation, and expanded portions developed for addressing weight loss. Portions of a video of participants’ experiences will be shared. Mindfulness meditation appears to act by rapidly promoting interoceptive-awareness of physical hunger and satiety in contrast to non-nutritive triggers for eating, internalization of control, and self-acceptance in individuals with compulsive eating problems associated with obesity. Experiential work will include guided meditations for the workshop participants to experience, including both general and mindful eating practice. This seminar is intended for a range of practitioners, with particular value for those working with health behavior change. However, because control around eating can be an issue for many, the approaches will be more broadly valuable.

CORRESPONDING AUTHOR: Jean L. Kristeller, Ph.D., Indiana State University, Terre Haute, IN; jkristeller@indstate.edu

Seminar 5

8:30 AM-11:15 AM

USING BAYESIAN HIERARCHICAL LINEAR MODELING TO ANALYZE WILLFUL HABITS AND THEIR MODERATORS

Yuelin Li, PhD.

Memorial Sloan Kettering Cancer Center, New York, NY

Old habits are hard to break and new habits are hard to form. Some habits are the kind of behaviors that we engage willfully and consciously – like wearing sunscreen or seek shade from the sun – while others appear to have an automatic and unconscious origin – like mindlessly overeating whenever we eat. In this seminar, we will pay special attention to the first kind of habit, the ones that we engage willfully and can be influenced by the circumstances in which they are expressed.

We will learn how to fit Bayesian hierarchical linear models, using real-world data collected in a grant (NIH R21 CA137532) on sun protection behaviors (sunscreen use, shade seeking, hat and protective clothing), assessed from 59 (37 females) first-degree relatives of patients with melanoma, accessed via IVR (Interactive Voice Response) twice daily (1 pm; 5 pm) over 14 summer days (1,304 total assessments, minimal missing data).

We will begin with a simple example with sunscreen use as the single outcome (like logistic regression, which should be familiar to you). We then move to a slightly more complex model (two behaviors, e.g., sunscreen & hat) to examine interactions. And then we move to a full model that includes all 4 sun protection behaviors interacting in a complex fashion under the moderating effects of gender and weather. This step-by-step approach should help attendees feel comfortable with the basic ideas before moving on to more complex examples. We then illustrate the full strengths of a Bayesian model, to address the question on why behavioral scientists should bother with a Bayesian approach when an ordinary HLM seems perfectly adequate? Simply, a Bayesian approach gives you more—important quantities not readily available in results from HLM or SAS PROC GLIMMIX. We will conclude by discussing how these analytic techniques in the specific context of sun protection behaviors can be applied generally to other areas of behavioral research, such as habits with an unconscious origin.

Learning Objectives:

1. Focus on practical analytic skills.
2. Theories explained with visual displays and plots to make them accessible to visual learners.
3. Substantive research questions, e.g.,
 - a. Habit: how much of each person's sunscreen use is attributable to habit?
 - b. Weather: how much influence from promoters, e.g., a sunny and hot day?
 - c. Moderators? Gender differences? Do women and men differ in sunscreen use when it is sunny and hot?

Do people who already use sunscreen frequently use even more on sunny and hot days, if so, by how much?
4. Learners can quickly translate these skills to their own research.

Other Recommendations:

1. Basic familiarity with R helps (e.g., logistic regression in R).
2. Consider bringing a laptop with R already installed, and also 'rstanarm' and 'rstan' packages installed.

Seminar 6

12:15 PM-3:00 PM

DESIGN SPRINTS & USABILITY TESTING: INNOVATIVE, FAST-PACED METHODS FOR CREATING USER-FRIENDLY DIGITAL HEALTH INTERVENTIONS

William Martinez, MD, MS, Lyndsay A. Nelson, PhD, Anthony Threatt, PhD, MArch

Vanderbilt University Medical Center, Nashville, TN

Health apps and web-based interventions offer novel and scalable approaches to engaging patients and improving health outcomes, however, they have delivered variable results. These mixed results have been attributed to differences in design and usability leading to varying degrees of user engagement. Health apps and web-based interventions with greater user engagement are associated with better outcomes. Involving users in the design process can improve engagement; however, many digital health interventions do not build in this critical step. Human-centered design is an approach to software development that emphasizes optimal user experience by integrating users directly into the design process and helps ensure the creation of a suitable user interface. A significant limitation of prior human-centered design approaches is the time and cost involved in relation to the rapidly evolving pace of technology. However, a recently published design method developed by Google Ventures (Alphabet, Inc.), called a Design Sprint, provides a highly efficient, five-phase, human-centered approach that utilizes design principles to rapidly understand the problem and the audience, explore creative solutions, identify and map the best ideas, prototype, and ultimately test. Usability testing ensures that health apps and web-based interventions meet users' expectations and work as intended such that users can efficiently and effectively engage with the technology. Our interactive workshop will introduce participants to Design Sprint methodology paired with mixed-methods, task-based usability testing. To illustrate the application of concepts to a real world situation, we will present a case study of a diabetes dashboard within a patient web portal that was recently developed by workshop leaders. Our interdisciplinary workshop faculty include: Dr. William Martinez, a physician and NIH-funded researcher focused on creating and testing digital health interventions for patients with diabetes; Dr. Anthony Threatt, a User-Interface Design Engineer with extensive experience designing healthcare-related apps; and Dr. Lyndsay Nelson, a behavioral health psychologist with expertise in usability evaluation methods. Participants will learn how to conduct a 5-day design sprint in order to rapidly create their own viable prototypes that can be subsequently tested. Participants will be taught a scientifically rigorous, mixed-methods approach to evaluating prototype usability to inform revisions and facilitate scholarly publication. For each of the five phases of a Design Sprint, participants will complete small group exercises to apply key concepts and receive feedback from workshop faculty. All participants will leave with the skills and resources needed to conduct a Design Sprint and apply a mixed-methods approach to usability assessment. Valuable hand-out materials outlining the process in detail and providing additional resources will be disseminated.

12:15 PM-3:00 PM

USING INTERVENTION MAPPING TO DESIGN A HEALTH EDUCATION PROGRAM TO INCREASE COLORECTAL CANCER SCREENING IN PUERTO RICO

Yolanda A. Serra- Martinez, MED/ Doctoral Student¹, Vivian Colón-López, PhD, MPH², Camille Vélez, MPH², Ileska M. Valencia-Torres, BS³, Adriana Acevedo-Montanez, MS⁴, Maria E. Fernández, Ph.D.⁵

¹University of Texas Health Science Center at Houston/ School of Public Health, Houston, TX; ²University of Puerto Rico Medical Sciences Campus & PR Comprehensive Cancer Center, San Juan, N/A, Puerto Rico; ³University of Texas Health Sciences Center at Houston Center for Health Promotion and Prevention Research, Clute, TX; ⁴University of Puerto Rico, San Juan, N/A, Puerto Rico; ⁵School of Public Health /University of Texas Health Science Center at Houston, Houston, TX

Introduction: Colorectal cancer (CRC) is a leading cause of cancer-related mortality in Puerto Rico (PR). Although largely preventable through screening and treatment of precancerous polyps, CRC incidence and mortality continues to increase in PR, while screening rates remain low.

Methods: We used Intervention Mapping (IM), a systematic framework using theory and evidence to plan and develop strategies and educational components to increase Colorectal Cancer Screening (CRCS) among Puerto Rican adults 50 years and older.

Results: We determined the CRC incidence and mortality rates in Puerto Rico using information from the PR Cancer registry and conducted a literature review to better understand behavioral and environmental factors influencing CRC in PR. We collected new data to inform the development of a logic model of the problem. We conducted seven focus groups with community to identify the community needs and resources and to identify the specific sub behaviors related to CRCS (performance objectives) and the determinants of CRCS. We then developed matrices of change objectives by crossing performance objectives and determinants. We selected two overarching.

Methods: entertainment education and behavioral journalism and developed practical applications, materials and messages containing several other methods including modeling, persuasion, information, and tailoring. We developed a tailored interactive multimedia intervention, newsletters, a patient action plan, and supplemental print materials for patients. The program also includes patient mediated provider materials to increase provider recommendation. Finally, we conducted two focus group to assess the usability, attractiveness, cultural sensitivity, and motivation generated by the components to perform the screening tests. The research team evaluated the suggestions of the participants and incorporated them into the final version of the educational components.

Conclusion: The use of Intervention Mapping for systematic planning produced a detailed coherent plan for the CRCS program. Guided by IM principles and steps, we used community level information, existing literature, theory, and new data to develop health education components that will likely influence CRCS in PR.

Seminar 8

12:15 PM-3:00 PM

HABITS OF HIGHLY SUCCESSFUL ACADEMICIANS: MAKING YOUR GRANDMOTHER (AND YOUR DEPARTMENT CHAIR) PROUD

Sarah S. Jaser, PhD, Scott C. Borinstein, MD, PhD, William B. Cutrer, MD, MEd, Joseph Gigante, MD, Jill H. Simmons, MD

Vanderbilt University Medical Center, Nashville, TN

Professional behavior is an important, but often overlooked, skill in graduate and post-graduate training. Despite being critically important for success in academia, little time is spent preparing trainees in these valuable skills. The goals of this workshop are to identify the key qualities of successful academic leaders and to help workshop participants develop techniques to improve how they are perceived by their colleagues. Using a combination of didactic, case-based, and small group learning techniques, important concepts of professionalism, communication, and time management will be addressed. These activities are designed for junior faculty and mid-career faculty to help them reach the next level in their careers. By the end of the workshop, participants will be able to use the CREDO acronym to be more effective academicians, have approaches for navigating academic politics and deciding which tasks to take on, and have an “Elevator Speech” they can use to briefly summarize their academic activities to others.

Seminar 10

3:15 PM-6:00 PM

MIXWILD: A NEW FREEWARE PROGRAM FOR MULTILEVEL STATISTICAL MODELING OF INTENSIVE LONGITUDINAL DATA

Donald Hedeker, Ph.D.¹, Genevieve F. Dunton, PhD, MPH², Eldin Dzubur, Ph.D.³

¹University of Chicago, Chicago, IL; ²University of Southern California, Los Angeles, CA; ³Cedars-Sinai Medical Center, Los Angeles, CA

Intensive longitudinal data are increasingly being obtained using modalities such as Ecological Momentary Assessment (EMA) and ambulatory sensor monitoring. In such studies, up to hundreds or thousands of observations may be obtained for each subject, and so one can characterize both the within-subject and between-subject variance, in addition to mean levels. The within-subject variance indicates how consistent/inconsistent a subject is, while the between-subject variance indicates how homogeneous/heterogeneous the population of subjects is. In terms of the between-subject effects, we might also have random intercepts and slopes to further characterize individual effects of subjects on their mean responses. The freeware software program MIXWILD was developed to allow researchers to model both the mean and variance structures in terms of covariates, and to allow the random subject effects to influence subject-level outcomes. Specifically, the 1st stage of the program estimates random subject mean (location, say intercept and slope) and variance effects which can then be used as covariates in a 2nd stage analysis of a subject-level outcome. This approach greatly extends the kinds of research questions one can address with intensive longitudinal data. For example, what factors might be related to a person's consistency/inconsistency of mood, and is a person's consistency of mood related to, say, their ability to maintain a health outcome. This workshop will begin by reviewing the statistical models that underlie the program and then illustrate program use with applications from EMA and ambulatory sensor monitoring studies.

Seminar 11

12:15 PM-6:00 PM

THE 'NUTS AND BOLTS' OF BEHAVIORAL INTERVENTION DEVELOPMENT: STUDY DESIGNS, METHODS AND FUNDING OPPORTUNITIES

Susan M. Czajkowski, Ph.D.¹, Sylvie Naar, PhD², Christine M. Hunter, PhD³, Frank Perna, Ph.D., Ed.D.⁴, Walter Dempsey, N/A⁵, Elizabeth Towner, PhD⁶, Lynda H. Powell, PhD⁷, Kenneth E. Freedland, PhD⁸, Ty Ridenour, PhD, MPE⁹

¹National Cancer Institute, NIH, Bethesda, MD; ²Florida State University, Royal Oak, MI; ³National Institutes of Health, Bethesda, MD; ⁴National Cancer Institute, Rockville, MD; ⁵Harvard University, Watertown, MA; ⁶Wayne State University, Detroit, MI; ⁷Rush University Medical Center, Chicago, IL; ⁸Washington University School of Medicine, St Louis, MO; ⁹RTI International, Research Triangle Park, NC

This seminar will provide investigators who are interested in the design and preliminary testing of health-related behavioral interventions an opportunity to (1) learn about a new framework for behavioral treatment development -- the ORBIT model (see <http://psycnet.apa.org/psycinfo/2015-03938-001/>); (2) learn about appropriate study designs and methods for early-phase behavioral intervention research, including which methods are appropriate at each phase of the behavioral intervention development process; (3) apply the ORBIT model and knowledge about relevant methodologies to their own behavioral treatment development projects; and (4) identify early-phase translational research funding opportunities and develop grant applications to support intervention development research. The format will include didactic presentations, question and answer sessions, and small group discussion in which participants will be provided with advice to help them design their own behavioral intervention development project. NIH scientists will provide information on suitable funding opportunity announcements and advice on how to develop applications for NIH support. Extramural behavioral scientists will describe their own experiences in designing behavioral intervention development studies, bringing these "lessons learned" to bear in advising seminar attendees on their individual projects. Didactic presentations will provide detailed information about methodologies and study designs most applicable to the early phases of behavioral intervention development (e.g., qualitative research, single-case designs, dose-finding studies, adaptive and fractional factorial designs, and pilot and feasibility studies), with ample time allotted for questions and discussion. In addition, experiential and small-group activities will deepen participants' knowledge of and skills needed for designing a behavioral intervention development program, allowing time for tailored advice and feedback. Participants will also be asked to submit in advance a 1–2 page synopsis (e.g., abstract, research aims, hypotheses, methods) of a behavioral intervention development project, which can be one they are considering submitting for funding, along with specific questions they may have regarding the process of behavioral intervention development. These will be discussed in small groups led by NIH staff and senior investigators, allowing participants to receive detailed feedback and advice to enhance the quality of their grant applications for designing and optimizing behavioral interventions.

Seminar 12

12:15 PM-6:00 PM

BREAKTHROUGHS IN POPULATION HEALTH AND MULTIPLE BEHAVIOR CHANGES (MHBCS): EXPANDING OUR REACH AND OUR IMPACTS

James O. Prochaska, Ph.D.¹, Leanne Mauriello, Ph.D.², Colleen A. Redding, PhD³, Andrea L. Paiva, PhD³, Janet L. Johnson, Ph.D.⁴, Janice M. Prochaska, Ph.D., MSW⁵

¹Cancer Prevention Research Center, University of Rhode Island, Kingston, RI; ²Spectrum Health System, Grand Rapids, MI 49506, MI; ³University of Rhode Island, Kingston, RI; ⁴pro-Change Behavior Systems, Inc., Wakefield, RI; ⁵Prochaska Change Consultants, Mill Valley, CA

Population Health is one of the most promising approaches to enhancing health while reducing health care costs. A key driver is the growing consensus that a small number of health risk behaviors (smoking, alcohol misuse, unhealthy eating and inadequate exercise) account for a large percentage of chronic diseases, disabilities, lost productivity, health care costs, and premature deaths. This Pre-conference combines these two forces to extend the reach and impacts of behavior medicine and population health. Eight 45-minute presentations with discussions begin with an evidence-based framework for more effective and inclusive care by complimenting 18 factors for individual patients with 18 for populations. Examples are reactive reach with individuals seeking care and proactive outreach for populations, and individual care in clinics and hospitals complemented by population care in homes, schools, and worksites. Next, results from two Randomized Population Trials (RPTs) in middle schools and high schools show interventions increasing maintenance of 4 healthy habits and reversal of 4 unhealthy habits. Then, three multi-arm RPTs compare interventions that succeeded and those that failed with populations of primary care patients, employees and parents with up to three of these four big risks. Next, examining data from across five RPTs show synergistic MHBCs that could not be predicted from treatment vs. control comparisons. An example is adolescents who change one energy balance behavior, like diet, are three times more likely to change a second behavior, like exercise, while controls are about 50% less likely to change the second behavior. Then, the first population cessation trial that compares incentives for participating in evidence-based CTIs to incentives for quitting smoking, also examines the transfer effects on MHBCs in untreated behaviors. Next, an impact equation (reach x efficacy) in a benchmarking approach for identifying MHBCs across 85 arms of different population interventions revealed small average impacts and high performing impacts that are 4 to 32 times greater. Then, the synergistic effects of decreasing three of the big four risk behaviors simultaneously increases multiple domains of well-being in a large vulnerable population. Next, an evidence-based model links the big four behaviors plus stress at individual and social levels to the biological immune system functioning. Finally, we focus on future steps with SBM and beyond.

6:30 PM-7:30 PM

A FACEBOOK-DELIVERED INTERVENTION FOR SUN PROTECTION AND SKIN SURVEILLANCE AMONG MELANOMA PATIENTS AND THEIR FAMILY MEMBERS

Elliot Coups, PhD¹, Kevin Criswell, PhD¹, Sara Frederick, MS¹, Evangelynn Murphy, MS¹, Sherry Pagoto, PhD², James Goydos, MD¹, Sharon Manne, PhD¹

¹Rutgers Cancer Institute of New Jersey, New Brunswick, NJ; ²University of Connecticut, Storrs, CT

Background: First-degree relatives (FDRs) of young onset melanoma patients (i.e., diagnosed < 40 years of age) are at elevated risk for melanoma. However, FDRs and patients do not sufficiently engage in sun protection and skin surveillance (i.e., skin self-examination and examination from a physician) behaviors. In this project, we tested the potential of a novel social media-based approach (secret Facebook groups) to address these behaviors in this population.

Methods: 48 young onset melanoma patients (*M* age = 34.5) and 40 of their family members (spouses/partners and first-degree relatives) (*M* age = 39.5) were recruited from Rutgers Cancer Institute and via the New Jersey State Cancer Registry. Using an iterative process, we conducted a series of 5 separate, Facebook groups (*n*s from 8–35 participants) that lasted from 2 (group 1) to 4 weeks (groups 2–5). We posted two messages per day that addressed skin cancer risks, protective behaviors, skin self-examinations, and physician skin examinations. For all groups, participants completed a baseline online survey regarding relevant psychosocial and behavioral factors (e.g., family support for behavior change, behavioral benefits/barriers, and behavioral intentions) as well as a semi-structured telephone interview immediately after the group. Participants in groups 2–5 also completed an online follow-up survey (same topics as the baseline survey as well as feedback regarding the Facebook group) one month later.

Results and Discussion: Interview feedback from group 1 participants suggested organizing the messages by weekly themes, expanding the group length, increasing interactivity, using personal narratives, and including “ask the doctor” posts. These changes were made for group 2, followed by further changes (triggered by participant feedback) for groups 3–5 (e.g., increasing the group size and the number of posts related to young adults). Participant engagement (assessed by the number of likes and comments per participant) was higher in groups 4 and 5 (likely in part due to their larger sizes, which triggered greater interaction among participants) compared to the earlier groups. Overall, evaluations of groups 4 and 5 were positive (all measured by averaging items using a 1–7 low to high scale): evaluation of the content, *M* = 5.98; the group helped prepare me, *M* = 5.68; social connectedness, *M* = 5.57; Facebook experience, *M* = 5.87. There was also evidence of statistically significantly increased pre-post behavioral intentions (sun protection, skin self-examination, physician skin examination) in groups 4 and 5 (*d*s = 0.41–0.54). Overall, there was evidence of feasibility of this innovative approach as well as indications of potential efficacy. The discussion will include a focus on lessons learned and next steps.

BARRIERS TO TOBACCO TREATMENT TRIAL ACCRUAL AND COMPLETION AMONG INDIVIDUALS USING TOBACCO AT CANCER DIAGNOSIS

Jamie L. Studts, PhD¹, Lauren Shelton², Christina Studts, PhD³, Michelle Punzal, BS⁴, Kristine Damron⁵, Brent J. Shelton, PhD, MS⁵, Joe Valentino, MD¹

¹University of Kentucky College of Medicine, Lexington, KY; ²University of Kentucky Markey Cancer Center, Lexington, KY; ³University of Kentucky College of Public Health, Lexington, KY; ⁴University of Kentucky College of Medicine, Russell, KY; ⁵University of Kentucky, Lexington, KY

Introduction: While there is ample evidence supporting the efficacy of pharmacologic and behavioral interventions in the treatment of nicotine dependence and tobacco use, a dearth of data exists to guide treatment recommendations and interventions in the oncology setting. Given the benefits of cessation following diagnosis, practical guidance is needed regarding tobacco treatment for the one-third of cancer survivors who continue to use tobacco. In rural, tobacco-producing regions of the country, the proportion of cancer survivors using tobacco is likely even higher. To address this clinical research gap, the investigative team developed and launched a randomized factorial trial, using the Multiphase Optimization Strategy (MOST) to screen candidate intervention components to include in a subsequent confirmatory phase trial. The candidate intervention components included pharmacotherapies, nicotine replacement strategies, and behavioral counseling.

Method: The aim of this report is to examine barriers to study accrual and participant trial completion among the consented participants to date. Patients diagnosed with a tobacco-related malignancy who were current tobacco users were invited to participate at 9 cancer care facilities throughout Kentucky. Data were drawn from accrual records, study surveys (e.g., demographics, tobacco use history), and disease and treatment records.

Results: Through 40 months of accrual, only 72 of the targeted 180 participants have been enrolled. Study records indicate that strong patient preferences for tobacco treatment approaches have hindered accrual, secondary to strong opinions regarding the pharmacotherapy component. Additionally, accrual rates have varied widely across centers, suggesting that system factors play a strong role in accrual. Sites with engaged clinician-investigators committed to integrating tobacco treatment guidelines have achieved substantially higher accrual. Of the 72 enrolled participants, 40 (56%) have completed the trial by providing data at the 6-month follow-up and one participant is currently on study. Analyses suggest that lesser nicotine dependence and greater confidence in quitting were the only demographic, disease/treatment, or tobacco use history variables associated with trial completion.

Conclusion: Despite the large proportion of eligible patients, enrolling early cancer survivors and supporting their continued participation in the trial has proven challenging, particularly in a predominantly rural and tobacco-producing region. These data suggest that investigators must account for strong patient treatment preferences, cancer care system parameters, and the need for extensive engagement efforts to support accrual and trial completion when attempting to conduct clinically-relevant research informing integration of tobacco treatment approaches in cancer care settings.

FACETS OF SPIRITUALITY AS PREDICTORS OF SLEEP QUALITY AND PSYCHOLOGICAL ADJUSTMENT ACROSS 12 WEEKS IN LUNG CANCER PATIENTS

Timothy J. Williamson, M.A., MPH¹, Annette L. Stanton, Ph.D.²¹University of California, Los Angeles, Los Angeles, CA; ²Department of Psychology, University of California, Los Angeles, Los Angeles, CA

Background: Spirituality is associated with better psychological outcomes among cancer patients, and specific facets of spirituality (i.e., meaning/peace, faith) are differentially influential for adjustment during cancer survivorship. However, these relationships are demonstrated in correlational more than longitudinal research and typically focus on psychological outcomes. This study investigates meaning/peace, faith, and their interaction as predictors of a behavioral health outcome (i.e., sleep quality) as well as psychological adjustment across 12 weeks in lung cancer patients. We also explore whether meaning-making coping strategies (i.e., coping through religion, acceptance, positive reinterpretation) and protective psychosocial factors (i.e., self-compassion, social support) predict changes in spirituality.

Method: Participants (n=82; 55% male, mean [SD] age=64.5[12.8] years) were men and women receiving medical treatment for lung cancer. Participants completed validated measures of spirituality, sleep quality, depressive symptoms, and cancer-related anxiety at study entry and at 6- and 12-week follow-up assessments. Participants also completed validated measures of self-compassion, coping strategies, and social support at study entry. First, multivariate regression were conducted in a structural modelling equation framework to assess meaning/peace, faith, and their interaction as predictors of sleep quality, depressive symptoms, and cancer-related anxiety at study entry as well as at 6- and 12-week follow-up. Next, multivariate regressions evaluated meaning-making coping strategies and protective psychosocial factors as predictors of spirituality at study entry as well as at follow-up. Missing data was addressed by using full-information maximum likelihood.

Results: Higher meaning/peace, but not faith, was correlated with better sleep quality, fewer depressive symptoms, and less anxiety at study entry (psConclusions: Consistent with research, meaning/peace was the more influential facet of spirituality in predicting favorable sleep-related and psychological adjustment. Findings also indicate self-compassion and coping through positive reinterpretation as malleable psychosocial factors that can potentially be harnessed through psychosocial interventions to bolster meaning/peace and, in turn, promote positive adjustment to cancer.

ONCOLOGY CARE PROVIDER ADHERENCE TO TOBACCO USE ASSESSMENT AND TREATMENT CLINICAL PRACTICE GUIDELINES

Sarah N. Price, B.A.¹, Jamie L. Studts, PhD², Heidi A. Hamann, PhD³¹The University of Arizona, Tucson, AZ; ²University of Kentucky College of Medicine, Lexington, KY; ³University of Arizona, Tucson, AZ

Introduction: Tobacco use after a cancer diagnosis negatively impacts health outcomes, while tobacco cessation improves symptoms, side effects, and overall prognosis. The Public Health Service and major oncology organizations have well-established guidelines for tobacco use treatment among cancer patients, including provider assessments of tobacco use at each visit. Oncology care providers (OCPs) play important roles in this process (noted as the 5As: Asking about tobacco use, Advising users to quit, Assessing willingness to quit, Assisting in quit attempts, and Arranging follow-up contact). However, many oncology care providers may not be using the “teachable moments” related to cancer diagnosis, treatment, and survivorship to provide cessation advice and assistance.

Methods: In this scoping literature review of articles from 2006–2017, we discuss: 1) frequency and quality of OCPs’ tobacco use assessments with cancer patients and survivors; 2) barriers to providing quality tobacco treatment for cancer patients; and 3) the efficacy and future of provider-level interventions to facilitate adherence to smoking cessation guidelines.

Results: Despite the importance of cessation for cancer patients and the existence of clear professional guidelines, OCPs are not adequately addressing smoking cessation with their patients. The reviewed studies indicate that while >75% assess tobacco use during an intake visit and >60% typically advise patients to quit, a substantially lower percentage recommend or arrange smoking cessation treatment or follow-up after a quit attempt. Less than 30% of OCPs report adequate training in cessation interventions.

Conclusions: Intervention trials focused on provider- and system-level change are needed to promote adherence to tobacco treatment guidelines. Attention must be given to the barriers faced by OCPs, such as limited training, when tailoring interventions for the oncologic context.

PHYSICAL HEALTH-RELATED QUALITY OF LIFE AND SPIRITUALITY IN BREAST CANCER SURVIVORS: A CROSS-LAGGED MODEL

Neha G. Goyal, PhD¹, Edward Ip, Ph.D.², John Salsman, PhD¹, Nancy E. Avis, PhD¹¹Wake Forest School of Medicine, Winston-Salem, NC; ²Wake Forest School of Medicine, Winston Salem, NC

Background/Purpose: A recent meta-analysis reported a significant positive relationship between religion/spirituality and physical well-being in cancer survivors. However, the included studies were primarily cross-sectional which prevents making inferences regarding the directionality of the relationship. This longitudinal study sought to examine the potential reciprocal relationship between physical-health related quality of life (HRQoL) and spirituality among breast cancer survivors (BCS).

Methods: BCS (N=634; M age = 55.5; 90% Caucasian) completed baseline assessments within 8 months of breast cancer diagnosis and 12 and 18 months later. Spirituality was assessed by the Functional Assessment of Chronic Illness Therapy- Spiritual Well-Being Scale (FACIT-Sp) which consists of 3 subscales: meaning, peace, and faith. Physical HRQoL was measured with the SF-36 Physical Component Summary (PCS). A cross-lagged structural equation model (SEM) was used to analyze the three-wave data to examine the reciprocal relationship between the observed variable, PCS, and the 3 subscales of the FACIT-Sp (treated as latent variables).

Results: Bivariate correlations confirmed significant cross-sectional relationships between meaning and PCS and peace and PCS, but not faith and PCS, at all three waves. The cross-lagged SEM yielded an adequate fit to the data: RMSEA = .036, CFI = 0.967, TLI = 0.959. After controlling for relevant socio-demographic (age, race, comorbidities) and cancer-related (stage, chemotherapy, radiation, time since diagnosis) variables, results revealed that only higher PCS at 12 months predicted greater meaning at 18 months (standardized parameter estimate = 0.097; $p = 0.013$). Baseline PCS did not predict meaning at 12 months and the reciprocal relationship of meaning predicting PCS was not significant. Neither peace nor faith was reciprocally related to PCS.

Conclusions: Results provide evidence of a unidirectional relationship between physical HRQoL and subsequent meaning among BCS during the period of early to later survivorship. Results also underscore the importance of examining spirituality as a multi-dimensional construct, as meaning, but not faith or peace, was longitudinally related to physical HRQoL. During the post-treatment phase, those who are doing better physically may be able to experience greater meaning in their life subsequently, as they may be able to engage more in activities that give purpose to life.

RELIGIOUS AND SPIRITUAL VARIABLES ASSOCIATED WITH NEUROIMMUNE BIOMARKER ACTIVITY IN BREAST CANCER SURVIVORS

Jennifer Hulett, PhD, APRN, FNP-BC¹, Brick Johnstone, PhD, ABPP², Jane Armer, PhD, RN, FAAN³, Rami Millsbaugh, BS⁴, Joshua Millsbaugh, PhD⁵¹University of South Carolina College of Nursing, Columbia, SC; ²Defense and Veterans Brain Injury Center, Fort Belvoir, VA; ³University of Missouri Sinclair School of Nursing, Columbia, MO; ⁴University of Montana, Wildlife Biology Program, Department of Ecosystem and Conservation Sciences, Missoula, MT; ⁵University of Montana Wildlife Biology Program, Missoula, MT

Background: Mindfulness-based interventions, rooted in Eastern religious/spiritual (R/S) traditions, appear to buffer adverse neuroendocrine-immune changes associated with chronic stress in breast cancer survivors. Evidence linking the R/S basis of these interventions with neuroendocrine function, i.e., hypothalamic-pituitary-adrenal axis (HPAA) and sympathetic-adrenal-medullary system (SAM), is limited. Previously we reported positive spiritual beliefs, i.e., beliefs in a loving God/ higher power, were associated with the magnitude of cortisol awakening response. This paper disseminates our new findings regarding relationships between R/S variables; health outcomes; biomarkers of SAM and HPAA activity, i.e., sAA and cortisol, respectively; as well as interleukin-6 (IL-6) as a biomarker of immune function.

Methods: This was an observational, cross-sectional pilot study. Female breast cancer survivors (N=41) provided salivary specimens at awaken (eyes open), awaken +30 minutes, and bedtime for 2 days. Participants completed the Brief Multidimensional Measure of Religiosity/Spirituality, SF-36v2 Health Outcomes, and demographic measures. Data analyses included descriptive statistics and Spearman's rho correlations.

Results: A majority of participants (88%) reported Christian faith traditions. Forgiveness was associated with lower morning sAA concentrations at awaken ($r_s = -.47$, $p < .01$; post-awaken ($r_s = -.39$, $p < .05$); mean daily sAA ($r_s = -.40$, $p = .01$); and sAA awakening response ($r_s = -.25$, $p = .13$). Positive spiritual beliefs were associated with steeper cortisol slope ($r_s = .37$, $p < .05$). Lower evening IL-6 was associated with positive congregational support ($r_s = .42$, $p < .05$) and social function ($r_s = .42$, $p < .05$).

Discussion: Based on this sample of breast cancer survivors, our data suggest forgiveness may be associated with daily SAM response while positive spiritual beliefs may be associated with daily HPAA reactivity. Social support may contribute to lower evening IL-6 suggesting an immunoprotective role against inflammation in breast cancer survivors. Our findings offer direction for future research regarding the utility of R/S variables in psychoneuroimmunological-based research.

RELINQUISHING CONTROL OF OUTCOMES TO GOD: AN EXAMINATION OF PHYSICAL AND EMOTIONAL OUTCOMES IN THE CONTEXT OF CANCER

Thomas V. Merluzzi, PhD, Errol J. Philip, PhD

University of Notre Dame, Notre Dame, IN

Introduction: In the context of a cancer diagnosis, relinquishing control by letting go or placing it in “God’s hands”, is an approach to dealing with the uncertainty of disease outcomes. The relative tendency to place outcomes in “God’s hands” have been associated with higher scores on measures of religious coping and quality of life, but physical health variables have not been closely examined.

Method: 533 cancer patients and survivors completed the Religious Problem Solving Scale (RPPS), and measures of symptoms, comorbidities, functional capacity, coping, and emotional well-being. The RPPS Deferring (D-placing outcomes in God’s hands) and Collaborative (C-being partners with God in determining outcomes) scales were very highly correlated and negatively correlated with Self-Directing (SD-taking personal responsibility for outcomes). A continuous variable (C+D-SD) was constructed. As scores increase there was a greater tendency to defer outcomes to God. Regression analyses were conducted with C+D-SD as the DV and the composite symptoms/comorbidities, the composite functional capacity, composite coping and the composite emotional well-being variables as IVs.

Results: Composite symptom/comorbidities and composite functional capacity were not significant predictors of C+D-SD ($p > .05$). However, the coping ($B = .248, t = 6.02, p = .001$) and emotional well-being ($B = .191, t = 4.57, p = .001$) composites were highly related to placing outcomes in “God’s hands”.

Conclusions and Implications: There was no advantage to letting go of outcomes in terms of having less concurrent symptoms or more functional capacity. The advantages appear to be in the domains of coping and emotional well-being. Perhaps placing outcomes in “God’s hands” reflects a belief in the continuing effort on God’s part, and one that provides some degree of relief from the stress associated with the uncertainty of outcomes. This approach may, in turn, provide a greater capacity for coping and could plausibly be associated with improved well-being over time. Longitudinal analysis would be important in determining the relationship between letting go and longer-term outcomes.

UNDERSTANDING REACH AND UPTAKE OF TOBACCO CESSATION TREATMENT DELIVERY IN A COMPREHENSIVE CANCER CENTER

Kristen E. Riley, Ph.D., Diana Kwon, B.S., Jamie Ostroff, PhD

Memorial Sloan Kettering Cancer Center, New York, NY

Introduction: Clinical guidelines for the treatment of tobacco dependence in cancer care exist (NCCN) and all leading oncology professional organizations have strongly endorsed tobacco use screening and treatment. Nonetheless, recent national surveys reveal that implementation of evidence-based tobacco treatment in cancer centers is inconsistent and suboptimal. In order to improve implementation quality, there is a need to better understand patient reach and acceptability.

Method: As standard of care at our comprehensive cancer center, all new patients are assessed for smoking status and current smokers are referred for evidence-based cessation counseling and pharmacotherapy provided by designated tobacco treatment specialists. Using annual (2016) clinical program data from a well-established tobacco treatment program (TTP) serving patients treated at a comprehensive cancer center, we sought to identify the % of current smokers (past 30 days) referred (reach) to the TTP, the % current smokers enrolled (uptake), as well as the stated reasons and characteristics of TTP refusers.

Results: In 2016, the MSK TTP received 3681 unique patient referrals reflecting a 61% referral rate (reach) of all current smokers. Recent former smokers and nondaily light smokers were less likely to be referred. Of those patients referred, we found that 37% ($n = 1362$) patients were unreachable with three call attempts and 30% declined ($n = 1104$) tobacco treatment services. In terms of most common reasons given by patients for TTP referral refusal, 19% prefer to quit on their own and 18% were not yet ready to quit.

Conclusion: Identification, referral and engagement of all current smokers are essential goals for improving the quality of tobacco cessation treatment delivery in routine cancer care. This presentation will discuss the ongoing application of an implementation framework to identify patient, provider and systems-level barriers to improve reach and uptake of tobacco cessation treatment so as to reduce tobacco-related morbidity and mortality in cancer care.

UNDERSTANDING THE NEEDS OF BREAST CANCER SURVIVORS WHO DECLINE A TRIAL OF A COUPLE-BASED INTIMACY ENHANCEMENT INTERVENTION

Jennifer B. Reese, PhD¹, Natalie M. Oppenheimer, BA¹, Kristen A. Sorice, BA¹, Laura Porter, PhD²¹Fox Chase Cancer Center, Philadelphia, PA; ²Duke University Medical Center, Durham, NC

PURPOSE: Despite researchers’ best efforts, recruiting couples to behavioral intervention studies in cancer is challenging. It is therefore important to understand why study candidates who are eligible decline such trials, how those who decline are different from those who accept, and what alternatives are preferable. In recruiting for a 4-session couple-based telephone sexual quality of life (SQOL) intervention for breast cancer survivors, the objectives were to (1) examine reasons for non-participation and intervention preferences of study-eligible women who declined (refusers) and (2) explore whether refusers differed from participants on key characteristics.

METHOD: Partnered early stage breast cancer survivors (6 months-5 years post-treatment) reporting sexual concerns > 3 [possible range 0–10] were recruited to the intervention study (91 women eligible; 31 couples consented; 29 couples randomized). Of the 60 eligible women who did not enroll, 35 were approached to complete a standardized 5-minute telephone survey assessing reasons for declining and preferences for SQOL support, 31 of whom agreed (89% acceptance rate). Demographic, clinical, and sexual concerns information were collected during telephone screens.

RESULTS: Among refusers [$N = 31$; mean age = 56 (SD = 9); 87% white; 81% on hormone therapy; mean time since treatment = 30 months (SD = 16); mean sexual concerns = 6.5 (SD = 2.1)], the most common reasons for non-participation were time commitment (65%) and partner non-interest (33%). The two most preferred SQOL resources were informational websites (45%) and meeting with a professional (26%), followed by written materials (23%) and support groups (7%). Fifty-five percent endorsed wanting their partners involved in a program to address sexual concerns whereas 10% did not want partners involved at all. Refusers and participants were compared on age, race, hormone therapy use, time since treatment, and sexual concerns using independent t-tests or Chi-Square tests; no group differences were found ($p > .50$).

CONCLUSION: Breast cancer survivors who declined a SQOL intervention were largely similar to those who participated on demographic and clinical characteristics, and level of sexual concerns. Most refusers cited the time commitment – rather than partner involvement – as a reason for non-participation, suggesting that developing briefer couple-based interventions and using shortened assessment surveys might be useful strategies to increase enrollment.

EXAMINING THE EFFECTS OF INTERACTIVITY ON SKIN CANCER WEBSITES: A FEASIBILITY STUDY ON WEB-BASED SKIN CANCER INTERVENTION

Zhaomeng Niu, Ph.D.

Rutgers, The State University of New Jersey, New Brunswick, NJ

Background: Characteristics of the interactive digital media being used for health interventions, such as interactivity, may impact individuals' perceptions of the health information, attitudes toward the health messages, behavioral intentions, and other health-related outcomes. The present study aims to examine (1) how different types of interactivity influence attitudes, behavioral intentions, and knowledge related to skin cancer, the most common cancer in the U.S., and (2) the feasibility of using these interactivity cues in online skin cancer interventions.

Method: Participants (N=287) were recruited from M-Turk to participate in a 2 (modality interactivity: high vs. low) x 2 (message interactivity: high vs. low) online experiment which examined effects of modality interactivity and message interactivity on knowledge, attitudes, and behavioral intentions toward skin cancer. General linear model (GLM) analyses were used to test the effects of the two independent variables on dependent variables. To test the mediating effects, a set of regression-based process macro models by Hayes were used.

Results: Participants in the high modality interactivity condition ($M=6.03$, $SE=.08$) scored high on attitudes toward the health information about skin cancer than participants in the low modality interactivity condition ($M=5.79$, $SE=.08$), $F(6, 281)=6.416$, $p<.05$. Participants who explored the high modality websites ($M=5.70$, $SE=.12$) scored higher on intention to use sunscreen in the future than participants who explored the low modality websites ($M=5.18$, $SE=.12$), $F(5, 282)=6.12$, $p<.001$. Participants in the high message interactivity conditions ($M=4.42$, $SE=.10$) scored higher on perceived knowledge than participants in the low message interactivity conditions ($M=4.99$, $SE=.10$), $F(6, 281)=12.56$, $p<.001$. There was an interaction effect of modality interactivity and message interactivity on the memory recall, $F(6, 281)=8.95$, $p<.001$. Participants who were in the high modality interactivity and high message interactivity condition had the highest score on the memory recall. Attitudes toward skin cancer mediated the effects of modality interactivity on intentions to use sunscreen.

Conclusions: The results suggest that high modality interactivity could improve attitudes and intentions of skin cancer-related outcomes while high message interactivity could increase the knowledge of skin cancer. The current study provides insights of designing a web-based skin cancer intervention and demonstrate the feasibility of using technological cues in health interventions.

NEED AND ACCEPTABILITY OF DIGITAL HEALTH INTERVENTIONS AMONG OLDER GASTROINTESTINAL CANCER SURVIVORS

Ashley B. Sanders, M.S.¹, David E. Conroy, Ph.D.², Kathryn H. Schmitz, MSeD, MPH, PhD³, Niraj Gusani, M.D.³

¹The Pennsylvania State University, State College, PA; ²The Pennsylvania State University, University Park, PA; ³Penn State University College of Medicine, Hershey, PA

Background: This study aimed to characterize physical activity (PA) and sedentary behavior (SB) profiles in older gastrointestinal (GI) cancer survivors, assess their interest in interventions to modify these behaviors, and evaluate the acceptability of digital tools for delivering interventions to modify these behaviors.

Methods: Survivors (M=65 years) from an outpatient survivorship clinic at the Penn State Cancer Institute completed a questionnaire during a clinic appointment.

Results: Most survivors failed to attain the recommended level of PA (79%) or exceeded an average of 8 hours of daily SB (42%). Access to internet and text messaging capabilities were high (70%), yet few survivors had access to smartphones or tablets (<40%) or reported interest in using digital tools to improve PA or reduce SB (<30%). Digital PA and SB interventions were more acceptable to younger survivors, survivors reporting more SB and survivors engaging in more PA. The monetary value ascribed to digital health interventions did not differ as a function of mode of delivery (i.e. text messages, web, email, tablet computer apps or smartphone apps).

Conclusions: Older GI cancer survivors can benefit from interventions to increase PA and decrease SB. Interest in such interventions was moderate and the acceptability of digital health tools for these interventions was limited. At the present time, behavioral interventions for older GI cancer survivors should not be delivered exclusively through digital tools, and strategies to improve adoption of various technologies should be implemented when using these tools to modify PA and SB.

OUTCOMES OF A TECHNOLOGY-BASED INTERVENTION TO SUPPORT PHYSICAL ACTIVITY AMONG CANCER SURVIVORS: A PILOT RANDOMIZED TRIAL

Nancy Gell, PhD, MPH¹, Kristen Grover, PhD², Liliane Savard, DPT¹, Daniel Ebenstein, BS¹, Kim Dittus, MD, PhD³

¹University of Vermont, Burlington, VT; ²University of Vermont Cancer Center, Burlington, VT; ³Larner College of Medicine at UVM, Burlington, VT

Background: Exercise has a positive impact on functioning and quality of life for cancer survivors, but few achieve the recommended levels for health benefits. Facility-based oncology rehabilitation exercise programs are beneficial for improved strength and fitness, however, sustained engagement in exercise is a challenge once a program ends. The aim of this pilot study was to evaluate a technology-based intervention to support maintenance of exercise following oncology rehabilitation.

Methods: Cancer survivors were recruited after completing exercise-based oncology rehabilitation (n=54; 81% female, mean age 61.9). Participants were randomized to an eight week intervention consisting of health coaching (1 in-person, 3 follow-up meetings by phone), text messages to a personal cell phone, and use of a Fitbit for self-monitoring of physical activity or to a group that received the Fitbit-only. The primary outcome of moderate-to-vigorous physical activity (MVPA) was assessed via Actigraph accelerometer, along with step counts, at baseline and eight weeks. Self-efficacy, social support, self-regulation, fatigue, and sleep disturbance were assessed by questionnaire at baseline and post intervention.

Results: Participants in the full intervention (n=25) maintained weekly minutes of MVPA from pre-intervention ($310.8.5 \pm 122.8$) to post-intervention (328.1 ± 204.5 ; $p=0.65$), whereas those in the Fitbit-only group (n=29) had a significant decrease in MVPA (306.1 ± 187.3 pre vs 247.8 ± 177.5 post; $p=0.05$). There was no significant change in mean daily step counts, self-efficacy, or self-regulation for either group. Full Intervention participants maintained social support for exercise and increased relapse prevention strategies, whereas the Fitbit-only group had a significant decrease in perceived social support and no change in relapse prevention skills. Sleep disturbance and fatigue decreased significantly for both full intervention and Fitbit-only participants.

Conclusions: The findings demonstrate that remote interventions using technology can promote engagement in MVPA outside of a structured program. Those in the Fitbit-only group experienced benefits in the form of reduced fatigue and sleep disturbance but did not maintain MVPA levels after eight weeks. Additional research is needed to assess if technology-based intensive interventions can sustain maintenance of MVPA in the long-term.

PHYSICAL ACTIVITY DURING BREAST CANCER TREATMENT PRESERVES STRENGTH AND PHYSICAL FUNCTION

Lindsey Hanson, BS¹, Jason Fanning, PhD², Gregory Russell, MS³, Edward Levine, MD³, Marissa Howard-McNatt, MD³, Shannon L. Mihalko, PhD⁴

¹Wake Forest University, Winston-Salem, NC; ²Wake Forest School of Medicine, Winston Salem, NC; ³Wake Forest University School of Medicine, Winston-Salem, NC; ⁴Wake Forest University, Winston Salem, NC

The American Cancer Society estimates that women diagnosed with localized breast cancer have 5-year survival rates between 72–100%, contributing to the more than 3.1 million breast cancer survivors in the United States. Due to high survival rates after diagnosis, it is important to examine factors that impact physical function over the course of cancer treatment.

Purpose: To prospectively analyze the extent to which physical activity predicted changes in strength, shoulder mobility, and physical function in a group of 400 women with recently diagnosed, staged breast cancer.

Methods: Three visits were included in this study: pre-surgery, one year, and two-years post-surgical intervention. At each session, participants were instructed to perform grip strength, bicep curl, and tests of shoulder flexion and abduction. Physical function difficulty and physical activity (PA) levels were also assessed at each time point via questionnaire.

Results: The majority of women in this study were diagnosed with early stage breast cancer, 90.4% stages 0, I, and II, with a mean age of 57 years ($SD = 11.87$; range 23–87 years) and a mean BMI of 29.24 kg/m^2 ($SD = 6.16 \text{ kg/m}^2$). Average scores on the baseline Godin leisure-time exercise questionnaire indicated low physical activity levels (≤ 23). Linear regression analyses, controlling for baseline outcomes and key demographic factors (i.e., age, BMI, treatment) indicated that baseline PA predicted year one bicep strength ($\beta = .266$, $p < .000$). Conclusions: Since pre-treatment as well as PA changes during treatment affect strength and physical function and physical activity levels before and during treatment are below national recommendations, future research should target PA interventions concurrent with treatment to preserve strength and physical function during survivorship.

PROJECT PAT (POSITIVE ABOUT TRIPLE NEGATIVE): ASSESSMENT OF THE PSYCHOSOCIAL AND BEHAVIORAL OUTCOMES OF TNBC SURVIVORS

Pierre A. Leon, M.A.¹, Deanna Denman, M.A.², Benjamin Willis, M.D., M.P.H.³, Alex Jaffe, B.A.¹, Breanna Willis¹, Rebecca Ashmore¹, Stephanie Scott¹, Georita Frierson, Ph.D¹

¹Rowan University, Glassboro, NJ; ²Southern Methodist University, Dallas, TX; ³The Cooper Institute, Dallas, TX

Background: Triple negative breast cancers (TNBC) are difficult to treat due to their negative expression of three specific hormone receptors. This diagnosis may have deleterious effects on a survivor's psychosocial functioning. Scarcity in the literature comparing TNBC vs. hormone sensitive survivors, research for new, tailored bio-behavioral interventions are warranted.

Methods: Project PAT is a correlational study assessing the relationship between individuals with TNBC and their bio-behavioral and socio-medical demographic characteristics, while also comparing them to hormone sensitive survivors from a study performed by Andersen *et al.* (2004). Eligible participants were female, ≥ 18 y.o., ≤ 3 years of TNBC diagnosis, and English speaking. Participants were recruited through the UTSW Medical School cancer tumor registry and medicially cleared to participate. Assessments consisted of demographic, psychosocial, behavioral, medical history, and health behaviors questionnaires.

Results: Participants' ($n=46$) ages ranged from 30–79 ($M = 53.51$; $SD = 12.48$). The sample was comprised of: 32.6% ($n = 15$) African American, 2.2% ($n = 1$) Asian, 60.9% ($n = 28$) Caucasian, and 4.3% ($n = 2$) Other. Within the sample, 8.7% ($n = 4$) identified as Latina/Hispanic. Within this sample, individuals diagnosed with TNBC reported significantly positively correlated scores on the CES-D and POMS-TMD (Total Mood Disturbance) $r(45) = .689$, $p \leq .000$ and the CES-D and SF-36-MCS (Mental Component Summary) $r(45) = -.629$, $p \leq .000$. Hormone sensitive survivors ($n = 210$) at 4 months post-diagnosis reported lower POMS scores ($M = 36.32$; $SD = 34.26$) compared to our sample ($M = 51.34$; $SD = 36.10$) - suggesting TNBC survivors have higher levels of overall psychological distress. Furthermore, age was positively correlated to self-breast examinations, $r(45) = .304$, $p < .000$, $r(27) = .689$, $p \leq .000$, respectively.

Conclusion: When assessing mood states, TNBC survivors reported higher levels of psychological distress than their hormone sensitive counterparts. Furthermore, when assessing relationship status, married compared to non-married TNBC survivors engaged in more BC screening behaviors.

Implications: These findings can lead to tailored bio-behavioral interventions for TNBC survivors, and potentially non-TNBC survivors.

SOCIAL NETWORKS OF NEURO-ONCOLOGY CAREGIVERS

Dana Ketcher, MPH, CPH¹, Maija Reblin, PhD¹, Peter Forsyth, MD², Eduardo Mendivil, LSCA³, Lauren Kane, Bachelor of Science in Biology³, Justin R. Pok, BS Multi-Disciplinary Design, Business Minor⁴, Yelena P. Wu, PhD⁵, Jim Agutter, March³

¹Moffitt Cancer Center, Tampa, FL; ²H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL; ³University of Utah, Salt Lake City, UT; ⁴University of Utah, Holladay, UT; ⁵Huntsman Cancer Institute, University of Utah, Salt Lake City, UT

Background: Family caregivers (FCGs) are increasingly recognized as a vital part of the comprehensive treatment of cancer. However, many FCGs, especially those caring for patients with primary malignant brain tumor (PMBT) report feeling overwhelmed by providing care. Social support can be protective for caregiving, but there is little research on social network composition in FCGs.

This poster will describe the type of people and resources FCGs of PMBT report having in their social network.

Methods: As part of a larger study, FCGs of PMBT were recruited from a neuro-oncology clinic at an NCI-designated comprehensive cancer center. FCGs were asked to list social network resources (e.g. people or organizations) that they either have approached or could approach for help in the following six areas: 1) hands on support, 2) informational support, 3) communication support, 4) financial support, 5) emotional support, and 6) self-care support.

Results: 29 FCGs provided data. Participants were mostly non-Hispanic White (93%), female (79%), spouses of patients (54%) with a mean age of 57 years (SD=12). On average, FCGs listed 10.8 unique people in their social network across all categories (range: 1–30). On average, FCGs listed fewer than 5 individuals in each category: hands on (M=4.9, 0–25), emotional (M=4.4, 0–25), self-care (M=2.6, 0–16), informational and communication (M=2, 0–6), and financial (M=1.5, 0–19). Complete lack of social support was reported among 47% (financial), 28% (self-care), and 7% (informational) of participants.

Conclusions: Support networks of FCGs of PWBT are highly variable. Most FCGs had at least some support in each category, with the most people in hands on and emotional support, but communication and financial support were less populated. This data provides important information for targeting interventions to address support needs in FCGs with PMBT.

A PCORI/REACHNET FEASIBILITY STUDY ON THE LANDSCAPE OF END-OF-LIFE CANCER CARE IN THE DEEP SOUTH

Leah Walsh, BS¹, Joel Epling¹, Brian Melancon, BS², Elizabeth Crull, MPH³, Ronald Horswell, PhD², Lucio Miele, MD, PhD⁴, John Lefante, PhD¹, San Chu, MS², Melanie Canterbury, PhD³, Elise Goff¹, Wasef Atiya¹, Michael Hoerger, PhD, MSCR¹

¹Tulane University, New Orleans, LA; ²Pennington Biomedical Research Center, Baton Rouge, LA; ³Louisiana Public Health Institute, New Orleans, LA; ⁴LSU Health Sciences Center, New Orleans, LA

Background: The Research Action for Health Network (REACHnet) is 1 of 13 clinical data research networks (CDRN) funded by the Patient Centered Outcomes Research Institute (PCORI). REACHnet connects multiple health care systems; data by creating a single healthcare record for each person within the database. REACHnet has longitudinal data on 5 million patients in Louisiana and Texas. This study aims to test the feasibility of using the database to examine whether race and specific comorbidities account for disparities in the quality of end-of-life care received by cancer decedents.

Methods: This study uses a PCORI-funded REACHnet database on cancer, which will be linked to tumor registry data on cause of death. Race and comorbidity are identified through the PCORnet Common Data Model. The indicators of lower quality end-of-life care in cancer are chemotherapy use less than 14 days before death, more than one ED or ICU visit in last month, inpatient hospitalizations in last month, mechanical ventilation, death in hospital, hospice enrollment less than 3 days before death, and lack of hospice.

Results: We provide an actionable overview of key steps toward partnering with a PCORI-funded CDRN. In support of feasibility of using REACHnet, we conducted a successful initial query of the system, identifying 1,256,765 total patients from the Tulane and Ochsner health systems, including 21,000 decedents, and 6,202 decedents with a cancer diagnosis on record. We are now partnering with the tumor registry to narrow the database to only those patients with cancer listed as the cause of death and expect to have the final database in October 2017. Using the REACHnet-derived database, we will test our hypothesis that African American patients receive poorer quality end-of-life care, and explore whether comorbid health conditions common in the Deep South (e.g., obesity, cardiovascular disease, tobacco dependence, alcohol dependence) also account for variation in the quality of end-of-life care.

Discussion: As a feasibility study, we demonstrated that it is possible to acquire data using REACHnet. Our team's experience can provide practical strategies for other investigators seeking to utilize PCORnet databases, with the hope of promoting "big data" research within the medical systems of the Deep South and across the country. Findings may have implications for understanding trends in end-of-life care in a racially diverse segment of the U.S. that has received limited attention.

A REVIEW OF ETHNIC DIFFERENCES IN SURVIVAL AMONG LUNG CANCER PATIENTS: EVIDENCE TO SUPPORT THE HISPANIC HEALTH PARADOX?

Sarah N. Price, B.A.¹, Heidi A. Hamann, PhD², John M. Ruiz, Ph.D.²¹The University of Arizona, Tucson, AZ; ²University of Arizona, Tucson, AZ

Introduction: The Hispanic Health Paradox refers to the finding that despite a significantly worse risk factor profile, Hispanics/Latinos experience lower incidence of many diseases and have lower mortality rates than non-Hispanic Whites (NHWs). For lung cancer, the leading cause of cancer death in the United States, Hispanics have significantly lower incidence rates. However, it is unclear whether there is an accompanying survival advantage for Hispanic patients after lung cancer diagnosis. We conducted a review of papers that explored ethnic differences in lung cancer survival to help determine whether the Hispanic mortality advantage extends to survival in the context of lung cancer.

Methods: Studies were identified through: 1) PubMed search for papers from January 1, 2011 to September 22, 2017 using three key categories (Hispanic/Latino, lung cancer, and survival), 2) Search of identified paper reference sections, and 3) Contacting key authors for any additional papers or data. This approach yielded 98 candidate articles. To be included, publications had to include a direct survival comparison between NHWs and Hispanics with lung cancer. The review of abstracts eliminated 62 papers and full review of the remaining 36 papers yielded a final sample of 11 papers.

Results: Data were reported from various subsets of the Surveillance, Epidemiology, End Results (SEER; 5 studies) database, the California Cancer Registry (4 studies), the Lung Cancer Mutation Consortium (LCMC; 1 study), and Cancer Care Outcomes & Surveillance Consortium (CanCORS; 1 study). Eight of the 11 studies had either unadjusted or adjusted models demonstrating a survival advantage among Hispanic lung cancer patients compared to NHWs (7–27% lower risk of overall mortality; 3–24% lower risk of cancer-specific mortality). One study reported no significant difference. Two studies focusing on non-smokers with lung cancer reported worse survival for Hispanics than NHWs, but this association disappeared in one study when the model excluded treatment variables.

Conclusions: This review supports a Hispanic advantage in lung cancer survival. Determining the strength of association based on variable adjustment, disease stage, and tumor type may help to clarify these effects. Future work should also explore potential moderating and mediating pathways, including sociocultural/interpersonal influences, biological factors, and health behaviors to inform psychosocial and behavioral interventions.

“FOLK THEORIES” OF THE CAUSES OF INSOMNIA AMONG CANCER SURVIVORS: ASSOCIATIONS WITH SURVIVOR CHARACTERISTICS

Kelly Shaffer, Ph.D.¹, Allison Applebaum, Ph.D.¹, Katherine DuHamel, Ph.D.¹, Sheila Garland, PhD², Philip Gehrman, PhD³, Jun Mao, MD, MSCE¹¹Memorial Sloan Kettering Cancer Center, New York, NY; ²Memorial University, St. John's, NF, Canada; ³University of Pennsylvania, Philadelphia, PA

Background: Patients' illness beliefs can affect treatment selection, satisfaction, and adherence. In people with insomnia, causal attributions of sleep disturbance are associated with perceived treatment efficacy. Yet unknown are the causal attributions patients make about insomnia following medical illness. This study describes cancer survivors' causal attributions of insomnia and whether these beliefs differ by key sociodemographic characteristics.

Methods: Cancer survivors meeting DSM-5 criteria for insomnia disorder were assessed prior to randomization in an insomnia treatment trial. Survivors endorsed how much they agreed that 12 different factors were causally related to their insomnia using the Causal Attributions of My Insomnia scale. Survivors also self-reported sociodemographic factors of age, gender, race, and marital status. Multinomial logistic regression was used to examine the association of item agreement with patients' sociodemographics. Latent class analysis (LCA) was used to examine patterns of agreement across items and whether survivors' sociodemographics were associated these patterns.

Results: Survivors (N=160, age M=62 [SD=12], 57% female, 70% white, 51% partnered) more commonly agreed that emotions (77%), thinking patterns (76%), sleep-related emotions (65%), and sleep-related thoughts (57%) were causally related to their insomnia. Survivors more commonly disagreed that developmental factors (69%) and genetics (68%) contributed to their insomnia. Younger, female, and partnered participants were more likely to agree with particular causal attributions ($p < .04$); effects on agreement by race differed by causal attribution ($p < .04$). In the LCA, three classes of item agreement were identified (AIC=3131, BIC=3404): Broad Agreement (estimated 40% of population share), Unsure (13%), and Broad Disagreement (47%). Older survivors were more likely to belong to the Broad Disagreement group relative to Broad Agreement (B=0.05, $p = .03$).

Conclusion: Cancer survivors with insomnia commonly reported belief that thoughts and emotions were contributed to their sleep disturbance, although younger, female, and partnered survivors were more likely to endorse these beliefs. Findings provide important information to the implementation and efficacy of personalized insomnia treatment for cancer survivors, as attending to illness beliefs during shared decision making for insomnia treatment may improve patients' satisfaction, adherence, and clinical outcomes.

ADDRESSING ONCOLOGY AND PRIMARY CARE COORDINATION FOR CANCER PATIENTS AND SURVIVORS FROM DISADVANTAGED POPULATIONS

Julie Armin, PhD¹, Yvonne M. Bueno, MPH, OTR/L¹, Heidi A. Hamann, PhD¹, Nancy J. Johnson, RN, PhD²¹University of Arizona, Tucson, AZ; ²El Rio Community Health Center, Tucson, AZ

Introduction: Oncology and primary care coordination remains a significant challenge in many U.S. health care settings, especially in systems that manage the care of disadvantaged populations. This study examined the strengths, needs, and barriers to effective communication and coordination with oncology providers as reported by a variety of primary care providers (PCPs) and staff employed in a federally qualified health center in Tucson, Arizona.

Method: The team conducted three focus groups (n=32) and coded the transcripts to identify dominant themes and explore variation within those themes, using constant comparative method, which is an iterative approach to analysis that aims to guide further data collection. Purposive sampling will guide the conduct of in-depth interviews that further explore the findings from the focus groups.

Results: Primary emergent themes included barriers to PCP-oncology team-based care, which centered on gaps in communication with oncology providers and offices, and the challenges of relying on patients to convey information about their oncology care. Providers articulated the need for more information regarding surveillance and long-term effects of cancer treatment, as well as clearly defined recommendations for follow-up visits with primary care. Clinic staff described patients'; need for additional support in adherence to recommended therapies and survivorship care, including financial assistance or community resources, linguistically appropriate care, and patient-centered communication. Participants suggested expanding survivorship care plans to include information about patient support networks and resources for extending identified support through psychosocial programming.

Discussion: Results suggest the need to enhance survivorship navigation that bridges the oncology-PCP care gap, especially for patients from disadvantaged populations. This formative research can help inform navigation and survivorship care planning efforts that incorporate culturally and linguistically appropriate care.

ADULT ATTACHMENT PREDICTS FEMALE CANCER PATIENTS' HEALTH RECOVERY

Amanda Ting, BS¹, Hannah-Rose Mitchell, MPH², Marcella May, MA², Patricia Pedreira, B.S.³, Charles S. Carver, PhD², Youngmee Kim, PhD²¹University of Miami, MIAMI, FL; ²University of Miami, Coral Gables, FL; ³University of Miami, Miami, FL

Cancer diagnosis is life changing and resulting stress can be manifested in poor quality of life (mental and physical functioning) over time. Lesser known is the extent to which adult attachment orientations around the time of diagnosis relate to longer-term patient-reported outcomes (PROs) of mental and physical functioning, and whether gender moderates the associations. This study aimed to extend current knowledge by investigating them.

Newly diagnosed colorectal cancer patients (Stage I to IV) participated in the longitudinal study (54% female; 55 years old; 57% Hispanic; 3-month post-diagnosis at enrollment). Self-reported gender and adult attachment orientations (MAQ: secure, avoidant, anxious-ambivalent worry, and anxious-ambivalent merger) were measured around the time of diagnosis (T1). PRO mental and physical functioning (MOSF-12) were assessed at T1 and again 11 months later (T2: n=47). Age, ethnicity, cancer stage, perceived cancer-specific stress, and outcomes at T1 were covariates.

Cancer patients reported mental and physical functioning that were below the 25th percentile of the US norm at both T1 and T2, which worsened at T2. General linear modeling simultaneously predicting PRO mental and physical functioning revealed that avoidant attachment related to improved mental functioning ($B=6.07, p<.04$), controlling for the effects of covariates. Furthermore, greater anxious-worry attachment related to more improved physical functioning, which was the case only among female patients, $B=11.63, p<.05$.

Findings provide evidence that adult attachment around diagnosis is associated with improved mental and physical functioning in patients across the illness trajectory. Findings suggest that patients'; use of self-soothing mechanisms, rather than reliance on external comfort from others, during the initial turmoil of cancer serves as a resource for better mental recovery over time. Anxiety and fear of losing relationships for females during adjustment to the diagnosis possibly elicits health behaviors that promote better physical functioning in the long run. Findings warrant further investigation for factors accounting for the nuanced role of gender in relationship quality linking to cancer patients'; improved health across the illness trajectory.

ADVANCED CANCER AS A RISK FOR GENERALIZED ANXIETY DISORDER

Kelly Trevino, PhD, Holly Gwen. Prigerson, PhD, Paul Maciejewski, PhD
Weill Cornell Medicine, New York, NY

Background: Advanced cancer is associated with increased risk for major depressive episodes. Less is known about the relationship between advanced cancer and rates of Generalized Anxiety Disorder (GAD). This gap is notable given the association between anxiety and poor quality of life, difficulty communicating with the treatment team, chemotherapy dose delays and reductions, and worse response to symptom management in cancer patients. The purpose of this study was to examine whether advanced cancer poses distinct risk for GAD relative to the general population.

Method: Advanced cancer patients from Coping with Cancer (CwC), a prospective cohort study of advanced cancer patients, were compared to general population controls from the National Comorbidity Survey Replication study (NCS-R). CwC patients had a prognosis of ≤ 6 months to live. The general population comparison sample was propensity-matched using a 2:1 ratio to be demographically similar to the CwC sample. CwC and the NCS-R used DSM-IV compliant tools to assess GAD. CwC utilized the Structured Clinical Interview for DSM-IV and the NCS-R used the Composite International Diagnostic Interview Version 3.0.

Results: The advanced cancer patient sample (N=627) was predominately white (71.3%) and married (60.4%) and approximately half male (50.4%) with an average age of 59.5 years (SD=13.1). The general population sample (N=1,254) was predominately white (72.2%) and married (62.3%) and approximately half male (48.8%) with an average age of 59.7 years (SD=15.5). Advanced cancer patients were two times more likely than individuals in the matched general population sample to meet diagnostic criteria for GAD [OR=2.1; 95% CI=1.1, 4.1; $p=.02$]. Of the advanced cancer patient sample, 3% met diagnostic criteria for GAD compared to 1.4% of the general population comparison sample.

Discussion: Advanced cancer is associated with increased risk for GAD relative to the general population. These findings suggest that advanced cancer patients should be screened for anxiety, in addition to depression. Patients with elevated anxiety may benefit from psychosocial services to prevent escalation of anxiety symptoms to GAD. In addition, improving patient access to cost-effective evidence-based treatments for GAD such as cognitive-behavioral therapy may reduce anxiety associated with advanced cancer and, in turn, improve patient quality of life, engagement with the healthcare team, and treatment response.

ASSOCIATION OF BODY ESTEEM WITH FITNESS AND BODY FAT AMONG COLORECTAL SURVIVORS

Madison M. DeMello, Ph.D.¹, Bernardine M. Pinto, Ph.D.¹, Shira Dunsiger, Ph.D.²

¹University of South Carolina, Columbia, SC; ²The Miriam Hospital/Brown University, Portsmouth, RI

Introduction: Survival rates among cancer survivors have improved, however treatment side-effects worsen their body esteem. Body esteem, or the satisfaction with one's appearance, can significantly affect quality of life and depression following cancer treatment. We examined the relationship between changes in fitness and body fat with changes in body esteem among colorectal survivors who participated in a randomized controlled trial that tested the effects of a 12-week telephone-based physical activity intervention.

Methods: Male and female colorectal survivors (< 5 years since diagnosis) were recruited to participate in a 12-week moderate-intensity physical activity intervention. Body esteem was assessed using the physical condition subscale of the Body Esteem Scale. Additionally, fitness was measured via the Treadmill walk test and body composition (fat mass) was assessed using bioelectrical impedance analysis (BIA- Quantum II R.J.L. system analyzer). All measures were assessed at baseline and follow-up visits (3, 6 and 12-month).

Results: 46 colorectal survivors (mean age = 57 years old, 57% female, 70% Stage 0–2, 30% Stage 3 disease) were randomized. Using generalized linear models, we examined whether changes in fitness and changes in body fat would predict changes in body esteem over time, controlling for group assignment, gender and disease stage. Improvements in fitness were associated with increased body esteem among men at 6-month ($b=6.50$, $SE=3.18$, $p=0.04$) and 12-month follow-ups ($b=1.36$, $SE=0.66$, $p=0.04$); while reductions in body fat were associated with increased body esteem at 12-months ($b=3.71$, $SE=1.79$, $p=0.05$) among women. In addition, controlling for gender and group assignment, improved fitness ($b=0.84$, $SE=0.36$, $p=0.03$) and reduced body fat ($b=5.99$, $SE=2.95$, $p=0.05$) among Stage 0–2 survivors were associated with significant improvements in body esteem at 12-months, with no changes in Stage 3 survivors.

Conclusions: Body esteem changes among colorectal cancer survivors have been underexplored. Results from this study showed that improved fitness and body composition can improve body esteem among these survivors; however, differences exist among gender and disease stage. Given the potential benefits of improved body esteem on quality of life and depression, these relationships merit further study.

BARRIERS, FACILITATORS, AND DECISION MAKING PROCESSES ABOUT HPV VACCINATION FOR HMONG AMERICAN ADOLESCENTS

Hee Y. Lee, PhD¹, Kathleen Culhane-Pera, MD², Shannon Pergament, MPH, MSW³, Serena Xiong, MPH⁴, Bai Vue, Master of Education⁵, Jay Desai, PhD, MPH⁶, Naly Vang, Masters of Social Work⁷, Houa Vang, N/A⁸, Maria Beatriz Torres, Doctorate⁹

¹University of Minnesota-Twin Cities, St Paul, MN; ²West Side Community Health Services, St Paul, MN; ³West Side Community Health Services, Inc., St. Paul, MN; ⁴Somali, Latino, and Hmong Partnership for Health and Wellness (SoLaHmo) - West Side Community Health Services, Brooklyn Center, MN; ⁵Somali, Latino and Hmong Partnership for Health and Wellness (SoLaHmo), MPLS, MN; ⁶HealthPartners Institute, Bloomington, MN; ⁷University of Minnesota, Brooklyn Park, MN; ⁸University of Minnesota School of Social Work, St. Paul, MN; ⁹Gustavus Adolphus College, Mankato, MN

Background: While vaccination rates against the Human Papilloma Virus (HPV) have been increasing for majority Americans, studies have shown that there are low rates of HPV vaccination in Asian American (AA) populations. There are no studies that have assessed HPV vaccination rates in the Hmong-American population, an AA group with reportedly greater risk of later stage cervical cancer and low cervical cancer screening rates. HPV vaccine rates in 2015 for Hmong children ages 9–17 at a local federally-qualified health center (FQHC) in Minnesota were 32% in girls and 20% in boys, which is lower than nationally published rates (60%). This exploratory community-based participatory action research study aimed to identify Hmong-American parents'; and adolescents'; barriers, facilitators, and decision-making processes about HPV vaccines for adolescents using the socio-ecological model in order to inform an educational program that could increase vaccine rates in Hmong-American adolescents.

Methods: Hmong 14–17 year-old patients who had received or had not received full HPV vaccine series and their parents at a local FQHC were contacted and invited to participate in focus groups. Bilingual-bicultural community researchers conducted 4 focus groups with parents (all mixed gender) and 4 focus groups with adolescents (2 groups of girls and 2 groups of boys) in English or in Hmong. Focus groups were audiotaped, transcribed and translated into English concurrently, and analyzed to identify major themes by using participatory thematic analysis.

Results: The following major themes emerged: (1) *Barriers:* Distrust of Western medicine; Concerns about side effects and pain; Lack of knowledge about HPV and HPV vaccine; Low risk-assessment; Access (barriers of language, literacy, cost, distance, limited time). (2) *Facilitators:* Adequate knowledge about HPV vaccine; Respect for authority (look to doctors, nurses, and teachers to educate, counsel, and recommend vaccine; accept if required for school). (3) *Decision-making processes:* Dependency (parents depend on clinics, schools, and teens to inform, educate, and counsel them); Variable patterns (some parents decide, some parents defer to kids, some kids accept or refuse parents'; decisions); Parent-teen factors influence variability (parents'; language, literacy, feelings; teen';s age, gender; parent-teen relationship).

Conclusion: Findings from the focus groups showed there were intrapersonal, interpersonal, institutional, community and policy level barriers and facilitators to HPV vaccine uptake among Hmong-American families. These results support that a linguistically-appropriate and culturally-tailored HPV educational program for parents and teens, which address these identified issues, could be successful in promoting HPV vaccine uptake and acceptability in the Hmong-American community.

CANCER RISK FACTORS IN A SAMPLE OF SEXUAL MINORITIES: DIETARY INTAKE, OBESITY, ALCOHOL, AND TOBACCO

Michael Johnson, PhD, RN, Raphael Avila-Cunanan, BSN, RN

University of Nevada, Las Vegas, Las Vegas, NV

Background: Research has found higher rates of certain behavioral cancer risk factors among lesbian, gay, and bisexual (LGB) people as compared to their heterosexual counterparts, including higher rates of alcohol intake, tobacco use, and obesity. However, findings have been inconsistent and warrant further investigation. The Nevada BRFSS has collected sexual orientation data for the past two years. The sexual orientation cases in this dataset have never been exclusively analyzed for behavioral cancer risk factors.

Purpose: The aims of this study were to 1) examine the prevalence of cancer risk factors among male and female sexual minority individuals, 2) examine the differences in cancer risk factors between male and female sexual minorities, and 3) examine the differences in cancer risk factors between sexual identities.

Methods: This study was a secondary analysis of 2015 NV-BRFSS data. The following variables were included in analyses: sexual orientation, sex, demographics, dietary intake (consumption of fruit juices, fruits, vegetables, beans or lentils), tobacco use, binge drinking behaviors, and last routine checkup. After coding the variables, descriptive and bi-variate analyses (chi-square, t-test, and ANOVA) were conducted. Statistical significance was set at 0.05.

Results: The sample (N = 133) was mostly female (63.9%), white (66.2%), single (60.2%) and urban-dwellers (81.2%). Among the total sample, 29.3% identified as gay/lesbian, 38.4% as bisexual, and 32.3% as other. Men were likely to report binge drinking than women (31.3% v 16.5%), and further analyses showed that gay men had the highest rate of binge drinking among the sexual orientation categories. Gay/lesbian people were more likely to be current smokers (41%) as compared to bisexual (33.3%) or other (14%). Although not statistically significant, gay/lesbian people had a higher rate of binge alcohol drinking (30.8%) as compared to bisexual (21.6%) and other (14%). Females were more likely to have a higher body mass index than men (28 vs 25.8). People who identified their sexual orientation as 'other'; were less likely to drink fruit juices (60.5%) compared to gay/lesbian (30.8%) and bisexual (37.2%).

Conclusions: This study established a rate of different cancer risk factors among sexual minority male and female individuals in a sample of Nevada residents, adding to the greater state of science. Statistically significant differences in binge drinking and tobacco were found between sex and sexual orientation. Sexual minorities who identify as 'other'; has been of recent focus to researchers, and this study highlights the differences between that group and gay/lesbian and bisexual groups.

CERVIXCHECK: A SPIRITUALLY-BASED SMS INTERVENTION TO PROMOTE CERVICAL CANCER AWARENESS AMONG AFRICAN AMERICAN WOMEN

Daisy Le, PhD, MPH/MA¹, Cheryl L. Holt, PhD²¹Johns Hopkins Bloomberg School of Public Health, Washington, DC; ²University of Maryland, College Park, College Park, MD

Background/Purpose: On a national level, African American women have a 34% higher incidence of cervical cancer and are twice as likely to die of the disease when compared to White women. In response to the need to improve cervical cancer prevention and Pap test screening knowledge and utilization, we developed and pilot tested a 16-day SMS text message-based intervention. The CervixCheck study was designed to develop, pilot test, and evaluate the feasibility, acceptability, and initial efficacy of a spiritually-based SMS text messaging intervention aimed at increasing cervical cancer awareness and Pap test screening intention in church-attending African American women ages 21–65.

Methods/Approach: The Theory of Planned Behavior guided the development of the CervixCheck intervention. This presentation provides findings from Phase 3 of the study. Phase 3 utilized a non-experimental one-group pretest-posttest design to pilot test the intervention. Of the 52 participants at baseline, 46 completed the post-program survey.

Results/Findings: The current study suggests evidence for the early feasibility, high acceptability, and some initial efficacy of the CervixCheck intervention. There was a significant pre-post increase observed for knowledge about cervical cancer and the Pap test ($p = .001$) and subjective norms ($p = .006$). Findings post-intervention also revealed that 83% of participants reported being either “satisfied” or “very satisfied” with the CervixCheck intervention and 85% found the SMS text messages either “useful” or “very useful”.

Conclusions/Significance: A spiritually-based SMS text messaging intervention could be a culturally appropriate and cost-effective method of promoting cervical cancer early detection information to church-attending African American women.

DAILY VARIATION IN COGNITIVE FUNCTIONING AMONG BREAST CANCER SURVIVORS: IMPACT OF FATIGUE AND DEPRESSED MOOD

Brent Small, PhD¹, Heather Jim, FL², Sarah Eisel, BA¹, Stacey Scott, PhD³¹University of South Florida, Tampa, FL; ²Moffitt Cancer Center, Tampa, FL; ³Stony Brook University, Stony Brook, NY

Background: One of the greatest concerns of cancer survivors is changes to their cognitive abilities. However, considerable variation has been observed with some persons reporting significant impairment, whereas others report being relatively unaffected. Moreover, little is known about cognitive functioning in daily life and whether other common symptoms that cancer survivors experience, such as fatigue and depressed mood, are related to cognitive performance. The goal of this study was to examine how fatigue and mood impact cognitive performance in daily life for breast cancer survivors.

Methods: We used ecological momentary assessment in which participants were prompted to complete brief surveys with mobile cognitive tasks five times daily over a 14-day period. Participants were provided with study smartphones programmed with tasks designed to measure processing speed, attention and memory. At each survey, participants provided ratings of their current fatigue and depressed mood on a visual analogue scale.

Results: Participants were 47 women (M age = 53.3 years) who were between 6 and 36 months post chemotherapy ($M = 17.3$ months) for early stage breast cancer (25.5% Stage I, 74.5% Stage II). There was high compliance with the EMA protocol with 92% of the surveys completed across the 14-day period. Between person differences accounted for over 60% of the variability in fatigue, mood, memory and processing speed was due to differences between individuals, but less than one-third of the variability in attention. Day to day fluctuations in fatigue were related to processing speed such that on days in which survivors rated their fatigue as approximately one SD unit higher than average, performance on the measure of processing speed was .3s slower ($p < .05$). Similar results were observed for the attention task, with accuracy decreasing by 1% on days in which survivors rated their fatigue one SD above their mean ($p < .05$). Depressed mood was unrelated to performance on any cognitive task.

Conclusion: In this sample of breast cancer survivors, we observed both individual differences in average daily cognitive performance but also performance fluctuations within survivors from day to day. On days in which a person rated themselves as more fatigued than usual, performance was worse on tests of speed and attention. Tailoring interventions for persons when they are most fatigued may lead to positive consequences for their cognitive performance.

DEVELOPMENT AND EVALUATION OF A NOVEL PSYCHOEDUCATIONAL INTERVENTION FOR PATIENTS WITH PANCREATIC CANCER

Eryn Tong, BSc, Chris Lo, PhD, Shari Moura, RN MN CON(C) CHPCN(C), Kelly Antes, MSW, RSW, Sarah Buchanan, RD, Louise Lee, MEd, MA, Ali Henderson, MSW, RSW, Gary Rodin, MD, FRCPC

Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: Pancreatic cancer has one of the poorest prognoses amongst all cancers globally. The disease places substantial physical and psychosocial burden on patients and their loved ones. The associated distress and uncertainty can be amplified by unmet informational and support needs, but standardized and proactive approaches to provide information and support for patients with pancreatic cancer and their families are not routinely implemented. Therefore, we developed and implemented a brief psychoeducational intervention to improve knowledge about the disease and its psychosocial impact, satisfaction with care, and to reduce uncertainty.

Objective: To develop an acceptable intervention and evaluate the feasibility of its implementation in an ambulatory pancreatic cancer clinic at a large tertiary cancer centre.

Methods: (i) Development: We used the Schofield & Chamber’s framework for supportive care interventions to inform the development process. The Consolidated Framework for Implementation Research (CFIR) guided the intervention development and evaluation phases, to assess its feasibility and sustainability in our context using a multi-methods design. (ii) Evaluation: Feasibility outcome data were documented across the evaluation phase. Measures assessing illness uncertainty, satisfaction with care, and knowledge were administered at baseline and at 1 month. Semi-structured interviews were conducted with participants and clinical staff to inform feasibility and acceptability.

Results: A representative group of stakeholders was identified and collaboratively established the intervention, CALMING, with key considerations to ensure clinical relevance and sustainability including the content, target audience, and mode of delivery. CALMING was developed as a 1.5-hour group session led by an interdisciplinary team (i.e., nurse, social worker, dietitian) to address disease management, communication with loved ones and HCPs, personal and family impact of cancer, preparing for the future, and palliative and supportive care services. Preliminary findings will be discussed regarding the feasibility of implementing psychoeducation into routine care of those with progressive medical disease.

Significance: A group psychoeducational intervention for people affected by pancreatic cancer may reduce uncertainty and facilitate adaptation to this life-threatening disease. An implementation science approach to intervention delivery can improve uptake and sustainability in the clinical setting.

DO INTERVENTIONS TO REDUCE EXCESSIVE ALCOHOL AMONG WOMEN NEED TO ADDRESS BREAST CANCER RISK?

Anatasha Crawford, Ph.D., MPH, Arica White, Ph.D., MPH, Mary C. White, ScD, MPH

Centers for Disease Control and Prevention, Division of Cancer Prevention and Control, Epidemiology and Applied Research Branch, Atlanta, GA

Background: Multiple authoritative reviews have concluded that even low levels of alcoholic beverage consumption can increase a woman's risk of developing breast cancer. However, many young women binge drink, and they may be unaware that alcohol intake increases their risk of developing breast cancer. The objective of this study was to examine perceptions about the influence of alcohol consumption on breast cancer risk among a national sample of females aged 15–44 years without a history of cancer.

Methods: We used 2011–2015 National Survey of Family Growth (NSFG) survey data to examine perceptions about alcohol intake and breast cancer risk among 11,300 females aged 15–44 years. We examined participant perceptions of whether drinking alcoholic beverages increases a woman's risk of developing breast cancer by demographic factors. Participants were asked, "Do you think that drinking alcoholic beverages increases a woman's chances of getting breast cancer?" Responses to this question included "a little", "a lot", "not at all", "no opinion", and "don't know".

Findings: Most participants believed consumption of an alcoholic beverage did not increase breast cancer risk (47.9%) or had no opinion (26.7%). An examination of breast cancer risk perceptions by race showed that a larger proportion of non-Hispanic (NH) Whites and NH-Blacks (50.8 and 48.3%) did not believe alcohol intake increased breast cancer risk when compared to Hispanics (42.1%; $p < 0.001$). Breast cancer risk perceptions by age (aged 15–29 and 30–44 years) showed that a similar proportion of younger and older participants did not believe alcohol intake increased breast cancer risk (48.3% and 47.5%). A similar proportion of participants with and without a family history of breast cancer (49.0% vs. 47.6%) and with or without a history of smoking (50.8% vs. 47.0%) believed that alcohol intake did not increase breast cancer risk.

Implications: Approximately three-fourths of females aged 15–44 years were unaware of the influence of alcohol intake on breast cancer risk. Also, knowledge of alcohol's effect on breast cancer risk did not differ by age, family history of breast cancer, or a history of smoking. These findings point to the need to disseminate information about alcohol intake and breast cancer risk and can be used to enhance the implementation of evidence-based interventions to reduce excessive alcohol among young women.

EVALUATING CERVICAL CANCER PREVENTION APPLICATIONS FOR EASE OF USE

Calandra Whitted, MSPH, Torhonda Lee, MPH, PhD, MCHES

Florida A&M University, Tallahassee, FL

Smartphone applications have become an integral part of disseminating information for many types of health information. Smartphone ownership is higher among minorities, people who live in urban areas, and young person's age 18–29 years old and those without high school diplomas. African Americans and Hispanics show a greater rate of growth in tablet usage compared to whites. To date, there have been no studies to analyze cancer related smartphone applications to determine if health literate design features are built into applications that may be used by populations that are traditionally associated attributes of low health literacy such as low income, medically underserved, or minority populations. These population attributes have also been shown to have higher rates of advanced stage cancer diagnosis and higher mortality compared to other groups. Younger populations may be prompted to seek information through smartphone applications due to advances in effective vaccination and screening. The aim of the study is to identify and analyze apps targeted towards cervical cancer prevention and screening to determine ease of use and literacy. Application content was analyzed based on that is recommended for creating health literate mHealth applications which is an evidence based guide for designing health websites that uses strategies for usability and health literacy. The Apple App store and Google play store were used to identify smartphone applications. Key words used to identify applications were "cervical cancer prevention and screening."

Preliminary results/findings: Using the selected keywords, 17 apps from the Apple App Store and 19 apps were identified from the Google Play Store. Content was analyzed using Health Literacy Online Strategies for creating health literate mHealth applications. During the preliminary evaluation, 3 apps from the Apple App Store and 2 from the Google Play Store were examined using the strategies for writing actionable content which is one of the six strategies. Preliminary findings show 80% of apps reviewed showed evidence of the following criteria: put the most important information first, describe the health behavior-the basics, stay positive and realistic (include benefits of taking action), and write in plain language. Further analysis include evaluating apps identified by the keyword search and evaluating them using additional health literacy online strategies to determine if cervical cancer screening and prevention information is effectively communicated to impact behavior change in populations at risk and populations that are accessing application information at higher rates. Evaluation based on the evidence based health literacy online strategies can provide consistency of cervical cancer prevention information to ensure populations are able to make effective health decisions.

EVOLVING RECOMMENDATIONS AND TRENDS OVER TIME IN PAP SCREENING WITH HPV CO-TESTING

Lila Finney Rutten, PhD, MPH¹, Kathy L. MacLaughlin, MD¹, Robert M. Jacobson, MD¹, Patrick M. Wilson, MPH¹, Debra Jacobson, MS¹, Chun Fan, MS², Carmen Radecki Breitkopf, PhD¹, Jennifer St. Sauver, PhD, MPH¹

¹Mayo Clinic, Rochester, MN; ²mayo clinic, byron, MN

Background: In 2012, the U.S. Preventive Services Task Force, the American Cancer Society, and the American College of Obstetricians and Gynecologists updated their cervical cancer screening guidelines to recommend Papanicolaou (Pap) testing every three years for women ages 21–65 years or Pap testing with HPV co-testing at 5 year intervals for women ages 30–65 years. ACOG recommends Pap/HPV co-testing as the preferred screening method for women ages 30–65. We assessed current use of Pap with HPV co-testing and described trends over time in both Pap and Pap/HPV co-testing in our local population.

Methods: We used the research infrastructure of the Rochester Epidemiology Project (REP) to assess Pap screening and Pap/HPV co-testing among women ages 16 years and older eligible for routine screening, living in Olmsted County, Minnesota each year from 2005–2016. We extracted all Current Procedure Terminology codes for Pap and HPV testing in this population from the REP electronic indices. Three-year moving prevalence rates of screening were calculated as a proportion of the eligible population. Trends in Pap screening and co-testing were modeled using negative binomial regression for the following age groups: 16-<21; 21-<30; 30-<65; and 65+ years.

Results: The population eligible for Pap screening each year ranged from 43,912 in 2016 to 49,844 in 2014. Within each age group, significant declines in Pap screening at least every three years were observed from 2005 to 2016. Declines were most dramatic among those aged 16 <21 years (from 19.2% in 2005 to 1.2% in 2016, $p < .001$) and among those aged 65+ years (from 17.2% in 2005 to 3.2% in 2016, $p < .001$). Pap screening with HPV testing at least every three years increased significantly among women aged 30-<65 years (from 0.91% in 2005 to 25.4% in 2016; $p < .0001$). A slight increase in co-testing was also observed among those aged 65+ years ($p < .05$), although overall rates were low (e.g. 2.61% in 2016). A significant decline in Pap screening with HPV testing was observed among those aged 16-<21 years ($p < .01$) and no change was observed among those aged 21-<30 years.

Conclusions: Overall, rates of Pap screening in our population have declined, even among age groups for whom screening is recommended. However, an increase in Pap with HPV testing was observed for women aged 30-<65 years demonstrating modest adoption of pertinent recommendations in clinical practice.

EXAMINING SEXUAL FUNCTIONING AFTER RADICAL PROSTATECTOMY

Heather Kruse, Ph.D.¹, Kelsey Sewell, Ph.D.¹, Donald Strassberg, Ph.D., ABPP², Christopher Dechet, MD³

¹University of Kansas Health System, Kansas City, KS; ²University of Utah, Salt Lake City, UT; ³University of Utah, Huntsman Cancer Institute, Salt lake City, UT

Introduction Prostate cancer is the most common cancer in men. Considering the common iatrogenic side effects its treatment, including the impact on sexual functioning, it is important that clinicians and their patients understand both the risks of each treatment option and how various factors influence quality of life after treatment, in order to ensure an educated treatment decision. This project examined the longitudinal trajectories of sexual quality of life after surgical treatment of prostate cancer. We hypothesized that the following four between-subjects factors would influence the rate of sexual functioning recovery: age, pre-treatment sexual functioning, type of surgical approach (open vs. robotic), and degree of nerve-sparing (none, modified, and bilateral). Methods Participants were recruited from the Huntsman Cancer Institute (HCI) and included 527 men preparing for prostatectomy. Participants were administered the Sexual Functioning subscale of the long version of the Expanded Prostate Cancer Index Composite prior to treatment, at baseline (~3 months post-surgery), and up to 9 times across 5 years. Results Multilevel modeling procedures were used. Results suggested that the average post-treatment baseline level of sexual functioning after surgery was 10.98, as measured by the 100-point EPIC subscale. For the intercept (i.e., post-treatment baseline), there were significant main effects of age ($B = -0.28$, $SE = .14$, $p < .05$), degree of nerve sparing ($B = 11.07$, $SE = 1.93$, $p < .001$), and pre-treatment sexual functioning ($B = 0.32$, $SE = .03$, $p < .001$). Of the level-2 fixed effects, the degree of nerve sparing had the greatest impact on baseline post-surgery sexual functioning, particularly for those who had bilateral nerve-sparing procedures ($B = 18.61$, $SE = 2.22$, $p < .001$). It was hypothesized that pre-treatment sexual functioning, age, degree of nerve sparing, and surgery type would vary between men over time, influencing their sexual functioning recovery rates; however, only pre-treatment sexual functioning significantly affected recovery rates ($B = 0.004$, $SE = 0.001$, $p < .01$). Conclusion Thus, overall, results suggested that men differed in their levels of sexual functioning after treatment, as measured by the EPIC questionnaire, both in terms of levels early after surgery and in their rates of recovery over time. This has clinical implications for improving the accuracy of the information provided to men about what to expect across time after surgery.

FACTORS INFLUENCING NURSE PRACTITIONER PROVIDER RECOMMENDATIONS OF THE HPV VACCINE

Brenda Cassidy, DNP, RN, CPNP-PC¹, Sandra Founds, PhD², Willa M. Doswell, BSN, MA, PhD, FAAN³, Betty Braxter, PhD, CNM¹, Joyce Penrose, DrPH, FNP⁴

¹University of Pittsburgh, Pittsburgh, PA; ²University of Pittsburgh, Wexford, PA; ³University of Pittsburgh School of Nursing, Pittsburgh, PA; ⁴Slippery Rock University, Pittsburgh, PA

Background: A majority of men and women are exposed to Human Papillomavirus (HPV), increasing their risk for HPV-related cancers. The HPV vaccine is an effective cancer prevention strategy routinely recommended for pre-teens. Despite the efficacy and safety of the HPV vaccine, national rates remain low. Recommendation by a healthcare provider is the strongest predictor of parents choosing to vaccinate their preteen. Although the President's Cancer Panel, Centers for Disease Control and Prevention and American Academy of Pediatrics strongly endorse routine administration of the HPV vaccine, the National Immunization Survey of Teens cites lack of provider recommendation as one of the top five reasons given by parents who did not vaccinate their preteen. Little research has been conducted to understand the recommendation practices of nurse practitioners (NPs).

Purpose of study: This study assessed barriers and facilitators impacting NP recommendations of the HPV vaccine to parents of girls and boys 11 years of age and older. Theoretical framework The Theory of Planned Behavior (TpB) was used to assess attitudes, norms, perceived control, and intentions of NPs to recommend the HPV vaccine to the parents of preteens.

Methods: A descriptive design was used to conduct an online survey of NP's in southwestern Pennsylvania. The survey utilized constructs of the TpB to evaluate HPV vaccine recommendation practices. Data were analyzed using descriptive statistics. Major findings Respondents recommended the vaccine more often for females and reported parents prefer vaccination at an older age. Most NPs held favorable attitudes and reported intention and recent behavior of recommending the vaccine, yet cited recommendation practices in the past month of only 67% and 39% for females and males respectively. NP's did not identify provider recommendation as the most important factor affecting parental decision to vaccinate, ranking it as third and fourth in importance for girls and boys respectively.

Conclusion: This study enhances our understanding about NP recommendation practices, revealing pre-teen gender and age differences that can influence strength of recommendation. NPs did not recognize the importance of provider recommendation despite evidence as a strong predictor influencing parents' decision to vaccinate.

Implications: The results of this study can inform education for NP providers to promote strong provider recommendation of the HPV vaccine to parents.

FALSE-POSITIVE SCREENING EVENTS AND WORRY ABOUT CANCER RISK PREDICT RISK-REDUCING SURGERY USE BY WOMEN AT HIGH-RISK FOR CANCER

M. Robyn Andersen, PHD, MPH¹, Beth Y. Karlan, MD², Charles Drescher, NA³, Nicole Urban, ScD⁴

¹Fred Hutchinson Cancer Research Organization, Seattle, WA; ²Cedars-Sinai Medical Center, Los Angeles, CA; ³Fred Hutch, Seattle, WA; ⁴Fred Hutchinson Cancer Research Center, Tucson, AZ

Background: Studies of cancer screening have found that false positive screening events (FPSE) can affect worry about cancer risk, and screening program use. We sought to explore whether worry might also influence the use of risk-reducing ovarian surgical procedures by women at high risk for cancer.

Methods: We examined the effects of ovarian cancer screening on participants in a randomized controlled trial (RCT) that compared two screening strategies that both employed serum markers followed by imaging to assess the impact of FPSE on worry about risk for ovarian cancer and use of prophylactic surgery. In total 1,100 women were enrolled, including 234 women aged 25–80 with a documented BRCA1/2 germ-line mutation (Risk Group 1) and 866 women aged 35–80 with a pedigree warranting testing for inherited cancer susceptibility (Risk Group 2). Women were screened semi-annually, and were followed for surgical procedures and cancer diagnoses for up to 6 years.

Results: Upon enrollment in the study 342 31% of women reported moderate or severe levels of cancer worry. During screening 258 women experienced one or more FPSE. FPSE were associated with transient elevations in women's levels of worry about their ovarian cancer risk that generally resolved within 6 months. Risk-reducing prophylactic bilateral salpingo-oophorectomy (pBSO) was predicted by levels of worry about ovarian cancer risk at study enrollment among mutation carriers (HR 1.74; $p < 0.01$). FPSE predicted subsequent pBSO among women with a high-risk pedigree who did not have a known mutation at the time of their study enrollment (HR 2.31; $p < 0.01$). Women receiving pBSO during the course of the study averaged 44.5 years in the mutation carrier group and 57 in the high-risk pedigree group.

Conclusions: Worry about ovarian cancer risk predicted use of preventative surgery among high-risk women with BRCA1/2 mutations enrolled in an ovarian cancer screening program. FPSE predicted risk-reducing ovarian surgery among high-risk women without a known mutation at the time of screening program enrollment. Overall, it appears that women at high-risk for ovarian cancer due to a family history or known mutation may choose to postpone surgery and participate in screening but over time while in screening do respond to cancer worry and screening events by revisiting their decisions on risk reducing surgery.

FRAMING OF SKIN CANCER CONTROLLABILITY INFLUENCES PERCEPTIONS OF CANCER BLOGGERS

Jennifer M. Bowers, M.A.¹, Sarah Nosek, Ph.D.², Anne Moyer, Ph.D.³¹Stony Brook University, Port Jefferson, NY; ²Southern Vermont College, Bennington, VT; ³Stony Brook University, Stony Brook, NY

Introduction: Some cancers, particularly those that are perceived as controllable such as lung and skin, carry a stigma. The current study aimed to understand how the perceived controllability of skin cancer may influence perceptions of and attributions about individuals with cancer.

Method: Participants, 306 undergraduates, read a blog entry written by a fictional individual with skin cancer that was described as being caused by a family history (low controllability), working outdoors (medium controllability), or using indoor tanning (high controllability). Participants then answered questions regarding attributions about the individual, perceptions of character, desired social distance, and expectations of posttraumatic growth, as well as background and demographic questions.

Results: Participant ages ranged from 18 to 44 ($M = 20.6$, $SD = 2.61$). Forty percent were White, 38% Asian, and 6% Black. Due to gender stratification, 50% were female and 50% were male.

Using ANCOVA, with gender, age, and experiences with cancer as covariates, the three versions of the blog were compared.

For attributions about the individual with cancer, significant differences were found across groups, $F(2,305) = 35.37$, $p < .001$. LSD post-hoc testing found that all pairwise comparisons resulted in significant differences, with the most positive attributions associated with the family history frame ($M = 2.15$, range = 1–7), and the most negative attributions associated with the indoor tanning frame ($M = 3.13$).

For trait perceptions about the individual with cancer, significant differences were found across groups, $F(2,305) = 3.29$, $p < .05$. LSD post-hoc testing found that one pairwise comparison resulted in significant differences, between family history (more favorable, $M = 2.84$, range = 1–7) and indoor tanning (less favorable, $M = 3.12$).

Significant differences were not observed for the outcome variables posttraumatic growth ($p = .70$) and social distance ($p = .21$).

Discussion: The findings of this study indicate that a cancer blogger was perceived unfavorably when describing their cancer diagnosis using a frame relating to a lifestyle factor, compared to using a frame relating to a family history. Participants were also more likely to attribute the cancer diagnosis to the lifestyle-frame blogger, with attribution items measuring constructs such as blame and sympathy. These results demonstrate stigmas faced by those diagnosed with cancers that may be perceived as more controllable.

GOING THROUGH CANCER TOGETHER AS A FAMILY: EXPERIENCES OF HISPANIC MOTHERS DIAGNOSED WITH CANCER

Rebecca Palacios, PhD¹, Frances Marcus Lewis, PhD², Karoline Sondgeroth, MPH, MSW¹, Clara Reyes, BA¹, Elizabeth Loggers, MD, PhD³¹New Mexico State University, Las Cruces, NM; ²University of Washington/Fred Hutchinson Ca Research Ctr, Seattle, WA; ³Fred Hutchinson Cancer Research Center, Seattle, WA

Approximately 1.5 million cancer survivors are parents of minor children, with approximately 80% of these survivors being women under the age of 50 years. Approximately 1/3 of these mothers are in the early phases of cancer treatment and recovery. Most of what is known about the challenges of parenting dependent children following a cancer diagnosis is based on studies with NHW mothers. However, relatively little is known about the experiences of Hispanic mothers diagnosed with cancer and their families, particularly those residing along the U.S.-Mexican border. This is unfortunate given that Hispanics demonstrate significant disparities in cancer care, outcomes and overall disparities compared to NHWs.

Purpose. The purpose of this study was to describe, in their own words, the lived experience of Hispanic mothers who are in the early phases of cancer treatment and recovery while concurrently rearing dependent children.

Method. Nine mothers participated in focus groups interviews. Their data were transcribed verbatim and coded using inductive content analysis within a framework of grounded theory.

Results. Analysis revealed 14 domains that organized participants'; responses around four key areas. Although one group of domains highlighted the mothers'; perceived advantages of being extremely open and honest with their children about the cancer (e.g., maintaining child';s trust; facilitating child';s coping; helping child to understand what to expect), a second group of domains highlighted the mothers'; struggles in knowing what and how much to share with their child. A third group of domains related to the mothers'; self-evaluation regarding the quality of her maternal role, guilt surrounding her availability to her children during the recovery phases, and fear over how the cancer would impact their children in the long run. A fourth major grouping of domains characterized the behaviors of the children which served to 1) protect and care for their mother, 2) preserve her role as "mom," and 3) engage in their own self-care so that mom could conserve her energy to fight her cancer.

Conclusion. In these families, the environment in which the Hispanic mothers managed the early phases of treatment and rehabilitation, was co-created with their children. Mothers and their children mutually protected each other from the negative impacts of cancer.

HEALTH COMPETENCY BELIEFS AND HEALTH-RELATED QUALITY OF LIFE AMONG SURVIVORS OF PEDIATRIC CANCER AND HEALTHY CONTROLS

Lora L. Black, PhD, MPH, Ahna LH. Pai, PhD

Cincinnati Children's Hospital Medical Center, Cincinnati, OH

Pediatric cancer survivors are at risk for chronic late-effects that require self-management throughout adulthood. However, the unique experiences associated with cancer diagnosis and treatment could alter survivors' health beliefs including their perceptions of and their competency to manage their health. Given that many survivors will be required to self-manage one or more late-effects, understanding survivors' health beliefs is important for identifying the support needs of survivors. Therefore, this study will examine whether health beliefs differ between survivors of pediatric cancer and a matched sample of healthy peers and whether health beliefs are associated with HRQOL in both groups. We predict that survivors will report poorer psychological functioning, health perception, competency, and autonomy than their healthy peers and will be significantly associated with HRQOL. We also predict that females will be at particular risk for poor HRQOL and psychological functioning.

Survivors (n=54) and healthy peers (n=54) completed measures about health competency beliefs (HCB) and HRQOL. T-tests were conducted to examine differences in HCB and HRQOL between survivors and healthy peers, and females and males. Separate linear regressions were conducted to investigate the association between HCB and HRQOL in each group.

Survivors reported poorer psychosocial functioning, total HRQOL, competence, autonomy, and health perception scores than their healthy peers. Female survivors reported poorer physical functioning and total HRQOL than male survivors; no gender differences were observed in the healthy peer group. In survivors, total HRQOL and psychosocial functioning were positively associated with cognitive competence and health perceptions, and physical functioning was positively associated with health perceptions. In healthy peers, total HRQOL and psychosocial functioning were positively associated with health perceptions, and physical functioning was associated with competence.

As predicted, survivors reported poorer total HRQOL and physical functioning and less competent health beliefs than their healthy peers. Female survivors are at particular risk compared to both male survivors and healthy peers, reporting poorer physical functioning and total HRQOL. In both groups, cognitive competence and health perceptions were associated with HRQOL. These findings highlight the importance of targeting health beliefs to optimize HRQOL in survivors of pediatric cancer.

HEALTH SERVICE UTILIZATION, HEALTH STATUS, AND CANCER RISK BEHAVIORS AMONG CANCER SURVIVORS WITH MENTAL HEALTH CONCERNS

Natasha Buchanan Lunsford, PhD¹, Jessica King, MPH², Juan L. Rodriguez, MPH, MS¹¹Centers for Disease Control and Prevention, Atlanta, GA; ²CDC, Atlanta, GA

Introduction: Psychosocial distress and mental health problems (MHPs) can affect cancer survivors' health outcomes. Less is known about differences in health behaviors, health status, and health care access and utilization among survivors with versus without MHPs.

Methods: Combined 2014 and 2016 Behavioral Risk Factor Surveillance System self-reported data from 10,089 survivors were analyzed. We conducted descriptive statistics and significance testing to compare factors among survivors with and without MHPs (depressive symptoms or frequent mental distress).

Results: Survivors with MHPs (29%), versus without, were younger, divorced/separated/widowed, unemployed and had less education. Most survivors with MHPs had health care coverage, routine check-ups and flu shots, but were less likely than those without MHPs to have health care coverage ($p < .001$). Survivors with MHPs (versus without) were more likely to report uncontrolled pain caused by their cancer or cancer treatment (32% vs. 14%, $p < .001$). Most survivors with MHPs were adherent to recommended colorectal, cervical and breast cancer screening, however, female survivors with MHPs (versus without) were less likely to report on-time breast cancer screening ($p < .001$). Survivors with MHPs also reported higher prevalence of fair/poor health status (54% vs 26%), asthma (23% vs. 9%), current smoking (30% vs 12%), physical inactivity (41% vs 29%), and inadequate sleep (45% vs. 28%).

Conclusion: Survivors with MHPs reported poorer health status, adverse health behaviors, uncontrolled pain, and lower prevalence of on-time breast cancer screening than survivors without MHPs. Cancer prevention and health promotion efforts need to include caring for the mental health needs of survivors.

PATIENT-ONCOLOGIST NONVERBAL CONVERGENCE MEDIATES RACIAL ATTITUDES AND OUTCOMES IN RACIALLY DISCORDANT INTERACTIONS

Lauren M. Hamel, PhD¹, Mark Manning, PhD¹, Louis Penner, PhD¹, Susan Eggly, PhD¹, Nicole Senft, PhD¹, Robert Chapman, MD², Terrance Albrecht, PhD¹

¹Wayne State University/Karmanos Cancer Institute, Detroit, MI; ²Josephine Ford Cancer Center, Detroit, MI

Introduction: Patient and physician racial attitudes (e.g., patient suspicion; physician implicit racial bias) influence communication and outcomes of racially discordant clinical (Black patients, non-Black physicians) interactions. Racial attitudes are likely manifested in nonverbal behaviors during interactions. Communication Accommodation Theory (CAT) posits that the relationship between attitudes and outcomes is mediated by the extent to which nonverbal behaviors between participants in interactions become more similar (convergence). This study investigated associations between patient and physician racial attitudes, nonverbal convergence during racially discordant oncology interactions, and interaction outcomes.

Method: Data were 114 video recordings of treatment discussions with Black patients and their non-Black oncologists, self-reported attitudes (oncologist implicit bias; patient suspicion of medical care and perceived past discrimination), and post-interaction perceptions (patient perceptions of oncologist patient-centeredness; oncologist perceptions of patient treatment-related attributes). Five one-minute slices from each interaction were extracted and randomized. Trained coders assessed frequency/duration of facial behaviors (smiling, eye gaze); body behaviors (lean, orientation, openness); and paraverbal behaviors (continuers, talk time, word count). Longitudinal dyad discrepancy models determined discrepancies in frequency/duration of behaviors between patients and oncologists in each slice. A multilevel latent growth model determined whether attitudes influence nonverbal convergence across interactions. Multilevel structural equation models determined whether attitudes influence nonverbal convergence across the interaction and, in turn, outcomes.

Results: Patient discrimination influenced convergence of openness frequency, continuer frequency, talk time and word count. Patient suspicion influenced convergence of gaze duration, openness duration, continuer frequency, and word count. Convergence of talk time and continuer duration mediated the effects of suspicion and discrimination on patient perceptions of oncologist patient centeredness and physician perceptions of patient attributes.

Conclusion: As predicted, the association between racial attitudes and outcomes was mediated by patient-oncologist nonverbal convergence. Future research should examine these relationships in other settings, using longitudinal designs to determine effects on treatment.

PERCEIVED COGNITIVE PROBLEMS AMONG CHRONIC MYELOGENOUS LEUKEMIA PATIENTS TREATED WITH TYROSINE KINASE INHIBITORS

Ashley M. Nelson, MA¹, Aasha I. Hoogland, PhD², Kelly A. Hyland, BA¹, Shannon M. Christy, PhD³, Brittany Kennedy, BS Public Health BS Biomedical Sciences⁴, James C. Root, PhD⁵, Tim Ahles, PhD⁵, Paul Jacobsen, PhD⁶, Heather Jim, FL²

¹Moffitt Cancer Center & the University of South Florida, Tampa, FL; ²Moffitt Cancer Center, Tampa, FL; ³University of Tennessee Health Science Center, Memphis, TN; ⁴Moffitt Cancer Center, Tampa, FL; ⁵Memorial Sloan Kettering Cancer Center, New York, NY; ⁶National Cancer Institute, Bethesda, MD

Background: Targeted therapies such as tyrosine kinase inhibitors (TKIs; e.g., imatinib) are increasingly being used to treat many forms of cancer including chronic myelogenous leukemia (CML). Anecdotal reports suggest that cognitive problems may be common among CML patients treated with a TKI. To our knowledge, no studies have conducted a detailed quantitative investigation of perceived cognitive problems among CML patients treated with TKIs. Accordingly, the goals of this first study were to: 1) describe perceived cognitive problems among CML patients treated with TKIs, and 2) compare their perceived cognition to that reported by individuals without cancer.

Method: CML patients treated with the same oral TKI for ≥ 6 months were recruited at Moffitt Cancer Center or Memorial Sloan Kettering Cancer Center. All participants provided socio-demographic information and completed a self-report measure of perceived cognitive problems (i.e., the Everyday Cognition Measure), which assesses perceived problems in memory, language, visual/spatial, planning, organization, divided attention, and satisfaction with cognition.

Results: Data were available for 51 patients (age $M = 52$ years, 47% female, 82% some college) and 87 non-cancer controls (age $M = 53$ years, 54% female, 91% some college). Controls did not differ from patients with respect to age, gender, or education (p values $> .05$). Patients reported worse memory, planning, and divided attention compared to controls (p values $< .05$) and less satisfaction with their cognition ($p < .001$). Patients and controls did not differ with respect to language, visual/spatial, or organizational abilities (p values $> .05$). Among patients, perceived cognitive problems were not associated with time on TKI treatment (p values $> .05$).

Conclusions: Results indicate that CML patients treated with TKIs are more likely to report problems with their cognition compared to non-cancer controls. Specifically, deficits were reported in memory, planning, and divided attention abilities. Future studies should seek to better understand the impact of TKIs on cognition using prospective, longitudinal designs and incorporating neurocognitive tests in addition to patient-reported measures.

PERCEPTIONS OF CARE COORDINATION AND DISTRESS FOR ETHNICALLY DIVERSE OLDER ADULTS LIVING WITH ADVANCED CANCER

Margaret Clayton, PhD¹, Hilda Haynes-Lewis, PhD², Lauren Clark, PhD³, Alyson Moadel-Robblee, PhD⁴, Shankar Viswanathan, PhD⁴, Michael Caserta, PhD³

¹University of Utah, Salt Lake City, UT, UT; ²Montefiore Medical Center, BRONX, NY; ³University of Utah, Salt Lake City, UT; ⁴Albert Einstein College of Medicine, Bronx, NY

Ethnically diverse older adults with advanced recurrent cancer have been shown to experience concerns about care coordination, distress, and have unmet supportive care needs (SCNs) yet many display resilience during treatment. Despite the increasing number of older mostly minority adults living with advanced cancer in poorly resourced urban communities, there is a lack of research that describes the impact of distress on their supportive care needs and care coordination. In addition, researchers have not explored potential differences in perceptions of these issues by urban ethnically diverse older adults. To better understand the perceptions of these patients we conducted semi-structured interviews with 31 community dwelling older adults with advanced or recurrent cancer who received oncology care at an urban academic medical center (20 men / 11 women; African Americans (35%); Caucasian (xx%); mean age 70 years). The most prevalent cancer diagnoses were prostate (32%), head and neck (29%) and breast (10%). 45% were actively receiving treatment. Findings demonstrated that patients (1) interpret care coordination as synonymous with trusting relationships and respectful communication with providers (2) are a valuable active partner in the healthcare team and that overall their SCNs were met, (3) believe race does not play a role in cancer development because cancer strikes randomly, (4) believe race can play a role in cancer care and (5) find inner strength that comes from God and family/community support. Participants exhibited personal strength, trust, awareness and resilience, despite limited resources.

Healthcare providers can promote care that emphasizes and acknowledges the skills, achievements and resilience of older adults when interacting with patients and families along the cancer care continuum. Nurses specifically are positioned to facilitate patient participation in care by developing trusting respectful relationships which provide important opportunities for need assessment, patient teaching, and the development of treatment plans that are congruent with the priorities of the older adults with advanced or recurrent cancer.

PROGRAM MANAGERS' REPORT OF IMPLEMENTATION CHALLENGES AND STRATEGIES FOR PEER SUPPORT PROGRAMS IN CANCER

Kaitlyn Brodar, MPH¹, Veronica Carlisle, MPH, CHES², Patrick Y. Tang, MPH³, Edwin B. Fisher, PhD³

¹University of Miami, Miami, FL; ²University of North Carolina-Chapel Hill, Linberger Comprehensive Cancer Center, Chapel Hill, NC; ³UNC Gillings School of Global Public Health, Chapel Hill, NC

Research shows that peer support is effective across the continuum of cancer prevention, care, and survivorship. However, little is known about how peer support is provided outside of research settings and on a regular, day-to-day basis. Following a systematic search of NCI-designated cancer centers and a web search of key words ("peer support," "navigator," etc.) for cancer peer support programs, we completed semi-structured phone interviews with program managers of 29 cancer peer support programs in the US, Canada, and England.

We found that peer support in cancer is widely implemented and highly valued by patients and their families. This value of peer support was indirectly underscored by the observation that many patients found it helpful just to be given the name of peers who had experienced similar cancer or treatment, even without ever contacting them. Peer supporters and those they help especially appreciate being connected to each other through a community or network; programs that provided multiple avenues for involvement seemed to have the greatest retention and program engagement of both supporters and support seekers.

Program managers described a variety of challenges to implementing peer support. Inconsistent funding and reliance on a constant flow of volunteers are primary obstacles. Additionally, nearly every program cited diversity and accessibility as a major challenge. Because both supporters and recipients are reported to be mostly older, white women, problems with diversity are better understood in social network terms than with an assumption that some groups are fundamentally disinterested in peer support. Thus, recruiting peer supporters from diverse communities is a priority. A final challenge identified was physician resistance. Although nurses and social workers generally encourage programs, some oncologists continue to express reservations, apparently related to concerns that peers might convey misinformation or encourage inappropriate or harmful treatments. Coordinating with and educating physicians about peer support programs are priorities. Added resources, especially for staff coordination, would help with each of these challenges. Peer support in cancer needs to be recognized and funded as a routine part of care and survivorship support so that adequate resources become available.

Our observations highlight key issues faced by cancer peer support programs and complement peer-reviewed studies in describing and characterizing the field. Increasing recognition that peer support makes important contributions to cancer care and funding commensurate with that recognition are important objectives for the future.

PROMOTING INFORMED SCREENING DECISIONS AMONG MEN AT HIGH RISK FOR PROSTATE CANCER

Ricardo Wray, PhD MS¹, Shannon Nicks, PhD, MPH², Prajakta Adsul, MBBS, MPH, PhD³, Michael Elliott, PhD M.S.⁴, Keri Jupka, MPH⁵, Anna K. Trainer, MPH, MA⁶, Merve Shahid, Sr., Nine year Prostate Cancer survivor⁷, Robin Wright-Jones, Retired Missouri State Senator⁷, Sameer Siddiqui, MD⁸

¹Saint Louis University College for Public Health and Social Justice, St. Louis, MO; ²Ohio University, Athens, OH; ³National Cancer Institute, Gaithersburg, MD; ⁴Saint Louis University College for Public Health and Social Justice, Saint Louis, MO; ⁵Parents as Teachers, St. Louis, MO; ⁶Simply Strategy, St. Louis, MO; ⁷The Empowerment Network, Inc., St. Louis, MO; ⁸Saint Louis University, St. Louis, MO

Recent years have seen differing recommendations on screening guidelines for prostate cancer (PCa) from national organizations such as the American Urological Association and the United States Preventive Services Task Force, reflecting the uncertainty of benefits and harms resulting from screening. Current guidelines encourage men to make individual screening decisions after consulting with their primary care provider to weigh the risks and benefits of undergoing Prostate Specific Antigen (PSA) testing. Many men at high risk of a PCa diagnosis (notably African American men) however, are more likely to be uninsured and lack a primary care provider. Mass community-based programs targeting underserved populations often provide the only opportunity for preventive screening services. The Saint Louis University Center for Cancer Prevention, Research and Outreach (CCPRO) redesigned its mass community-based screening program to ensure access to services to underserved men, while at the same time incorporating a session with a trained clinical educator in the community settings, designed to increase knowledge and promote informed decision making regarding PSA testing. To evaluate program efficacy, ninety men completed pre- and post-test surveys evaluating the outcomes of interest. The results showed that participants'; knowledge, beliefs, attitudes, anxiety levels, and self-confidence all improved from the pre-test to the post-test at a statistically significant level. Most notably participants'; awareness that PCa is often not life-threatening, and that watchful waiting is a reasonable treatment option increased after the encounter. More than half of the study sample felt they had received enough knowledge to make an informed decision about whether the PSA test was right for them. The findings of the evaluation show that the program had a positive effect on men';s ability to make informed decisions about PCa screening, and demonstrate that educational outreach programs with an emphasis on informed decision making can effectively balance screening guidelines with the needs of underserved populations in community settings to improve outcomes.

REFUSAL IN RESPONSES TO SEXUAL ORIENTATION AND GENDER IDENTITY SURVEY ITEMS AMONG CANCER SURVIVORS

Hayley S. Thompson, Ph.D.¹, Nicole Senft, PhD², Deirdre A. Shires, MSW, MPH, PhD³, Anne Katz, RN, Ph.D.⁴, Deborah Charbonneau, PhD⁴, Judith Abrams, PhD⁵, Elisabeth Heath, MD², Ke Zhang, Ph.D.⁴, Jennifer Beebe-Dimmer, MPH, PhD⁴

¹Wayne State University -Karmanos Cancer Institute, Detroit, MI; ²Wayne State University/Karmanos Cancer Institute, Detroit, MI; ³Michigan State University, East Lansing, MI; ⁴Wayne State University, Detroit, MI; ⁵Karmanos Cancer Institute, Detroit, MI

There is growing evidence of sexual and gender minority (SGM) disparities in cancer risk, incidence and morbidity but data on sexual orientation and gender identity (SOGI) in the context of cancer prevention and control are limited. In particular, SOGI data are unavailable within the National Cancer Institute's Surveillance and Epidemiology End Results (SEER) program due, in part, to lack of SOGI data collection in hospital-based cancer registries and patient records - main sources of SEER data. Health systems have not historically asked SOGI questions, which are often assumed to be sensitive questions with higher non-response rates. SOGI items have recently been included in some national population-based health surveys, albeit inconsistently (e.g., inclusion of SO but not GI items or item administration limited to younger respondents). However, the extent to which cancer investigators collect SOGI data in smaller-scale research studies is unclear, especially in work focused on racial/ethnic groups when such items might be culturally unacceptable. The current study examined SOGI and other potentially sensitive question refusal rates in a sample of 357 breast, prostate, and colorectal cancer survivors recruited from the Metropolitan Detroit Cancer Surveillance System (MDCSS), part of the SEER program. Participants were recruited as part of an ongoing technology use study and all were directly asked potentially sensitive questions by trained interviewers via telephone. Mean age of participants was 62 years; 67% identified as female, 33% identified as male; 57% were African American (AfAm), 43% were white. Refusal rates were compared across sexual orientation (gay, straight, or other), gender identity (male, female, or transgender), household income, education level, and body weight. To adjust for sampling bias, responses were weighted on each respondent';s probability of selection and stratified by gender/race based on representation in the MDCSS. None of the respondents refused to answer items about sexual orientation, gender identity, or education. All participants who identified as gay were AfAm. Refusal rate for body weight was also relatively low (0.6% 95% CI: 0, 4.7; n=3). However, 8.4% (95% CI: 16.5, 45.3; n=28) refused to answer the income question. Findings suggest that concerns about SOGI items may be unwarranted even in older, racially diverse populations and that these items can be routinely included in health surveys, with great potential benefit for advancing the science of SGM cancer disparities and appropriate interventions.

THE RELATIONSHIP BETWEEN CANCER-RELATED DISTRESS AND BIOPSYCHOSOCIAL CONCERNS AMONG VETERANS IN OUTPATIENT ONCOLOGY

Lauren Z. Rynar, M.S.¹, Desiree Azizoddin, Psy.D.², Joanna Martin, M.D.³, Susan Payvar, Ph.D.³, Robert Molokie, M.D.⁴, Joshua Hauser, M.D.⁵, Hidayatullah Munshi, M.D.⁵

¹Rosalind Franklin University of Medicine and Science, Chicago, IL; ²Department of Anesthesia, Perioperative, and Pain Medicine, Stanford University Health Center, Redwood City, CA; ³Jesse Brown VA Medical Center, Chicago, IL; ⁴University of Illinois at Chicago and Jesse Brown VA Medical Center, Chicago, IL; ⁵Northwestern Memorial Hospital and Jesse Brown VA Medical Center, Chicago, IL

Background: The Commission on Cancer recommends supportive oncology and survivorship care for all patients with cancer, which includes systemic screening for cancer-related distress. In accordance with this recommendation, a needs-based screening tool was implemented in a VA oncology clinic and the resulting data were examined. Understanding the interrelationships between multiple cancer-related concerns is important for effectively identifying needs.

Methods: Veterans (N=115) completed the “Patient Screening Questions for Supportive Care” by the Coleman Foundation. The following domains were assessed: psychological distress, practical, self-care, caregiver/family, spiritual, nutritional, physical activity, and treatment concerns, pain, and fatigue. One-way ANOVA were used to examine differences in concerns across level of distress (normal, mild, moderate, severe). Logistic regression was performed to ascertain the effects of cancer-related concerns on the likelihood that Veterans had positive depression or anxiety screens.

Results: Concerns did not vary based on race, type of cancer, or stage of cancer. 34.7% of participants presented with psychological distress based on the PHQ-4. Participants who endorsed mild (PHQ-4=3–5) or moderate (PHQ-4=6–8) distress were more likely to also endorse physical ($p<.001$), nutrition ($p=.001$), physical activity ($p<.001$), and treatment ($p=.002$) concerns, and to report worse fatigue ($p<.001$), than individuals who were not distressed. Logistic regression models revealed that increases in fatigue ($\text{Exp}(B)=2.8$, $p<.001$) and treatment concerns ($\text{Exp}(B)=2.2$, $p<.01$) increased the odds of a positive anxiety screen. Fatigue ($\text{Exp}(B)=3.2$, $p<.001$) and treatment concerns ($\text{Exp}(B)=1.5$, $p=.05$) increased the odds of a positive depression screen.

Conclusions: Veterans in an outpatient oncology clinic frequently endorsed psychological distress. It is evident that when Veterans experience even mild psychological distress, they also present with a wide range of biopsychosocial concerns. This finding highlights the importance of screening Veterans within oncology clinics for depression, anxiety, and other cancer-related concerns, and implementing appropriate follow-up procedures, to improve overall functioning.

6:30 PM-7:30 PM

THE ROLE OF ETHNICITY IN THE EFFECT OF CANCER PATIENTS' EMOTIONAL COPING STRATEGIES ON PHYSICAL SYMPTOMS AND QUALITY OF LIFE

Marcella May, MA, Hannah-Rose Mitchell, MPH, Amanda Ting, BS, Charles S. Carver, PhD, Youngmee Kim, PhD

University of Miami, Coral Gables, FL

Cancer diagnosis and treatments trigger intense emotions that compromise quality of life when not managed adequately. There are large individual differences in how cancer patients manage such emotions, and this may account for disparities in health recovery among cancer survivors. The present study investigated the effects of emotional coping strategies on patient-reported health outcomes (PROs) and the potential moderating role of ethnicity (Hispanic vs non-Hispanic) in the associations.

Patients who were newly diagnosed with colorectal cancer (Stage I to IV; 62% female; 62% Hispanic; age $\bar{x}=55.0$) participated in a longitudinal study: initial assessment approximately 3 months post-diagnosis (T1) and follow-up approximately 11 months post-diagnosis (T2; $n = 56$). Four types of emotional coping strategies (emotional expression, emotional processing, denial, and venting: CTEA and B-COPE) to manage cancer-related stress and self-reported ethnicity, all measured at T1, served as primary predictors. Outcomes of overall health-related quality of life (FACT-G) and physical symptoms (Emmons Physical Symptoms Scale) were measured at T1 and T2. Age, gender, education, and outcomes measured at T1 served as covariates.

General linear modeling revealed, after controlling for the effects of covariates, that the use of venting tended to be related to increased physical symptoms for all patients, $B=.197$ $p<.07$, and that this was more prominent among non-Hispanic patients $F(1, 41)=5.70$, $p<0.02$. On the other hand, the use of emotional processing tended to be related to better quality of life only among Hispanic patients $F(1, 41)=3.13$, $p<0.08$.

Results indicate that ethnicity is an important moderator of the efficacy of some of these specific emotional coping strategies. As advances in cancer treatment increase the duration of patient survival, therapies and techniques that improve patient quality of life are of paramount importance, and further research should therefore continue to take sociocultural moderators of therapeutic effectiveness into consideration.

THE ROLE OF PSYCHOSOCIAL PROCESSES AND DEMOGRAPHIC CHARACTERISTICS IN UNDERSTANDING STIGMA AMONG LUNG CANCER PATIENTS

Heidi A. Hamann, PhD¹, Megan J. Shen, PhD², Sarah N. Price, B.A.³, Jamie Ostroff, PhD⁴¹University of Arizona, Tucson, AZ; ²Weill Cornell Medicine, New York, NY; ³The University of Arizona, Tucson, AZ; ⁴Memorial Sloan Kettering Cancer Center, New York, NY

Introduction: The experience of stigma is pervasive and harmful for lung cancer patients. Developing effective psychosocial interventions requires identifying those at greatest risk and targeting modifiable facilitators of stigma. Our previous work has identified three correlated, yet conceptually distinct, aspects of lung cancer stigma: Perceived Stigma (PS), Internalized Stigma (IS), and Constrained Disclosure (CD). The goals of the following analyses were to: 1) understand correlates of lung cancer stigma, and 2) identify factors that moderate relationships between PS, IS, and CD.

Method: Participants included 231 individuals diagnosed with lung cancer (64% women; mean age=63 years). Bivariate analyses examined associations between PS, IS, CD (measured by corresponding Lung Cancer Stigma Inventory [LCSI] subscales) and demographic/clinical variables (age, education, race/ethnicity, smoking status, disease stage), along with psychosocial processes (social constraints, patient activation). Moderation was tested by analyzing interactions in linear regression models.

Results: Smoking status (ever v. never smokers), race/ethnicity, patient activation, and social constraints were associated with the LCSI factor scores. Ever-smokers reported higher levels of IS compared with never-smokers ($p < .001$) and patient activation was inversely correlated with CD scores ($p < .05$), but neither moderated relationships between stigma components. Non-Hispanic White (NHW) patients reported higher levels of IS than racial/ethnic minority patients. Greater reporting of social constraints was associated with higher PS, IS, and CD. As noted by significant interactions, higher levels of social constraints were associated with stronger relationships between all three factors: PS and IS ($p < .01$), PS and CD ($p < .001$), IS and CD ($p < .01$).

Conclusions: Higher levels of social constraints were not only independently associated with IS, PS, and CD, but also strengthened relationships between these underlying elements of lung cancer stigma. The ability to mitigate social constraints and facilitate adaptive social relationships will be important components of effective stigma-reducing interventions for lung cancer patients. With the limited exceptions of smoking status and race/ethnicity, elements of stigma do not significantly differ based on demographic factors, suggesting that stigma is not limited to specific subpopulations of lung cancer patients.

USING HINTS TO EXPLORE CANCER BELIEFS AND HEALTHY BEHAVIORS ASSOCIATED WITH PAP TESTING IN ASYMPTOMATIC WOMEN

Prajakta Adsul, MBBS, MPH, PhD

National Cancer Institute, Gaithersburg, MD

Cervical cancer is a public health burden for aging women and secondary prevention through pap testing can help reduce this burden. However, cancer screening is a complex process and requires an asymptomatic individual to engage in a behavior that may result in a cancer diagnosis. In addition, women receive multiple and sometimes conflicting, recommendations from various healthcare organizations with regards to frequency and intervals on undergoing Pap tests. In this context, we wanted to describe socio-demographic

Towards this objective, we used the Health Information National Trends Survey (HINTS) which is a nationally representative survey and target adults aged 18 years or older in the civilian non-institutionalized population of the United States. This study was conducted on the HINTS 5 (Cycle 1) data.

Given the specific age groups recommended by the United States Preventive Services Task Force recommendations for screening, we focused our analyses regarding the adherence to Pap test on women between the ages of 21- 65 years of age. According to the recommendations, we considered women were adherent if they had their Pap test up to 3 years ago. We excluded all cases with a history of cancer. We conducted bivariate analysis to describe sociodemographic factors, cancer related health beliefs and other behaviors associated with adherence to cancer screening behaviors.

A total of 1079 women were included in the analysis for Pap test, of which 902 (83.6%) were adherent to the recommendations. Age, occupational status, educational status, marital status and having insurance ($p < .05$) was associated with women adherent to cervical cancer screening recommendations. There were no associations seen in women with the following beliefs: likelihood of getting cancer, everything causes cancer, preventing cancer is not possible, too many recommendations for cancer, cancer is more common than heart disease, cancer is fatal, and personal worry about getting cancer. However, women adherent to the Pap testing recommendations showed association ($p = .006$) with the statement "I'd rather not know my chance of getting cancer." In addition, there was association between physical activity ($p = .008$) but not with diet or tobacco use.

The study provides descriptive information about asymptomatic women who are adherent to the USPSTF recommendations including their socio-demographic characteristics, health beliefs, and their participation in other healthy behaviors such as physical activity and diet. These factors are important to understand in how they might be utilized in interventions directed at promoting women's adherence to screening recommendations. Interventions promoting screening behaviors and health communication campaigns designed to motivate asymptomatic women to undergo screening may need to target specific factors identified in the study.

ASSOCIATIONS BETWEEN CAROTID INTIMAL MEDIAL THICKNESS AND NEUROCOGNITIVE PERFORMANCE IN A COMMUNITY SAMPLE OF OLDER ADULTS

Desiree C. Bygrave, PhD¹, Regina Wright, PhD¹, Denee T. Mwendwa, PhD²¹University of Delaware, Newark, DE; ²Howard University, Washington, DC

Atherosclerosis is a common pathologic process underlying cardiovascular disease (CVD). Subclinical atherosclerosis may be independently associated with cognitive decline among adults without clinically evident CVD. Carotid intima-media thickness (IMT), a marker of subclinical atherosclerosis, has emerged as a correlate of poorer performance on neuropsychological tests of cognitive function. Further underscoring this association are racial disparities in CVD morbidity and mortality that may translate to more pronounced carotid IMT and neurocognition relations among African Americans. To this end, the study examined the association between carotid IMT and neurocognitive performance in a diverse sample of older adults. In addition, the study examined race-stratified associations between carotid IMT and neurocognitive performance, adjusting for subclinical covariates. Data were analyzed from The Healthy Heart and Mind Study, a cross-sectional examination of relations of subclinical and traditional cardiovascular risk factors to brain volumes and cognitive performance among older adults. Fifty-three participants (38% male; 38% African American) with a mean age of 68.94y (SD=6.25) completed an eligibility screening, neuropsychological test battery, vascular testing, a blood draw, and structural MRI. Multiple regression analyses examining relations of carotid IMT to neurocognitive performance were adjusted for age, gender, education, supine mean arterial pressure and depression. Results showed that greater far wall carotid IMT was negatively associated with attention and response inhibition ($p=.055$). Results suggest subclinical atherosclerosis may impact specific neurocognitive domains via unique race-related pathways. Future studies should 1) further examine race-related differences in a larger, diverse sample; 2) examine related frontal brain volumes; and 3) examine psychosocial and demographic factors that may inform interventions to delay or prevent atherosclerosis and neurocognitive decline.

BODY IMAGE AMONG YOUNG ADULT SURVIVORS OF CONGENITAL HEART DISEASE

Jamie L. Jackson, PhD¹, Carine Leslie, B.S.¹, Canice E. Crerand, PhD²¹Nationwide Children's Hospital, Columbus, OH; ²The Research Institute at Nationwide Children's Hospital, Columbus, OH

Objective: Congenital heart disease (ConHD) often requires surgical intervention to correct or palliate a cardiac lesion. Many ConHD survivors undergo multiple surgeries during their lifetime, leaving prominent scars on the chest and/or trunk. While it is known that body image concerns can negatively affect well-being, limited research has examined the association of scar-related body image concerns on patient-reported outcomes among ConHD survivors. The aim of this cross-sectional study was to 1) compare body image concern scores for ConHD survivors to other populations and 2) identify associations between body image concerns and patient-reported outcomes.

Methods: Participants were 128 young adult ConHD survivors (M age = 29.7 + 7.1 years, range = 18–42; 56% female; cardiac lesion severity = 12% simple, 52% moderate, 36% complex) recruited for a larger study. Participants completed the Body Image Disturbance Questionnaire (BIDQ) that was tailored for ConHD (e.g., Are you concerned about the appearance of your cardiac surgery scar[s]?), Hospital Anxiety and Depression Scale, and RAND 36-Item Health Survey 1.0. T-tests were performed comparing the average BIDQ scores for this sample to other patient populations and examining sex differences. Pearson correlations identified associations between body image concerns, emotional distress, and health-related quality of life (HRQoL).

Results: Means scores for the BIDQ were 1.3 + 0.5, with only 2 participants scoring above 3, a clinical cutoff for body image disturbance. Over 70% reported no preoccupation with their cardiac surgery scars. Mean scores on the BIDQ were significantly lower for this sample compared to college students (M = 1.8), teens with craniofacial conditions (M = 1.7), and teens with idiopathic scoliosis (M = 1.5). Females (M = 1.4) reported higher BIDQ scores than males (M = 1.2). Higher BIDQ scores were associated with more depressive ($r = 0.2$) and anxiety ($r = 0.4$) symptoms, poorer physical ($r = -0.2$), emotional ($r = 0.3$) and social ($r = -0.3$) functioning, as well as more pain ($r = -0.3$) and worse general HRQoL ($r = -0.2$).

Conclusions: Young adults with ConHD reported fewer body image concerns than the general population, as well as other populations who have visible signs of medical conditions. However, scores on the BIDQ were associated with risk for emotional distress and poor HRQoL. Those presenting with body image concerns should receive psychosocial resources to prevent worsening patient-reported outcomes.

CHALLENGES AND BARRIERS TO CARING FOR A PERSON WITH HEART FAILURE

Lauren Bangerter, PhD¹, Joan M. Griffin, PhD², Shannon Dunlay, MD, MS¹¹Mayo Clinic, Rochester, MN; ²Mayo Clinic, Rochester MN, MN

This study examines the experience of caregivers of heart failure (HF) patients, a chronic condition that is often accompanied by other complex comorbidities and characterized by high rates of hospitalization. The aim of this study was to identify significant challenges for caregivers of HF patients and to identify potential areas for further intervention research. We conducted qualitative, semi-structured interviews conducted by phone. Interviews included questions about challenging components of caring for a HF patient. Interviews were digitally recorded and transcribed verbatim for analysis. Content analysis procedures were used to identify various themes and patterns contained in the text. Semi-structured interviews were conducted with 16 caregivers (14 female; median age = 63 years) of Southeastern Minnesota residents recently hospitalized with HF (5 female; median age 83.5 years). Findings reveal that caregiver challenges were rooted in interpersonal difficulties with the patient as well as the complexities of the patient's comorbidities. Caregivers described difficulty in dealing with the demands and expectations of the HF patient as well as shifts in the patient's personality and mood. Another challenge identified was managing other complex comorbidities of the HF patient including depression, cognitive decline, pre-existing illness, and acute injury. Caregivers identified significant challenges rooted in the caregiving demands and the comorbidities of the HF patient. These challenges contributed extensively to caregiver burden, frustration, and overload. Findings indicate the importance of addressing interpersonal issues with the caregiver and patient as well as practical aspects of caring for a patient with complex comorbidities. Caregivers of HF patients may benefit from enhanced support services to address difficulties with demanding patients and effectively manage complex care tasks for comorbidities. Further research is needed to understand how best to provide caregivers with effective social support and education.

COMORBID OBESITY AND DEPRESSION AS CARDIOVASCULAR RISK AND ACCESS TO CARE AMONG RURAL WOMEN

Amnazo Muhirwa, MSN-FNP(s), BSN, RN, BA¹, Elijah O. Onsomu, PhD, MPH, MS, MCHES¹, Devon Noonan, PhD, MPH, FNP-BC², Leigh Ann Simmons, PhD, MFT²¹Winston-Salem State University, Winston Salem, NC; ²Duke University, Durham, NC

Title: Comorbid Obesity and Depression as Cardiovascular Risk and Access to Care Among Rural Women

Background: Rural women experience greater disparities in rates of cardiovascular heart disease (CVD) compared to their urban counterparts. Comorbid obesity and depression increase both short-term and long-term risk for hypertension, stroke, hypercholesterolemia, and myocardial infarction. In addition, poor access to care delays early detection and successful illness management, leading to poor health outcomes.

Objective: To examine the association between depression, obesity and access to health care among rural women.

Method: A retrospective cross-sectional analysis was conducted using data from the Rural Families Speak about Health (RFSH) Study, a national study of rural low-income women (N = 442) living in households with incomes at or below 185% of the federal poverty line. Multivariate logistic regression was used to examine the covariate adjusted associations between obesity, depression, their co-occurrence, and access to care obtaining adjusted odds ratios (AOR) and 95% confidence intervals.

Results: The majority of participants (77%, n = 307) were overweight or obese, 35% (n = 154) were depressed, and 28% (n = 124) had a co-occurrence of both depression and obesity. Approximately, 70% (n = 310) had access to care, which was determined by if one had a personal doctor who regularly cared for them. Those participants who were overweight were 47% (AOR = 0.53, $p = 0.034$) less likely to have access to care compared to those who had a normal weight or below. Those who were depressed were 34% (AOR = 0.66, $p = 0.39$) less likely to have access to care compared to those who were not depressed. Among those with co-occurrence of obesity and depression, they were 38% (AOR = 0.62, $p = 0.043$) less likely to have access to care compared to those who did not have a co-occurrence.

Discussion: Findings show that a large proportion of rural women have cardiovascular disease risk as defined by obesity and depression, both treatable disorders. Most notably, the rate of CVD among rural women may be decreased by broad reach preventative health efforts that address both depression and overweight/obesity simultaneously among these medically underserved women.

SOURCES OF TENSION DURING THE EVALUATION AND THERAPY PROCESS AMONG PARENTS OF CHILDREN WITH DEVELOPMENTAL DELAYS

Hannah J. Badal, MPH¹, Courtney Scherr, PhD¹, Laura J. Sudec, MSW², Anna Dolezal, MS¹, Charlotte G. Marshall-Fricker, N/A², Megan y. Roberts, PhD²

¹Northwestern University, Chicago, IL; ²Northwestern University, Evanston, IL

Background: Developmental delays in children are common, but up to 90% of toddlers with developmental delays do not receive early intervention services. Early intervention is crucial to maximize functional outcomes. The process of learning about a child's developmental delay and obtaining services can be challenging and a significant emotional stressor on parents. Yet, few studies have examined parents'; experience with the identification of developmental delays in children.

Methods: Semi-structured in-depth interviews ($N=10$) were conducted via telephone with self-identified White parents of children identified with a developmental delay between 18–36 months old and who participated in the Illinois Early Intervention program. This program provides free assessment, evaluation, and therapy services for children under 3 years. We recruited parents from a network of early intervention families and clinical partners using flyers and social media posts. Two study team members conducted thematic analysis using interview transcripts to identify common themes in parents'; experience.

Results: Parents in this sample experienced tensions between voicing concerns about their child's development, and receiving dismissive responses from others. For example, although parents are told to be aware of developmental milestones, in our sample pediatricians often encouraged a "wait and see" approach, and family and friends suggested everything was fine. Parents often second-guessed their concerns and waited to obtain services for their child based on these responses. They encountered a secondary tension when their concerns were validated during the evaluation process and they learned the benefits of early intervention. This awareness increased parental guilt for not starting therapy as early as possible. Once a developmental delay was identified, parents reported adverse emotional responses including feelings of guilt and self-blame, sadness, frustration, and feeling overwhelmed and unsupported.

Conclusion: Parent's adverse emotional responses to learning about a child's developmental delay and obtaining early intervention services were complicated by tensions between their concerns and others'; minimizations or attempts at reassurance. These findings indicate social support parents receive during this process may increase parents'; emotional stress later on. Addressing the dismissal of parental concerns by others may help parents advocate for their child.

DO BELIEFS ABOUT THE CAUSES OF HIGH BLOOD PRESSURE PREDICT INTENTIONS TO CHANGE LIFESTYLE BEHAVIORS AMONG HINTS PARTICIPANTS?

Aisha T. Langford, PhD, MPH¹, Craig Solid, PhD, MS², Azizi Seixas, PhD, MS, MA³

¹NYU School of Medicine, New York, NY; ²Solid Research Group, LLC, Saint Paul, MN; ³NYU Langone Health, New York, NY

Background: About 75 million U.S. adults have hypertension (HTN). Lifestyle behaviors such as unhealthy diet and low levels of exercise increase a person's risk for developing HTN. However, uptake and adherence to lifestyle change interventions is low.

Objective: (1) Describe causal beliefs for developing HTN by sociodemographic factors and HTN status, and (2) evaluate associations between causal beliefs (genetic and lifestyle) and intentions to change behaviors.

Methods: Data from the 2014 Health Information National Trends Survey (HINTS) 4 Cycle 4 were evaluated ($N=3677$). Causal questions included: 1) "How much do you think health behaviors like diet, exercise, and smoking determine whether or not a person will develop high blood pressure/hypertension?"; and 2) "How much do you think genetics, that is characteristics passed from one generation to the next, determine whether or not a person will develop high blood pressure/hypertension?" Behavior change intention questions related to fruit, vegetable, and soda intake; weight management, and exercise. Chi-square tests assessed differences in observed proportions. Multivariate ordinal and nominal logistic regressions evaluated associations between causal beliefs and behavior change intentions among those with HTN.

Results: A total of 1602 out of 3677 respondents (~44%) reported having HTN. Those with HTN were more often older, Black, less educated, and obese. There was no difference between those with HTN and those without HTN in beliefs about the role that behaviors play in developing HTN ($P=0.1442$). However, those with HTN had significantly stronger beliefs in the role of genetics in developing HTN compared to people without HTN ($P<0.001$). In logistic regression models, there was a noticeable pattern: the less strongly people believed in the impact of behavior on developing HTN, the lower their odds for intentions to change behavior. For example, compared with those who believed that behavior had "a lot" of influence on developing HTN, those who said behavior had "some-what" of an impact had a 40% lower chance of intentions to increase fruit intake ($OR=0.60$; $CI: 0.40, 0.91$, $P=0.017$), 39% lower change of intentions to increase vegetable intake ($OR=0.61$; $CI: 0.41, 0.91$, $P=0.014$), and 51% lower chance of intentions to increase exercise ($OR=0.49$; $CI: 0.31, 0.78$, $P=0.002$). Beliefs about genetic causes of HTN were not associated with any intentions change behavior. Women had higher odds of intentions to change behaviors compared to men. Blacks and Hispanics were significantly more likely than Whites to report intentions to lose weight.

Conclusions: Beliefs about behavioral causes of HTN, but not genetic, are associated with intentions to change behaviors. Health messages that incorporate causal beliefs about HTN and sociodemographic factors may enhance behavior change attempts.

EXPLORING OLDER AFRICAN AMERICAN WOMEN'S PERSPECTIVES ON INFORMATION SHARING TO IMPROVE HEALTH IN YOUNGER GENERATIONS

Lenette M. Jones, PhD, RN, ACNS-BC¹, Karen O. Moss, PhD, RN, CNL², Kathy Wright, PhD, RN³, Marie-Anne S. Rosemberg, PhD, RN⁴, Cheryl Killion, PhD, RN FAAN⁵

¹University of Michigan School of Nursing, Ann Arbor, MI; ²Case Western Reserve University, Cleveland, OH; ³The Ohio State University, Columbus, OH; ⁴University of Michigan, Ann Arbor, MI; ⁵Case western Reserve University, Cleveland, OH

Purpose: The prevalence of hypertension is highest among African American women, who often occupy caregiving roles. The purpose of this study was to describe intergenerational caregiving and communication themes that emerged during focus groups on information sharing and self-management of hypertension.

Theoretical Framework: Self-management incorporates health-related behaviors into the daily lives of individuals and their families. The process includes social facilitation, meaning that family members influence, support, and collaborate with one another, in order to achieve specific outcomes, such as improved health status and quality of life.

Methods: Older African American women diagnosed with hypertension ($N = 13$, mean age = 73), participated in focus groups designed to explore their thoughts and perceptions about blood pressure information sharing. Data were audio recorded and transcribed verbatim. Transcripts were analyzed for codes, categories, and themes that emerged from these data.

Results: Thematic analysis revealed two overarching themes: Caregiving Responsibilities and Improving the Health of Younger Generations. The women expressed that they wanted to help younger generations to better manage their blood pressures: *...how do we...get young people to come and do [something]?* They felt compelled to share information with younger family members in order to prevent them from enduring the same suffering that they had experienced: *...I'd just like to know how to help; Maybe this generation here could help the next generation...*

Conclusion: This study suggests that intergenerational relationships may have an important role in managing health conditions, such as hypertension. Further examination of intergenerational relationships as targets for self-management intervention is warranted. Future studies are needed to explore these established relationships as a mode for intervention – 1) addressing the need for the women to share their wisdom and 2) helping to improve blood pressure management among African Americans across the lifespan.

NAIVE MODELS OF BLOOD PRESSURE FLUCTUATION AND THE RELATIONSHIP TO MEDICATION ADHERENCE

Julia D. O'Brien, PhD¹, Megan C. Turner, MD², Zachary Zenko, PhD¹

¹Duke University, Durham, NC; ²Duke Health, Durham, NC

Home blood pressure (BP) monitoring offers more precise BP estimates and has a small impact on lowered BP values, thus is it commonly recommended to patients as part of standard care. Regular BP monitoring may lead to habit formation around hypertension management, however it may also provide biometric feedback to patients that is misinterpreted or misunderstood. We present results from three online studies that describe the “naïve models” individuals hold around BP fluctuation over time, and how these naïve models are associated with BP medication adherence.

In Study 1 we found that participants are overly optimistic about how quickly their BP will change in response to medication. Despite having greater experience with BP, hypertensive participants reported even faster expectations ($M = 9.29$ days), compared to non-hypertensive participants ($M = 15.57$). We replicated this pattern in Study 2, where we also found that participants who expected a faster decrease in BP after starting a hypertensive medication reported significantly lower adherence intentions in a hypothetical scenario.

We tested the causal relationship between BP value fluctuation and adherence intentions in Study 3 and found that hypertensive participants with lower chronic adherence levels were more sensitive to hypothetical fluctuations in BP compared to more adherent participants. When less adherent hypertensive participants were randomly assigned to a condition that was shown BP values that were higher than they would have expected, they reported significantly stronger adherence intentions. When these participants were randomly assigned to a condition that was shown BP values that were lower than expected, they reported significantly weaker adherence intentions. Participants with higher chronic adherence levels did not alter their adherence intentions in response to the BP values.

Taken together, our research shows that patients are likely to have unrealistic expectations for how BP should fluctuate over time, and that deviations from these expectations are associated with nonadherence for some patients. Home BP monitoring may be valuable for habit formation and disease management, however further researchers and clinicians should identify the best method of presenting BP values to patients so as to minimize the potential impact of naïve models on medication adherence.

RESPIRATION AND APPLIED TENSION STRATEGIES TO REDUCE VASOVAGAL REACTIONS TO BLOOD DONATION: A RANDOMIZED CONTROLLED TRIAL

Serena Mennitto, BA¹, Johanna Harrison, MSc¹, Thomas Ritz, Ph.D.², Pierre Robillard, MD³, Christopher R. France, Ph.D.⁴, Blaine Ditto, Ph.D.⁵

¹Department of Psychology, McGill University, Montreal, PQ, Canada; ²Department of Psychology, Southern Methodist University, Dallas, TX; ³Héma-Québec, Saint-Laurent, PQ, Canada; ⁴Department of Psychology, Ohio University, Athens, OH; ⁵McGill University, Montreal, PQ, Canada

Vasovagal reactions (VVR) leading to syncope and milder symptoms such as weakness and dizziness are common in medical settings, especially those involving needles and blood. They are typically stress-related, e.g., more common in those fearful of medical procedures, and can adversely impact health and health-care behaviour. Two behavioural strategies to reduce VVR were examined in 547 volunteers at university blood clinics (51% female; $X = 21.2 \pm 2.5$ years; $X = 1.9 \pm 2.3$ previous donations). They were assigned randomly to groups that 1) learned an Applied Tension (AT) muscle-tensing technique in a brief 5-minute pre-donation training session, 2) learned a slow and shallow breathing anti-hyperventilation technique (RESP) before donation, 3) learned a procedure combining AT and RESP, or 4) followed the normal procedure with no pre-donation training. Dependent measures included the self-report Blood Donation Reactions Inventory (BDRI), whether or not the donor required treatment for a VVR or fainted, blood pressure, heart rate, and respiration rate. The primary analyses were 2 AT (yes/no) x 2 RESP (yes/no) x Medical Fear Survey Score (treated as a continuous variable) general linear models (GLM) or logistic regression equations. All treated groups benefited somewhat compared to no treatment as indicated by an AT x RESP interaction effect in the GLM of systolic blood pressure, $F(1,498) = 4.46, p = .035$, reflecting significantly smaller pre- to post-donation decreases in all treated groups. However, RESP produced more clinical benefits. In the logistic regression predicting whether or not the donor was observed to faint by a research assistant, there was a modest but significant main effect of RESP, $OR = 3.2, 95\% CI = 1.1-9.9, p = .039, 3.5$ vs. 5.5% , respectively. The effect of RESP was qualified by an interaction with Medical Fear in the analysis of whether or not the participant was treated for vasovagal symptoms, $OR = 0.46, 95\% CI = 0.28-0.76, p = .003$. Respiration control did not reduce the odds of needing intervention among the more fearful participants but significantly reduced need for intervention among those with less pronounced fear, $X^2(1) = 6.41, p = .011$. A similar interaction was observed in the GLM of BDRI scores, $F(1,530) = 7.99, p = .005$. The results provide further evidence that medically-related VVR can be reduced by simple behavioural procedures though further refinements are needed to help those most susceptible to such reactions.

TELEVISION VIEWING MODERATES THE RELATIONSHIP BETWEEN PHYSICAL ACTIVITY AND BODY FAT IN FEMALES BUT NOT MALES

Mackenzie Perkett, B.S.¹, Richard Suminski, mph, phd², Freda Patterson, PhD¹, Katie M. Heinrich, PhD³, Walker SC. Poston, Ph.D., M.P.H.⁴

¹University of Delaware, Newark, DE; ²department of behavioral health and nutrition, center for innovative health research, university of delaware, newark, DE; ³Kansas State University, Manhattan, KS; ⁴National Development and Research Institutes, New York, NY

Sedentary behavior has emerged as a determinant of poor cardiometabolic health outcomes, even after adjustment for physical activity levels. Less clear is the extent to which sedentary behavior interacts with physical activity to impact cardiometabolic outcomes, such as body fat percentage (BF%). This study addressed this gap by testing the hypothesis that increased sedentary behavior in the form of television viewing would be associated with a higher BF% among physically inactive versus active adults. The study sample were 568 adults who were part of the Kansas City Built Environment and Health Study. Trained interviewers collected study data at participants' homes. BF% was objectively assessed with Tanita foot-to-foot bioelectrical impedance analyzer (Model TBF-305; Tanita). Sedentary behavior (hours spent watching television per week) and physical activity (International Physical Activity Questionnaire - IPAQ) were self-reported. Socio-demographic variables (age, sex, marital status, race, educational attainment, employment status), depression symptoms, perceived stress, restless sleep, fruit and vegetable intake, and perceived neighborhood support for physical activity were assessed as covariates. Linear regression models of BF% were generated and stratified by physical activity level (defined as inactive vs. active according to IPAQ criteria) to test for interaction effects. The sample was 69.9% female with a mean age of 45 years ($SD=14.6$). Majority of participants were Non-Hispanic White (66.5%), married (52.9%), had some college education or more (74.0%), and were employed (60.2%). Nearly 63.0% of the sample were categorized as inactive. For males and females, the average BF% was 26.3% ($SD=9.7$) and 36.0% ($SD=10.3$), respectively. In terms of sedentary behavior, women watched an average of 19.1 ($SD= 16.3$) hours of television each week while males watched an average of 23.6 ($SD=17.8$) hours. Bivariate analysis showed that television viewing was associated with BF% in females but not males, thus regression models were generated for females only. Results showed that among \geq minimally active women, weekly hours of television viewing were not significantly associated with BF% ($B=.038, p=.73$), and that the addition of the television viewing variable to the model did not improve the R^2 . In contrast, among inactive women, weekly hours of television were associated with BF% ($B=.139, p=.04$) and the addition of this variable increased the model predictive capacity by 1.4%. These data indicate that inactive women may be more vulnerable to the negative health effects of increased sedentary time from watching television than \geq minimally active women. The effects of interventions to reduce sedentary time on body composition in inactive women warrants investigation.

THE IMPACT OF DEPRESSION ON TREATMENT ADHERENCE AND CARDIORESPIRATORY FITNESS IN CARDIAC REHABILITATION

Sheau-Yan Ho, Ph.D.¹, Kelly Rohan, Ph.D.², Philip Ades, M.D.³, Patrick Savage, M.S.³¹VA New Jersey Health Care System, New York, NY; ²University of Vermont, Burlington, VT; ³University of Vermont Medical Center, South Burlington, VT

Major depression and coronary heart disease are two strongly linked, major causes of death and disability. After an acute coronary event, many patients are referred to cardiac rehabilitation (CR), a medically supervised exercise intervention and lifestyle training program. Depression may partially account for poor CR adherence and resulting cardiovascular problems in patients with a history of heart disease; however, underlying mechanisms through which depression impacts cardiac functioning are not yet well understood. The current project tests a theoretical model in which CR adherence (i.e., number of CR sessions attended) mediates the relation between baseline depression and cardiorespiratory fitness after CR. A community sample of 858 older adults initiating CR after hospitalization for a coronary event completed a symptom-limited exercise stress test before and after the 12-week exercise program. Cardiorespiratory fitness was measured via VO₂max, peak MET, and total duration of the stress test. Depression was measured at baseline using the Patient Health Questionnaire Depression Scale. CR adherence did not mediate the relation between baseline depression scores and fitness outcomes in the full sample. However, higher levels of depression predicted poorer CR adherence in a subsample of 74 patients with moderate to severe depression. These findings lend support to depression as a predictor of treatment nonadherence in CR. Screening for depression in the context of coronary heart disease and implementing evidence-based depression interventions in secondary prevention settings can help alleviate a massive public health burden.

THE MODERATING ROLE OF PERCEIVED BARRIERS IN PREDICTING THE IMPACT OF INTENTION ON CARDIAC REHABILITATION PARTICIPATION

Tamara M. Williamson, BSc., BA¹, Codie Rouleau, M.Sc.¹, Sandeep Aggarwal, MD FRCPC², Ross Arena, PhD³, Tavis Campbell, PhD¹¹University of Calgary, Calgary, AB, Canada; ²TotalCardiology, Calgary, AB, Canada; ³University of Illinois Chicago, Chicago, IL

Purpose: Participation in cardiac rehabilitation (CR) improves cardiovascular risk factors and reduces morbidity and mortality following acute coronary syndrome. Eligible patients who receive a referral to CR typically report strong intention to attend, yet CR participation rates remain low. The CR Barriers Scale (CRBS) is a self-report questionnaire that assesses well-documented obstacles to CR participation, including healthcare factors, logistical constraints, work/time conflicts, and physical comorbidities. Total CRBS scores are negatively associated with CR participation, but the extent to which specific CR barriers prevent translation of intention into actual CR participation has not been evaluated. This study investigated whether specific CR barriers, characterized by CRBS subscales, moderate the association between intention to attend CR and actual CR participation (i.e., enrollment and attendance).

Methods: One-hundred patients with acute coronary syndrome who were referred to, but not yet enrolled in, a 12-week outpatient CR program in Calgary, Canada, completed the CRBS and a validated two-item measure of intention to attend CR. Actual CR enrollment and attendance were subsequently determined by chart review. Each CRBS subscale was examined as a potential moderator of the association between intention to attend CR and CR participation in two sets (one for CR enrollment, one for CR attendance) of four moderation analyses (one for each CRBS subscale).

Results: On average, patients reported high intention to attend CR ($M=6.08/7.0$, $SD=1.80$) and low CR barriers in terms of healthcare factors ($M=1.53/5.00$, $SD=0.53$), logistical issues ($M=1.86/5.00$, $SD=0.94$), work/time conflicts ($M=2.15/5.00$, $SD=0.98$), and comorbidities ($M=1.68/5.00$, $SD=0.71$). Yet, 17% did not enroll in CR, and the average patient missed 36% of CR sessions. Weaker intention to attend CR corresponded to lower CR enrollment ($b=0.46$, $p=.004$) and poorer attendance ($b=2.26$, $p<.001$). Higher healthcare barriers predicted lower CR enrollment (OR=0.03, 95% CI <.01, 0.17) and poorer attendance ($b=-9.59$, $p<.001$). Work/time barriers were inversely associated with attendance ($b=-2.53$, $p=.008$). Logistical barriers moderated the association between intention and CR enrollment ($b=-0.32$, $p=.027$) and attendance ($b=-1.30$, $p=.005$). Specifically, among patients who reported high logistical barriers ($>M+1.4SD$), stronger intention to attend CR did not significantly predict CR participation.

Conclusion: Perceived logistical barriers influence whether patients successfully translate their “good intention” to attend CR into actual program participation. Interventions to address issues such as financial and transportation constraints among prospective CR patients may be beneficial.

6:30 PM-7:30 PM

THE ROLE OF AGE AND BODY MASS INDEX IN PSYCHOLOGICAL DISTRESS FOLLOWING AN ACUTE CORONARY SYNDROME

Emily H. Feig, PhD¹, Rachel A. Millstein, PhD, MHS¹, Christopher Celano, M.D.¹, Jeff Huffman, MD²¹Massachusetts General Hospital, Boston, MA; ²MGH, Boston, MA

Background: Psychological distress following an acute coronary syndrome (ACS) is common and associated with adverse medical outcomes. Age and body mass index (BMI) may be linked to the presence of—and recovery from—post-ACS distress, but such links are not well-studied. Accordingly, we examined how age and BMI may be associated with distress shortly after ACS, and how they were prospectively related to improvement in psychological symptoms.

Method: The two datasets used for this analysis included participants (Study 1: $N = 126$, M age = 63 years, 59% female; Study 2: $N = 164$, M age = 61 years, 17% female) who experienced an ACS in the prior 3 weeks. Study 1 compared several versions of a positive psychology intervention that lasted up to 16 weeks, and assessed symptoms at 0, 8, and 16 weeks. Study 2 was observational and included symptom measures at 0, 12, and 24 weeks. Symptoms were measured with the Perceived Stress Scale, Hospital Anxiety and Depression Scale, and Patient Health Questionnaire-9. Multivariable regressions were run for each outcome, controlling for race, sex, marital status, prior ACS, and illness severity.

Results: In Study 1, BMI was positively associated with perceived stress, anxiety, and depression at baseline, but these relationships were no longer significant once controlling for age. Age was negatively related to stress and anxiety (p 's < 0.05), but not depression. Controlling for other sociodemographic and health factors, the negative association between age and baseline anxiety persisted ($p < 0.01$). BMI was unrelated to symptom change at 8 or 16 weeks, and younger age predicted a smaller reduction of perceived stress at 8 weeks ($p = 0.01$) but not 16 weeks. In Study 2, BMI was unrelated to distress at baseline, while age was negatively associated with stress, depression, and anxiety (p 's < 0.05). Controlling for other health/demographic factors, age, but not BMI, was still negatively associated with the three psychological variables (p 's < 0.01). BMI was unrelated to change in any psychological variable. Younger age was associated with a smaller decrease in depression and anxiety at 12 and 24 weeks (p 's < 0.05).

Conclusions: Overall, younger patients had greater post-ACS stress, depression, and anxiety. Relationships between BMI and distress appeared to be explained by those with higher BMI being younger. Further, particularly when not receiving a behavioral intervention, younger patients were less likely to have improvement in anxiety and depression over time. Younger, mid-life ACS patients may be vulnerable to psychological distress and could benefit from interventions designed to meet their unique needs.

LONG-TERM WEIGHT LOSS AND METABOLIC SYNDROME IN U.S. ADULTS

Kerem Shuval, Researcher¹, Gregory Knell, Post Doc², Qing Li, Senior Analyst¹, Kelley Pettee Gabriel, Associate Prof.³¹American Cancer Society, Atlanta, GA; ²University of Texas, Houston, TX; ³University of Texas, Austin, TX

For chronic disease prevention, studies suggest that overweight adults reach a 5–10% weight loss maintenance target for optimal health. However, it is not sufficiently clear whether higher levels of long-term weight loss (LTWL) incrementally lead to lower levels of cardiovascular disease risk. Therefore, in the current study we examine the association between various thresholds of LTWL and metabolic syndrome (MetS) among adults who at one point were overweight or obese. Data on 10,842 adults from a U.S. sample with pertinent variables were included in the analysis. LTWL thresholds were 5–9.9%, 10–14.9%, 15–19.9%, and $\geq 20\%$ and MetS (yes/no) was defined based on the AHA/NHLBI criteria. Multivariable logistic regressions models were estimated using a partially adjusted model including socio-demographics and a fully adjusted consisting of variables in the first models plus health variables (e.g., smoking status, health status). Results from the partially adjusted model indicated that all weight loss thresholds were associated with a lower likelihood of MetS, with the lowest odds in the 15–19.9% and $\geq 20\%$ categories, in comparison to the reference group of less than 5% weight loss (OR=0.62, 95%CI 0.44–0.87; OR=0.54, 95%CI 0.42–0.69; respectively). However, a clear incremental pattern was not apparent, with 26% reduced odds for MetS in the 5–9.9% category and only 20% lower odds in the 10–14.9% group. In the fully adjusted model only the $\geq 20\%$ category was significantly related to lower odds of MetS (OR=0.69, 95%CI 0.52–0.91). In conclusion, findings suggest that higher levels of LTWL might be necessary to significantly reduce the odds of MetS.

ACCESS IS NECESSARY BUT NOT SUFFICIENT: FACTORS INFLUENCING DELAY AND AVOIDANCE OF HEALTH SERVICES

Kyle T. Smith, N/A¹, Denise Monti, BA², Nageen Mir, MPH², Ellen Peters, PhD³, Renuka Tipirneni, MD, MSc⁴, Mary Politi, PhD²¹Washington University in St Louis School of Medicine, Rochester, NY; ²Washington University in St Louis School of Medicine, St Louis, MO; ³The Ohio State University, Columbus, OH; ⁴University of Michigan, Ann Arbor, MI

Background: Despite recently expanded access to health insurance, consumers still face barriers to using their coverage to obtain needed healthcare.

Objective: To examine the characteristics of those who delay or avoid healthcare due to costs.

Methods: Participants were recruited via Amazon mTurk and completed a survey assessing demographic characteristics, financial toxicity, healthcare minimizer-maximizer tendencies, health insurance knowledge, numeracy, delaying/avoiding any care, and delaying/avoiding 6 common healthcare services (3 preventive and 3 non-preventive services). Validated measures were used when available. Delay/avoidance behaviors were categorized into delaying/avoiding any care, preventive care, and non-preventive care. Separate logistic regression models examined 1) financial toxicity, 2) minimizer-maximizer tendencies, 3) numeracy, 4) health insurance knowledge, and 5) knowledge of preventive care coverage as they relate to delay/avoidance behaviors, controlling for chronic conditions, insurance status, and/or income where appropriate.

Results: Of 518 respondents, 470 did not fail attention-check questions and were used in analyses. 45% of respondents reported delaying/avoiding care due to cost. Multivariable analyses found that financial toxicity was related to delaying/avoiding any (OR=0.888, $p < 0.001$), preventive (OR=0.905, $p < 0.001$), and non-preventive (OR=0.903, $p < 0.001$) care. A tendency to minimize seeking healthcare (OR=0.734, $p < 0.001$) and subjective numeracy (OR=0.794, $p = 0.023$) were related to delaying/avoiding any care. General health insurance knowledge (OR=0.990, $p = 0.030$) and knowledge of preventive care coverage (OR=0.422, $p < 0.001$) were related to delaying/avoiding preventive care.

Conclusions: Many people delay or avoid healthcare due to costs, even when insured. Results suggest that there may be different reasons individuals delay or avoid preventive and non-preventive care. Findings may inform interventions to educate consumers and support discussions about healthcare costs to facilitate appropriate healthcare utilization.

6:30 PM-7:30 PM

ADAPTIVE DECISION-MAKING IN RESPONSE TO NARRATIVES OF HURRICANE-ASSOCIATED LOSS AND INCOME LOSS IN DRINKERS

Alexandra Mellis, BS¹, Sarah E. Snider, Ph.D.², Warren K. Bickel, Ph.D.²¹Addiction Recovery Research Center, Roanoke, VA; ²Virginia Tech Carilion Research Institute, Roanoke, VA

Both resource scarcity and the simulation thereof can direct attention towards immediate needs, leading to more myopic decisions. This resource scarcity may be evoked in multiple ways, including conventional settings of economic loss (i.e., layoffs) and in natural settings (i.e., natural disasters). Previous research has demonstrated that income loss increases both preference for immediate rewards (e.g., delay discounting) and craving for substances of abuse. We hypothesized that narratives of hurricane-associated loss may evoke similar effects.

To test these hypotheses, data were analyzed from $n=392$ regular binge drinkers from Amazon Mechanical Turk (mTurk). Participants completed demographics including the Alcohol Use Disorders Identification Test (AUDIT) and were randomly assigned to a narrative describing either an ongoing hurricane disaster ($n=95$), a minor storm ($n=100$), job loss ($n=99$), or economically neutral job transfer ($n=98$). Participants then completed a task of delay discounting of \$1000, and a measure of craving (the Alcohol Craving Questionnaire-Short Form, or ACQ-SF), and other scales. Demographics and AUDIT did not differ between groups.

Data were analyzed in a linear model, with “content” (negative or control) or “setting” (natural or employment-related) as fixed effects. As hypothesized, participants who engaged with negative narratives describing loss ($F=66.6$, $p < 0.001$), and a natural disaster narrative setting ($F=5.24$, $p = 0.02$) demonstrated higher main effect discount rates. Post-hoc analyses revealed that these differences were preserved in planned comparisons between narratives of hurricanes compared to minor storms ($F=25.6$, $p < 0.001$) and narratives of job loss compared to job transfer ($F=46.0$, $p < 0.001$). Furthermore, after controlling for the correlated variable of AUDIT score as a random effect, we observed a significant main effect of narrative content (Chi square = 6.85, $p = 0.008$) on craving for alcohol. However, this effect was only seen in narratives in the employment-related setting (Chi square = 6.11, $p = 0.013$), and not within the natural setting (Chi square = 1.13, $p=0.29$).

These results suggest that both hurricane-associated loss and employment-related loss increases preference for immediate rewards. However, only employment-related loss increased craving for alcohol, which may represent a lack of desire to consume alcohol in an ongoing hurricane scenario despite increased desire for immediate reward receipt.

AMBIVALENCE ATTENUATES THE RELATIONSHIP BETWEEN ATTITUDES AND INTENTION TO DONATE BLOOD

Kristen R. Fox, M.S.¹, Christopher R. France, Ph.D.²¹Ohio University, Athens, OH; ²Department of Psychology, Ohio University, Athens, OH

BACKGROUND: Within the Theory of Planned Behavior (TPB), an established model of blood donation intention, the relationship between donation attitudes and intention is consistently among the strongest in the model. Yet, ambivalence has been shown to attenuate the relationship between attitudes and intention in health-related behaviors, and donation-related ambivalence, and – in particular – its relationship to the TPB, has received little empirical attention. Thus, the present study sought to determine if individual differences in ambivalence moderate the relationship between attitudes and donation intention.

METHODS: A sample of blood donors and non-donors ($N = 241$) participated in an online survey of donation attitudes, donation-related self-efficacy, and donation intention. Participants also completed the Blood Donation Ambivalence Survey (BDAS), which includes subscales of commitment and indecision. Scores on the BDAS range from 1 to 7, with lower commitment scores and higher indecision scores reflecting greater ambivalence. Regression analyses were performed to detect moderation effects, and the Johnson-Neyman procedure was used to identify regions of significance for significant interactions.

RESULTS: A significant interaction was observed between commitment and attitudes on the prediction of intention ($\beta = .21$, $p < .01$). Participants with commitment scores of 2.7 and below evidenced non-significant relationships between commitment and attitudes, whereas commitment and attitudes were significantly related when commitment scores were greater than 2.7. Likewise, a significant interaction was observed between indecision and attitudes ($\beta = -.20$, $p < .01$). Participants with an indecision score of 4.7 or greater demonstrated non-significant attitudes - intention relationships, and indecision scores below 4.7 were associated with significant relationships between attitudes and intention. Similar results were obtained when self-efficacy was entered into the models as a covariate.

CONCLUSIONS: Ambivalence attenuates the relationship between attitudes and intention. The inclusion of ambivalence in TPB models may refine our understanding of donation intention and inform interventions aimed at increasing donation behavior. Future research should explore the relationship between ambivalence, attitudes, and donation behavior.

COGNITIVE AND AFFECTIVE DECISION-MAKING FACTORS MEDIATE THE RELATION BETWEEN SES AND PREVENTIVE HEALTH BEHAVIORS

Marc T. Kiviniemi, PhD¹, Lynne B. Klasko, N/A², Elizabeth Gage-Bouchard, PhD³

¹University at Buffalo, Buffalo, NY; ²University at Buffalo, SUNY, Buffalo, NY; ³Roswell Park Cancer Institute, Buffalo, NY

BACKGROUND: Disparities in preventive health behaviors by socioeconomic status (SES) are common. For example, individuals with lower SES tend to engage in less physical activity and eat fewer fruits and vegetables. There is a known relation between both cognitive (e.g. perceived barriers) and affective (e.g. associated feelings of pleasure, disgust) decision-making constructs and engagement in each of these behaviors. Given this, a plausible hypothesis is that SES may influence these decision-making constructs and that the SES-decision making relation may help to account for observed SES-behavior disparities.

METHOD: 446 community adults completed a telephone survey assessing positive and negative affective associations as well as perceived benefits and barriers for each of two behaviors – vigorous physical activity and fruit/vegetable consumption. They also reported level of education. Bootstrap modelling was used to estimate the indirect effects of decision-making constructs as a mediator of the relation between education and behavior.

RESULTS: Education was associated with both behaviors; higher education was associated with both more vigorous physical activity and more fruit/vegetable consumption ($B_s > 0.11$, $ps \pm 0.13$, $ps < .05$; the only exception was physical activity barriers). Tests of the mediational model showed that the relation of SES to each behavior was mediated by the decision-making constructs. For fruit/vegetable consumption, the total indirect (mediated) effect was 0.65 (95% CI=0.27, 1.16), accounting for 41% of the relation of SES and behavior. For physical activity, the total indirect (mediated) effect was 0.69 (95% CI=0.03, 0.13), accounting for 38% of the SES-behavior relation.

DISCUSSION: These findings suggest that decision-making constructs explain some of the SES disparities in both fruit/vegetable consumption and physical activity. There are several plausible mechanisms for this, including differences in knowledge about behaviors, structural differences in ability to engage in behaviors, and differences in perception of future outcomes of present actions. Interventions to address these decision-making mechanisms might be fruitful approaches to address SES-preventive behavior disparities.

COUPLES' INTENTIONS TO SHARE EXOME SEQUENCING RESULTS WITH FAMILY

Erin Turbitt, Ph.D.¹, Megan C. Roberts, PhD², Rebecca Ferrer, PhD³, Jennifer M. Taber, PhD⁴, Katie Lewis, ScM⁵, Barbara Biesecker, PhD⁶, William Klein, PhD⁷

¹National Human Genome Research Institute, Bethesda, MD; ²National Cancer Institute, Bethesda, MD; ³National Cancer Institute/NIH, Rockville, MD; ⁴Kent State University, Kent, OH; ⁵National Institutes of Health, Bethesda, MD; ⁶National Human Genome Research Institute, NIH, Bethesda, MD; ⁷National Cancer Institute, Potomac, MD

Background: Some variants detected by genome sequencing have no effect on personal disease risk but can increase risk of disease for biological relatives (i.e., carrier results). Given familial implications of genetic information, it is important to understand factors that influence intentions to share carrier results with family members. Dyadic analyses account for variance in interpersonal phenomena between two individuals (i.e., within a dyad), with evidence and theory suggesting that decision making is often conducted within couples. To our knowledge, no studies have examined the dyadic associations of spousal perceptions and beliefs when both spouses are undergoing exome sequencing.

Methods: Survey responses from 136 individuals (68 couples) undergoing sequencing in a research study offering return of select individual variants were analyzed using dyadic analyses (intraclass correlation coefficient and actor-partner interdependence modeling). Variables hypothesized to be associated with individuals' intentions to share carrier results with other family members (perceived value, worry, and attitudes) were examined concurrently.

Results: Intentions to share carrier results with family members was correlated between spouses ($ICC=0.43$; 95%CI: 0.21–0.61; $p=0.004$), as was worry about risk of a genetic condition in the family ($ICC=0.45$; 95%CI: 0.24–0.62; $p<0.001$). Perceived value of result and worry about risk of a genetic condition in the family were associated with one's own intentions to share carrier results. However, spousal variables (i.e., partner effects) did not explain additional variance in an individual's intentions.

Conclusions: Although we found no partner effects on intentions, spouses converged in their intentions to share carrier results, suggesting it may be important to account for non-independence in other research studies that use exome sequencing.

MODIFIABLE FACTORS OF FAMILY CAREGIVERS' CONFIDENCE IN MAKING FUTURE MEDICAL DECISIONS FOR PERSONS WITH CANCER

James Dionne-Odom, PhD, MA, RN¹, Deborah Ejem, PhD¹, Andres Azuero, Associate Professor¹, Richard Taylor, DNP, CRNP, APRN-BC², Gabrielle Rocque, MD¹, Yasemin Turkman, PhD¹, Moneka Thompson, M.Div., BCC³, Sara J. Knight, Alabama¹, Michelle Martin, PHD⁴, Marie Bakitas, DNSc, CRNP, FAAN¹

¹University of Alabama at Birmingham, Birmingham, AL; ²University of Alabama at Birmingham School of Nursing, Birmingham, AL; ³UAB Medicine, Pelham, AL; ⁴University of Tennessee Health Science Center, Memphis, TN

Background: Family caregivers often lack confidence in having to potentially make future medical decisions for their care recipients with cancer should they become too ill to make decisions for themselves.

Purpose: Determine a parsimonious set of modifiable factors associated with family caregivers'; confidence in making future medical decisions for their care recipients with cancer.

Methods: Cross-sectional mail survey conducted in communities of 8 cancer centers in Tennessee, Alabama, and Florida. Family caregivers of Medicare beneficiaries with pancreatic, lung, brain, ovarian, head and neck, hematologic, and stage IV cancers completed validated measures of their social and mental health, self-care behaviors, coping styles, and confidence in making future medical decisions for patients. Using linear modeling, the Bayesian information criterion was used to identify a small set of caregiver factors associated with decision-making confidence. Bootstrap methods and a random forest approach were used to assess generalizability of results.

Results: Caregivers(n=294) were on average age 65.5 years and mostly female (72.8%), white (91.2%), and care recipients'; spouse/partner (60.2%). Patients averaged 75.3 years and were mostly male (54.4%). The resulting parsimonious set of factors associated with caregiver decision-making confidence included: spiritual growth self-care behaviors, avoidant coping, emotional social support, and care recipient age (in-sample $R^2=.22$). These factors were also identified by the random forest approach as important in predicting decision-making confidence. After overfitting adjustment (shrunken $R^2=.09$), the strongest associations were: spiritual growth self-care behaviors (adjusted standardized $B=.17$, $p=.005$) and avoidant coping (adjusted standardized $B=-.12$, $p=.045$).

Conclusions: Encouraging caregivers'; spiritual growth and enhancing their coping skills to lessen avoidance of stressful situations may be promising targets for interventions to improve family caregivers'; confidence in future medical decision-making.

NARRATIVE THEORY: HURRICANE-ASSOCIATED LOSS INCREASES DELAY DISCOUNTING, DEMAND, AND CONSUMPTION OF SNACKS IN THE OBESE

Sarah E. Snider, Ph.D., Lindsey M. Poe, BS, Matthew A. Kocher, BS, Warren K. Bickel, Ph.D.

Virginia Tech Carilion Research Institute, Roanoke, VA

Narrative theory describes that vividly imagining oneself in a hypothetical, yet realistic, scenario can acutely alter decision-making. In particular, delay discounting, a measure of self control, has been shown to increase or decrease following consideration of a scarcity scenario (e.g., negative income shock) or positive imagination of the future (e.g., episodic future thinking), respectively. Excessive delay discounting, suggested as a behavioral marker for substance use disorder, is also becoming increasingly recognized as related to other negative health behaviors, including obesity. Therefore, understanding how obese individuals make decisions in different contexts is important to understand. The present study measured changes in delay discounting, valuation, and consumption of highly palatable snack foods following either a negative or neutral scenario in obese individuals. Participants ($n=41$) with a BMI >30 and no plans to change their eating patterns, were invited to enroll into the 2-session study. At the first session, participants rated their liking of 7 different calorie-dense snack items commonly found in a vending machine. Participants were asked to complete several discounting tasks and a purchase task for their top-rated snack. At the second session participants, were asked to read and consider how they would feel in their randomly assigned hypothetical scenario (i.e., a devastating hurricane [negative] or mild storm [neutral]). Then, participants completed the same tasks as presented at the first session, and were given ad-libitum access to their top 3 ranked snack foods. Results indicated the delay discounting and demand for participants'; top-rated snack food increased significantly in the hurricane group, compared to the mild storm group ($p>0.05$). Moreover, those in the hurricane group consumed significantly more calories when given free-access to their favorite snack foods, even when hunger was standardized with a preload meal bar ($p>0.05$). Consistent with the new theory of reinforcement pathology, these results suggest that vivid consideration of a negative scenario, such as a devastating hurricane, will constrict the temporal window and increase valuation of hedonic snack foods among obese individuals.

POSITIVE AFFECT BUT NOT NEGATIVE AFFECT ASSOCIATED WITH BREASTFEEDING INTENTIONS IN AFRICAN AMERICAN MOTHERS

Maria Keller, NY¹, Marc T. Kiviniemi, PhD², Renee Cadzow, PhD³, Deborah Erwin, PhD⁴¹University at Buffalo, SUNY, Buffalo, NY; ²University at Buffalo, Buffalo, NY; ³D'Youville College, Buffalo, NY; ⁴Roswell Park Cancer Institute, Buffalo, NY

BACKGROUND: Breastfeeding in the U.S. is socially patterned—African American mothers have the lowest rates of breastfeeding initiation (60%) compared to all other racial/ethnic groups (CDC, 2007). Due to the health benefits of breastfeeding, it is important to understand and reduce these disparities. Numerous studies have examined the psychosocial components of breastfeeding decision-making in African American mothers (e.g., convenience, pain/discomfort, social/cultural acceptance, employment, and lack of knowledge, time, or access to information or support services) (See Jones, Power, Queenan, & Schulkin (2015) for a review). Few studies have examined positive and negative affect relating to breastfeeding as a predictor of breastfeeding intentions.

METHODS: The associations between perceived benefits/barriers to breastfeeding, positive/negative affect, and intentions to breastfeed were examined in 88 pregnant African American women enrolled in WIC. The association between individual positive emotions (happy, delighted, satisfied, relaxed) and negative emotions (disgusted, angry, annoyed, sad, embarrassed) in relation to breastfeeding intentions were examined. Mediation analyses were used to assess possible indirect effects of composite measures of positive/negative affect on the relationship between benefits/barriers and breastfeeding intentions.

RESULTS: Individual positive emotions, happy ($r=.32$), delighted ($r=.36$), and relaxed ($r=.33$) were associated with increased intentions to breastfeed ($p<.01$ for all). Negative emotions, except sadness ($r=.14$, $p<.05$), were not associated. The relationship between perceived benefits to breastfeeding and breastfeeding intentions was partially mediated by positive affect (indirect effect (1.22)(.66)=.81, 95% bias-corrected CI based on 10,000 bootstrap samples -.04,1.9). Positive affect did not mediate the relationship between perceived barriers and intentions, and negative affect did not mediate the relationship between benefits or barriers and intentions.

DISCUSSION: This relationship between affect and breastfeeding intentions seems to be through the behavioral affective associations pathway (Kiviniemi, Voss-Humke, & Seifert, 2007); positive affect but not negative affect was related to breastfeeding intentions and positive affect partially mediated the relationship between benefits and intentions. Interventions to encourage breastfeeding should address the impact of affect, especially positive affect.

PREFERENCE FOR SHARED DECISION MAKING AMONG PATIENTS AT INCREASED RISK OF HOSPITALIZATION

Lauren Wiklund, BA¹, Ilana Engel, BA², Andrea E. Kass, PhD³, Andrea Flores, MA³, Gregory Ruhnke, MD, MS, MPH⁴, David Meltzer, MD, PhD³¹University of Chicago, Biological Sciences Division, Chicago, IL; ²University of Chicago Medicine, Biological Sciences Division, Chicago, IL; ³University of Chicago, Chicago, IL; ⁴Assistant Professor, University of Chicago Department of Medicine, Chicago, IL

Background: Shared decision making (SDM) is increasingly recognized as vital to patient care. However, patient preferences for SDM vary by individual characteristics and social and environmental context. This study evaluated factors associated with preferences for SDM among adults at increased risk of hospitalization. Engaging high-utilizing patients in SDM may lead to less invasive interventions and improve satisfaction.

Methods: Study participants were 2,000 adults (mean age=63 ± 16y; 86% Black; 63% female) hospitalized in the year prior to enrollment in a RCT comparing a hospital-based intervention to standard care. Interviews were completed every three months and included two measures of SDM: "I prefer that my doctor offers me choices and asks my opinion" and "I prefer to leave decisions about my medical care up to my doctor." Analyses included 1974 respondents. Baseline data were analyzed using chi-square, t-test, and logistic regression analyses. Follow up data were analyzed using logistic regression, based on the subset of participants (68%) alive one year after enrollment and who reported on hospitalization at each of the follow-ups (responses from which were aggregated into one variable of "future hospitalization").

Results: At enrollment, 98% of participants wanted their doctor to offer choices, but 55% preferred to leave medical decisions up to their doctor. Individuals who preferred to leave medical decisions up to their doctor were more likely to be male (Odds Ratio (OR) 1.35; 95% CI=1.12–1.62), Black (vs non-Black; OR 1.37; 95% CI=1.0–1.9), have lower income ($p=.001$; $d=0.20$), complete less education ($p<.001$; $d=0.25$), and report less impairment in activities of daily living (ADL; $p=.002$; $d=0.12$) or instrumental ADL ($p=.001$; $d=0.15$) than their counterparts. Groups did not differ according to age, ethnicity, overall health, number of hospitalizations in the past year, mental health, depressive or anxiety symptoms, psychosomatic complaints, disordered personality traits, or indices of health literacy ($ps>.06$). SDM preference did not predict future hospitalization, controlling for study group or whether they were hospitalized in the prior year (OR 0.87; 95% CI=0.71–1.11), and did not differ between study group at each follow up assessment ($ps>.71$).

Conclusions: Patients, regardless of health status, need more empowerment to engage in SDM. Individuals with lower income, less education, and who identify as male or Black may need enhanced support.

THE IMPORTANCE OF FEAR AND ANXIETY IN PREDICTING BLOOD DONATION INTENTION

Philippe Thomas, Gilchrist, Ph.D.¹, Barbara Masser, Ph.D.², Claire Fedoruk, B.A.³, Kristin J. Horsley, B.A.³, Blaine Ditto, Ph.D.³¹University of Cambridge, Cambridge, England, United Kingdom; ²The University of Queensland, St Lucia, Queensland, Australia; ³McGill University, Montreal, PQ, Canada

BACKGROUND: About 94–97% of the eligible population never donate blood. The Theory of Planned Behaviour (TPB) is widely used to describe and understand donor motivation and to help predict donation intention, though little is known about the role of deterrents to donation such as fear and anxiety. It was hypothesized that higher medical fears would predict lower donation intention, and that this effect would be mediated by donation attitudes and self-efficacy (e.g., the belief in one's ability to manage the fear).

METHODS: 348 donors (n=78) and non-donors (n=270) living in Québec participated in the study (age=18–65; 24% female). Following written consent, data was collected by online questionnaires including: donation history, the Medical Fears Survey assessing various fears related to medical settings (MFS-SF; Olatunji et al., 2012), and a TPB questionnaire assessing donation attitudes and intention to donate (Godin et al., 2005).

RESULTS: There was a significant relation between higher medical fears and decreased self-efficacy ($\beta=-.075$, $t(221)=-3.93$, $p=.0001$) and attitudes ($\beta=-.031$, $t(221)=-2.90$, $p=.0041$), as well as decreased donation intention ($\beta=-.034$, $t(221)=-2.27$, $p=.025$). Higher self-efficacy and attitudes were also both positively associated with greater donation intention, $\beta=.26$, $t(219)=4.25$, $p<.0001$, and $\beta=.45$, $t(219)=5.66$, $p<.0001$, respectively. Because these paths were significant, bootstrapping analyses were conducted, confirming significant indirect effects of medical fears on intentions mediated by both self-efficacy ($\beta=-.0195$, CI= $-.0346$ – $-.0090$) and attitudes ($\beta=-.0142$, CI= $-.0285$ – $-.0047$). Finally, the direct-effects of medical fears on intention became non-significant when controlling for self-efficacy and attitudes, suggesting full mediation, $\beta=.013$, $t(219)=1.20$, $p=.23$. 44% of the variance in donation intention is accounted by both the proposed mediators, $R^2=.436$. When analyses were done separately for donors and eligible non-donors, these patterns were present mainly among non-donors. Donors showed slightly less pronounced effects possibly due to the fact that these types of fears are lower among those who actually choose to donate.

CONCLUSION: Those with higher fears have lower intentions to donate as a result of reduced self-efficacy and attitudes to donate. Identifying and addressing fear and anxiety among donors is of particular practical importance for both donation clinics and promotional campaigns.

USING EXPECTANCIES AND VALUES TO PREDICT HEALTH-RELATED OUTCOMES: HOW MEASUREMENT AFFECTS THE PREDICTION OF MARIJUANA USE

Lauren A. Fowler, MPhil, Zeljka Macura, B.S., Philip Moore, PhD

George Washington University, Washington, DC

Background. The expectancy-value (EV) framework is one of the most prominent approaches to understanding and predicting psychological and behavioral outcomes. By and large, EV models assume that 1) expectancies and values should be aggregated multiplicatively, and 2) these factors should be assessed using bipolar response scaling. However, the validity, theoretical implications and practical applications of these assumptions have yet to be examined.

Method. For 301 participants (59% female, 73% white, mean age=19.0 years, 72% used marijuana at least once), aggregation (additive/multiplicative) and scaling (unipolar/bipolar) of expectancies and values regarding marijuana use were systematically varied in a 2x2 within-subjects experimental design, within the framework of the Theories of Reasoned Action and Planned Behavior. Outcomes included participants'; intentions to use marijuana, frequency of marijuana use over the past year, and typical social weekend use over the past 30 days.

Results. Multiplicative aggregation and bipolar scaling combined to consistently increase the predictive power of attitudes, and decrease that of subjective norms. This same pattern was demonstrated with the addition of perceived behavioral control to the model. Additive aggregation of EV factors consistently predicted the least variance in marijuana use intentions and behavior, as compared to multiplicative aggregation.

Conclusion: Differential aggregation and scaling can profoundly influence the impact of attitudes and norms on intentions and behavior. These findings also have significant implications regarding the psychological nature of these factors, how to improve their predictive power, and future research to assess the generalizability of the current results to other research populations, designs, settings, constructs and behaviors.

USING NARRATIVES TO ALTER CIGARETTE VALUATION: REINFORCER PATHOLOGY INTERPRETATION

Liqia Athamneh, MA, Warren K. Bickel, Ph.D.

Virginia Tech Carilion Research Institute, Roanoke, VA

According to the reinforcer pathology, commodities with abuse liability are excessively preferred in terms of immediacy (i.e., delay discounting) and excessively valued (i.e., high demand) by clinical populations compared to controls. According to the narratives theory, individuals presented with an economic scarcity narrative (job loss and related income depletion) discount the future more compared to those presented with neutral narratives. In this study, we tested the reinforcer pathology model by manipulating delay discounting using the scarcity narrative. We hypothesize that, compared to the control condition, an intervention involving economic scarcity will increase not only rates of discounting but drug valuation as well. One hundred and thirty-five smokers were recruited from an online crowdsourcing (Amazon Mechanical Turk, or MTurk) to assess the discounting of hypothetical delayed money and valuation of cigarettes after being randomly assigned to one of two economic narratives (scarcity and neutral). Analysis showed that the scarcity narrative increased the participants'; choice preference to the immediate but smaller rewards ($p=0.000$) compared to the neutral narrative. Moreover, reading and vividly imagining the scarcity narrative significantly increased cigarette';s valuation (0.042) compared to reading and vividly imagining the neutral one. These findings are consistent with the notion of reinforcer pathology suggesting that delay discounting is a valuable target for interventional therapies that aim to alter cigarette valuation and therefore consumption. In addition, this study findings demonstrated that using narratives to manipulate discounting may show potential as a component of future behavioral addiction interventions.

A COUPLES-BASED APPROACH FOR INCREASING PHYSICAL ACTIVITY AMONG COUPLES WITH TYPE 2 DIABETES: A PRELIMINARY STUDY

Jennalee S. Wooldridge, MA¹, Krista Ranby, PhD²¹VA Palo Alto Health Care System, Mountain View, CA; ²University of Colorado Denver, Denver, CO

Collaborative implementation intentions (collaborative IIs) involve a couple planning when and where they will perform a specific physical activity (PA) behavior and have been shown to be more effective than individual IIs for some health behaviors. The current study examined feasibility and acceptability of a collaborative IIs intervention within a type 2 diabetes (T2D) population and examined preliminary evidence of the efficacy of collaborative IIs to increase PA and improve other psychosocial outcomes. Participants (N = 40 couples, 80 individuals) included adults with T2D and their romantic partners. A 3-arm (collaborative IIs, individual IIs, control) 6-week intervention was examined using a prospective, longitudinal, experimental design. Accelerometers and the International Physical Activity Questionnaire (IPAQ METs) were used to assess PA. Psychosocial measures included self-efficacy for PA, partner investment in diabetes management, and PA social support. Participants in both experimental conditions reported the intervention was acceptable, rating the intervention highly in the categories of “beneficial”, “pleasant,” “good”, “valuable”, and “enjoyable,” and reported being highly committed to the PA plans they developed. Further, 32 couples were retained through 6 weeks. A linear regression controlling for baseline IPAQ METs and baseline depression revealed that the effect of condition on IPAQ METs at 6 weeks was in the intended direction and approached statistical significance [$M_{\text{CollaborativeII}} = 1711.24$, $SD = 369.29$; $M_{\text{IndividualII+Control}} = 758.77$, $SD = 299.92$; $B_{\text{condition}} = 952.45$, $p = .06$. The full model explained 49% of the variance in IPAQ METs [$F(3, 28) = 2.93$, $p = .05$, $R^2 = .49$]. The collaborative II condition did not predict an increase in PA as measured by accelerometer compared to the other conditions. A linear regression controlling for baseline PA social support, diabetes distress, depression, and patient gender, revealed that condition significantly predicted PA social support at 6 weeks ($M_{\text{CollaborativeII}} = 3.08$, $SD = .12$; $M_{\text{IndividualII+Control}} = 2.63$, $SD = .10$; $B_{\text{condition}} = .49$, $p < .01$). The full model explained 89% of the variance in PA social support [$F(5, 29) = 21.74$, $p < .001$, $R^2 = .89$]. Change in the other psychosocial outcomes did not differ among conditions. Results indicate a collaborative IIs intervention was feasible and acceptable and may improve PA in adults with T2D.

IF YOU BUILD IT, WILL THEY COME, ENGAGE, AND STAY? MOTHERS IN MOTION LIFESTYLE INTERVENTION CHALLENGES AND LESSONS LEARNED

Mei-Wei Chang, RN¹, Susan Nitzke, PhD²¹The Ohio State University, Columbus, OH; ²Univ. of Wisconsin-Madison, Cottage Grove, WI

Mothers in Motion (MIM), a community-based lifestyle intervention, was designed to reduce stress and increase healthy eating and physical activity with the ultimate goal of preventing further weight gain in low-income overweight or obese mothers with young children. MIM was a collaborative program between researchers and the Special Supplemental Nutrition Program for Women, Infants, and Children (WIC) in Michigan. In this paper, we will present key challenges and lessons learned regarding recruitment, intervention procedures, data collection, and retention. We will also recommend strategies to overcome these challenges. Recruitment. Our recruitment was conducted by peers of the target population. By addressing the unique challenges of working with peer recruiters we gained a deeper understanding of the target population. For example, we learned that gaining recruiters' trust in the intervention's usefulness affected recruitment success. Peer recruiters helped identify reasons that many consented participants were not following up by enrolling in MIM. Showing preview videos and previous participants' success stories motivated WIC professionals to refer their clients to participate in MIM. Intervention. Our intervention participants watched MIM videos in DVD format at home and joined peer support group teleconferences led by peer educators and WIC dietitians trained in motivational interviewing (MI) techniques and group facilitation skills. We experienced significant challenges in training our moderators to routinely apply MI skills. We also learned that our intervention participants enjoyed sharing tips and challenges to help their young children eat healthier, but not as much for themselves during the peer support group teleconference. Moreover, participants preferred sharing information from MIM regarding psychological distress more than healthy eating and physical activity. Data collection. While data collection via phone reduced literacy challenges, contacting women to schedule a phone interview proved to be time consuming. Retention. We learned that text messages with caring content and tailored to each individual participant increased success of retention. Also, a positive relationship between peer recruiters and participants enhanced retention. Retention rates were increased when we used diapers as incentives. Also, life events affected retention.

LESSONS LEARNED FROM THRIVE FOR HEALTH: A LIFE SKILLS-BASED INTERVENTION TO PROMOTE HEALTHY WEIGHT IN LOW-INCOME PRESCHOOLERS

Temitope Erinosh, PhD¹, Dianne S. Ward, EdD²¹University of North Carolina at Chapel Hill, Chapel Hill, NC; ²Gillings School of Global Public Health, Chapel Hill, NC

Purpose. This paper presents lessons learned from implementing THRIVE for Health, a parent-focused life skills-based intervention to promote healthy weight in preschoolers from low-income families.

Methods. THRIVE is an ongoing randomized-controlled trial for low-income parents of children age 2–5. Parents are recruited through WIC, Head Start, and flyers posted at community locations. The 12-week intervention addresses self-care, eating healthy/doing family activities on a budget, communication, and time/budget management. The intervention is delivered via in-person sessions, coaching telephone calls, text messaging, and print materials. The control arm participate in a children's book club. Measures assess changes in child diet, physical activity, and weight, and parental quality of life. Thirty-six parents are currently enrolled and we are on target to meeting our study goal of 40 parents total. Lessons learned have come in the areas of recruitment, implementation, measurement, and retention.

Results. Parental recruitment was a challenge. To address this, we identified two research assistants with backgrounds in public health and psychology, prior experience with children, and highly enthusiastic about working with disadvantaged families. The research assistants are highly zealous about the project and committed to ensuring that it is a success; making these staff-related changes helped to improve parental recruitment significantly. Within program implementation, we found parents were failing to attend group sessions. To navigate this, we offered the option to choose between group and one-on-one sessions; all participants; to-date have opted for one-on-one, thus, increasing parental engagement. While distractions from children posed challenges in-home, we learned to allot extra time for meetings and have an additional research assistant on-hand to engage children. Keeping to the 12-week intervention timeline was a challenge, given participants'; life stressors/work schedules; we learned to be flexible to accommodate their preferences. Measurement was the third challenge area, with participants taking a long time to complete surveys; thus, we scaled down measures to those most relevant to the study outcomes. Additionally, obtaining post-intervention measures proved to be a challenge when participants changed telephone numbers. Making unscheduled home visits and organizing group celebrations helped to address this issue. Retention has not been a major issue, likely because participants establish positive relationships with the interventionists and perceive that the intervention is addressing their needs. Incentives are also provided.

Conclusions. Lessons presented may inform other researchers in developing, implementing, and evaluating obesity interventions for children from low-income families.

A VEGETARIAN DIET DOES NOT NECESSITATE HEALTH BEHAVIORS: HEALTH GAINS MAY BE DRIVEN BY DIET ALONE

Sydney Heiss, BA¹, Jaime A. Coffino, B.A., M.P.H.², Julia M. Hormes, Ph.D.¹¹University at Albany, SUNY, Albany, NY; ²University at Albany, State University of New York, Albany, NY

Introduction. Recent work has shown that limiting the consumption of animal products leads to beneficial health outcomes, such as reducing the risk for heart disease, diabetes, and cancer. Simultaneously, it is unknown whether the health behaviors of vegetarians differ from omnivores, which could in part be the driver of the differences in health outcomes. We hypothesize that no differences between omnivores and subgroups of vegetarians will be found, supporting the idea that the health benefits of vegetarian and vegan diets are driven largely by differences in food intake alone.

Methods. Community participants completed a battery of online self-report questionnaires, including demographics, cigarette smoking and quantity, height, weight, exercise length, frequency of exercise, and the Alcohol Use Disorders Identification Test (AUDIT) to measure problematic alcohol use. To determine vegetarian group status participants were asked if they restrict any animal product from their diet. If they responded 'no,' they were categorized as omnivores ($n = 220$; 75% female). Those who responded 'yes' were then redirected to more specific questions regarding their diet. "Meat reducers" ($n = 67$; 84% female) were defined as those who minimized meat in their diet or who ate some meat but restricted others (e.g., ate chicken but refrained from beef). "Lacto-ovo-vegetarians" ($n = 108$; 81% female) were defined as those who restricted animal flesh but consumed dairy and eggs. "Vegans" ($n = 356$; 84% female) were defined as restricting all animal products from the diet. Participants were compared in a series of ANOVA and chi-square.

Results. Vegetarians and omnivores did not differ on basic demographics, with age, gender, and ethnicity all being non-significant (all $p > .05$). No significant differences were found on any measures of health behavior, including exercise frequency ($F(3,505) = 1.32$; $p = .27$; partial eta sq $< .01$), exercise length ($F(3,466) = .51$; $p = .68$; partial eta sq $< .01$), AUDIT scores ($F(3,389) = 1.63$; $p = .18$; partial eta sq $= .01$), cigarette smoking ($\chi^2 = 5.48$; $p = .48$; $\Phi = .09$), cigarette quantity ($F(3,652) = .89$; $p = .45$; partial eta sq $< .01$), or body mass index ($F(3,711) = 1.55$; $p = .20$; partial eta sq $< .01$).

Discussion. These null results support the hypothesis that the benefits of vegan and vegetarian diets are largely driven by difference in the diet itself, and not differences in health behaviors. The results are interesting for two reasons: 1. They may suggest that switching to a vegan diet can be beneficial for health without changing behaviors, though future work is needed, and 2. Those who restrict meat from the diet appear to engaging in unhealthful behaviors at similar rates to their omnivorous counterparts, and therefore practitioners should not assume a healthy lifestyle when engaging with a meat-restricting client.

ADOLESCENTS DRINK MORE SUGAR SWEETENED BEVERAGES WHEN THEY ARE AVAILABLE AT HOME REGARDLESS OF AVAILABILITY AT SCHOOL

Christina F. Haughton, MPH¹, Molly E. Waring, PhD², Monica Wang, ScD, MS³, Milagros C. Rosal, MS, PhD⁴, Lori Pbert, PhD⁴, Stephenie Lemon, Ph.D.⁵

¹UMass Medical School, Worcester, MA; ²University of Connecticut, Storrs, CT; ³Boston University School of Public Health, Boston, MA; ⁴University of Massachusetts Medical School, Worcester, MA; ⁵UMass Worcester Prevention Research Center, Worcester, MA

Background: Sugar sweetened beverage (SSB) consumption is the largest source of added sugar and caloric intake in US adolescents' diets. It has been argued that the increased intake of SSBs has contributed to the rising prevalence of obesity. The availability of foods and beverages in various behavioral settings (e.g., home, school, community) to which adolescents are exposed can influence their food and beverage choices and consumption. It is unknown if efforts to reduce the availability of SSBs in the home may be less impactful when adolescents have access to SSBs elsewhere.

Objective: To examine the association between SSB availability at home and adolescent daily SSB consumption, and to assess whether this association is consistent across school and school neighborhood SSB availability.

Methods: Secondary analyses were conducted using data from the Family Life, Activity, Sun, Health and Eating (FLASHE) study of 1,484 adolescents (12–17 years old). We conducted ordinal logistic regression analyses to examine the association between self-reported SSB availability in the home (never, rarely/sometimes, often/always available) and adolescents' daily SSB consumption (non-daily [i.e., <1 per day], 1–<2 daily, ≥2 daily), adjusting for adolescent age, sex, race, BMI, parent marital status, and housing security. We conducted stratified regression analyses to examine the association by school and school neighborhood SSB availability.

Results: A third (32.6%) of adolescents were non-daily consumers of SSBs, 33.9% consumed 1<2 SSBs daily, and 33.5% consumed ≥ 2 SSBs daily. Almost half (44.4%) reported that SSBs were often/always available in their home. More frequent SSB availability at home was associated with greater SSB consumption (OR:3.12[CI:3.11–3.13] for rarely/sometimes available at home; OR:7.05[CI:7.02–7.07] for often/always available at home, compared to never available). Associations were similar regardless of availability of SSBs at school or in the school neighborhood.

Conclusions: Regardless of availability of SSBs in other environments, availability in the home remains an important predictor of SSB consumption and a target for obesity prevention efforts. Parents can play a critical role in reducing adolescent SSB consumption by restricting availability of SSBs in their home. Public health practitioners and clinicians are well positioned to share this information with families to promote child health and decrease the prevalence of childhood obesity.

BARRIERS AND FACILITATORS TO HEALTHY EATING POSTPARTUM AMONG NON-HISPANIC BLACK MOTHERS.

Melissa C. Kay, PhD, MPH, MS, RD¹, Heather Wasser, PhD, MPH, RD, IBCLC², Linda S. Adair, PhD², Amanda Thompson, Ph.D., MPH², Anna Maria Siega-Riz, PhD³, Chirayath Suchindran, PhD⁴, Margaret Bentley, PhD⁵

¹Duke Global Digital Health Science Center/Duke University, Carrboro, NC; ²University of North Carolina at Chapel Hill, Chapel Hill, NC; ³University of Virginia, School of Medicine, Charlottesville, VA; ⁴Professor, University of North Carolina at Chapel Hill, Chapel Hill, NC; ⁵Gillings School Global Public Health University North Carolina-Chapel Hill, Chapel Hill, NC

Poor diet quality is common among women, particularly during the postpartum period, which places themselves and their families at risk for obesity. To better understand barriers and facilitators to healthy eating during the first two years postpartum, in-depth interviews were conducted with 22 non-Hispanic black mothers who participated in the *Mothers and Others: Family-based Obesity Prevention for Infants and Toddlers* intervention trial. Ten themes were identified around barriers and facilitators to healthy eating. Mothers believed that time and taste were significant barriers to eating healthy. Social influence and social support had both positive and negative influences on mothers'; ability to adopt healthy eating behaviors. Despite their children often being a facilitator to healthy eating, many mothers struggled with finding the time, energy and desire to focus on themselves when it came to healthy eating. Healthy eating appeared to be what most of the mothers strived for, but time, taste, social influence and lack of social support made it difficult. Future interventions should focus on strategies that incorporate goal-setting and self-monitoring, while including hands-on skill-building activities around cooking and grocery shopping. Emphasizing time-saving methods for planning and preparing healthy meals and snacks and enrolling a support person to participate in the study with mothers, to learn and adopt new behaviors alongside her, may elicit behavior change.

BMI AND PSYCHOSOCIAL IMPAIRMENT ASSOCIATED WITH ADULT PICKY EATING: A LATENT PROFILE ANALYSIS

Jordan Ellis, MA¹, Hana F. Zickgra, MA², Matthew Whited, PhD, Licensed Psychologist¹, Amy T. Galloway, Ph.D.³

¹East Carolina University, Greenville, NC; ²Pennsylvania State University College of Medicine, Harrisburg, PA; ³Appalachian State University, Boone, NC

Research on children has identified eating behavior profiles that include picky eating (PE) behaviors and high satiety responsiveness that are associated with underweight and elevated psychosocial comorbidity. These associations have not been investigated in adults. Better understanding the traits that cluster with adult PE, including its relationship with other food approach/avoidance behaviors, is important because it is currently unclear how adult PE is associated with factors such as anxiety, eating-related interference, and inadequate fruit and vegetable intake, which could lead to serious social and nutrition-related impairment. The aim of the present study was to identify eating behavior profiles in an adult sample and examine differences between observed eating profiles on measures of psychosocial impairment and BMI. It was hypothesized that adult PE would cluster with other food-avoidance traits, and a PE profile would predict elevated social eating anxiety, depression, and eating-related impairment compared to normative eating profiles.

A sample of 1339 MTurk workers (60% women, 80% Caucasian, M age=40.39) completed an online survey which included: a modified CEBQ for adults; Adult Picky Eating Questionnaire (APEQ); Eating Disorder Diagnostic Scale (EDDS); PHQ-9; Clinical Impairment Assessment; and a measure of social eating anxiety. Latent profile analysis (LPA) was employed to identify eating profiles based on adult CEBQ subscales ANCOVAs (covarying gender and age) compared profiles on outcome variables and BMI.

The LPA converged on a 4-profile solution similar to profiles observed in children: "moderate" (no impairment; $n=590$), "PE" (restricted eating; $n=222$), "binge/disordered" (chronic overeating; $n=86$), and "joyful" (eating for pleasure; $n=441$). The PE profile showed low food enjoyment, high satiety responsiveness, and high PE. ANCOVAs indicated that profiles differed significantly on all outcomes. Post hoc tests indicated that PE showed significantly higher levels of social eating anxiety ($h^2=.032$) and lower BMI ($M=26.18$ $h^2=.022$), compared to all other profiles. The PE group showed elevated depression ($h^2=.030$) and eating-related impairment ($h^2=.021$) in comparison the moderate and joyful groups.

This study supports an operative definition of adult PE based on a profile of food approach and avoidance behaviors, and highlights the contrast between the social costs and potential protective factors (e.g., lower BMI) associated with adult PE.

COMMUNITY-BASED COMMUNITY-LED PROMOTION OF HEALTHY COOKING: A PILOT STUDY WITH COMMUNITY HEALTH WORKERS

Carolyn C. Johnson, BA, MS, PhD; LPC, NCC¹, Catherine G. Haywood, BSW¹, Keelia O'Malley, MPH², Carolina Gallop, N/A³, Leann Myers, PhD⁴

¹Tulane University School of Public Health and Tropical Medicine, New Orleans, LA; ²Tulane Prevention Research Center, New Orleans, LA; ³Tulane School of Public Health - PRC, New Orleans, LA; ⁴Tulane University School of Public Health & Tropical Medicine, New Orleans, LA

Background: Diet with healthy food preparation is a top public health priority to combat obesity in the U.S. The Oldways scientifically and culturally based curriculum for healthy eating (A Taste of African Heritage Cooking) focuses on whole grains, herbs/spices, legumes, tubers, vegetables and fruit.

Purpose: The purpose of this pilot study was to test the feasibility of Community Health Workers (CHWs) and community-based host organizations to co-present Oldways cooking classes to community residents. Emphasis was on the work of the community (CHWs and hosts) to recruit residents, implement the program, and evaluate behavior change, receptivity and dissemination.

Methods: Five neighborhood organizations were recruited to host cooking classes and were offered an honorarium if they agreed to: 1) provide their kitchen for the classes, 2) recruit community residents to participate in the classes, and 3) provide a volunteer to help facilitate the classes to assure sustainability within the organization and neighborhood. CHWs were trained to conduct the classes along with the host volunteer. Pre- and post-surveys were administered that examined changes in food purchasing and preparation, receptivity to the program, and dissemination efforts into the community.

Results: Five host organizations were successfully recruited but one dropped because of noncompliance with requirements. The four host organizations had a total of 42 pre-surveys and 40 post-surveys. Some participants increased use of targeted foods, but no significant differences were found from baseline to follow-up. Participants appreciated eating in more traditional ways (n=21). The majority of participants were positive about the classes stating that they would make no changes (n=22) or would increase the classes (n=5). Twenty (57%) said they had cooked the recipes at home. Participants reported their intentions to share cooking methods with family (n=34) and with friends (n=32), and to prepare food using the Oldways methods to share with family and friends (n=34).

Conclusions: This pilot study demonstrated the feasibility of CHWs and community organizations working together to bring healthy food preparation into the neighborhoods. Participants liked the program and intended to share with family and friends.

DEVELOPMENT OF A SURVEY TO ASSESS STUDENT DIET PATTERNS AND PERCEPTIONS OF HEALTH-PROMOTING PRACTICES AT SCHOOL

Hannah Lane, PhD, MPH¹, Rebecca Driessen, BS², Elizabeth A. Parker, PhD, RD³, Katie Campbell, MPH¹, Rachel Deitch, MS, CHES⁴, Lindsey Turner, PhD⁵, Erin Hager, PhD¹

¹University of Maryland School of Medicine, Baltimore, MD; ²Creighton University, Baltimore, MD; ³Center for Integrative Medicine University of Maryland School of Medicine, Baltimore, MD; ⁴University of Maryland, School of Medicine, Baltimore, MD; ⁵Boise State University, Boise, ID

Introduction. School-based interventions are recommended to prevent childhood obesity. Such interventions are typically multi-level and complex; thus, robust evaluation methods are needed to determine student-level reach and impact. Few instruments have been validated to assess two key outcomes: (1) perceptions of the school environment and (2) school-specific dietary patterns. This study describes validation of a survey that addresses these outcomes.

Methods. Part 1 of the survey included 47 items with 5-item Likert response sets (never to always; totally disagree to totally agree), which asked students their perceptions of the policies, physical environment, and classroom practices related to healthy eating/physical activity at their school. Part 2 assessed usual intake (i.e. frequency, location obtained, and type of food consumed) of breakfast and lunch using a 5-item Likert response set (never to always). Types of foods consumed were presented by MyPlate categories (i.e., Fruits, Vegetables, Grains). Students in 3rd, 6th and 9th grades participated in the two-phased study: (1) cognitive pre-testing (n=10) and (2) validity and reliability testing (n=58). Students took the surveys twice, one week apart, to assess test-retest reliability of Parts 1 and 2. Daily food records over 5 days were used to validate Part 2. Percent agreements described reliability and validation results. Acceptability of ≥70% was considered acceptable, ≥80% good, and >90% excellent.

Results. Cognitive pre-testing provided feedback on content and age-appropriateness. In the validity/reliability study, students were 53% male, 79% Caucasian, and represented schools in 8 of 24 (33%) state school districts. Percent agreements were acceptable for both test-retest reliability and validation of Parts 1 and 2. For Part 1, agreement between the two survey administrations ranged from 66%-89%. Items with lower than acceptable agreement (n=13) were adapted or removed; the final version of Part 1 consisted of 34 items in 4 subscales (alpha ≥0.78). For Part 2, 91% ate breakfast and lunch most or all days. Most (n=51, 88%) usually got breakfast from home. Lunch locations included home (n=33; 57%), school (n=17, 29%), both home/school (n=6; 10%), or other (n=1; 2%). Agreement for breakfast location was 79% for reliability and 85% for validation. Lunch agreement was 81% and 75%, respectively. For types of foods consumed at breakfast, reliability agreement ranged from 73%-92%, and validation agreement ranged from 68%-91%. For types of foods consumed at lunch, ranges were 75%-95% and 75%-88%, respectively.

Conclusion. Both parts of the instrument demonstrate acceptable reliability and validity to assess perceptions of the school environment and usual dietary patterns in students across a broad age range. This demonstrates appropriateness for use in evaluation of school-based obesity prevention initiatives.

DRIVE FOR THINNESS MEDIATES THE RELATIONSHIP BETWEEN BMI AND DIETARY RESTRAINT

Jaime A. Coffino, B.A., M.P.H.¹, Sydney Heiss, BA², Julia M. Hormes, Ph.D.²¹University at Albany, State University of New York, Albany, NY; ²University at Albany, SUNY, Albany, NY

Introduction: Research has established that dietary restraint, the conscious attempt to restrict food intake, is associated with an increase in body mass index (BMI). The opposite relationship has also been found: that people with a higher BMI are more likely to attempt to restrict their food intake. In light of data that suggest drive for thinness is also associated with dietary restraint, we hypothesized that the relationship between BMI and dietary restraint would be mediated by drive for thinness.

Methods: A community sample ($n = 417$, 80.4% female, M Age = 31.33 ± 13.13 , M BMI = 24.51 ± 6.98) filled out a battery of online questionnaires focused on eating and health behaviors, including the drive for thinness subscale of the Eating Disorder Inventory (EDI), and the “restrained eating” subscale of the Eating Disorder Examination Questionnaire (EDEQ). The hypothesized mediation model was tested using Hayes’ (2013) PROCESS macro.

Results: A Pearson’s product moment correlation showed that dietary restraint, BMI, and drive for thinness were all significantly correlated ($p < .05$). The direct regression of dietary restraint on BMI was significant, $\beta = .13$, $t(411) = 2.92$, $p = .003$. The regression of BMI on drive for thinness was also significant, $\beta = .18$, $t(412) = 3.98$, $p < .001$. The regression of drive for thinness on restraint, controlling for BMI, was significant $\beta = .63$, $t(411) = 15.52$, $p < .001$. Controlling for drive for thinness scores, BMI was no longer a significant predictor of dietary restraint, $\beta = .02$, $t(411) = .62$, $p = .54$. A Sobel test confirmed full mediation in the model ($z = 3.84$, $p < .001$).

Discussion: Findings provide initial evidence that the drive for thinness fully mediates the relationship between BMI and dietary restraint. Our findings add to our understanding of the relationship between BMI and dietary restraint and have implications for the development of more effective interventions targeting eating disorder behaviors and symptoms. It may be beneficial to look at drive for thinness as a proximal predictor of dietary restraint and target the cognitions centered around the “thin ideal”.

EATING BEHAVIORS AND PREDICTORS OF WEIGHT GAIN DURING RAMADAN IN A MUSLIM COMMUNITY SAMPLE

Jaime A. Coffino, B.A., M.P.H.¹, Amina Mahmood, PhD², Julia M. Hormes, Ph.D.³¹University at Albany, State University of New York, Albany, NY; ²HPA/Livewell, Clifton Park, NY; ³University at Albany, SUNY, Albany, NY

Introduction: Preliminary research suggests that religious fasting during Ramadan is associated with modest weight loss, but that most of the weight lost during Ramadan is regained within a few weeks. This study aimed to examine predictors of weight change in a traditionally understudied population of practicing Muslims pre- and post-Ramadan. It was hypothesized that Muslim participants would gain weight while fasting for Ramadan only if they endorsed disordered eating behaviors and attitudes.

Methods: Muslim community members ($N = 72$, 84.3% female, Age = 33.46 ± 8.89 , BMI = 25.18 ± 6.7) were recruited in person at a religious community center as well as online via a social media platform. Participants completed a questionnaire on eating behaviors prior to Ramadan (time 1) and up to two weeks after fasting ended (time 2). Measures relevant to this study included the Binge Eating Scale (BES), a measure of “loss of control” eating and binge severity, and the Dutch Eating Behaviors Questionnaire (DEBQ), a measure of eating styles.

Results: 50% of participants ate Suhoor (breakfast) every morning and 72.7% reported that they ate about the same amount or less during Suhoor compared to their typical breakfast outside of Ramadan. 88.6% of participants ate Iftar (evening meal) every night and 71.4% reported that they ate about the same or more during Iftar compared to their usual evening meal. Additionally, 19.4% of participants reported that they experienced a loss of control over eating during Iftar. There was no significant change in BMI (M diff = $.23 \pm 1.05$, $t(30) = 1.21$, $p = .24$, $d = .02$) or reported binge eating severity (M diff = 1.25 ± 5.01 , $t(19) = 1.1$, $p = .28$, $d = .16$) between time 1 and 2. Binge eating severity and eating in response to “diffuse” emotions was significantly and positively correlated with change in BMI ($p = .04$; $p = .02$, respectively).

Discussion: Perceived loss of control or binge eating and eating in response to emotions was associated with weight gain during Ramadan. Findings contribute to a better understanding of the health-related consequences of religious fasting, and point to interventions that could be used to enable the Muslim community to make healthier decisions during Ramadan.

EXAMINING ASSOCIATIONS BETWEEN BASELINE STRESS, DEPRESSIVE SYMPTOMS, AND DIET QUALITY AMONG DIVERSE PREGNANT WOMEN

Alycia Boutte, MPH, Gabrielle Turner-McGrievy, PhD MS RD, Sara Wilcox, PhD, Jihong Liu, ScD, Jan Eberth, PhD, Andrew Kaczynski, PhD MS

University of South Carolina, Columbia, SC

Background: Optimal diet quality during pregnancy is important for increasing the chances of successful birth outcomes. During pregnancy, women have increased risk of experiencing stress and depressive symptoms, both of which have been associated with poor diet quality. Few studies have examined racial differences in these factors among women who begin pregnancy overweight or obese. Our purpose was to examine the associations between baseline stress, depressive symptoms, and diet quality among women enrolled in the Health in Pregnancy and Postpartum (HIPP) study.

Methods: HIPP is a randomized controlled trial targeting excess gestational weight gain (GWG) among overweight and obese pregnant women in South Carolina (N=133 enrolled to date). Baseline demographic and psychosocial data were collected through self-report surveys. Participants completed two ASA24 diet recalls. Pearson correlations, t-tests, and linear regression models were used to summarize the data.

Results: At baseline, participants were racially-diverse (65% White, 34% African-American (AA)), young (mean age=30), and generally well-educated (60% college graduates). Participants had low levels of stress (mean Perceived Stress Scale score= 4.7 ± 3.2 points, max=16 points) and depressive symptoms (mean Edinburgh Prenatal/Postnatal Depression Scale score= 5.7 ± 3.9 points, max=30 points). Participants had poor diet quality (mean Healthy Eating Index (HEI) score = 50.5 ± 12.6; max score=100). Stress had a weak negative relationship with total HEI scores ($r=-0.20$; $P=0.02$), while depressive symptoms were not significantly related to total HEI scores ($r=-0.11$; $P=0.19$). There were no differences in stress, depressive symptoms, or overall HEI scores by race (P 's all >0.05). AA participants had significantly higher refined grain consumption (6.6 ± 3.18 oz.) compared to their White counterparts (5.3 ± 3.4 oz.; $P=0.04$). There were no racial differences in the other HEI diet components. Perceived stress significantly predicted lower HEI scores ($b=-0.80 \pm 0.34$, $P=0.02$), while depressive symptoms did not significantly predict HEI scores ($b=-0.37 \pm 0.28$, $P=0.19$). Race did not moderate the relationship between stress and HEI scores ($b=0.10 \pm 0.69$, $P=0.88$).

Conclusions: Overall, higher stress significantly predicted lower diet quality among HIPP participants and overall diet quality was poor; however, race was not a moderator. Future research should examine if stress management interventions can improve diet quality in pregnancy.

FACTORS UNDERLYING SELF-REPORT OF NUTRITION LABEL USE FREQUENCY

Lisa S. Miller, PhD¹, Jacqueline J. Bergman, PhD², Tanja Gibson, MS¹, Angelica M. Hernandez, Bachelor of Science³, Mellanie R. De Guzman, Bachelor of Science⁴¹University of California, Davis, Davis, CA; ²UC Davis, Davis, CA; ³University of California, Davis, Ontario, CA; ⁴University of California, Davis, Fairfield, CA

Nutrition labels on US packaged foods are intended to communicate the recommendations put forth in the Dietary Guidelines for Americans¹. The majority of studies examining label use rely on measures of label-use frequency (LUF), which have advantages but make implicit assumptions underlying factors that drive frequency of use. LUF reflects the need for the label information to inform healthy food choices. The need, in turn, reflects what consumers already know - and their interest in knowing - about the foods they buy. Thus, lower label use can result from: 1) already knowing the information, and 2) lacking interest in eating healthy foods. In order to accurately interpret LUF measures, it is important to have a clear understanding of these nonuse reasons. We examined moderating effects of *already know* and *not interested* in eating healthy foods, on the relationship between LUF on the one hand and attitudes and abilities surrounding understanding and using nutrition information on the other.

Sixty female college students indicated “the frequency with which you use food labels to make choices regarding healthful food to buy, especially when buying foods for the first time,” and, “When and if you do not use labels, it is because 1) you already know if the foods are healthy and 2) you’re not interested in eating healthy foods.” They also completed measures assessing attitudes and abilities related to understanding and using nutrition information. Data were analyzed in two 2(LUF: low, high) x 2(Nonuse: agree, disagree) ANOVAs on abilities and attitudes, as a repeated measure. Results showed a LUF x Already Know x Outcome type interaction, $p < .05$, such that abilities increased from Low- to High Agree in High- but not Low- LUF group, whereas attitudes increased from Low- to High-Agree in both LUF groups (Figure 1).

Figure 1. LUF x Already Know x Outcome type

Although the LUF x Not Interested ANOVA yielded a significant effect of LUF, $p < .001$, and a LUF x Outcome Type interaction, $p < .01$, neither the main effect of No Interest, nor the LUF x No Interest x Outcome type were significant, $F < 1$.

Findings indicate that Already Know reflects different characteristics for consumers who frequently versus infrequently use labels. For those who use labels less frequently, already know nonuse does not reflect objective measures of ability. An “already know” misperception could serve as a barrier for learning more about how to use nutrition information to select healthy foods.

FEASIBILITY AND ACCEPTABILITY OF A BEVERAGE INTERVENTION FOR HISPANIC ADULTS

Kristin Morrill, B.S.¹, Benjamin Aceves, MPH, MA², Luis A. Valdez, PhD, MPH³, Cynthia Thomson, PhD, RD¹, Iman A. Hakim, MBBCH; PhD, MPH⁴, Melanie Bell, PhD³, Brooke A. Rabe, MS¹, Jessica A. Martinez, PhD⁵, David O. Garcia, PhD⁶

¹University of Arizona, Tucson, AZ; ²University of Arizona, Mel and Enid Zuckerman College of Public Health, Tucson, AZ; ³The University of Arizona, Tucson, AZ; ⁴Mel & Enid Zuckerman College of Public Health at University of Arizona, Tucson, AZ; ⁵University of Arizona Cancer Center, Tucson, AZ; ⁶The University of Arizona / Mel and Enid Zuckerman College of Public Health, Tucson, AZ

Introduction: The consumption of green tea and Mediterranean lemonade and their constitutive polyphenols and *d*-limonene may serve as an effective strategy for improving cardiometabolic biomarkers. No research to date has assessed whether consumption of these beverages demonstrates acceptability and efficacy in a pilot study among overweight/obese Hispanics.

Purpose: The objective of this study was to assess the feasibility and acceptability of a beverage intervention in obese Hispanic adults.

Methods: Hispanic adults were randomized to one of three beverages: Mediterranean lemonade (ML), Green Tea (GT), or flavored water control (FW). After completing a 2-week washout period, participants were asked to consume 32 oz./day of study beverage for 6-weeks while avoiding all other sources of tea, lemonade, citrus, juice, and other sweetened beverages; water was permissible. Fasting blood samples were collected at baseline and 8-weeks to assess the primary efficacy outcomes: total cholesterol, high-density lipoprotein (HDL), and low-density lipoprotein (LDL). Secondary outcomes included fasting glucose and hemoglobin A1c (HbA1c).

Results: 52 participants were recruited over 6 months; 50 were randomized (ML, n=21; GT; n=19; FW, n=10). The study population had a mean age of 44.6 (SD \pm 10.2) yrs; BMI: 35.9 (\pm 4.6) kg/m²; 78% were female. Four were lost-to-follow-up and 2 were excluded prior to treatment due to health concerns. Three participants in the ML group switched to GT at 3-weeks due to gastrointestinal distress. Forty-four (88%) completed the 8-week assessment. Self-reported adherence was high, with 93% of the drinks being consumed by 44 completers. No significant change in total cholesterol (mg/dL) from baseline was shown (-1.7 (95%CI: -14.2, 10.9), -3.9 (-17.2,9.4) and -13.2 (-30.2,3.8) for ML, GT and FW respectively); HDL (mg/dL) changed by -2.3 (-5.3,0.7) (ML), -1.0 (-4.2,2.2) (GT) and -3.9 (-8.0,0.2) (FW); LDL (mg/dL) changed by 0.2 (-11.3,11.8) (ML), 0.5 (-11.4,12.4) (GT) and -9.8 (-25.0,5.4) (FW). Fasting glucose (mg/dL) increased by 5.2 (2.6,7.9) (ML), 3.3 (0.58,6.4) (GT) and -1.4 (-5.0,2.2) (FW); no change in HbA1C was demonstrated; weight change (kg) was -0.1 (-1.0,0.8) (ML), -0.30 (-1.3,0.7) (GT) and -1.7 (-3.0, -0.53) (FW).

Conclusion: These results suggest that changes in cardiometabolic biomarkers were not demonstrated with this beverage intervention, with the exception of FW consumption. However, recruitment and retention figures indicate that a larger scale trial, designed to demonstrate definitive efficacy, is feasible.

6:30 PM-7:30 PM

HOLD THE FRIES: A SYSTEMATIC REVIEW OF EXECUTIVE FUNCTION AND DIETARY INTAKE AMONG YOUTH

Amy Heard Egbert, MA¹, Chloe Creber, BS², Dorothy McLeod, MA¹, Amy Bohnert, Ph.D.³

¹Loyola University Chicago, Chicago, IL; ²School of Applied Health Sciences, University of Illinois at Chicago, Chicago, IL; ³Loyola University of Chicago, Chicago, IL

Over the past two decades, unhealthy dietary intake has emerged as a key contributor to the obesity epidemic. Although the determinants of dietary intake are multifaceted, some individuals appear to struggle with resisting unhealthy foods more than others. There is evidence to suggest that these differences may be linked to impairments in executive function (EF), which can be observed in childhood. Despite the importance of investigating the relation between EF and dietary intake, methodological challenges, including lack of longitudinal research, have made the interpretation of this literature difficult. The current study sought to systematically review 1) cross-sectional research on associations between EF and dietary intake in youth ages 1–18, and 2) longitudinal research investigating EF as a predictor of dietary intake in this same age group. Specifically, the contribution of the major domains of EF (i.e., inhibition, working memory, cognitive flexibility) and their relation to dietary intake were examined while contextualizing the changes in EF that occur across development.

Initially, 4,390 abstracts were screened for eligibility. Independent coders then reviewed the full text articles of all abstracts that met criteria. A total of 13 articles were included in the review. Results demonstrated moderate support for a cross-sectional association between poor EF and unhealthy dietary intake in children, while showing an equivocal relation between EF and dietary intake longitudinally. Although most studies measured only one domain of EF, inhibition, similar patterns were found for the few studies that measured either working memory or cognitive flexibility. Heterogeneity between cross-sectional and longitudinal findings was likely impacted by the small number of longitudinal studies in the literature (n=2). Additionally, the method of EF measurement (self-report vs. objective neuropsychological measure), the way EF was conceptualized (unitarily or domain-specific), and which aspects of diet were considered (overall nutrient intake vs. consumption of specific foods), also contributed to the mixed findings. Future research should employ longitudinal designs to investigate the causal impact of EF on diet using a multi-method approach to measuring EF, while also considering the rapid development of EF skills in children between childhood and early adolescence.

PORTION CONTROL PLATES OUTPERFORM PORTION CONTROL TRAINING FOR REDUCING PORTION SIZES IN YOUNG ADULTS

Joel W. Hughes, PhD¹, Julie W. Schaefer, Ph.D.², Carly M. Goldstein, PhD³, Carly Logan, BA⁴, Jessica W. Mulvany, BS⁵, Misty Hawkins, PhD⁶, Amy Sato, Ph.D.¹, John Gunstad, PhD¹

¹Kent State University, Kent, OH; ²Medical Mutual of Ohio, Kent, OH; ³The Miriam Hospital/The Alpert Medical School of Brown University, Providence, RI; ⁴University of Florida, Gainesville, FL; ⁵College of Public Health, Kent, OH; ⁶Oklahoma State University, Stillwater, OK

Objective: Large portion sizes are believed to promote energy imbalance and contribute to high rates of overweight and obesity. Portion control strategies include portion size training and portion control dishware. Although these approaches are not mutually exclusive, we hypothesized that using a portion control plate would be more effective than brief portion size training in yielding smaller self-served portion sizes. We further hypothesized that portion size training would be more effective than a reading passage in increasing knowledge of recommended portion sizes.

Design: The study was a 2 (Plate; portion control vs. standard) x 2 (Training; portion control training vs. portion size reading) between-participants design. Participants completed portion size training or the reading and returned to the laboratory after 48 hours to select food portions of protein, grains, and vegetables. The portion size training was designed by a registered dietician.

Setting: A university psychology laboratory setting in the United States.

Subjects: Participants were 64 student volunteers (32 men and 32 women aged 20.0 ± 2.3 years).

Methods: Participants were randomized to 10 min portion size training or a brief reading about how portion sizes have increased, and also to using a portion control plate or a large standard dinner plate for self-selecting portion sizes of protein, grains, and vegetables.

Results: Training increased knowledge of correct portion sizes, as the interaction term was $F(2,62) = 13.61, p < .0005$. Simple main effects revealed that participants who received training had an increase in portion size knowledge between the first ($M = 3.61, SD = 1.8$) and second administration ($M = 8.39, SD = 2.5$), $p < .0005$. Use of a portion control plate also resulted in smaller portion sizes for protein, $F(1, 56) = 31.179, p < .001, \eta^2 = .35$, vegetables, $F(1,56) = 21.31, p_2 = .276$, and grains, $F(1,56)=23.76, p_2 = .298$. Brief portion size training had smaller or no effect. See Figures for means and standard errors.

Conclusion: Use of a portion control plate resulted in smaller portion sizes for protein, starch, and vegetables, and in contrast, brief portion size training had smaller effects. Although portion control was emphasized in the 2010 and 2015 USDA dietary guidelines, people have difficulty learning and consuming correct portion sizes. Portion control tools such as plate and dish designs appear to reduce self-selected portion sizes.

6:30 PM-7:30 PM

RESULTS OF THE BUILDING HEALTHY COMMUNITIES PROGRAM ON YOUTH HEALTHY EATING KNOWLEDGE, ATTITUDES, SELF-EFFICACY AND BEHAVIOR

Noel Kulik, Ph.D., CHES¹, E. Whitney G. Moore, PhD, CSCS*D¹, Erin E. Centeio, Ph.D¹, Alex Garn, Ph.D.², Jeffrey Martin, NA³, Bo Shen, phd⁴, Cheryl Somers, Ph.D.¹

¹Wayne State University, Detroit, MI; ²Louisiana State University, Baton Rouge, LA; ³NA, Detroit, MI; ⁴wayne state university, ann arbor, MI

While data trends show obesity levels among school-aged children have stabilized, prevalence rates remain high. It is recommended youth eat a variety of fruits and vegetables as part of a healthy diet, however, few children meet these goals. School-based interventions have the potential to reach a majority of children, especially when they involve multiple components. The purpose of this study is to determine the effectiveness of a multicomponent school-based program on children's healthy eating (HE) knowledge, attitudes, self-efficacy for HE, and eating habits over time. A quasi-experimental pre-post design over eight months was used with 4 treatment (Tx) and 2 comparison (C) schools in a large metropolitan area. Data were collected from a diverse group of 628 5th students (377 Tx, 251 C). To examine the mean differences and relationships of the students'; pre-post nutritional knowledge, attitudes-efficacy (SASE), and SPAN healthy eating index (SHEI) values, a path analysis was conducted. Both groups significantly ($\Delta = 52.03, p < .001$) increased their SHEI scores over time. The Tx SHEI post scores were significantly higher than the C post scores ($\Delta = 11.66, p < .001$). Tx post-knowledge ($M = 6.90$) was significantly ($p < .001$) greater than the C group ($M = 4.04$). The final, pruned model maintained good model fit ($CFI = .969, RMSEA = .041, 90\%CI [.010, .064]$). The Tx group had two significant ($p < .01$) indirect effects: a) pre-SASE through post-SASE to post-SHEI ($\beta = .13$), b) total effect of pre-SHEI predicting post-SHEI directly, and indirectly through post-nutrition knowledge and post-SASE ($\beta = .46$). Overall, the Tx model accounted for 14% of post-nutrition knowledge, 33% of post-SASE, and 35% of post-SHEI. Findings from this study showed: 1) a school-wide healthy school transformation program can improve HE knowledge and behavior among youth, 2) the magnitude of relationships between knowledge, SASE, and SHEI was not different between groups, and 3) nutrition knowledge is a significant predictor of both future knowledge and behavior. There was a significant change in HE behavior predicted by both SASE and knowledge. Among the Tx group specifically, there was a significant indirect effect of pre-SASE on post-HE behaviors (i.e., SHEI through post-SASE). In this study, we showed that compared to non-intervention schools, a school-based intervention can improve children's knowledge more, which can positively affect their behavior.

TRD LIGHTLY: ADHERENCE TO LOW BURDEN SELF-MONITORING AND WEIGHT LOSS OUTCOMES IN A TIME RESTRICTED DIET TRIAL

Shirlene D. Wang, BA¹, Angela F. Pfammatter, PhD², Elyse Daly, BA¹, Bonnie Spring, PhD³¹Feinberg School of Medicine, Chicago, IL; ²Northwestern University Feinberg School of Medicine, Chicago, IL; ³Northwestern University, Chicago, IL

Intermittent fasting alternates between periods of fasting and non-fasting, and, despite absence of intentional calorie restriction, may have health benefits similar to continuous calorie restriction. The TRED study, a pilot time-restricted diet trial aided by technology, was conducted to determine if the diet is feasible and acceptable and causes weight loss. This project examined adherence to diet self-monitoring (SM) when subjects were asked to complete full food diaries (high burden) and when asked only to indicate meal, snack, or beverage intake without tracking specific food details (low burden). The hypothesis was that there would be greater adherence to SM with low burden. The criterion for feasibility of adherence to SM was set as > 65% of participants recording dietary intake on ≥80% of intervention days.

Healthy women with a BMI of 25–40 were recruited. During the 24-week intervention period, subjects were instructed to restrict eating to a 10 hour time window and record dietary consumption in a smartphone application. For 4 weeks throughout the study (weeks 1, 2, 12, and 24), subjects were asked to complete full food diaries. During the other weeks participants practiced low burden SM without intentional calorie restriction reinforced with weekly coaching phone calls for the first month, and then biweekly calls for the rest of the intervention.

Of the 42 women enrolled, 26 completed the 6-month assessment and their SM data during the intervention were analyzed. The mean age at baseline was 48.04 years ($SD=11.10$) and mean BMI was 32.68 kg/m² ($SD=4.43$). 13/26 (50%) of women who completed the trial recorded dietary intake on at least 80% of intervention days. There was no significant difference in average SM during high burden days ($M=71.70$, $SD=32.95$) and low burden days ($M=71.57$, $SD=31.27$). A comparison of proportions for SM adherence for each participant showed only 5/26 had a significant difference ($pSD=3.23$) or -1.14% of the baseline weight ($SD=3.79$). Linear regression demonstrated that adherence to SM did not predict weight loss ($\beta= -0.01$, $t(24)= -0.57$, $p=.57$, $R^2=.013$). Findings suggest that adherence to time-restricted feeding is challenging and not necessarily made easier by simplifying diet intake recording requirements. Nonetheless, even without intentional energy restriction, confining food intake to a 10 hour window appears to produce modest weight loss.

BEYOND TRADITIONAL EDUCATION: INTERSECTIONS OF HEALTH, RACISM, AND COMMUNICATION

Naomi King Englar, BA¹, Shokufeh Ramirez, MPH², Keelia O'Malley, MPH³, Pasangi Perera³, John Marmion, MPH⁴, Carolyn C. Johnson, BA, MS, PhD; LPC, NCC⁵¹Tulane School of Public Health and Tropical Medicine, New Orleans, LA; ²Tulane Center of Excellence in Maternal and Child Health, New Orleans, LA; ³Tulane Prevention Research Center, New Orleans, LA; ⁴Tulane University, New Orleans, LA; ⁵Tulane University School of Public Health and Tropical Medicine, New Orleans, LA

Background: For 10 years, Tulane Center of Excellence in Maternal and Child Health and Tulane Prevention Research Center have partnered to host a seminar series on communication skills meant to enhance traditional public health education skills and professional development. In 2015, the series evolved from communication product-oriented trainings to focus on intersections of health, communication, and racism. Target audiences are public health students, practitioners, faculty, researchers, and community organizers. Seminars range from 1–1.5 hours, are free, open to the public, and held in an academic setting during the lunch hour.

Methods: This study evaluates the success of these seminars by analyzing self-reported post-seminar evaluations (using a Likert scale of 1–5 with 5 being the most positive response option) and comparing audience attendance data before and after the change in focus in 2015. The study also analyzes factors that may have facilitated more successful seminars during the post-change time period.

Results: Data show that median seminar attendance increased by more than 200% after the series changed focus from 2012–2014 (median=17; IQR: 15, 23.5) to 2015–2017 (median=53; IQR: 24, 87). Additionally, the proportion of attendees who were not affiliated with the university grew (2012–2014: 4%, n=11; 2015–2017: 22%, n=125). Post-seminar evaluation scores did not change significantly from the 2012–2014 series (average of 4.56) to the 2015–2017 series (average of 4.63). After the series changed in 2015, attendance data show that seminar topics with the highest median attendance focused on police violence (median=96; IQR: 87, 119), mass incarceration (median=74; IQR: 22, 96), mental health (median=73; IQR: 22, 87) and racism (median=69.5; IQR: 24, 87). Other factors related to seminar logistics were also analyzed; having a high-profile speaker (median=91.5; IQR=52.5, 107.5), providing food (median=74; IQR: 30, 87) and co-sponsoring seminars with student groups (median=74; IQR: 30, 87) resulted in higher median attendance.

Conclusions: Building upon communication trainings already in place was a logical way to engage public health students and professionals around effective communication related to racial health equity. The new series has attracted audiences outside of academia, which leads to richer presentations and interactions between academics and practice professionals. Providing food and co-sponsoring with students are also important factors in successful seminar implementation. The new focus aligns with university and state and local government agendas by providing learning experiences to understand the impact racism has on health and become comfortable talking about such.

INTEGRATION OF NARRATIVE MEDICINE IN FAMILY MEDICINE PRACTICE - PRACTICING WHAT WE PREACH

Angela Antonikowski, PhD

Albany Medical College, Albany, NY

Evidence based interventions are the cornerstone of behavioral medicine practice. Physician wellness has been the focus of academic medicine research due to the relationship present between wellness and burnout, suicide, and general well-being and satisfaction and patient mental health. Educators have an obligation to inform their clinical practices with these interventions as well and support the use with those in training. The evidence base supporting narrative medicine for physician health is overwhelming. Despite this support, using evidence based information for physician mental health continue to be a taboo discussion so interventions focus mostly on wellness activities such as financial health and nutrition. While these wellness activities are important, there is evidence that physician wellness activities do not have a great impact on physician mental health. Wellness programs that focus on general wellbeing often fail to address the suffering and very real barriers that physicians face. The barriers to self-care are numerous with time, normalization of problematic symptoms, and stigmatization highlighted as concerns. The glaring issue is that patients receive much of their mental health from primary care providers, yet there continues to be a paucity of resources and stigma associated with the mental health of those providers which contributes to using wellness interventions as opposed to evidence based interventions.

Family Medicine, with the emphasis on longitudinal, holistic care and behavioral health should, therefore, encourage practical, introspective practices for resident and physician wellbeing. Narrative medicine has been identified as an empirically supported practice to facilitate physician self-awareness. Given the inherent difficulties associated with these practices but the clear utility of their purpose, we sought to examine the process of implementing such a program within our residency. We implemented a narrative medicine curriculum in our 6-6-6 Family Medicine residency. Program beginning in 2016. The current discussion will explore the integration and implementation of a narrative medicine and mindful medicine program in a family medicine residency program to further the discussion of the importance of providing care to providers in training.

This session is important to those involved in behavioral medicine and medical educators, as residents in particular face challenges such as burn out and depression. Having time for self-reflection and awareness as well as opportunity to practice mindful medicine through narrative medicine practices combats that. As a family medicine educator, being aware of the residents'; situation and helping them pick up ways of reflection to further improve their practice produces a mindful physician who will in turn continue to self-reflect and improve their patient care even after residency training.

TEACHING TRAUMA-INFORMED PRIMARY CARE IN A VA HOSPITAL PRIMARY CARE CLINIC

Andrea Shamaskin-Garroway, PhD¹, Elizabeth McLaughlin, PhD², Noel Quinn, Ph.D.², Frank Buono, PhD³

¹University of Rochester School of Medicine and Dentistry, Rochester, NY; ²VA Connecticut Healthcare System, West Haven, CT; ³Yale School of Medicine, West Haven, CT

Despite the central role that psychological trauma can play in patient health, primary care providers often report discomfort discussing trauma and do not receive adequate training in this area (Green et al., 2011). The current study expands on a previous pilot study (Shamaskin-Garroway et al., 2017) and assesses the feasibility and effectiveness of a trauma-informed primary care (TIPC) curriculum integrated with the Center of Excellence in Primary Care Education, a VA interprofessional training program where health psychology residents learn and collaborate with members of other health professions. The year-long TIPC curriculum combines: 1) structured didactics about psychological trauma and impacts on health, 2) live observation of medical encounters individualized feedback from integrated health psychology resident on TIPC skills. Didactic sessions included "reflection rounds" for trainees to share their experiences working with patients who have psychological trauma histories. A pre-curriculum assessment questionnaire examining medical trainees'; knowledge, attitudes, beliefs, and self-reported practices regarding trauma-informed primary care was developed using an expert panel of health psychologists. Content validity was tested and deemed adequate. Medical trainees (n = 23), including medicine, nurse practitioner, and pharmacy residents, completed the pre-curriculum assessment. The assessment included 12 items, each item ranked on a Likert scale from 1 (strongly disagree) to 7 (strongly agree). Average subscale scores were: beliefs: $M = 6.07$, $SD = 0.75$; attitudes: $M = 5.13$, $SD = 0.96$; knowledge: $M = 4.68$, $SD = 1.04$; self-reported practice: $M = 4.42$, $SD = 1.05$. Trainees'; belief scores regarding trauma-informed primary care were significantly higher than their scores on self-reported practice ($t(22) = 7.79$, $p < .001$), knowledge ($t(22) = 6.68$, $p < .001$), and attitudes ($t(22) = 5.68$, $p < .001$). Their scores on attitudes were significantly higher than their scores on practice ($t(22) = 3.13$, $p = .005$). Female trainees ($n = 16$) scored significantly higher ($M = 4.73$, $SD = 1.03$) on self-reported practice than male trainees ($n = 7$, $M = 3.71$, $SD = 0.76$; $F(1,21) = 5.47$, $p = .029$). Post-curriculum questionnaire data will be collected at the end of the training year. The baseline findings suggested that trainees value trauma-informed care, but do not feel that they consistently integrate it into their practice, which the live observation and feedback is intended to target. Next steps will examine post-curriculum measure outcomes and trainee feedback on the curriculum.

VICARIOUS POST TRAUMATIC GROWTH AMONG CLINICIANS WORKING WITH TERMINALLY ILL PATIENTS

Sara G. Bybee, LCSW, PhD Student

University of Utah College of Nursing, Salt Lake City, UT

As clinicians working in hospice and palliative care, we often talk about Post-Traumatic Stress Disorder and how it negatively affects those who undergo trauma. Working with terminally ill patients and their families is difficult emotional work and can be traumatizing. Being an integral member of the patient's care team often means being present at the end-of-life and witnessing traumatizing events such as codes being called, patients suffering in pain or the loss of life. These experiences are stressful, emotionally draining and can lead to high turnover, burnout and compassion fatigue. Supporting patients and their families through the end-of-life can certainly be traumatic for providers, but there is also a positive aspect to trauma that is less often discussed. This poster presentation aims to define posttraumatic growth and the five domains of posttraumatic growth, discuss the current research into posttraumatic growth and vicarious posttraumatic growth among patients and clinicians and explore methods of assessing posttraumatic growth and the limitations of those assessment tools. Posttraumatic growth and its intersection with oncology, grief and spirituality will also briefly be reviewed.

We will discuss three empirically validated measures for assessing posttraumatic growth: the Posttraumatic Growth Inventory, the Benefit Finding Scale and the Stress-Related Growth Scale. In addition, we will discuss how to foster posttraumatic growth among patients with strategies such as therapeutic journaling and emotional expression. Ways to foster posttraumatic growth among clinicians such as organizational factors that facilitate growth will also be reviewed. Finally, this poster will explore the implications that this developing field of research has on our clinical practice as well as strategies for fostering posttraumatic growth in our places of work.

As clinicians, it is important that we obtain a knowledge of the basic concepts of posttraumatic growth as well as identify ways to foster growth. The implications for this research are on both the micro and macro levels. There are ways as clinicians that we can foster growth and reduce the distress of our patients. An awareness of posttraumatic growth as a possibility can help to bring new hope to our patients. In addition, this research demonstrates concrete ways growth can be encouraged among clinicians. Given that this research introduces ideas that may increase retention of clinicians, it is also a cost-saving approach. Hiring and training new staff and investing money into their development is a large monetary commitment and reducing turnover could curb this financial strain.

ASSOCIATIONS BETWEEN BMI, WEIGHT-RELATED HEALTH BEHAVIORS, ACADEMIC PERFORMANCE, AND COGNITIVE ABILITY

Katie Hosteng, MS¹, Lucas Carr, PhD¹, Krista Mattern, PhD², Jeremy Burrus, PhD²¹University of Iowa, Iowa City, IA; ²ACT, Iowa City, IA

Background: U.S. childhood obesity rates have tripled since 1970. While childhood obesity has been shown to negatively associate with several measures of academic performance, it is still unclear whether obesity or obesity-related health behaviors associate with objective measures of cognitive ability.

Objective: To determine the relationship between body mass index (BMI), several obesity-related health behaviors and both high school grade point average (GPA) and American College Testing (ACT) scores in a national sample of ACT-tested high school students.

Methods: We recruited a national sample of 9th-12th grade students who took the April 2017 ACT exam to report their height, weight, and weight-related health behavior questions taken from the 2017 Youth Risk Behavior Survey targeting physical activity, sedentary behavior, sleep and dietary intake. Pearson partial correlation coefficients between BMI, health behaviors, GPA, and ACT scores were calculated while controlling for socioeconomic status (parental income), gender, and race/ethnicity.

Results: Based on data from 2,962 students, high school GPA significantly ($p < 0.001$) associated with BMI ($r = -0.13$), weekday TV time ($r = -0.09$), weekday sleep time ($r = 0.07$), weekend sleep time ($r = 0.12$), number of sports teams ($r = 0.08$), soda consumption ($r = -0.13$), fruit consumption ($r = 0.11$), vegetable consumption ($r = 0.10$), and eating breakfast regularly ($r = 0.13$). ACT scores significantly ($p < 0.001$) associated with BMI ($r = -0.13$), days physically active ($r = -0.10$); participation on sports teams ($r = -0.09$), weekday TV time ($r = -0.15$), weekend TV time ($r = -0.08$), video game playing time ($r = 0.08$), weekend sleep time ($r = 0.16$), soda consumption ($r = -0.13$), fruit consumption ($r = 0.10$), and vegetable consumption ($r = 0.11$).

Conclusions: Students who watched less TV, slept more, ate a healthier diet, and had a healthier weight tended to report higher grades and performed better on the ACT exam. School-based programs targeting each of these areas are thus warranted as part of a well-rounded curriculum.

COLLABORATIVE DATA INTERPRETATION AND PLANNING TRAINING FOR COMMUNITY SUBSTANCE USE STAKEHOLDERS AND PROVIDERS IN HAWAII

Danilyn Goya, MPH¹, Allison Wagner, M.A.¹, Claudio Nigg, Ph.D.²¹University of Hawai'i at Manoa, Honolulu, HI; ²University of Hawaii, Honolulu, HI

BACKGROUND: Data plays an important role in public health, as it provides the information necessary to successfully plan, implement, evaluate, and sustain intervention programs. However, organizations often underutilize data and have a deficit in their capacities for incorporating data. Data interpretation and planning trainings were provided to individuals across the 4 counties of Hawaii who work in the field of substance abuse prevention and treatment as an effort to bridge this gap.

PURPOSE: To evaluate trainings about data interpretation based on locally conducted needs assessments and other data sources, and about planning concepts for counties, coalitions, and other stakeholders.

METHODS: Pre- and post-tests were administered to all participants to assess participants' knowledge of program planning, logic models, epidemiological profile data, capacity building, and cultural competence. Participants also completed a satisfaction survey upon completion of the training program to evaluate the course content, trainers, course materials, and overall satisfaction.

RESULTS: There were 72 participants (69% female; mean age = 44.55 [SD=11.34]). Trainings were delivered at five different sites across all 4 counties of Hawaii. The differences between percentages correct on pre- and post-tests showed a significant improvement ($t(68) = -7.54, p < .001$) from 77.46% (SD=12.39) to 90.14% (SD=10.14). McNemar's test was used to further analyze each question. Participants showed a significant increase in number of participants who answered correctly on questions regarding next steps for the grant ($p < .001$), major issues identified in the needs assessment discussed ($p < .001$), epidemiological statistics ($p < .001$) and components of a logic model ($p < .001$). In addition, most participants (87% or more) were satisfied with the course.

CONCLUSIONS: Participants increased their knowledge of key topic areas and were overall satisfied with the training provided. Multiple participants also expressed interest in additional opportunities for trainings through continued partnerships. Given the popularity and effectiveness of this program, the collaborative trainings should be both continued and expanded.

FUNDING: Strategic Prevention Framework Partnerships for Success Initiative (SPF-PFS) of the Substance Abuse and Mental Health Services Administration (SAMHSA), under grant number: 1U79SP020167-01.

COMMUNICATION BETWEEN THE SCIENTIST AND STATISTICIAN DRIVE THE DEVELOPMENT OF A GRANT APPLICATION AND CLINICAL PROTOCOL

Dawn A. Morales, Ph.D., Experimental Psychology¹, William Sones, PhD Pharmacology, MSc Applied Statistics²¹National Institutes of Health, BETHESDA, MD; ²Oxford University, Oxford, England, United Kingdom

Starting in January 2018, the NIH changed how it accepts clinical trial applications. For example, grant submissions to the NIH for a clinical trial are required to include a clinical protocol synopsis. The consequence of this is that many scientists with no experience writing clinical trial protocols will now be required to compile these complex documents. Writing a clinical trial protocol that is based on a grant application requires collaborative communication between the primary investigator and the study statistician at numerous points along the way. How to convert a grant application into a protocol is described, along with the critical points in the conversion and development process that require this kind of collaborative communication. We also discuss historical trends in basic clinical science research and quantitative analysis, training and background of scientists and statisticians, as well as misuse of statistics.

IMPROVING TRAINEE SKILLS IN THE CLINICAL ASSESSMENT OF SOCIAL NEEDS BY USING STANDARDIZED ADOLESCENT PATIENTS

Shawna M. Sisler, MS, MA, MAPP, RN, PHN, C-PNP, PMHS¹, Linda Stephan, RN, MSN, PNP², Victoria Keeton, RN, MS, PNP², Andrea Wallace, PhD RN³, Jayme Mejia, RN, MSN, FNP², Naomi Schapiro, RN, PhD, PNP²¹University of Utah, San Francisco, CA; ²UCSF School of Nursing, San Francisco, CA; ³University of Utah, Salt Lake City, UT

Background: New Institute of Medicine (IOM) and Centers for Medicare & Medicaid Services (CMS) guidelines assert the importance of screening all patients for social needs (e.g. food and housing insecurity), suggesting that health service delivery that is informed by patients' social needs and resources are more likely to facilitate self-management of chronic conditions, reduce health service utilization, and overall health care costs. While health systems implement these guidelines into routine care (i.e. Accountable Health Communities Model), there is a need (gap) to integrate social need screening and related clinical decision-making into curricula or practicum settings at the trainee level.

Purpose: The purpose of this study is to explore culturally and socially appropriate ways for graduate health science students to improve their ability to assess and address social needs during their trainee education using adolescents as standardized patients in a simulation setting. Additionally, it had the goal to further motivate disadvantaged youth to enter health careers through their involvement in the simulation.

Methods: Through an intensive health careers exploration program, adolescents were trained as standardized patient actors by an academic health sciences simulation lab. During an urgent care visit scenario, each youth was given the same simulation script introducing a variety of behavioral health and social need situations. The NP students were naive to the patient's sociocultural context and were not instructed to evaluate for social needs. All dyads were recorded and reviewed by nursing faculty who rated students on various dimensions. All NP students filled out a self-reflection following the encounter.

Results: Nine adolescents from disadvantaged communities and 17 second year NP students participated in the simulation. Analyses underway are using grounded theory to evaluate the footage and self-reflection to provide data for analysis. Preliminarily, we found that some students addressed circumstances of housing instability or difficulty accessing transportation, but most social needs were unaddressed. Students tended to rely on illness-specific details for psychoeducation.

Conclusions: Through a simulated setting and standardized patients who can most authentically represent adolescents, we demonstrated the need for to develop explicit instruction addressing social needs for trainees.

The original project is a collaboration between UCSF School of Nursing, Alameda County Health Systems, Oakland high school health academies, and the OUSD Linked Learning office. Funding for this year's training and analysis are supported by a HRSA grant focusing on the integration of primary care and behavioral health, and funding from Alameda County to increase representation of minority and disadvantaged youth in health professions.

MEDICAL STUDENT MENTORS: A POTENTIAL NEW MODEL FOR SPECIALIZED ADOLESCENT PATIENT SUPPORT

Adrienne Viola, MPH¹, Elliot Coups, PhD², Hanin Rashid, M.Ed, PhD³,
Katie Devine, MPH, PhD¹

¹Rutgers Cancer Institute of NJ, New Brunswick, NJ; ²Rutgers Cancer
Institute of New Jersey, New Brunswick, NJ; ³Rutgers Robert Wood Johnson
Medical School, Piscataway, NJ

Introduction: Peer mentoring and the benefits of social support have been successfully used to promote positive changes for a number of health behaviors. Medical students have been utilized as peer mentors for adolescent and young adult patients with a variety of chronic conditions. Medical students have the unique quality of being integrated into the healthcare system and being a similarly-aged “peer” to the patient. Little research has focused on medical student interest in acting as a mentor for adolescents with chronic disease, or the potential reciprocal benefit this program model could provide for both patient and student. In this study, we examined medical student experiences, interest, and expectations for a mentoring experience working to improve transition outcomes for adolescents with chronic disease. This research is being used to inform the development of such a program.

Methods: 164 medical students (58% female, M age = 25.1, SD = 2.39; 26.2% 1st, 31.3% 2nd, 20.0% 3rd, and 22.5% 4th year medical students) were recruited from Robert Wood Johnson Medical School. Participants completed a survey measuring previous mentoring experience, interest in mentoring adolescents with chronic disease, and expectations for participating in a mentor program to improve transition outcomes for adolescents with chronic disease.

Results: Two-thirds of respondents indicated that they had served as a mentor during medical school, most commonly serving as a mentor for other medical students. Overall, 57% of students reported that they would “definitely” or “probably” be interested in program mentoring a young adult with chronic illness (M = 2.4 on 5-point scale; 1= definitely interested). Students interested in participating thought that a mentoring opportunity would allow them to learn more about chronic disease management (60.2%), establish a relationship with a patient (59.6%), and learn more about patient navigation within the healthcare system after completing the program. Students expressed interest in receiving training about health insurance (51.7%) and disease specific information (51.7%) before participating. Nearly half of the interested sample reported they would be willing to dedicate 4 or more hours per month to their mentee.

Conclusions: This study indicates that medical students are interested in serving as a mentor for adolescents with chronic disease. The results indicate that there is potential reciprocal benefit for medical student education, as well as patient outcomes. The results of this study are being used to guide the development of a medical student mentor program to improve transition outcomes for adolescents with chronic disease.

PEER HEALTH COACH TRAINING PRACTICUM: EVIDENCE FROM A FLIPPED CLASSROOM

Kathryn J. Southard, M.S., Gregory J. Welk, Ph.D., Laura Ellingson, PhD

Iowa State University, Ames, IA

Purpose: Health coaching is an effective method to assist individuals in gaining motivation to engage in healthy lifestyle behavior changes. We developed a new flipped classroom practicum course designed to offer undergraduate students the opportunity to learn an important skill called motivational interviewing (MI) commonly used in health coaching. The 16-week, 2-credit course (led by four trained, graduate student health coaches) consists of online video lectures, in-class activities, experiential training, and supervised practicum experiences in health coaching. The aim of this study is to evaluate the process, impact, and outcomes of this new health coaching practicum.

Methods: Surveys were administered to all participants, (n = 13; 11 female; average age 21.4 ± 1.8); seven participants consented to provide a recorded MI conversation to evaluate fidelity of the training. Surveys assessed participant satisfaction and impact using 6-point Likert scales and were analyzed descriptively (mean \pm SD). Recordings of MI conversations were independently coded by three of the instructors using the Motivational Interviewing Treatment Integrity (MITI) Coding Manual 4.2.1.

Results: Survey results demonstrated that students felt comfortable (4.9 ± 0.49) and confident (4.7 ± 0.49) using MI. Students reported that they found the course useful, (5.46 ± 0.52) and would most likely use this skill in the future (5.7 ± 0.63). Inter-rater agreement showed high reliability between coders (95% agreement, $p < 0.001$) with average scores being reported. Results from the MITI showed that six of the seven students met the proficiency level for relational components of MI, two of the seven students scored at or above the proficiency level for technical, and two of the seven students met proficiency levels for the percent of complex to simple reflections used.

Conclusions: These preliminary results support the utility of a flipped classroom practicum course designed to teach undergraduate students the skills of MI, however extended practice with the use of MI may be needed for students to meet proficiency levels.

REACHING ACROSS THE HEALTH DISCIPLINE DIVIDE: ASSESSING STUDENT OUTCOMES FROM AN INTERPROFESSIONAL TRAINING PROGRAM

Natalie Fenn, BA¹, Zoe Mushkat, BS², Alexandra N. Murray, MA², Mark Robbins, PhD², Erica Estus, Pharm.D., CGP², Geoffrey Greene, PhD, MPH, MS, BS², Mary Cloud, MSN, RN², Janice Hulme, PT, MS, DHS, CEEAA²

¹University of Rhode Island, Providence, RI; ²University of Rhode Island, Kingston, RI

Intro: There is an increasing demand for interprofessional education (IPE) to address the healthcare needs of older adults. While there are often barriers to delivering interprofessional healthcare effectively, team decision-making can be improved with targeted education. The current study evaluated outcomes of an IPE training program designed to bolster competency and attitudes toward working on interprofessional teams, specifically among older adults with many cross-disciplinary needs.

Methods: Students (N=45) from multiple health-related disciplines [Pharmacy (N=33), Nursing (N=7), and Nutrition (N=5)] at a midsize northeastern university participated in a three-day Interprofessional Senior Health and Wellness program. Students were taught teamwork principles and provided collaborative screening, educational materials, and referral suggestions to older adults from the community. Students completed the Team Skills Scale (TSS) and the Attitudes Towards Health Care Teams Scale (ATHCTS) once directly before and after the IPE program to assess for perceived skills and attitudes towards interprofessional team care.

Results: Students were primarily women (78%), English speaking (95%) young adults (M=23.4 yrs, SD=5.0). Over 70% were Clinical Doctorate or Master's students, 23% were pursuing an undergraduate degree, and 35% of students entered the program without any prior experience in interprofessional teamwork. Students reported a significant improvement in team skills ($t=-2.32$, $p=.025$). Students also reported significant improvement on 4 of the 17 individual skills items (e.g., "I am able to identify contributions to patient care that other disciplines can offer"). Attitudes scores did not significantly change across the program [Pre: M=83.35 (SD=13.3); Post: M= 87.96 (SD=11.9)], although 3 of 21 individual items significantly declined in the opposite direction than hypothesized (e.g., "In my opinion, developing an interprofessional patient care plan is excessively time consuming").

Discussion: Perceived skill mastery improved overall and most notably on four items. While three attitudes items did trend in the opposite direction than predicted, students entered the program with generally positive attitudes toward IPE that were maintained across the program. Findings from this relatively small sample suggest that students across health disciplines could benefit from IPE trainings to bolster team skills in working with older adults, yet further research is needed to address the complexities of attitudes towards team decision-making.

VOCATIONAL ORIENTATION WORKSHOPS FOR STRENGTHENING OCCUPATIONAL COMPETENCIES IN YOUTH AT A GERMAN YOUTH EDUCATIONAL CENTER

Carina Mnich, N/A¹, Claudio Nigg, Ph.D.²

¹University of Applied Sciences, Regensburg, Regensburg, Bayern, Germany; ²University of Hawaii, Honolulu, HI

Background: During youth, it is important to strengthen occupational competencies in young people for the entry in job life. A major part of this process is to find about which profession matches with one's own skills as a prerequisite for a satisfactory career and a healthy future as an adult. Therefore, a Youth Educational Center covering predominantly one district (Bezirk) of Bavaria, Germany have has implemented a workshop curriculum to this effect with middle school classes over several years.

Purpose: To evaluate vocational orientation workshops implemented at the Youth Educational Center Waldmuenchen with middle school classes in grade 8 since 2012 on learning about one's own skills and developing professional competencies.

Methods: The 5-day workshop consists of different topics. In the first part, youths do different exercises to find out about their skills before they investigate and identify their desired occupation. A presentation about themselves allows them to get feedback about the impression they project, while the team training requires collaboration with the whole class. In a simulation game, youths learn about the job application procedure and the job market prior to a simulated interview. Post-test surveys (1: agree; 2: agree somewhat; 3: disagree somewhat; 4: disagree) were administered to all workshop participants between 2012–2017. The item means were used to track the evaluation over the last few years.

Results: There were 289 workshops (annual $M=48.2$, $SD=8.0$) implemented with 5,358 participants (12–15 years old, annual $M=893.0$, $SD=134.5$). Participants on average agreed that they had learnt about their own strengths and skills ($M=1.4$, $SD=0.2$) as well as about their desired occupation and an alternate occupation ($M=1.5$, $SD=0.2$). In terms of job application process outcomes, participants endorsed that they felt safe in job interviews due to the camp ($M=1.7$, $SD=0.2$) and that they know what to do next for getting an apprenticeship ($M=1.5$, $SD=0.2$). Regarding social skills, participants confirmed that they can work better in a team due to the camp ($M=1.7$, $SD=0.3$) and group cohesion improved ($M=1.8$, $SD=0.4$). No estimates were significantly when compared by year of implementation (all $p>0.5$).

Conclusions: The results indicate that the camp had a positive effect on occupational competencies as well as on figuring out a suitable profession for the participants. This indicates that the program is suitable to strengthen competencies of youths, likely positively affecting future job entry. Further evaluation of the workshops is recommended, especially a longitudinal follow-up of the participants in terms of the choice of apprenticeship/employment, later job satisfaction, as well as longevity in a position and quality of life.

Acknowledgement: We appreciate the Youth Educational Center in Waldmuenchen in Bavaria, Germany, who provided the data set.

CHARACTERISTICS OF SLEEP IN PERSONS WITH VARYING LEVELS OF HEALTH LITERACY

Joshua Riederman, BS¹, Raymond Ownby, MD, PhD²¹NOVA COM Psychiatry & Behavioral Medicine, Plantation, FL; ²Nova Southeastern University, Fort Lauderdale, FL

Introduction: Health literacy is a measure of how one can interpret new health information, and is related to a variety of health variables including utilization, quality of life, and even mortality. Although factors such as socio-economic status, mood, or education in part explain these relations, our previous work suggest they do not completely. Research on the effects of sleep is not complete, however we do know that sleep is closely related to health. The purpose of these analyses was to explore the relation of health literacy to aspects of sleep in individuals with different levels of health literacy – a relationship that has not been studied previously.

Methods: Using data from a previous study of health literacy in 497 English and Spanish-speaking individuals (n = 245 and 252, respectively) recruited to represent a range of ages (18 to 93; mean 53.1 years) and levels of education (0 to more than 20; mean 12.3 years). Persons were categorized according one of four levels of health literacy: below basic, basic, intermediate, or proficient. Participants also completed the Pittsburgh Sleep Quality Index (PSQI), a widely-used measure of sleep quality that includes questions assessing various aspects of sleep. Mood was determined based on the Center for Epidemiological Studies Depression Scale (CES-D). The relation of group membership to sleep characteristics was explored using multivariate analysis of covariance (MANCOVA), controlling for age, gender, race, language, and mood.

Results: Analyses showed overall between group differences on PSQI items (F 13, 393 = 31.07, p<0.001). Between group differences were found for PSQI items sleep duration (F 8, 405 = 10.65, p<0.001), disturbances in sleep (F 8, 405 = 18.43, p < 0.001), sleep latency (F 8, 405 = 9.49, p < 0.001), and sleep efficiency (F 8,405, p <0.001). Evaluation of between group differences via post-hoc tests however, revealed few significant differences.

Discussion: The results from the study support the idea that health literacy may be related to sleep. Because sleep plays an important role in health, it is worthwhile to assess the relationship between health literacy and sleep. It could be that those with lower health literacy levels are not aware of the benefits of sleep. On the contrary it could also be thought that poor sleep quality could affect the ability of participants to read and analyze new medical information.

DOES PHYSICIAN GENDER PLAY A ROLE IN COLLEGE STUDENTS' HUMAN PAPILLOMAVIRUS (HPV) VACCINATION DECISIONS?

Jennifer Orr¹, Laurel M. Peterson, Ph.D¹, Nils Olsen, Ph.D²¹Bryn Mawr College, Bryn Mawr, PA; ²The George Washington University, Washington, DC

HPV prevalence is high on college campuses, yet the majority of students are unvaccinated. Physician recommendation is the most influential determinant of HPV vaccination, however little research has explored how physician characteristics (e.g., gender) affect HPV vaccination decisions (Holman et al., 2014). Some research indicates that gender concordance is associated with patient message acceptance (Schiber et al., 2014). Competing research indicates that both female and male patients are more likely to receive preventative services (e.g., cancer screenings) from female physicians (Krähenmann-Müller et al., 2014). We experimentally investigated whether *physician gender concordance* or *female physician gender* was associated with college students'; adherence to physician HPV recommendations.

College students (N = 227, 67% male, 69% White, $M_{age} = 19.47$) who had not received the HPV vaccine completed an online module where they were randomly assigned to envision a physician appointment with a male or female avatar physician photo. Participants read identical physician advice regarding HPV risks, vaccine efficacy and availability. Participants then completed a survey on perceived vulnerability for contracting HPV, HPV vaccine intention, and general adherence to physician recommendations.

All ANOVAs controlled for participant gender. No significant differences emerged for participant/physician gender concordance in perceived vulnerability, vaccine intention, or adherence ($ps > .12$). For the female physician effect, there were no significant differences in perceived vulnerability or vaccine intention ($ps > .77$), but significant results did emerge for adherence to physician recommendations [$F(1, 222) = 5.14, p = .03$, scale 1–9]. Participants randomly assigned to the female physician reported greater adherence to physician recommendations ($M = 7.15, SD = 1.58$) than participants assigned to the male physician ($M = 6.69, SD = 1.66$).

These results provide the first known experimental head-to-head comparison of *physician gender concordance* and *female physician gender* effects. Results indicate that female physicians may induce greater general adherence, but this may not apply to HPV-specific medical suggestions. Future studies should explore in vivo physician gender manipulation and whether the *female physician effect* applies to general and HPV-specific adherence in naturalistic settings. With that said, these data suggest that HPV vaccination decisions may be uninfluenced by physician gender.

EFFECTS OF ATTITUDE-DISCORDANT NEWS ON SUBSEQUENT ONLINE SELECTIVE EXPOSURE AMONG PRO- AND ANTI-VACCINATION INDIVIDUALS

Nicholas Schmuhl, PhD¹, Rachel Kornfield, MA², Albert Gunther, PhD³¹School of Medicine & Public Health, University of Wisconsin-Madison, Madison, WI; ²University of Wisconsin, Chicago, IL; ³University of Wisconsin-Madison School of Journalism & Mass Communication, Madison, WI

Rationale. The Internet allows individuals to pursue congenial content and avoid non-congenial content (i.e., “selective exposure”). The internet may also allow vaccine hesitant individuals to seek content affirming vaccine hesitancy. Despite evidence for selective exposure, questions remain about its proximal determinants. In this study, we ask whether exposing partisans to news about vaccination prompts subsequent selective exposure, and we examine affective response and bias perception as drivers of selective exposure.

Methods. 333 individuals with strong opinions on childhood vaccination were recruited via MTurk and online interest groups and randomized to one of three stimuli (news articles that were concordant or discordant with participants’ vaccination positions, or neutral). After reporting affective responses and bias perceptions, participants completed an online news-browsing task, capturing: 1) proportion of selections concordant with their positions, and 2) proportion of time on concordant selections.

Results. Results showed a significant effect of stimulus on affect, $F(2,292) = 6.71$, $p = .001$, with those exposed to concordant articles reporting less negative affect than those exposed to neutral or discordant articles. Results also showed a significant effect of stimulus on perceived bias, $F(2,298) = 45.935$, $p < .001$, with those exposed to concordant articles perceiving less bias toward their positions than those exposed to discordant or neutral articles. Those reading neutral articles perceived less bias than those reading discordant ones.

Results from the news-browsing task revealed a significant effect of stimulus on proportion of subsequent concordant selections, $F(2,229) = 3.354$, $p = .037$, with those exposed to concordant stimuli selecting a lower proportion of concordant articles than those exposed to neutral or discordant stimuli. Stimulus also affected distribution of reading time, $F(2,229) = 4.170$, $p = .017$, with those exposed to concordant stimuli spending less time on concordant articles than those exposed to discordant or neutral stimuli.

Mediation analysis found that stimulus affected proportion of concordant selections via negative affect [indirect effect: $M (SE) = -.0176 (.0097)$; 95% BCa $CI = [-0.040, -0.002]$] but not via bias perceptions. Likewise, we found that stimulus affected the time spent on concordant selections via negative affect [indirect effect: $M (SE) = -.0176(.0108)$; 95% BCa $CI = [-0.042, -0.001]$] but not via bias perceptions.

Discussion. Online “selective exposure” risks isolating individuals from accurate and comprehensive health information. Our findings suggest that exposing partisans to counter-attitudinal health news may have unintended consequences, driven by negative affect, wherein partisans engage in compensatory information seeking that confirms their original positions.

MOVIN’ FOR LIFE: SOCIAL MARKETING TO PROMOTE A COMMUNITY-BASED HEALTH PROMOTION PROGRAM IN NEW ORLEANS

Naomi King Englar, BA¹, Keelia O’Malley, MPH², Madison Monahan, MPH(c)³, Catherine G. Haywood, BSW⁴, Revonda Darensbourg, MSW⁵, Carolyn C. Johnson, BA, MS, PhD; LPC, NCC⁴¹Tulane School of Public Health and Tropical Medicine, New Orleans, LA; ²Tulane Prevention Research Center, New Orleans, LA; ³Tulane Prevention Research Center, Tulane School of Public Health and Tropical Medicine, New Orleans, LA; ⁴Tulane University School of Public Health and Tropical Medicine, New Orleans, LA; ⁵Tulane Prevention Research Center, Tulane University School of Public Health and Tropical Medicine, New Orleans, LA

Background: *Movin’ for LIFE* (Lasting Improvements for Fitness and Energy) is a multi-level, community-based program in New Orleans 9th Ward - an underserved, predominantly black neighborhood - that coordinates, sponsors and promotes free health promotion activities for residents related to physical activity and healthy eating. This study’s purpose is to evaluate a social marketing campaign implemented in summer 2017 for two *Movin’ for LIFE* health promotion activities, a Family Health Fair and 5K Run/Walk.

Methods: The campaign utilized a range of strategies to reach potential participants including print and online ads with news media, social media ads, outdoor ads, printed flyers, and word of mouth. Data for message reach was collected using Google Analytics, Facebook and Twitter analytics, news media readership and impressions, outdoor advertising company estimates for impressions based on traffic counts, and number of flyers distributed via two part-time Community Health Workers to outlets in the community.

Results: The campaign resulted in 11,000 flyers distributed to more than 80 neighborhood businesses, churches and nonprofits. Two months of ads on 3 billboards generated 1.09 million impressions, one month of bus shelter ads generated 2.61 million impressions, and 1 month of ads on 8 bus exteriors generated 9.74 million impressions. 2,339 users accessed the program website during the 3-month campaign, compared to the total 3,395 users that visited the website during its 1-year lifespan. Print and digital ads with news media outlets resulted in 918,000 impressions. Facebook ads reached 12,520 people and Twitter ads generated 52,810 impressions. The Family Health Fair had 156 participants. A total of 280 people registered for the 5K Run/Walk, and an estimated 250 participated.

Conclusions: Best practices recommend utilizing a variety of marketing strategies to saturate audiences and reinforce messages through repetition and multiple exposures. Our study shows that using multiple strategies is a viable method for recruiting participants for health promotion activities.

MULTIPLE SCLEROSIS (MS) HEALTH BELIEFS AND THEIR ASSOCIATION WITH DEPRESSION AND SUICIDALITY IN PERSONS WITH MS

Lara M. Stepleman, PhD¹, Rebecca M. Floyd, PhD², Rebecca Howell³, Biana Hughes³¹Medical College of Georgia at Augusta University, Augusta, GA; ²Hennepin County Medical Center, Minneapolis, MN; ³Augusta University, Augusta, GA

Background. Persons with multiple sclerosis (MS) have increased prevalence of depression and suicidality compared to the general population. Lack of MS health literacy, or specifically, endorsement of false beliefs about the disease may contribute to poorer emotional functioning. The purpose of this study was to examine MS health beliefs, depression, and suicidality.

Methods. The present survey study examined depression using the Hospital Anxiety and Depression Scale (HADS; Zigmond & Snaith, 1983), suicidality using a single item of suicidal thoughts, and beliefs about common MS facts/myths using an author derived 14-item measure. The internet-based sample consisted of 212 mostly White (77.8%), female (81.1%) adults ($M_{age} = 46.38$, $SD = 11.36$) living in the US (82.1%) and diagnosed with MS (80.2% relapse-remitting).

Results. Bivariate correlations were used to examine the relationship between strength of endorsement of MS false beliefs and depression and suicidality. Total endorsement of false belief items was significantly correlated to both depression ($r = .47$, $p = .00$) and suicidality ($r = .26$, $p = .00$). At the item level, the MS health beliefs most strongly associated with depression were “People with MS cannot keep working” ($r = .42$, $p = .00$), “Exercise makes MS worse” ($r = .40$, $p = .00$), “MS is a death sentence” ($r = .34$, $p = .00$), “People with MS cannot have a satisfying sex life” ($r = .34$, $p = .00$), and “If you have MS, you will end up in a wheelchair” ($r = .30$, $p = .00$). At the item level, the MS health beliefs most strongly associated with suicidality were “MS is a death sentence” ($r = .27$, $p = .00$), “If you have MS, you will end up in a wheelchair” ($r = .24$, $p = .00$), “People with MS cannot keep working” ($r = .22$, $p = .00$), “People with MS cannot have a satisfying sex life” ($r = .22$, $p = .00$), and “Physicians who suggest patients see a mental health provider are telling them that they are ‘crazy’; or that ‘it’s all in their head’;” ($r = .21$, $p = .00$).

Conclusion. The current study suggests that beliefs about MS disease and course are associated with depression and suicidality. Similar sets of MS beliefs, mostly quality of life driven, were linked to depression and suicidality; however, depression was most strongly connected to beliefs about ability to work whereas suicidality was most strongly connected to beliefs about MS being a death sentence. Given these findings, health care providers may wish to carefully assess patients’ understanding of MS, especially when psychological distress is part of the clinical presentation. Further, health literacy information should address MS health beliefs directly and dispel myths that may be related to poorer emotional functioning, and consequently, quality of life.

6:30 PM-7:30 PM

OPTIMISTIC BIAS FOR NEGATIVE PROGNOSTIC INFORMATION PREDICTS HYPOTHETICAL CANINE B-CELL LYMPHOMA TREATMENT DECISION MAKING

Samantha Siess, MA¹, Lauren Sikorski, DVM, DACVIM (Internal Medicine)², Anne Moyer, Ph.D.¹¹Stony Brook University, Stony Brook, NY; ²East End Veterinary Emergency & Specialty Center, Riverhead, NY

Background: The majority of patients in the ICU do not have an advance health care directive, as a result surrogate decision makers are left with the burden of interpreting prognoses and making end-of-life decisions. Surrogates for critically ill patients tend to be optimistically biased when interpreting poor prognoses. With the increasing importance of companion animals in the family and advanced veterinary care, more individuals will serve as surrogate decision makers for a critically-ill companion animal. Despite this, very little attention has been paid to surrogate decision making with regard to veterinary medicine.

Objective: This study examined this bias in a hypothetical veterinary medical context and whether it is affected by the framing of prognostic information in terms of “dying” vs. “surviving;” and if it predicts hypothetical canine B-cell lymphoma treatment decisions, along with comfort received from and attachment to a companion animal, the companion animal’s prognosis (good vs. poor), owner’s insurance status (has insurance vs. has no insurance), and veterinarian recommendation (toward treatment with a full protocol of chemotherapy vs. euthanasia vs. no recommendation), after controlling for factors that may influence such a decision, such as dispositional optimism, personality traits, and spirituality/religiousness.

Methods: 300 undergraduates interpreted hypothetical prognoses and made treatment decisions for their dog with a hypothetical diagnosis of canine B-cell lymphoma.

Results: Participants interpreted prognostic statements in an optimistically biased manner (p ’s < .001). When the prognosis indicated a *low risk of dying* (5% and 10%), framing in terms of *dying* resulted in significantly *lower* perceived chance of survival (p ’s < .001). However, when the prognosis indicated a *high risk of dying* (95%), framing in terms of *dying* resulted in significantly *higher* perceived chance of survival ($p < .05$). Furthermore, the greater the amount of optimistic bias for prognoses, greater attachment to and less comfort received from the dog, and a veterinarian recommendation towards a full protocol of chemotherapy or no recommendation for a particular treatment, predicted a greater likelihood of approving some form of B-cell lymphoma treatment over euthanasia ($p < .001$).

Conclusions: These results suggest that veterinarians should be cognizant of the optimistic bias for poor prognoses that they may encounter when delivering poor prognoses. This bias may be exacerbated in owners who receive a greater amount of comfort from their animals and are more attached to their animals. Further, greater optimistic bias is associated with a tendency to approve some form of treatment over euthanasia.

THE DEPARTMENT OF DEFENSE COMPREHENSIVE HEARING HEALTH PROGRAM: A PILOT STUDY

Natasha Gorrell, MSPH¹, Tanisha Hammill, PhD, MPH², Julieta Scalo, PhD², Elsa Granato, MPH³, Sara Murphy, MPH³, John Merkley, AuD⁴

¹Hearing Center of Excellence, Richardson, TX; ²Hearing Center of Excellence, JBSA Lackland, TX; ³Research Administrator, JBSA Lackland, TX; ⁴Army Audiology Liaison, JBSA Lackland, TX

The World Health Organization estimates that 700 million to 1 billion people worldwide have a hearing loss. For Fiscal Year 2016, the Department of Veterans Affairs reported that 1.6 million and 1.1 million Veterans received disability compensation for tinnitus and hearing loss, respectively. The Department of Defense Hearing Center of Excellence (HCE) created a Comprehensive Hearing Health Program (CHHP) to reduce the incidence of military hearing injury through Education, Protection and Monitoring. The Education component aims to reduce hearing loss incidence among Service Members (SMs) through patient education sessions during audiology appointments. To assess the impact of the sessions, HCE designed a study with a three-group, quasi-experimental design to measure SMs' knowledge, attitudes, beliefs, and behaviors (KABB) regarding hearing loss before, immediately and 6 months post-education session. Questions rating the educational experience were included.

Baseline and post-surveys were administered at three participating military installations. The preliminary baseline data (N=92 of total study N=432) shows the overall self-reported prevalence of hearing loss was 30%, with the Air Force having the lowest (8%) and the Army having the highest at 50% ($p < 0.01$). Seventy percent of Army and Navy subjects reported wearing hearing protection on the job at least 75% of the time, and 48% of Air Force subjects reported doing so ($p < 0.01$). Over half of the Army and Navy respondents reported that their supervisors remind them to wear their hearing protectors at least 75% of the time, and 36% of Air Force subjects reported similarly. Final study data, including available 6 month follow-up questionnaire responses, will be presented to demonstrate effectiveness of these hearing health promotion efforts on the KABB of SMs across all branches of the military.

6:30 PM-7:30 PM

THE EFFECT OF SEVERITY OF PROGNOSIS AND FRAMING ON AN OPTIMISTIC BIAS FOR NON-NUMERICAL PROGNOSSES IN THE VETERINARY SETTING

Samantha Siess, MA, Natalia Paone, BS, Anne Moyer, Ph.D.

Stony Brook University, Stony Brook, NY

Background: Physicians often report prognoses in non-numerical format which are subject to an optimistically biased appraisal by surrogate decision makers when the prognosis is poor which has implications in EOL decision making. Veterinarians also report non-numerical prognoses, the effect of which has not been previously examined. Owners of companion animals are inherently surrogate decisions makers and may be subject to the same optimistic bias.

Objective: To determine how commonly used non-numerical statements are interpreted numerically and if there was an effect of severity of prognosis and framing on an optimistic bias for non-numerical prognoses in a sample of dog owners.

Methods: 300 participants interpreted 14 non-numerical prognostic statements about their dog with varying levels of risk framed in terms of dying or surviving. They indicated what they believed the likelihood of survival to be, on a scale from 0% to 100%.

Results: Poor prognostic statements were compared to good prognostic statements based on the distance from their respective end-points (0% and 100% chance of surviving). "Your dog will definitely not survive," the most negative prognostic statement, was interpreted significantly more optimistically ($M = 17.94\%$), in terms of distance from its reference point, than "Your dog will definitely survive" the most positive prognostic statement ($M = 94.83\%$), $t(299) = 10.44$, $p < .001$. Overall, poor prognostic statements were interpreted in a significantly more optimistically biased way than their same framed, good prognostic counterparts, p 's $< .001$. A 2x2 completely within-group ANOVA was conducted to examine the main and interactive effects of framing (in terms of dying vs surviving) and prognostic outcome (good vs poor) in response to the statements "It is very likely that your dog will die" ($M = 24.49\%$), "It is very unlikely that your dog will die" ($M = 88.55\%$), "It is very likely that your dog will survive" ($M = 89.84\%$), and "It is very unlikely that your dog will survive" ($M = 21.69\%$). There was a main effect of framing $F(1, 299) = 6.81$, $p < .01$, indicating that prognoses with the same chance of survival, were more likely to be interpreted in an optimistically biased manner when framed in a more threatening way (in terms of dying vs surviving). There was a main effect of prognosis, $F(1, 299) = 101.31$, $p < .001$, indicating that poor prognoses are more likely to be interpreted in an optimistically biased manner than good prognoses. There was no interaction of framing and prognostic outcome $F(1, 299) = 1.04$, $p = .31$.

Conclusions: Veterinarians, like physicians, should be aware that when communicating non-numerical poor prognoses they are likely to be interpreted in an optimistically biased way, which may be exacerbated when the prognoses are framed in a more threatening manner.

ARE PATIENTS EXPECTING ENOUGH FROM THEIR PROVIDERS?

Kathryn Ziemer, PhD¹, Megan Weber, BA²¹Ipsos, Alexandria, VA; ²Ipsos, Washington DC, DC

Patient expectations directly impact how satisfied patients are with their care. If the care meets or exceeds expectations, patients tend to be more satisfied with their experience (Jackson, 2001). The Consumer Assessment of Healthcare Providers and Systems (CAHPS) survey measures patients' actual experience with the healthcare system. The highest quality of care, as defined by the CAHPS, is when experiences that *should* happen (e.g., clear communication) *always* happen. We compared ratings of actual experiences with how often people *expect* to have these experiences when seeing their primary care provider. We used the national CAHPS Database to assess average ratings of actual experiences and compared these to the expectations of a random sample of 1,010 US adults from Ipsos's online panel.

Chi-Square tests were conducted to compare the CAHPS data with the expectations data. Across all categories, participants had significantly lower expectations for providers as compared to what patients report actually experiencing (all $ps < .001$). Participants had the lowest expectations for getting timely appointments for routine care ($\chi^2=605.9$) and getting enough time with the provider ($\chi^2=653.8$) as compared to actual experience. Their expectations and experience aligned the most for talking about prescription medications ($\chi^2=36.69$), the provider knowing the patients'; medical information ($\chi^2=101.8$), and following up with test results ($\chi^2=107.4$).

Logistic regression analyses were also conducted to estimate the adjusted odds ratios of expectations for demographic characteristics. Sex, age, race, education, income, and health literacy were all included as independent variables in the model. High health literacy was associated with higher odds of always expecting providers to be respectful (AOR=2.7), to spend enough time with the patient (AOR=2.0), to talk about medication (AOR=1.4), to know the patient's medical history (AOR=1.8), to listen carefully (AOR=2.4), to explain things clearly (AOR=2.7), to follow-up on test results (AOR=2.2), and to provide appointments for urgent care as soon as needed (AOR=1.5) as compared to low health literacy (all $ps < .05$). Women and older adults also had higher odds of always expecting more from providers than males and younger adults.

Overall, the results suggest that people may have inappropriately low expectations for primary care providers, especially men, younger adults, and those with low health literacy. Implications will be discussed.

BEYOND FATALISM: NUTRITION INFORMATION OVERLOAD AND SOURCES OF CONFUSION AMONG BICULTURAL MEXICAN AMERICAN WOMEN

Kimberly Arellano, MPH, CHES, CPH¹, Stephanie Gamboa, BA², A. Susana Ramirez, PhD, MPH¹¹University of California, Merced, Merced, CA; ²University of California, Merced, Centerville, VA

Background. Individuals who hold fatalistic beliefs about disease – that disease is predetermined and death is inevitable upon diagnosis – have lower rates of cancer screening, and are less likely to engage in healthy behaviors to reduce cancer risk. Latino and other minority populations are more likely to hold fatalistic beliefs than Non-Latino Whites, potentially contributing to health disparities. However, the mechanisms linking fatalism to cancer prevention behaviors are poorly understood. Recent research considers exposure to information from the media to be one cause for fatalistic beliefs.

Purpose. The aim of this study was to examine fatalistic beliefs about diet and disease risk and sources for nutrition information among bicultural, English-speaking Latinas who face increased risk from dietary acculturation.

Methods. Mixed-methods (semi-structured interview, survey) with bicultural Mexican American women ages 18–29 (N=24) in rural California.

Results. Contrary to previous studies, this sample of bicultural Latinas did not endorse fatalistic beliefs, demonstrating a clear understanding of the link between diet and risk of certain diseases. Participants noted that sugar was a major cause of diabetes; obesity and heart disease were similarly understood to be a function of diet and within one's control. Cancer risk was not associated with diet. Despite articulating the link between diet and disease, participants expressed sentiments capturing information overload about diet and nutrition advice that comes from multiple sources and channels, including mass media, school, and family and friends. Some participants expressed confusion due to conflicting messaging from multiple sources. In terms of mixed messaging, participants distinguished between nutrition information available and nutrition information needed, and expressed a desire for deeper knowledge and specific skills.

Conclusion. This study found minimal support for fatalistic beliefs among a sample of young adult Mexican American women, but considerable confusion and concern about the nature of public and interpersonal communication about diet and nutrition. Opportunities for nutrition communication to raise awareness of cancer and diet risks among this growing, high-risk population, and more broadly, opportunities to improve the clarity of communication about nutrition science and dietary recommendations, are discussed.

BRIDGING THE GAP: PATIENT ACCESS TO MEDICAL INFORMATION DURING HOSPITALIZATION

Marge M. Benham-Hutchins, PhD, RN

University of Texas at Austin, Austin, TX

Background: Patient access to information during hospitalization supports informed decision making and reflects a patient's right to partner in their own care across the continuum of care. Patients with a chronic disease are often faced with bridging the gap between home, hospital, and providers. The purpose of this qualitative study was to determine patient perceptions about barriers and facilitators to information access and participation in provider-patient information exchange during hospitalization.

Methods: After IRB approval, data was collected through an online survey and two focus groups. Study inclusion criteria: over 18, living in the US, chronic disease diagnosis, and have had an inpatient hospitalization after initial diagnosis. Two focus groups were held to gather the perspectives of Spanish speaking Hispanic patients. Social media snowball sampling was used to recruit online survey participants. This survey included both limited choice and open-ended questions. The open-ended responses were coded using qualitative content analysis.

Results: The survey participants (n=34) were predominantly female (88%), Caucasian (91%), highly educated (29% some college, 32% college graduates, and 32% some graduate school or an advanced degree), and ranged in age from 20–76 ($\mu=48$; $SD=16.87$). Hospitals in all four US geographical regions and urban, rural, and suburban settings were represented. The survey participants identified multiple provider behaviors that inhibited patient participation in medical rounds and bedside shift change handoff. The majority of this group expressed a desire to “know everything” and frustration about access to medical information. This group used multiple paper and electronic methods to keep track of their medical information. The all-female, Hispanic, focus group participants (n=6) were recruited locally and ranged in age from 47–66 ($\mu=55$, $SD=7.11$) and had a primary (5) or high school (1) education. The focus group participants expressed satisfaction with provider communication during hospitalization, including access to translation services, and a preference for written discharge instructions.

Discussion: Findings revealed a wide variation in the level of participation and type of information desired by patients during hospitalization. Future research is needed to identify methods to determine individual patient information desires and level of participation, identify provider behaviors that encourage provider-patient information exchange, and develop interventions that support the level of participation and information desired by patients during hospitalization.

COMMUNICATION OF RECOMMENDATIONS TO DISPOSE OF UNUSED OPIOIDS BY HEALTHCARE PROVIDERS AND OTHER STAKEHOLDERS IN THE NEWS MEDIA

Megan Petrik, PhD¹, Patrick McNamara, PhD², Susan Moeschler, MD³, Benjamin Blair, PhD⁴

¹University of Minnesota Medical School, Minneapolis, MN; ²Marquette University, Milwaukee, WI; ³Mayo Clinic College of Medicine, Rochester, MN; ⁴University of Colorado School of Public Health, Minneapolis, MN

Background:

Opioid use and abuse has reached epidemic status. Proper disposal of unused opioids may be an avenue for upstream prevention of abuse, addiction, and potentially fatal overdose. The U.S. Food and Drug Administration (FDA) recommends that certain medications that can be harmful or fatal with one dose (e.g., opioids such as oxycodone hydrochloride and fentanyl) should be disposed of quickly through a take-back program. If this option is not readily available “it is recommended that these medicines be flushed down the sink or toilet as soon as they are no longer needed.” Toilet disposal may not be perceived as an option since previous research has suggested that pharmaceuticals can negatively impact the aquatic environment. Yet, recent research has found negligible eco-toxicological and human health risk for the majority of the pharmaceuticals recommended by the FDA for toilet disposal.

Aim: To understand the communication of opioid disposal recommendations in the news media. Specifically, to evaluate when take-back programs are discussed, if toilet disposal is also presented as a recommendation for disposing of certain opioid medications, per FDA recommendations.

Methods: This study conducted a content analysis of 350 U.S. newspaper articles published during 1/1/2014–6/30/2017. The search strategy included the terms “opioid, opiate, or painkiller” and “take-back” using the LexisNexis database. Articles were coded for the following: the presentation of and recommendation for opioid disposal practices (take-back programs and toilet disposal) and other strategies to prevent misuse of opioids. The person or entity responsible for the statement was also captured.

Results: Results regarding the presentation of take-back programs and toilet disposal by various stakeholders will be presented. Preliminary results suggest toilet disposal is infrequently recommended when take-back programs are presented. Other themes identified in the news media as key strategies to mitigate the abuse of opioids include prescription drug monitoring programs and recommendations to modify prescribing practices.

Discussion: This is the first study to evaluate the communication of FDA opioid disposal recommendations by the news media. Implications for improving the communication of FDA opioid disposal guidelines by healthcare providers, government employees, and other stakeholders in the news media will be discussed.

EXAMINING THE ASSOCIATION BETWEEN HEALTH LITERACY AND HEALTH INFORMATION SEEKING

Xuewei Chen, PhD¹, Jennifer L. Hay, Ph.D.², Erika Waters, PhD, MPH³, Marc T. Kiviniemi, PhD¹, Caitlin Biddle, Ph.D.¹, Elizabeth Schofield, MPH², Yuelin Li, PhD.², Kimberly Kaphingst, ScD⁵, Heather Orom, PhD¹

¹University at Buffalo, Buffalo, NY; ²Memorial Sloan Kettering Cancer Center, New York, NY; ³Washington University in St. Louis, St Louis, MO; ⁴CCNY Inc, Buffalo, NY; ⁵University of Utah, Salt Lake City, UT

Purpose: Health information from nonprofessional sources, especially that available on the Internet, has been criticized for being of poor quality because it lacks peer review or regulation. Misleading information could result in negative outcomes such as delayed health care. The purpose of our study was to test whether people with lower health literacy levels use and trust lower quality health information sources. We reasoned this would be the case if people with lower health literacy are less likely to evaluate the quality of health information sources than those with higher health literacy.

Methods: Six hundred participants (50% non-metro residents) from a GfK panel completed an online survey. We assessed their levels of health literacy using the Newest Vital Sign (continuous scores ranged from 0–6), the sources from which they obtained health information (dichotomous variable), and the extent to which they trusted the health information from these sources (ordinal variables). We performed binary and ordered logistic regressions, controlling for demographic characteristics (race/ethnicity, age, gender, education, income, and metro/non-metro status), to test if lower health literacy was associated with higher use and trust for health information from lower quality sources.

Results: Lower health literacy was associated with more use of social media (OR = 1.27, $p = .006$) and blogs (OR = 1.23, $p = .048$) but less use of online search engines (OR = 0.85, $p = .023$) and medical websites (OR = 0.83, $p = .021$) for health information. Lower health literacy was also associated with more trust in health information from social media (OR = 1.23, $p = .004$), blogs (OR = 1.20, $p = .016$), religious organizations (OR = 1.18, $p = .015$), pharmaceutical companies (OR = 1.23, $p = .002$), and other companies (OR = 1.20, $p = .016$), but less trust in health information from health professionals including specialist doctors (OR = 0.87, $p = .046$) and dentists (OR = 0.85, $p = .024$).

Discussion: People with lower health literacy were more likely than their higher health literacy counterparts to use and trust potentially low quality health information from nonprofessional or non-evidence-based sources. When designing messages and other interventions for people with lower health literacy, it may be important to promote media literacy strategies for identifying professional health information sources, critically analyzing the quality of health information, and differentiating low quality from high quality sources. Results also indicate that social media could be an effective health education channel to reach people with lower health literacy levels.

HEALTH AND APPEARANCE SMOKING MESSAGES ON WORRY, PERCEIVED RISK, AND MOTIVATION TO QUIT

Renee Magnan, PhD, Mary K. Nelson, N/A, Bethany Shorey Fennell, M.S.

Washington State University Vancouver, Vancouver, WA

One approach to motivate health behavior change is highlighting consequences of harmful health behaviors via communications to enhance perceptions of risk. This approach typically focuses on highlighting health consequences of harmful health behaviors; however, a small, but growing body of literature provides evidence for the utility of highlighting appearance consequences of harmful health behaviors to motivate behavior change. The purpose of the current study was two-fold: 1) To compare health and appearance messages on the degree to which they elicit perceived risk and worry about smoking relative to a control and 2) to directly compare perceived risk and worry as predictors of motivation to quit. Smokers (N=107) were randomly assigned to one of three conditions in which they were prompted via a smartphone application to read messages related to the health consequences, the appearance consequences of smoking, or control messages about daily hassles six times daily. At the end of two weeks, participants completed assessments of perceived risk and worry about health and appearance consequences of smoking, and motivation to quit. Controlling for pre-test smoking and perceived statement relevance, compared to control, smokers exposed to appearance, but not health messages, reported greater health worry ($p=.01$), perceived health risk ($p=.01$), perceived appearance risk ($p=.001$), and motivation to quit ($p=.002$). Further analysis showed that both risk perceptions and worry about health significantly independently mediated the relationship between message type and motivation to quit. However, in a multi-mediator model, only worry about health remained a significant mediator (indirect $b = 2.47$, CI: .62–3.39). These findings suggest that the effect of messages about health behaviors on motivation may be because of the emotional experience elicited from the messages. Further, appearance-related consequences may be an important target to enhance motivation for health-protective action.

ILLNESS PERCEPTIONS AND ACUTE HOSPITAL VISITS IN PATIENTS WITH CHRONIC ILLNESS

Eleanor Rivera, MSN, RN, Colleen Corte, PhD, RN, FAAN

University of Illinois at Chicago College of nursing, Chicago, IL

Background/Purpose: Chronic illness accounts for 80% of hospitalizations in adults. The purpose of this study is to determine whether number of emergency room and hospital visits differ according to how heart failure and chronic kidney disease (CKD) patients understand their illness.

Framework: We used the Common Sense Model, which proposes that people develop mental models of health conditions (illness perceptions) that drive their treatment goals and health behaviors.

Methods: A cross-sectional design was used. Patients from heart failure and kidney disease clinics at a Midwestern medical center were recruited. Participants completed the Revised Illness Perception Questionnaire (IPQ-R) and questions about number of emergency room visits and hospitalizations in the last year. The IPQ-R (5-point Likert scale) has seven subscales reflecting perceptions about disease timeline, consequences, personal control, treatment control, understanding of the illness (coherence), stability of disease pattern (cyclical), and emotions. T-tests were used to examine differences in IPQ-R subscale scores according to presence/absence of past-year emergency room visits and hospitalizations.

Results: Participants include 118 adults with heart failure or CKD (mean age 64.2 years, 47% male, 73% Black). In the last year, 54% of the sample reported at least one emergency room visit and 42% reported at least one hospitalization. IPQ-R subscale means were generally above the scale midpoint (3.4 to 3.7), indicating perceptions that the disease is chronic, has many consequences, is under personal control, can be controlled by treatment, and is well understood. The emotions and cyclical patterns subscales were neutral (3.0). Those who reported at least one emergency room visit in the past year perceived a lower level of treatment control over their illness than those who did not (3.37 vs 3.63, $p=0.028$). Those who reported at least one hospitalization in the past year perceived more consequences (3.69 vs 3.24, $p=0.0006$) and a more cyclical illness pattern than those who did not (3.21 vs 2.87, $p=0.023$). No differences were found for any other IPQ-R subscale.

Conclusions: Perceiving many consequences, poor treatment control, and a cyclical illness pattern is associated with negative health outcomes. As potential harbingers of negative outcomes, health assessments should include these factors.

6:30 PM-7:30 PM

IN THEIR OWN WORDS: HOW ADOLESCENTS DEFINE HEALTH LITERACY

Sasha A. Fleary, PhD

Tufts University, Medford, MA

Background: Health literacy (HL) is a relatively new concept with Ratzan and Parker (2000) defining it as the ability to obtain, process, and understand health information. Nutbeam (2000, 2008) further divided HL into functional, communicative, and critical HL. Adolescence is marked by poor impulse control and increased sensation-seeking, yet it is at this phase in development that individuals are expected to navigate autonomy including assuming increasing responsibility for their health. Given the prevalence of unhealthy behaviors in adolescents, and that HL is implicated in health behaviors in adults, we are interested in how HL influences adolescents' health behavior decision-making. To better understand this relationship, we explored adolescents' definition of HL and their perceptions of the HL/health behaviors relationship.

Method: We conducted three focus groups with adolescents ($n=21$, 86% female, 33% White, Mean age =15.57 years). Adolescents completed the Newest Vital Sign (NVS) and a demographic questionnaire. Adolescents were asked (1) to define HL, health risk behaviors, and preventive health; and (2) explain the health risk behaviors/HL and preventive health/HL relationships. Responses were content-analyzed independently by two raters. Disagreements about themes were discussed until consensus was achieved.

Results: The average NVS score was 3.86 ($SD=1.61$), 42% of adolescents had low to limited functional HL ($NVS=0-3$). Adolescents explained that HL included reading nutrition and/or prescription labels, understanding health/health terms, and finding health information. However, some adolescents also described HL as learning about the human body and "a profession like English literature but for health terms." They described preventive health as taking steps to prevent a health issue or disease and health risk behaviors as engaging in behaviors that one knows is bad for one's health. Regarding the HL/preventive health connections, adolescents discussed that the more they knew about behaviors and impact on disease, the more likely they were to engage in prevention. Adolescents also discussed that HL allowed for them to communicate with adults and doctors about prevention (e.g., sexual health). Regarding health risk behaviors, adolescents reported that HL allowed for them to learn about the risks of behaviors on their own and the more they learned on their own, the less they ignored what "parents say" about risk behaviors.

Discussion: Adolescents have a rudimentary understanding of what constitutes HL. Some of their perceptions of how HL is related to health behaviors are consistent with the adult literature. However, some of their perceptions are specific to their developmental level and warrant further investigation. Specifically, HL may likely serve as a protective factor for health risk behaviors in adolescents.

INDIVIDUALISM AND HIERARCHISM ARE ASSOCIATED WITH LOWER TRUST IN GOVERNMENT HEALTH INFORMATION

Xuewei Chen, PhD¹, Jennifer L. Hay, Ph.D.², Marc T. Kiviniemi, PhD¹, Erika Waters, PhD, MPH³, Caitlin Biddle, Ph.D.⁴, Elizabeth Schofield, MPH², Yuelin Li, PhD², Heather Orom, PhD¹

¹University at Buffalo, Buffalo, NY; ²Memorial Sloan Kettering Cancer Center, New York, NY; ³Washington University in St. Louis, St Louis, MO; ⁴CCNY Inc, Buffalo, NY

Purpose: In the U.S., trust in government has been experiencing periods of decline since the mid-1960s. Trust in government health information sources has likely been similarly impacted. The purpose of this study was to identify characteristics of individuals with low trust in government health information to inform messaging for this group. People tend to vary on the extent to which they favor freedom of action for individuals and limiting government's involvement in people's lives (individualism) and in their belief in the value of hierarchical social structures (hierarchy). We hypothesized that people who were more individualistic or hierarchical would be less likely to trust government health information.

Methods: Six hundred participants from a GfK panel (50% non-metro residents) answered Kahan's worldview questionnaire (range=1-4) assessing high individualism/low collectivism and high hierarchy/low egalitarianism and indicated the extent to which they trusted government health information. We tested if individualism and hierarchy were associated with distrust in health information from government sources, controlling for health literacy levels and demographic characteristics (race/ethnicity, age, gender, education, income, and metro/non-metro status) using ordered logistic regressions.

Results: Mean individualism was 2.79 ($SD=0.56$) and mean hierarchy was 2.36 ($SD=0.74$); they were also associated ($r=0.45$, $p<.001$). Compared to people who were more collectivistic, those who were more individualistic were less likely to trust the health information from local health departments ($OR=0.50$, $p<.001$) and federal health organizations ($OR=0.45$, $p<.001$). Compared to people who were more egalitarian, those who believed more in hierarchy were less likely to trust the information from local health departments ($OR=0.63$, $p<.001$) and federal health organizations ($OR=0.59$, $p<.001$). When entering individualism and hierarchy simultaneously, the association between individualism and trust in government health information remained ($OR_{local\ health\ departments}=0.57$, $p=.007$; $OR_{federal\ health\ organizations}=0.51$, $p=.001$), but the association between hierarchy and trust in government health information became non-significant.

Discussion: Both individualism and hierarchy beliefs may undermine trust in government health information, although associations for hierarchy may be largely due to individualism and hierarchy having been associated in our sample. When trying to reach an audience who distrust government sources, it may be helpful to test message credibility with this group or provide strong counter-arguments to beliefs about the untrustworthiness of government sources. Enhancing transparency and interaction between government and individuals on public health issues could also help build trust in government.

PARENT ATTITUDES, PROVIDER COMMUNICATION, AND ADHERENCE TO PEDIATRIC CLINICAL PRACTICE GUIDELINES

Lindsay N. Fuzzell, Ph.D.¹, Andrew S. LaJoie, PhD, MSPH², Kyle T. Smith, N/A³, Sydney E. Philpott, BS⁴, Katherine M. Jones, MD⁵, Mary Politi, PhD⁴

¹Washington University in St. Louis, St. Louis, MO; ²University of Louisville, Louisville, KY; ³Washington University in St Louis School of Medicine, Rochester, NY; ⁴Washington University in St Louis School of Medicine, St Louis, MO; ⁵Washington University School of Medicine, Saint Louis, MO

Background: The American Academy of Pediatrics recommends many child health and safety policies to guide parents and pediatric healthcare providers (HCPs). However, parents' adherence to these guidelines remains lower than expected. Information provided by a trusted HCP can increase adherence to some guidelines. Research has not yet explored the complex relationship between parents'; attitudes towards guidelines, HCP communication, and the impact on adherence to a broad range of child safety policy recommendations.

Methods: Using Amazon Mechanical Turk for recruitment, we administered a survey to parents of children under age 6. Parents were asked to answer about their oldest child under 6 if they had more than one. Based on the theory of planned behavior, parents responded to items about attitudes toward their child'; HCP and toward nine pediatric health and safety guidelines, self-efficacy for following guidelines, communication with HCPs about guidelines (yes/no), and adherence to each guideline. Attitudes and adherence to policies focused on car seat/booster seat use, infant safe sleep practices, routine sunscreen use, gun safety, furniture anchoring, large trampoline use, influenza and routine vaccinations, and newborn Vitamin K injections.

Results: 256 primary caregivers participated, whom were mostly married (72%), White (81%) and female (60%) biological parents, with a mean age of 33 (SD=6.83, range=20–59). Child';s age ranged from 1–70 months. In separate linear regression analyses, parent agreement with HCP advice about guidelines ($\beta=.42, p<.001$), parent trust in HCPs ($\beta=.40, p<.001$), self-efficacy to follow HCP advice about guidelines ($\beta=.46, p<.001$), and comfort talking about guidelines ($\beta=.35, p<.001$) predicted number of pediatric clinical practice guidelines to which parents adhered. In separate logistic regression analyses, communication about each guideline significantly and positively predicted adherence to that guideline (ORs from 2.23 (furniture anchoring) to 30.84 (routine vaccinations), all $p<.05$) with the exception of adherence to gun safety, $OR=1.21, n.s.$). One anomaly was trampoline use, where HCP communication was associated with lower likelihood of adherence to trampoline guidelines ($OR=.25, p=.001$).

Discussion: Findings demonstrate the clinical and public health significance of discussions about safety guidelines and the importance of interpersonal relationships between parents and HCPs when discussing health and safety during routine pediatric visits.

PATIENT-PROVIDER COMMUNICATION IN MOTIVATIONAL INTERVIEWING WEIGHT LOSS SESSIONS WITH AFRICAN AMERICAN YOUTH AND CAREGIVERS

Sarah Martinez, BA¹, Jessica Durkin, M.Ed¹, Kathryn Brogan-Hartlieb, PhD², Sylvie Naar, PhD³, Deborah Ellis, PhD⁴, Susan Eggly, PhD⁵, April Carcone, PhD⁴

¹Wayne State University, Detroit, MI; ²Wertheim College of Medicine, Florida International University, Miami, FL; ³Florida State University, Royal Oak, MI; ⁴Wayne State University School of Medicine, Detroit, MI; ⁵Wayne State University/Karmanos Cancer Institute, Detroit, MI

Background: Motivational Interviewing (MI) is an empirically supported communication technique to increase motivation for behavior change. Research on how MI works has focused on skilled MI providers with less attention to paraprofessionals'; delivery of MI-based interventions. Fit Families (FF) is a 6 month weight loss intervention delivered by community health workers (CHWs) to African American adolescents with obesity (AAAOs) and their caregivers (CGs). In FF, families are taught evidence-based cognitive-behavioral weight loss skills using MI-communication strategies. The goal of this study was to understand how use of MI by CHWs in FF treatment sessions was related to AAAOs and CG change talk (CT; motivational statements about weight loss) and sustain talk (ST; amotivational statements about weight loss).

Methods: We analyzed one motivation-building session (MB, n=60) and one of two skill-building sessions, self-monitoring (SM, n=38) or environmental control (EC, n=31) for 75 enrolled families. Two coders used the Minority Youth-Sequential Code for Observing Process Exchanges to code communication behaviors, such as CT and ST (k= .457-.711 with 96.8–99.3% agreement). Relative rates of communication behavior to session duration were calculated (frequency of communication behavior/length of session).

Results: AAAOs expressed significantly more CT and ST in skill sessions than in MBs (CT: $M_{MB}=22.6, M_{SM}=50.8, M_{EC}=47.6$; ST: $M_{MB}=3.5, M_{SM}=8.5, M_{EC}=21.5$). There were no differences in CGs'; CT across sessions but CGs expressed significantly more ST in ECs vs MBs ($M_{MB}=3.3, M_{SM}=4.8, M_{EC}=6.5$). CHWs asked significantly more questions eliciting CT in SMs and ECs vs MB ($M_{MB}=19.7, M_{SM}=37.0, M_{EC}=34.3$); no differences were found in reflections of CT. CHWs reflected significantly more ST in ECs vs MBs and SMs ($M_{MB}=1.76, M_{SM}=1.44, M_{EC}=9.0$) and asked significantly more questions eliciting ST in ECs vs MBs and SMs ($M_{MB}=1.8, M_{SM}=2.6, M_{EC}=10.9$). All $ps \leq .01$

Conclusions: AAAOs'; higher rates of CT and ST during skills sessions may reflect therapeutic work to resolve ambivalence about weight-related behavior change. CGs'; higher rates of ST during ECs may reflect a lack of motivation for change or perceived barriers to change. CHWs may influence low motivation by asking more questions of ST and reflecting more ST during EC sessions. CHWs may need more training in how to acknowledge ST and transition to eliciting CT to move towards behavior change. Next steps include sequential analysis to examine the temporal sequencing of patient-provider communication related to weight loss (i.e., which CHW behavior leads to CT in MB session vs skill-building sessions).

RECURRENT RISK COMMUNICATION WITH FAMILY AND PHYSICIANS

Kimberly M Kelly, PhD, MS¹, Jamie L. Studts, PhD², Mark Dignan, PhD, MPH³, Paul Cornelius, MBA¹, Pragya Rai, MS¹¹West Virginia University, Morgantown, WV; ²University of Kentucky College of Medicine, Lexington, KY; ³University of Kentucky, Lexington, KY

Numerous models provide recurrence risk information for breast cancer patients based on tumor characteristics, and such models have clinical utility in surgical, hormonal, and chemotherapeutic decision-making. Along with needing to understand this risk information to share in treatment decision-making, patients can also communicate this risk information with family members who may assist with and be affected by these decisions. The current analysis explored baseline patient communication with family and physicians in an RCT of a risk communication intervention. Breast cancer patients (n=167) with Stage 0–2 breast cancer who were predominantly from the medically-underserved Appalachian region were included. Over a quarter of these breast cancer patients believed their risk lower than an average woman. Most felt that they had quite a bit/very much knowledge of their cancer diagnosis (83.5%), but fewer perceived this level of knowledge for their recurrence risk (48.2%). Most had talked to their families (61.9%) and physicians (70.0%) about their recurrence risk, and some noted talking to their families daily about their risk. The patient initiated conversations with family members 69.1% of the time and with physicians 49.6% of the time. Most patients planned to talk to family (78.3%) and physicians (93.9%) about their recurrence risk in the future. A logistic regression comparing those who had/had not talked to their family indicated that those who had talked to family were younger (OR=.34, 95%CI .14-.84, p<.02), had higher subjective knowledge of recurrence risk (OR=1.52, 95%CI=.97-2.39, p<.07), and greater worry (OR=1.87, 95%CI=.94-3.72, p<.08). A logistic regression comparing those who had/had not talked to their physician indicated that those who had talked to their physician were younger (OR=.20, 95%CI=.07-.53, p<.01) and had higher cancer worry (OR=1.64, 95%CI=1.03–2.60, p<.04). When dividing the sample into younger and older age groups, the relationships were strengthened for the younger age group. The younger age group was more likely to talk to family and physicians overall (p's<.01). In sum, younger age and worry may be driving greater discussion about recurrence risk, perhaps due to concern about hereditary cancer and risk to biological relatives. In addition, many patients do not have accurate perceptions of their own risk and perceive that their physicians are not communicating recurrence risk to them. Thus, there is an apparent disconnect between available recurrence risk information and patient understanding, and this may be more pronounced in older breast cancer patients.

SUPPORTING CANCER CONTROL CAPACITY AMONG COMMUNITY HEALTH WORKERS: EVALUATION OF A CULTURALLY-RELEVANT INITIATIVE IN ALASKA

Katie Cueva, ScD MAT MPH¹, Melany Cueva, EdD RN MA-CT², Laura Revels, BA², Mark Dignan, PhD, MPH³¹Institute of Social and Economic Research, University of Alaska Anchorage, Anchorage, AK; ²Alaska Native Tribal Health Consortium, Anchorage, AK; ³University of Kentucky, Lexington, KY

Objective: In response to tribal primary care providers' requests, a research team at the Alaska Native Tribal Health Consortium developed a culturally-respectful course designed to support cancer control in rural Alaska through online education. Cancer is the leading cause of death in Alaska, and harsh weather patterns, limited funding, and geographic expanse, limit the amount of in-person training that can be provided to support cancer control.

Methods: The semester-long university course incorporates ten interactive modules, digital storytelling, and synchronous sessions. Course development, implementation, and evaluation were guided by Empowerment Theory and the Community Based Participatory Action Research framework. The course was created with input from an advisory group of Alaska's tribal primary care providers and partners. Course participants were invited to complete evaluation surveys at the beginning of course, end of course, and six months post-course, as well as a 2–3 month post-course interview. While enrollment and evaluation is ongoing, as of September 2017, a total of 37 individuals had enrolled in three course offerings.

Results: Measured cancer control capacity variables increased from beginning to end of course, with little to no attrition from end of course to 6-months post-course. For example, as a result of course participation, learners' comfort sharing cancer information with their communities increased by 32% from beginning to end of course (a shift from 3.4 to 4.4 on a scale of 1 to 5), persisting through 6-months post-course (4.4). At the beginning of the course, learners reported consuming an average of 1.2 vegetables per day in the prior month, which increased to 1.7 at end of course, and rose to 2.7 by 6-months post-course. At 6-months post-course, 93% of learners reported reducing their own cancer risk as a result of course participation; increasing physical activity, getting cancer screenings, and cutting down on tobacco.

Conclusions: The course addresses a need for online education to support cancer control capacity, and has supported increased capacity and health behavior change. The course could serve as a model for online education that supports cancer control capacity. In the words of learners:

"I didn't know a whole lot about cancer before starting this whole cancer education course and now I feel a lot more comfortable in handing out information to patients and family."

"By talking to our patients, we can save a life"

TAILORED TEXTS: AN APPLICATION OF REGULATORY FIT TO TEXT MESSAGES DESIGNED TO REDUCE HIGH-RISK DRINKING

Elizabeth M. Glowacki, PhD¹, Jay M. Bernhardt, PhD, MPH²¹Boston University, Henry M. Goldman School of Dental Medicine, Boston, MA; ²University of Texas at Austin, Austin, TX

Although there are robust findings on text-message delivery and outcomes for health interventions, little work has been done to look at message content from a communication and message language perspective. The goal of this study was to compare two versions of text message wording and the impact that each has on college students'; drinking behaviors. The study used regulatory focus and regulatory fit as the frameworks for message language manipulation. Regulatory fit is a model used to explain how individuals make decisions about engaging in goal-oriented behaviors and rests on the assumption that individuals are either promotion-oriented (i.e., focused on accomplishment and obtaining positive outcomes) or prevention-oriented (i.e., focused on vigilance and avoiding negative outcomes). Messages can be framed as either prevention-oriented or promotion-oriented, and preference for either type of message is determined by the attitudes and values of the message recipient; people react to messages in ways that are consistent with their current goal orientations.

In this 2 (regulatory fit orientation- prevention or promotion) x 3 (treatment group- congruent, incongruent, or control) x 2 (pre-test, post-test) experiment, participants (N=279) were randomly assigned to one of three groups: the congruent group (received text messages that matched their regulatory focus), incongruent group (received text messages that were mismatched with their regulatory focus), and the control group (received general health text messages). Messages were tailored by regulatory fit (prevention-oriented or promotion-oriented), which was assessed prior to the intervention. Mixed factorial analyses of covariance revealed that prevention-oriented individuals who received text messages that were incongruent with their regulatory focus reported drinking alcohol for more hours than participants in the congruent or control groups. Mean scores illustrated a pattern suggesting that prevention-oriented individuals who received incongruent messages were also more likely to consume a higher quantity of drinks and engage in high-risk drinking behaviors than individuals in the congruent and control groups. Therefore, there is reason to believe that sending text messages about alcohol that do not match an individual';s regulatory focus can lead to negative drinking behaviors.

WHAT WE WANT AND NEED IN END-OF-LIFE CARE: A REGULATORY FOCUS PERSPECTIVE

Kristen Tyszkowski, MD¹, James Shah, PhD²¹Grace Consultancy, Brooklyn, NY; ²Duke University, Durham, NC

Background: Despite the publication of *Dying in America* (IOM, 2014) advocating more attention to advance care planning, and the fact that prior study has demonstrated the advantage of advance care planning in terms of quality of end-of-life care (Brinkman-Stoppelenburg, 2014), individuals continue to resist planning care at the end-of-life.

Object: The present study seeks to examine how individuals'; basic regulatory focus on promotion and prevention (Higgins 1997) may predict not only what individuals'; seek to plan about end-of-life care, but what may encourage or discourage such planning.

Method: Participants (N =419) completed an online survey regarding end-of-life care planning preferences, as well as a composite measure of their promotion and prevention focus (see Hawes et al 2010).

Results: From initial factor analyses, separate totals for participants'; general sensitivity to the challenges and incentives for end-of-life care planning were created. Subsequent regression analyses that controlled for participants'; current well-being found that participants'; promotion focus strength significantly predicted a general sensitivity to incentives for such planning ($pr=.26$, $F(1,414)=28.7$, $p < .001$), but it was non-significantly (and negatively) related to a sensitivity to the challenges of such planning ($pr= -.06$, $F(1,414)= 1.4$, $p > .2$). Alternatively, participants'; prevention focus strength was found to predict their general sensitivity to the challenges of end-of-life planning ($pr=.23$, $F(1,414)=23.3$, $p < .001$). Participants'; prevention focus strength did predict their general sensitivity to incentives for such planning, but significantly less so than their promotion focus strength ($pr=.15$, $F(1,414)=9.2$, $p < .01$).

An additional factor analysis revealed distinct preferences for specifying the nature of end-of-life care and for specifying who this care would involve. Separate totals for each preference were calculated and subsequent regression analyses that again controlled for participants'; current well-being found that participants'; promotion focus positively predict their preference for specifying who would be involved with this care ($pr=.19$, $F(1,414)=16.1$, $p < .001$), but negatively predict their preference for planning the care itself ($pr=-.15$, $F(1,414)=9.4$, $p < .01$). Alternatively, participants'; prevention focus was found to positively predict their preference for planning the nature of the care ($pr=.11$, $F(1,414)=5.2$, $p < .05$), as well as their preference for planning who would be involved ($pr=.18$, $F(1,414)=14.6$, $p < .001$).

Conclusion: The present findings suggest that differences in regulatory focus may predict how individuals approach planning for end-of-life care, as well as what may encourage or discourage such planning. Implications for message-tailored interventions will be discussed.

BRIEF INTERVENTION TO INCREASE PHYSICAL ACTIVITY LEVELS AMONG OBESE MEN WITH SERIOUS MENTAL ILLNESS: A FEASIBILITY STUDY

Ahmed-Jerome Romain, PhD¹, Reginald Cadet, Master², Aurélie Baillot, PhD³¹University of Montreal Hospital Research Centre (CRCHUM), Montreal, PQ, Canada; ²Université du Québec en Outaouais, Repentigny, PQ, Canada; ³Université du Québec en Outaouais, Gatineau, PQ, Canada

Context: People with serious mental illness (SMI) have a reduced life expectancy notably because of cardiovascular disease and their metabolic consequences, including obesity. While physical activity (PA) is recommended to manage these metabolic complications, people with SMI are insufficiently active and have high levels of sedentary behaviours. Moreover, while nurses have an important role to play in that context, they expressed a lack of training and time to promote PA in their clinical routine. So, there is a need to develop new feasible interventions to increase PA. The objective of the present study was to evaluate the feasibility of a brief intervention on PA level among adults with obesity and SMI.

Methods: Open 6-week brief intervention (with 2 individuals meetings lasting 10 to 15 minutes) using a volitional help sheet based on the processes of change from the transtheoretical model and the implementation intention. The intervention was provided by a nurse who received 3 training sessions on motivation to PA and the volitional help sheet. PA and time spent in sedentary behaviours were evaluated using the International Physical Activity Questionnaire. Experiential and behavioural strategies of motivation were also measured by questionnaires.

Results: Sample size of 12 men (mean age: 33.2 ± 10.1) with obesity (mean BMI: $35.8 \pm 7.7 \text{ kg/m}^2$) and diagnosis of SMI (75% with schizophrenia) were recruited and included in the 6-week brief intervention. In terms of feasibility, the adherence rate was 100% and no drop-out was noted. Regarding satisfaction, 80% of participants reported that the project met their expectations and 92% would refer a relative or a peer to the project. Moreover, 77% reported that the project has facilitated another behaviour change (e.g., healthy eating). In terms of impact, a significant improvement were found regarding total PA ($+30 \pm 21.2 \text{ min/week}$; $d = 0.76$), walking behaviour ($+65 \pm 79.4 \text{ min/week}$; $d = 1.01$) and reduction in time spent sitting ($-1.66 \pm 0.16 \text{ hours/day}$; $d = -0.75$). To increase their PA, participants used behavioural strategies ($+0.30 \pm 0.63$; $d = 0.41$) rather than experiential strategies ($+0.01 \pm 0.65$; $d = 0.02$).

Conclusion: The motivation-based brief intervention using a volitional help sheet is feasible and has promising results for both, participants and nurse. However, replication is needed with a larger sample size and a longer duration to validate our results.

PSYCHOLOGICAL STATUS IN PATIENTS DIFFERS AS A FUNCTION OF TIME, SEX, AND/OR CORONARY ARTERY DISEASE STATUS

Monica Vaillancourt, BA.¹, Bianca D'Antono, PhD²¹University of Montreal/Research Center, Montreal Heart Institute, Montréal, PQ, Canada; ²Research Centre, Montreal Heart Institute/Université de Montréal, Montreal, PQ, Canada

Psychological distress is generally more prevalent and severe among patients with coronary artery disease (CAD) compared to healthy individuals. However, little is known regarding its time course, and whether these differences extend to individuals with non-cardiovascular (CV) illnesses.

Objective: Examine the presence, severity, and time course of psychological distress in men and women with CAD and those of similarly aged individuals suffering from other non-CV conditions.

Method: A total of 1294 individuals (61% men; mean_{age} = 60 ± 7.2 yrs) with CAD or non-CV illnesses completed questionnaires on social support, hostility, stress, as well as symptoms of anxiety and depression at baseline as well as 4.8 ± 0.8 yrs later. Analyses involved mixed (Sex*CAD status*Time) repeated measures analyses on continuous data, as well as Chi square and McNemar analyses on categorical clinical cut-off scores.

Results: At T1, women with CAD reported more symptoms of depression, anxiety and stress compared to the men and to women without CV (all p 's < 0.001). By T2, women with CAD still reported more symptoms of depression compared to the other groups, as well as more anxiety compared to the men (p 's < 0.01). While anxiety and perceived stress decreased over time, depression, hostility and social support increased (all p 's < 0.001). Patients with CAD reported only slightly less social support ($p < 0.001$) and more hostility compared to non-CV participants ($p = 0.014$). Analyses using categorical data showed that women with CAD fell within the clinical range for depression (17% vs. <7%, $p < 0.001$), anxiety (42% vs. <25%, $p = 0.001$), and stress (25% vs. <14%, $p = 0.030$) more frequently compared to others at T1. By T2, differences were less notable, though still significant for depression ($p = 0.009$) and stress ($p = 0.002$). More individuals fell within the clinical range of depression at T2 compared to T1 (12% vs. 8%), with the most notable increases observed in men with CAD ($p < 0.001$) and women without CV ($p = 0.038$). The prevalence of clinical anxiety decreased significantly in all groups by T2.

Conclusion: While psychological distress was prevalent among these patients with diverse health conditions, women with CAD were particularly and chronically vulnerable. The evolution of patient distress differed as a function of the measure examined, their sex, and/or CV status. Findings suggest the need for repeated screening for distress, and tailoring of the psychosocial services offered.

RELATIONSHIP BETWEEN SEDENTARY TIME AND MILD COGNITIVE IMPAIRMENT AMONG OLDER ADULTS IN CHINA

An-Nuo Liu, graduate student¹, Zheng-Wen Pan, graduate student², Hong-Yan Liu, graduate student², Lu-Lu Wang, graduate student², Yan Jiang, graduate student², Ma Ying, Dr.², Dong-Mei Zhang, Dr.², Gui-Mei Chen, Dr.², Li Wang, Dr.², Su-Fang Wang, Dr.², Jie Sheng, Dr.², Kai-Yong Liu, Dr.², Qu-Nan Wang, Dr.², Lin-Sheng Yang, Dr.², Edwin B. Fisher, Ph.D.³, Fang-Biao Tao, Dr.²

¹Anhui Medical University, Chapel Hill, NC; ²Anhui Medical University, Hefei, Anhui, China (People's Republic); ³Department of Health Behavior, Gillings School of Global Public Health, University of North Carolina-Chapel Hill, Chapel Hill, NC

High sedentary time may constitute an important risk factor for cognitive health. However, the association of sedentary time with mild cognitive impairment (MCI) among elderly people has not been studied extensively. This study aimed to investigate the association between sedentary time and MCI in elderly residents of urban communities in China. Participants were from the Health and Environment Control Study of older adults of Lu'an city in Anhui province. A total of 1217 individuals aged at least 60 years old were recruited by telephone of whom 1077 (88.5%) completed questionnaire survey, face-to-face interviews, and physical examination. Sedentary time was categorized as 0–1 hours per day – 369 participants (34.3%); 1–2 hours per day – 292 participants (27.1%); 2–3 hours per day – 163 participants (15.1%); and > 3 hours per day – 253 participant (23.5%). Cognitive function was evaluated by the Mini-Mental State Examination (MMSE). 184 participants (17.1%) were identified as at risk for MCI. Binary logistic regression was used to evaluate the associations between sedentary time and MCI. On univariate analysis, sedentary time was significantly associated with residential area, occupation, degree of education, and annual income. MCI was significantly associated with residential area, gender, age, occupation, income, education level, alcohol use, working condition, siesta (midday nap) and sedentary time (all p s < 0.05). After adjustment for confounders (residential area, gender, age, occupation, annual income, education level, alcohol use, working condition, and siesta), sitting for 2–3 hours per day was correlated negatively (OR=0.514, 95%, CI=0.275–0.961) with MCI. That is likelihood of MCI was less among those sitting 2–3 hours per day than among those sitting for fewer than 2 or more than 3 hours per day. This complex relationship suggests that sedentary time is not a simple variable but may be associated with other characteristics, such as mental work at moderate, 2–3 hours per day, or more passive activity at more than three hours per day sedentary time.

TRAIT ANXIETY AND RESTRICTIVE EATING AS PREDICTORS OF SLEEP ONSET LATENCY AND SLEEP QUALITY

Jamie L. Walker, M.A., LPC¹, Megan Douglas, M.A.², Jessica R. Dietch, M.A.², Danica C. Slavish, Ph.D.², Aurora Brown², Brett Messman, B.S.², Bella Scott, B.A.³, Daniel J. Taylor, Ph.D.², Heidemarie Blumenthal, Ph.D.²

¹The University of North Texas, lewisville, TX; ²University of North Texas, Denton, TX; ³Stanford University, Stanford, CA

Reports of anxiety, eating disorders, and sleep disturbances are common among college students, and high rates of comorbidity exist among these complaints. The associations among these issues are likely due to complex overlapping psychophysiological factors. Anxiety may predict impaired sleep by leading to increases in intrusive thoughts and worries that make it difficult to fall asleep and obtain good quality sleep. Restrictive eating (i.e., reducing food intake and/or restricting calories) may predict impaired sleep by altering metabolism (e.g., leptin, glucose, or ghrelin levels) and contributing to negative mood. Although it seems intuitive that restrictive eating, anxiety, and sleep would be associated, no studies have systematically examined associations between these variables in a diverse sample of college students. Therefore, the present study examined trait anxiety and restrictive eating as predictors of subjective sleep. Trait anxiety was measured using the State Trait Anxiety Inventory. Restrictive eating was measured using an item from a national youth risk survey that asked about restriction of food, calories, or fat-content in food intake with the intent of weight loss over the past 30 days. Sleep was measured via two self-report items asking about satisfaction with current sleep pattern (i.e., sleep quality) and number of minutes it typically took to fall asleep over the past month (i.e., sleep onset latency, SOL). Participants were 452 college students ages 18–25 (66% female; 59% White). Analyses were conducted using multiple linear regression (using separate models for each sleep outcome) and controlled for gender and BMI. The overall models were significant for both sleep quality ($F(4, 410) = 20.24, p < .001$) and SOL ($F(4, 408) = 9.90, p < .001$). Predictors accounted for 17% of the variability in sleep quality and 9% of the variability in SOL. When trait anxiety and restrictive eating were examined as predictors of sleep quality and SOL, only trait anxiety significantly predicted poorer sleep quality ($\beta = -0.93, p < .001$) and longer SOL ($\beta = 0.73, p < .001$). These results suggest anxiety may play a more important role in the subjective experience of sleep than does restrictive eating. Future research should examine if these same results hold using more objective measures of sleep and food restriction. To improve treatment outcomes, it may be beneficial to address overlapping comorbidities (e.g., sleep difficulties and anxiety).

YOGA AND SEVERE MENTAL ILLNESS

Em Adams, CTRS, C-IAYT, RYT

Clemson University, Clemson, SC

Schizophrenia spectrum disorders (SSD) are a group of related psychiatric conditions involving some degree of reality distortion that affect approximately 51 million people worldwide. SSDs are characterized by hallucinations, delusions, disorganized thought, and are often accompanied by social skills deficits, and lack of motivation. Standard treatment for SSDs includes pharmacotherapy and psychotherapy. In recent years the efficacy of adjunct treatments such as aerobic exercise and social skills training have come to the forefront of research and practice. The purpose of this literature review was to review the effect of a yoga intervention on SSD symptoms. Databases used for this review included: Academic Search Premier, Health Source: Nursing/Academic Edition; MEDLINE; Psychology and Behavioral Sciences Collection, PsycARTICLES; and PsycINFO. The search engine EBSCOHost was used to simultaneously search these databases without a date restriction. The search terms used were “yoga AND schizophrenia,” “yoga AND negative symptoms,” and “yoga AND positive symptoms.” Inclusion criteria for studies were: 1) must have used some type of yoga intervention; 2) study participants must have had a SSD diagnosis; 3) had measurable outcomes, and 4) were available in English. This search located a total of 80 articles. Duplicates were eliminated leaving 63 articles, 18 of which met the criteria. The majority (n=11) of the studies were randomized control trials, and outcomes included reduced positive symptoms, reduced negative symptoms, improved facial emotion recognition, increased global functioning, reduced stress and anxiety, and higher quality of life. In conclusion, the efficacy of therapeutic yoga as an adjunctive therapy for people with a SSD appears promising, and deserves further attention and research.

12 MONTH SMOKING CESSATION OUTCOMES FOR SMOKERS WITH MENTAL HEALTH SYMPTOMS: RESULTS FROM A LARGE WEB-BASED RANDOMIZED TRIAL

Noreen Watson, PhD¹, Jaimee Heffner, PhD¹, Kristin E. Mull, MS¹, Jennifer B. McClure, PhD², Jonathan B. Bricker, PhD¹¹Fred Hutchinson Cancer Research Center, Seattle, WA; ²Kaiser Permanente Washington Health Research Institute, Seattle, WA

BACKGROUND: Mental health conditions (MHCs) are associated with a greater prevalence of cigarette smoking as well as difficulty quitting smoking. Web-based interventions offer a promising treatment modality for smokers with MHCs by making treatment more accessible (e.g., low-cost, high-reach, ability to be accessed anytime). To date, however, little is known about how smokers with MHCs respond to web-based cessation interventions. Using data from a large trial of two web-based smoking interventions, we compared the 12-month abstinence rates for smokers who screened positive for MHCs to those who did not.

METHODS: Participants were adult smokers enrolled in a large (N=2,637) web-based randomized controlled trial for smoking cessation who completed follow-up surveys at 12-months post-randomization (88% data retention). At baseline, participants completed self-report measures of depression, social anxiety disorder (SAD), post-traumatic stress disorder (PTSD), generalized anxiety disorder (GAD), and panic disorder. Outcomes were 30-day point prevalence abstinence at 12-months post-randomization. Data were analyzed via logistic regression models controlling for treatment condition.

RESULTS: Abstinence rates at 12 months were significantly lower for smokers who screened positive for depression [24%; OR=0.78; 95% CI=0.62–0.98, p=.030], PTSD [24%; OR=0.77; 95% CI=0.61–0.98, p=.030], and panic [23%; OR=0.73; 95% CI=0.57–0.93, p=.010] relative to smokers who did not screen positive for a MHC (29%). Smokers who screened positive for two or more were also less likely to successfully quit [24%; OR=0.78; 95% CI=0.62–0.98, p=.033]. Screening positive for SAD or GAD was not associated with differential odds of quitting.

CONCLUSIONS: This is the first study to examine long-term quit rates in response to a web-based intervention among smokers screening positive for mental health conditions. Although smokers screening positive for SAD and GAD demonstrate similar quit rates to smokers without MHCs, those with elevated symptoms of depression, PTSD, and panic and those who screen positive for multiple MHCs may benefit from web-based interventions that address their mental health symptoms.

AN UNDERSTANDING OF THE RELATIONSHIP BETWEEN HORMONAL BIRTH CONTROL AND DEPRESSION IN COLLEGE-AGED WOMEN

Jamie Paola, B.A., MPH candidate, Rita DeBate, PhD, MPH, FAED, FAAHB, Jennifer Bleck, PhD, MPH

University of South Florida, Tampa, FL

Aims: Decades of speculation have suggested a relationship between hormonal birth control (BC) use and depression. Although previous literature has yet to determine a definitive conclusion on this issue, the current study reports findings based on an integrative life course theoretical framework to investigate the association of hormonal BC and depression.

Methods: Secondary analysis of data from the National Longitudinal Study of Adolescent to Adult Health was conducted using data from 7,563 sexually active women between 18 and 32 years old. Participants self-reported past year contraceptive use and depression including lifetime diagnosis, past week symptoms, and past year treatment utilization. Analysis included z-tests for proportions, t-tests, and logistic regressions.

Results: Some women reported using more than one hormonal BC within the past year, most often BC pills and the BC shot. Women who used both the pill and shot within the past year had a higher rate of diagnosed depression (23.0%) than women using the pill only (15.4%) and those using non-hormonal methods (15.7%, p

Conclusion: Findings support a relationship between hormonal BC use and treatment of depression, including therapy and medication use, with an additive effect when women use both the pill and shot within the past year. While there is a higher rate of diagnosed depression among women using hormonal BC, this association may be contributed to demographic characteristics and past sexual behavior. There was no association found between past week depressive symptoms and hormonal BC use, suggesting that the relationship between hormonal BC and depression may be specific to the identification and treatment of depression and the prevalence of depression.

ANXIETY SENSITIVITY, EMOTION REGULATION AND SOMATIC SYMPTOMS AMONG PATIENTS WITH AND WITHOUT BORDERLINE PERSONALITY DISORDER

Nicole Musalo, Psychology B.A.¹, Juan C. Hernandez, Psychology, B.A.², Cynthia A. Cervoni, Ph.D.³, Adam Gonzalez, PhD⁴, Brittain Mahaffey, PhD⁴¹Stony Brook University, Massapequa pk., NY; ²Stony Brook University, San Antonio, TX; ³Stony Brook University, Franklin Square, NY; ⁴Stony Brook University, Stony Brook, NY

Background. Borderline Personality Disorder (BPD) is characterized by emotional lability, impulsivity, instability in relationships and unstable sense of self. BPD occurs in 1–3% of nonclinical samples and 10% of outpatient populations. National data indicates that patients with BPD are also at elevated risk for physical health problems compared to patients without BPD. Anxiety sensitivity (AS; fear of fear) and emotional dysregulation (ED; difficulties with regulating emotions) are well established cognitive-emotional vulnerability factors relevant to patients with BPD. These vulnerability factors may also contribute to the elevated experience of physical health symptoms in patients with BPD. The objectives of this study were to compare levels of AS (Anxiety Sensitivity Index-3; ASI3), ED (Difficulties with Emotion Regulation Scale; DERS) and severity of somatic symptoms (Patient Health Questionnaire-15; PHQ15) among patients with and without BPD; and to evaluate the role of AS in the relationship between ED and somatic symptoms among patients with and without BPD.

Method. Patients (N=56) presenting for outpatient psychotherapy were consented to participate in a study evaluating the effectiveness of psychotherapy treatments. Patients completed electronic self-report measures and a structured diagnostic interview with a therapist.

Results. Fifty percent of the sample met DSM-IV criteria for BPD (n=18) or had elevated BPD features (>3 features; n=10). These groups were collapsed into one BPD group and compared to patients without BPD (n=28). The BPD group had significantly higher scores on the DERS (M=119.07, SD=4.57) compared to patients without BPD [M= 92.71, SD=19.36; t(56)=-4.62, p ASI3 or PHQ15. Results from mediation analyses conducted via the PROCESS macro for SPSS revealed a significant indirect effect of ED on somatic symptoms via AS, b=.07, CI [0.15, 0.26] but only in the BPD group. AS accounted for roughly 75% of the total effect, P_M=.76.

Conclusions. Our findings suggest that patients presenting with BPD or elevated BPD features for psychotherapy demonstrate greater ED relative to patients without BPD. Poor emotion regulation appears to indirectly affect somatic symptoms via AS in patients with BPD. Future inquiry regarding the impact of ED and AS on physical health in patients with BPD is needed to better inform psychotherapy treatment approaches for this population.

ASSOCIATION BETWEEN SLEEP QUALITY, DISORDERED EATING, AND DEPRESSIVE SYMPTOMS AMONG COLLEGE STUDENTS

Caroline Kaufman, Bachelors degree, Idia B. Thurston, Doctorate, Andrew Paladino, BA, Kristina Decker, Masters Degree

University of Memphis, Memphis, TN

Background: Approximately one-fifth of college students report experiencing depression. Correlates of depressive symptoms in this population include: substance use, disordered eating practices, and body mass index (BMI). However, there is a paucity of research examining how sleep quality is related to depressive symptoms in the context of these health and mental health factors. Given that substance use, elevated weight, disordered eating, and sleep may be amenable to health promotion interventions, understanding the association among these factors is key to improving the well-being of college students. Thus, we explored the association between sleep quality and depressive symptoms; accounting for BMI, disordered eating, alcohol and drug use.

Method: 172 college students between the ages of 18 and 25 ($M=19.67$, $SD=1.78$) participated in this study. A total of 41% self-identified as White, 36% as Black, 10% as multiracial, 9% as Hispanic, and 4% as "Other race"; with 75% being female. Participants completed measures of depressive symptoms (Center for Epidemiological Studies Depression Scale), alcohol use (Alcohol Use Disorders Test), drug use (Drug Use Disorders Test), disordered eating (Restraint Subscale of the Eating Disorder Examination Questionnaire) and sleep quality (Pittsburg Sleep Quality Index). Measured height and weight were used to calculate BMI (kg/m^2). A hierarchical regression was conducted across 3 steps to predict depressive symptoms. Gender and race/ethnicity were entered into Step 1 as covariates; BMI, disordered eating, alcohol use, and drug use were entered into Step 2; and sleep quality were entered into Step 3.

Results: The final step of the regression model was significant, $F(11, 161)=8.00$, $Adj. R^2=.31$, $p<.001$, with higher sleep quality ($B=-.47$, $p<.001$) associated with lower depressive symptoms and more disordered eating practices ($B=.18$, $p<.05$) associated with higher depressive symptoms. BMI, alcohol use, and drug use were not significantly associated with depressive symptoms in this sample.

Discussion: Even accounting for the association between disordered eating and depressive symptoms, sleep quality uniquely contributed to the variance in depressive symptomatology among college students. Future research is needed to explore mechanisms by which sleep quality is associated with depressive symptoms (such as physiological dysregulation) in order to guide the design and implementation of effective health promotion interventions.

ASSOCIATIONS BETWEEN RELIGIOSITY/SPIRITUALITY AND MENTAL HEALTH BEHAVIORS IN YOUNG ADULTS

Shannon Gwin, PhD¹, Laurette Taylor, PhD², Paul Branscum, PhD, RD³, Sarah Maness, PhD, MPH, CPH⁴, Melissa Frey, PhD, Faculty member¹, Marshall Cheney, PhD, PhD¹, Ying Zhang, PhD, PhD⁵

¹University of Oklahoma, Norman, OK; ²The University of Oklahoma, Norman, OK; ³Miami University, Oxford, OH; ⁴Department of Health and Exercise Science, University of Oklahoma, Norman, OK; ⁵University of Oklahoma Health Science Center, Oklahoma City, OK

The purpose of this study was to evaluate the association between religiosity and mental health outcomes among young adults. Young adults ($n=775$) from colleges and universities in a southwestern state were surveyed to assess associations between young adult depressive symptoms and suicide ideation, religiosity beliefs, and protective assets of the relationships with dad and mom. Logistic regression, which produced odds ratios (ORs), was used to determine significant associations between religiosity and depression and suicide ideation. Findings indicated significant inverse associations between higher scores in higher levels of organizational religious activities (OR range = 0.208 - 0.555), higher levels of non-organizational religious activities (OR range = 0.282 - 0.399), and the most positive responses to the three items measuring intrinsic religiosity (OR range = 0.216 - 0.489) with young adult depressive symptoms during the last week. In addition, higher scores on the religiosity subscales were significantly associated with fewer reports of suicide ideation in the last 12 months. OR findings suggest that participants with higher scores in religiosity had less risk for development of depression and suicide ideation. Overall, religiosity beliefs and practices appear to be associated with fewer depressive symptoms and suicide ideation. Inclusion of religious/spirituality-oriented components may be important to include in mental health programming for those emerging adults that report having high religiosity.

BARRIERS AND FACILITATORS TO OBESITY MANAGEMENT IN RURAL ADULTS WITH SERIOUS MENTAL ILLNESS

Kathryn A. Richardson, B.A.¹, Christine L. McKibbin, PhD², Katherine Kitchen Andren, PhD², Andrea E. Slosser, B.A.², Morgan E. Longstreth, B.S.²

¹The University of Wyoming Department of Psychology, Laramie, WY; ²The University of Wyoming, Laramie, WY

Background: Adults with Serious Mental Illness (SMI) are more likely to be overweight or obese (OW/OB) and to experience obesity-related diseases such as metabolic syndrome, diabetes mellitus (Correll, et al., 2009), or cardiovascular disease (Lavie et al., 2013). Engagement in health behavior is also poor in this population (Scott & Happell, 2011). Moreover, development of healthy lifestyle interventions often fail to include the needs and perspectives of those residing in rural areas.

Purpose: The purpose of this study is to develop a rich understanding of the needs and barriers regarding healthy lifestyle practices among rural adults with SMI. The study answers the following questions: (1) What prevents rural adults with SMI from engaging in health behaviors, (2) What would facilitate their engagement in health behaviors, and (3) What components would form acceptable and rurally accessible intervention.

Methods: Participants were recruited from community mental health centers in Wyoming and Colorado. Participants were age 18 years or older, had a diagnosis of a SMI and provided informed consent. Qualified participants engaged in 60-minute focus groups across five communities. Data were transcribed verbatim and analyzed in three stages according to methods of Corbin and Strauss, 2008.

Results: Among participants ($n=27$) a majority were women ($n = 17$, 63%), Non-Hispanic ($n = 26$, 96.3%), and White ($n=27$, 100%), had a diagnosis of schizophrenia ($n = 18$, 66.7%), some college education ($n=13$, 48.1%), and lived alone in an apartment ($n=14$, 51.9%).

Discussion: Thematic barriers to healthy behaviors included rural environmental conditions, such as lack of transportation, limited access to programs, and perceived stigma. In addition, participants identified mental health symptoms and medication side-effects as barriers. Facilitators included social support, tangible support from providers, and establishing routines.

Conclusion: Strategies to address healthy lifestyle barriers for adults with SMI in rural areas are needed. These persons may benefit from expansion of tangible supports and strategic leveraging of limited resources. Dissemination of healthy lifestyle programs by way of telehealth or train-the-trainer methods may increase intervention access. Modification of existing programs to directly address and problem-solve rural barriers is needed. Findings are limited to rural areas in Wyoming and Colorado and may not generalize to other rural or urban areas.

BINGE WATCHING: A SEDENTARY BEHAVIOR ASSOCIATED WITH INCREASED ANXIETY AND DEPRESSION

Alexandra Sanders, N/A¹, David Rivetti, N/A², Natalia Prokop, N/A¹, Julia Carroccio, N/A², Chelsey Parker, BS³, Thomas Lawler, N/A², Jacob Burmeister, PhD¹

¹University of Findlay, Findlay, OH; ²University of Dayton, Findlay, OH; ³Ball State University, Findlay, OH

Binge watching has rapidly become a common sedentary behavior. Netflix reported that more than 80% of their 83,000,000 subscribers binge watch. However, little quantitative research has attempted to measure psychosocial correlates of binge watching. The current study tested whether binge watching frequency is associated with anxiety and depression. Participants ($N = 338$) were recruited and completed a survey online in the autumn of 2016. Individuals who binged more than 3 times per week had increased levels of depression ($F(3,328)=5.94$; $p = .001$; $\eta^2 = .06$ and anxiety $F(3,301)=3.52$; $p = .016$; $\eta^2 = .04$). Participants were also asked to describe their binge watching behaviors. Qualitative data suggest that participants see binge watching as a generally positive aspect of their life. Less than 9% of participants described their binge watching habits as a negative aspect in their life. Though associated with depression and anxiety, binge watching may represent an adaptive or maladaptive coping response. Future research should seek to establish directionality and rule out the influence of outside variables.

CHANGES IN ACUTE INFLAMMATORY MARKERS IN RESPONSE TO EXERCISE IN MAJOR DEPRESSIVE DISORDER

Maria Perez, M.S.¹, Jacob Meyer, MS, PhD¹, Laura Ellingson, PhD¹, Charles Raison, MD², Christopher L. Coe, PhD³, Dane B. Cook, PhD²

¹Iowa State University, Ames, IA; ²University of Wisconsin-Madison, Madison, WI; ³University of Wisconsin, Madison, WI

Introduction: Depression is a burdensome and challenging illness, in part, due to its heterogeneous etiology. Symptoms of depression have been associated with inflammation in major depressive disorder (MDD) and chronic exercise has anti-inflammatory effects. Although chronic exercise generally results in a decrease in inflammatory markers, acute exercise can result in a pro-inflammatory response both during and shortly after the exercise session. However, research on the inflammatory response to exercise has largely been limited to high-intensity or long-duration exercise in healthy adults.

Purpose: To examine the inflammatory response to an acute bout of moderate-intensity exercise for women with MDD compared to a quiet rest control condition, and to explore the influence of depression severity.

Methods: Participants were 20 women (age 39.9 ± 14.3 years) with mild ($n=7$) or moderate-to-severe ($n=13$) MDD based on the Beck Depression Inventory-II (cutoff:19.5). Pro-inflammatory cytokines (interleukin 6 [IL-6], interleukin 8 [IL-8], and Tumor Necrosis Factor- α [TNF- α]) were measured in serum from blood drawn before and within 10 minutes after a 20-minute moderate intensity (rating of perceived exertion: 13) cycling session or a quiet rest condition on separate days. Independent-samples t-tests compared group changes for each condition. Cohen's d effect sizes determined the magnitude of differences between the severity subgroups.

Results: There were no significant differences in cytokine levels between groups at baseline for either testing condition. No significant pre-post differences were observed in the quiet rest condition for any cytokine ($p>.05$). For the exercise condition, no significant difference was observed between groups for IL-6 ($p=.91$) or TNF- α ($p=.98$). However, for IL-8, there was a significant group difference in change from pre- to post-exercise ($p=0.02$; large effect: $d=1.3$) with an increase of $40 \pm 42.7\%$ for the mild-to-moderate group and a decrease of $12.3 \pm 37.7\%$ for the severe group.

Conclusions: A greater pro-inflammatory response (via IL-8) to moderate exercise was observed for women with mild MDD compared to women with moderate-to-severe MDD. These results suggest an interaction between depression severity and the inflammatory response to acute exercise. A clearer understanding of inflammatory responses to different stressors could provide additional information on the pathophysiology of MDD and may lead to targeted treatments.

CLIMATE SCHOOLS COMBINED STUDY: MENTAL HEALTH OUTCOMES OF AN ONLINE APPROACH TO PREVENT SUBSTANCE USE AND MENTAL HEALTH PROBLEMS

Maree Teesson, BSc Psych(Hons), PhD¹, Nicola C. Newton, PhD¹, Tim Slade, PhD², Cath Chapman, PhD¹, Louise Mewton, BA (Psych, Hons), PhD³, Louise E. Birrell, PhD, BPsy(hons), BSocSc⁴, Brad Shaw, BSc¹

¹UNSW Sydney, Sydney, New South Wales, Australia; ²University of New South Wales, Randwick, New South Wales, Australia; ³UNSW, Randwick, New South Wales, Australia; ⁴National Drug and Alcohol Research Centre, UNSW, Sydney, New South Wales, Australia

Background: Anxiety, depressive and substance use disorders account for three quarters of the disability attributed to mental disorders and frequently co-occur. While programs for the prevention and reduction of symptoms associated with (i) substance use and (ii) mental health disorders exist, research is yet to determine if a combined approach is more effective. This paper describes the mental health outcomes of a cluster randomised controlled trial to evaluate the effectiveness of the CLIMATE Schools Combined intervention, a universal approach to preventing substance use and mental health problems among adolescents.

Methods: Data come from 6,411 school students from 71 schools across Australia participating in the CLIMATE Schools Combined study (mean age at baseline=13.5). Linear mixed models were implemented to evaluate 36-month trial outcomes on symptoms of depression, generalised anxiety disorder and social phobia.

Results: In the control group there was an increasing trajectory of mental health symptoms, whereas these symptoms remained stable in the CLIMATE Schools Combined intervention group. This pattern was evident for depression symptoms ($b = -0.63$ [0.27], $p = 0.021$), GAD symptoms ($b = -0.38$ [0.25], $p = 0.006$) and social phobia symptoms ($b = -0.35$ [0.17], $p = 0.045$).

Conclusion: For the first time, there is evidence that a combined approach to the prevention of both substance use and mental health results in significantly lower growth in mental health symptoms related to depression, generalized anxiety disorder and social phobia.

COMPARING NETWORK TO EXPLORATORY FACTOR ANALYSIS IN PSYCHOSOCIAL SYNDemics IN HIGH-RISK HIV-NEGATIVE MEN WHO HAVE SEX WITH MEN

Jasper S. Lee, BS¹, Sierra A. Bainter, Ph.D.¹, Tiffany R. Glynn, MS¹, Brooke G. Rogers, MPH¹, Conall O'Ceirigh, Ph.D.², Kenneth H. Mayer, M.D.³, Steven Safren, Ph.D., A.B.P.P.¹

¹University of Miami, Coral Gables, FL; ²Massachusetts General Hospital, Boston, MA; ³Fenway Health Institute, Boston, MA

Introduction: In the U.S., HIV acquisition risk is highest among men who have sex with men (MSM). Syndemics, psychosocial problems that interact with each other and poor health behavior, are additively associated with increased condomless sex, HIV incidence, and HIV prevalence among MSM. However, information about how these syndemics interrelate with each other is under-explored.

Methods: To examine the associations between nine syndemic problems in 184 MSM at high risk of HIV acquisition, we first examined bivariate correlations, and then compared exploratory factor analyses (EFA) to a network analysis. Syndemics were assessed by self-report measures. Network analyses (presented graphically) consist of variables, called nodes, and the associations between variables, called edges. This regularized network employed the graphical LASSO algorithm and Extended Bayesian Information Criteria with a hyperparameter of $\gamma=.5$ to produce a graphically parsimonious yet sensitive network.

Results: Correlation analyses revealed that many of the syndemics were associated with each other, but this was not always the case. Based on the eigenvalues, the 2- and 3-factor models were potential solutions. However, the EFA did not yield a definitive solution across either 2- or 3-factor models. Network analysis, however, revealed that the relationships (absolute edge weights) between suicidal ideation (SI) and injection drug use (IDU; $b=.56$, $SD=.17$, 95% CI[.34, .94]), IDU and substance use ($b=.33$, $SD=.20$, 95% CI[.10, .85]), social anxiety and SI ($b=.29$, $SD=.21$, 95% CI[.09, .82]), and depression and SI ($b=.25$, $SD=.16$, 95% CI[.01, .66]), were all significant, with SI being the most central.

Discussion: This is the first study to conduct a network analysis of syndemics to describe interrelatedness of conditions, beyond additive associations. It is also the first to compare network analysis to EFA in syndemics. Network analysis may be methodologically preferable to EFA in examining the interrelatedness of syndemics because it provides measures of centrality, which can potentially indicate the conditions that drive increased HIV acquisition risk, and lends itself to a visual presentation of the interrelatedness among these intertwined problems. Further research is needed to determine how clusters of conditions, and potentially which symptoms within such conditions, interact most to confer the greatest HIV acquisition risk.

DO DISEASE CLUSTERS PREDICT DEPRESSIVE SYMPTOMATOLOGY IN OLDER ADULTS?

Jacquelyn Minahan, MA, Tamara Baker, Ph.D.

University of Kansas, Lawrence, KS

Multimorbidity is a common occurrence among older adults and has significant ramifications on mental health. As depression is expected to become the top contributor to chronic disease burden, it is important to understand the effect of multimorbidity on depressive symptoms, and whether particular disease clusters are associated with increased depressive symptoms. The present study investigated whether chronic diseases clustered among an older adult population, and whether these clusters predicted depressive symptom severity. Secondary analyses were performed using interview data from the National Social Life, Health, and Aging Project (NSHAP). Participants were Black, White, and Hispanic adults > 65 years of age ($M=73.7$, $SD=5.7$) who reported at least two chronic illness diagnoses (mean diagnoses = 3.1, $SD = 1.2$). Patterns of comorbidity were assessed using tetrachoric factor analysis and a multivariable linear regression model. Factor analysis demonstrated five disease patterns: cancers, arthritis, pulmonary, metabolic, and stress factors. Analyses demonstrated that the five factors were not predictive of increased depressive symptom severity. However, the total number of conditions was significantly associated with increased depressive symptomatology. This is likely due to the stress associated with chronic disease symptom management, and reflective of poor or unsuccessful disease management and symptom burden. These findings add to the limited body of knowledge investigating disease patterns in older adults, and help to better understand the reciprocal impact of chronic conditions on mental health.

6:30 PM-7:30 PM

EDUCATION ON PERINATAL DEPRESSION DURING THE ANTEPARTUM PERIOD IS COMMON AND WELL RECEIVED BY WOMEN

Rachel H. Salk, PhD¹, Neeta Shenai, M.D.², Rachel P. Kolko, PhD¹, Maria Tina Benno, BS³, Britny A. Hildebrandt, PhD¹, Marsha D. Marcus, PhD⁴, Michele D. Levine, PhD⁴

¹University of Pittsburgh School of Medicine, Pittsburgh, PA; ²University of Pittsburgh, Western Psychiatric Institute and Clinic, Pittsburgh, PA; ³University Of Pittsburgh School of Medicine, Pittsburgh, PA; ⁴University Of Pittsburgh, Pittsburgh, PA

Prenatal and postpartum depression affect approximately 8–14% of US women; however, less than a quarter of these women receive depression treatment. Lack of education about perinatal depressive symptoms and available resources are barriers to treatment. To further assess education received on perinatal depression during the antepartum period, we examined women's perceptions of communication with their healthcare providers through an online survey. Participants were recruited from a postpartum unit at a large women's hospital, with a total of 79 women completing the survey.

Most women reported that during the antepartum period a healthcare provider discussed treatment options for depression during pregnancy (52%, $n = 41$) and after their baby was born (62%, $n = 48$). Additionally, women reported that the majority of providers offered examples of how depression may feel (73% and 89%, for prenatal and postpartum, respectively) and provided phone numbers for services (75% and 71%, for prenatal and postpartum, respectively). Women were generally satisfied with the information provided on what to do if they felt depressed during pregnancy ($M = 3.80$, $SD = 1.22$ on a scale from 1- not at all satisfied to 5- very satisfied) and after their baby was born ($M = 3.83$, $SD = 1.10$). Women who received information about depressive symptoms and treatment resources reported greater satisfaction than those who did not receive this information ($ps \leq 0.05$). Although women were generally satisfied with the information provided on perinatal depression, they were also interested in additional opportunities to discuss their mood during pregnancy. Women (43%) indicated they would have been interested in talking with a mental health professional about their mood following a prenatal appointment in the same clinic.

Given recent recommendations by the United States Preventive Service Services Task Force to screen for depression during pregnancy, it is promising that most providers are discussing both prenatal and postpartum depression during prenatal care. Moreover, women are satisfied with the information provided on perinatal depression, especially when providers discuss common depressive symptoms and treatment options. In addition to screening for depression in the perinatal period, integrated mental health services in prenatal care settings may also benefit and further meet the needs of pregnant women.

ENDOCANNABINOID AND MOOD RESPONSES TO MODERATE AND PREFERRED INTENSITY EXERCISE SESSIONS IN MAJOR DEPRESSIVE DISORDER

Jacob Meyer, MS, PhD¹, Kevin Crombie, MS², Dane B. Cook, PhD², Cecilia Hillard, PhD³, Kelli Koltyn, PhD²¹Iowa State University, Ames, IA; ²University of Wisconsin-Madison, Madison, WI; ³Medical College of Wisconsin, Milwaukee, WI

Introduction: The endocannabinoid (eCB) system has been implicated in the pathophysiology of depression and, in healthy non-clinical populations, is responsive to acute aerobic exercise.

Purpose: To examine the acute eCB and mood responses to a moderate intensity and a self-selected/preferred intensity exercise session in women with major depressive disorder (MDD).

Methods: Women with MDD ($n = 17$) exercised in separate sessions for 20 min on a stationary bicycle at a moderate (rating of perceived exertion: 13) or a self-selected exercise intensity in a within-subjects, randomized and counter-balanced design. Blood was drawn before and within 10 min after completion of each session and serum concentrations of eCBs (*N*-arachidonylethanolamine [AEA] and 2-arachidonoylglycerol [2AG]) were quantified using stable isotope-dilution, liquid chromatography/mass spectrometry/mass spectrometry. The profile of mood states (POMS) and state-trait anxiety inventory (state only) were completed prior to, 10 min, and 30 min post-exercise. Changes in eCBs were compared across each session using paired sample *t*-tests and Cohen's *d* effect sizes. Changes in mood were related to changes in eCBs using Spearman's ρ .

Results: Significant elevations in AEA ($p = 0.013$) occurred post-exercise in the moderate session (moderate effect sizes: $d = 0.58$), while no significant changes in eCBs were found after the preferred session. Correlational analyses indicated significant ($p < 0.05$) negative associations in the moderate exercise session between changes in AEA and mood at 10 min post-exercise (depression, confusion, fatigue, total mood disturbance [TMD] & state anxiety) and 30 min post-exercise (confusion, TMD & state anxiety). In addition, significant ($p < 0.05$) negative associations were found in the moderate exercise session between 2-AG and mood at 10 min post-exercise (depression & confusion) and 30 min post-exercise (confusion & TMD). No significant eCB-mood relationships were found in the preferred exertion session.

Discussion: In women with MDD, moderate intensity exercise elevated one of the primary eCBs (AEA), while exercise performed at a patient-selected intensity did not. Further, changes in both AEA and 2AG across moderate exercise were associated with improvements in mood up to 30 min following exercise. Exercise can modulate the eCB system acutely in MDD and these changes could play a mechanistic role in the mood-enhancing effects of prescribed acute exercise.

6:30 PM-7:30 PM

EXAMINATION OF TRIAGE WORKFLOW FOR CRISIS INTERVENTION

Heather Kruse, Ph.D., Kelsey Sewell, Ph.D., Jessica Hamilton, Ph.D.

University of Kansas Health System, Kansas City, KS

Introduction: Suicide is currently the tenth leading cause of death in the United States, but many healthcare systems are unprepared with how to prevent or treat suicidal ideation (SI). Given this, the purpose of our study was to pilot and evaluate procedures for triaging suicidal patients within the University of Kansas Health System's Cancer Center (CC) outpatient clinics, which are accredited by the National Cancer Institute.

Methods: Data for this quality improvement study were collected from November 2016 to August 2017. During this time, our psychology faculty ($n = 5$) within the CC implemented a crisis pager system for healthcare providers at the CC to utilize should a patient express SI. This crisis pager number was widely distributed via email, meetings, and the creation of a "badge buddy" for nursing staff. Each psychology faculty member was assigned a specific "on call" day to respond to crisis pages each week (M – F).

Results: During this pilot, we received 38 total crisis calls. Out of all consultations, only seven patients endorsed SI. We completed four crisis safety plans for those who endorsed means/plan to harm oneself, but no intent. Only four patients required hospitalization, although two of these patients were not admitted for acute suicidality, but for uncontrolled symptoms of serious mental illness. Wednesdays were our busiest day, accounting for 12 of the pages. There was variety in the providers who utilized the crisis pager system; i.e., it was not one or two providers paging our team for consultation.

Discussion: A concern amongst healthcare systems is the availability of providers to triage patients when they express SI. Although our CC has a large number of psychologists, these results may still be applicable for smaller programs, particularly given that we responded to every call, regardless of whether the patient was actively suicidal. This study highlights the importance of training on what constitutes a suicidal crisis for all providers within our healthcare system. The benefit of using a crisis pager (or similar system) is that healthcare providers feel supported and know who to contact when a patient expresses SI. Additionally, we found that this system allowed psychologists to share the caseload of crisis patients. We encourage other healthcare systems to evaluate our model and determine if a variation of it would be feasible within their settings.

FEELING CALM AND PEACEFUL AMONG INDIVIDUALS AT HIGH RISK OF HOSPITALIZATION: THE ROLE OF AGE, GENDER, AND SELF-REPORTED HEALTH

Ilana Engel, BA¹, Lauren Wiklund, BA², Andrea E. Kass, PhD², Andrea Flores, MA², David Meltzer, MD, PhD²

¹University of Chicago Medicine, Biological Sciences Division, Chicago, IL; ²University of Chicago, Chicago, IL

Background: As adults age, they experience more positive and less negative emotions (e.g., feeling calm and peaceful) and better regulate their mood. Although these constructs have been studied with healthy older adults, it is important to study this among adults at high risk of hospitalization, given that hospitalization and chronic illness can elevate stress, which can negatively impact health. This study evaluated, among adults at high risk of hospitalization, the relation between feeling calm and peaceful and patients' health over one year.

Methods: Adults ($N=2,000$; Age= 63 ± 16 y; 86% Black; 63% female) who had been hospitalized in the last year or were in the emergency department were recruited for a RCT comparing a hospital-based intervention to standard care. Interviews were completed every three months, which included asking "How much of the time in the past 4 weeks have you felt calm and peaceful?" For this study, responses were grouped into: feeling calm all, most, and a good bit versus some, little, or none of the time; analyses excluded non-responders ($n=15$).

Results: At baseline, 57.6% of participants endorsed feeling calm and peaceful. Men were more likely to endorse feeling calm than women ($p<.001$). Compared to their counterparts, individuals who felt calm were older, had better health ratings, were less likely to be hospitalized in the past year, and endorsed less impairment in activities of daily living (ADL) or instrumental ADL ($ps<.003$); they also endorsed better mental health and fewer depressive and anxiety symptoms, disordered personality traits, and psychosomatic complaints ($ps<.001$). There were no between-group differences in race, ethnicity, income, education level, or number of hospitalizations in the past year ($ps>.19$). Among the subset of participants (68%) who were alive one year after enrollment and reported hospitalizations in each of the follow-ups (responses from which were aggregated into one variable of "future hospitalization"), feeling calm did not predict future hospitalization, controlling for study group and whether individuals were hospitalized in the year prior (OR=0.8; 95% CI=0.6–1.0), and did not significantly differ between study groups at each follow up ($ps>.09$).

Discussion: In this sample, feeling calm and peaceful was associated with older age and better physical and mental health, but did not predict future hospitalizations, a key health outcome. Interventions to help patients at risk of hospitalization feel calm and peaceful more often may be beneficial.

GENDER DIFFERENCES IN ASSOCIATIONS BETWEEN RESILIENCY AND DEPRESSION AMONG NEURO-ICU CAREGIVERS

Ann Lin, B.S.¹, Michelle Jacobo, Ph.D.², Jamie Jacobs, Ph.D.², Tara Tehan, R.N.¹, Danielle Salgueiro, R.N.¹, Jonathan Rosand, M.D., M.Sc.¹, Ana-Maria Vranceanu, Ph.D.², Emily Zale, Ph.D.²

¹Massachusetts General Hospital, Boston, MA; ²Massachusetts General Hospital/Harvard Medical School, Boston, MA

Informal caregivers (CGs) of patients (PTs) admitted to the Neuroscience-ICU are at risk for depression, with repercussions to both CG and PT functioning. Modifiable psychosocial resiliency factors may reduce risk of depression in Neuro-ICU CGs, and these relationships may vary by gender. We tested interactions between gender and modifiable resiliency factors on depression symptom severity cross-sectionally at the time of admission and prospectively through 6-months post-discharge. CGs ($N = 96$; $M_{age} = 53$; 62% female; 87% White) were enrolled as part of an ongoing prospective study in the Neuro-ICU of a major academic medical center. Sociodemographics and resiliency factors (coping, mindfulness, self-efficacy, intimate bond, and preparedness for caregiving) were assessed at PT's admission (i.e., baseline). Depressive symptoms were measured using the depression subscale of the Hospital Anxiety and Depression Scale at baseline, 3 months, and 6 months after patient discharge. Separate ANCOVAs were used to test potential interaction effects between gender and each resiliency variable at each timepoint. At baseline, ANCOVA models revealed main effects for resiliency variables such that greater levels of coping, mindfulness, self-efficacy, and preparedness for caregiving were associated with lower concurrent depressive symptoms (all $ps < 0.026$); these relationships did not differ by gender. At 3 months, greater CG self-efficacy was associated with lower depression regardless of gender ($p = 0.041$). At 3-month and 6-month follow-up, ANCOVAs (controlling for baseline depression) revealed an interaction between CG gender and mindfulness, such that male CGs with high mindfulness demonstrated lower levels of depression than did males with low mindfulness ($p = 0.026$ and $p = 0.013$). Similarly, at 6 months, female CGs with high intimate bond at baseline reported the lowest levels of depression symptoms ($p = 0.020$). CGs are likely to benefit from skills training that improve multiple dimensions of resiliency in the acute stage following a loved one's hospitalization. Gender differences in associations between depression and both mindfulness and intimate bond suggest that tailored programs may be used to address specific modifiable resiliency dimensions among male and female CGs.

6:30 PM-7:30 PM

INTRA-COUPLE VARIATION IN PTSD AND NICU VISITATION

Meghan Sharp, M.A., Erin Haley, M.Ed., Christyn Dolbier, Ph.D.

East Carolina University, Greenville, NC

Introduction: Research consistently supports that parental visitation has a positive influence on development of infants hospitalized in a neonatal intensive care unit (NICU). Despite unit efforts to create a family-friendly environment, variation in NICU visitation frequency between and within families persists. Parental psychological distress including symptoms of posttraumatic stress disorder (PTSD) may be related to visitation frequency. Limited research has investigated this relationship and no research has explored intra-couple variation in visitation or PTSD.

Method: Participants: 10 sets of biological parents to infants hospitalized in a NICU for at least two days ($M=51$). Characteristics: 40% married, all cohabitating, $M_{age}=29$ years, 60% White, 80% employed full-time, 50% minimum 2-year college degree, 70% Medicaid. Infants: 90% preterm ($M=31$ weeks), 100% low birth weight ($M=1327$ grams). Survey: Perinatal PTSD Questionnaire and literature-based NICU visitation barriers. Electronic health record abstraction: parent visitation frequency and infant medical history. Significance level of $p=.10$ was used to account for small sample size.

Results: Mothers had higher PTSD scores ($M=11.00$) than fathers ($M=2.70$), $t(11.23)=1.85$, $p=.09$; and visited their baby a greater proportion of days ($M=25.41$) than fathers ($M=21.67$), $t(19)=3.55$, $p=.002$. Paired analyses revealed the same pattern of findings, as well as that mothers reported fewer visitation barriers ($M=1.60$) than their partner ($M=2.70$), $t(8)=2.09$, $p=.07$. Visitation was significantly correlated within couples ($r=.96$, $pr=.26$, $p=.50$), and number of barriers ($r=.45$, $p=.19$) were not. Only among mothers were significant correlations observed between number of barriers and PTSD score ($r=.75$, $p=.019$) and visitation ($r=.67$, $p=.04$). PTSD score and visitation were not correlated among mothers or fathers.

Conclusions: Results indicate that mothers of NICU infants may be at greater risk to experience PTSD, and that they perceive fewer visitation barriers, and visit their baby more often than their partners. Despite perceiving fewer barriers, the barriers mothers reported were positively related to their PTSD scores and visitation. Among mothers, visitation barriers and PTSD symptoms may exacerbate each other; and reporting barriers may be capturing concerns that lead them to visit and/or visiting may highlight barriers. PTSD did not directly serve as a visitation barrier for mothers or fathers.

KEEPING OUR STAFF IN MIND: IMPROVING PHYSICAL FITNESS OF MENTAL HEALTH STAFF THROUGH A PHYSICAL ACTIVITY INTERVENTION

Hamish Fibbins, Bachelor of Exercise Physiology, AEP¹, Elisa C. Rossimel, Bachelor of Nutrition and Dietetics², Jo Poole, N/A³, Oscar P. Lederman, Bachelor of Exercise Physiology⁴, Andrew Watkins, NSW⁵, Jackie Curtis, MBBS, FRANZCP⁶, Philip B. Ward, BMedSc, PhD⁷, Simon Rosenbaum, PhD⁸

¹South Eastern Sydney Local Health District, Sydney, New South Wales, Australia; ²South Eastern Sydney Local Health District, Maroubra, New South Wales, Australia; ³South Eastern Sydney Local Health District, Maroubra, N/A, Australia; ⁴NSW Health, Sydney, New South Wales, Australia; ⁵South East Sydney Local Health District, Bondi Junction, New South Wales, Australia; ⁶SESLHD, Sydney and University of New South Wales, Sydney, Sydney, New South Wales, Australia; ⁷UNSW Sydney, Liverpool BC, New South Wales, Australia; ⁸UNSW Sydney, Sydney, New South Wales, Australia

Background: People with severe mental illness (SMI) have a life-expectancy up to 20 years less than the general population, primarily due to cardiovascular (CV) risk factors. Lifestyle interventions that promote physical activity assist in reducing CV risk for people living with SMI, however implementation of successful programs within mental health care settings are scarce. Staff culture surrounding physical health remains a major barrier to convert research findings into clinical practice. As such, Keeping our Staff in Mind (KoSiM), a staff-focused lifestyle intervention, was delivered to mental health staff members of a local health district in Sydney, Australia with the aim of improving physical fitness, CV risk and staff culture.

Methods: All clinical mental health staff within the district who opted to partake in the KoSiM intervention were offered an initial consultation with an exercise physiologist to discuss physical activity habits and perform goal setting followed by physical fitness testing. Participants were then offered weekly consultations with the exercise physiologist for four weeks with follow-up occurring at week 16. Outcomes assessed included: physical activity levels, aerobic fitness, upper body strength, weight, waist circumference and blood pressure.

Results: In total, 106 staff members participated in the study and prior to beginning the program, 90% of staff had never met with an exercise physiologist. Follow-up aerobic fitness testing was completed by 61 participants with a mean increase in VO_2 max of 2.8ml/min/kg ($p<0.001$). A mean increase of 25.8 minutes to weekly vigorous physical activity occurred in addition to a mean decrease of 110.3 minutes of daily sedentary time ($p<0.001$). Statistically significant reduction in waist circumference was observed, with a mean decrease of 1.9cm ($p<0.001$).

Conclusion: Lifestyle interventions are effective in improving the physical health and fitness of mental health staff. To incorporate physical health interventions within routine care for people living with mental illness a focus on improving staff culture is essential.

MENTAL HEALTH PROVIDER INTENTIONS TO OFFER WEIGHT MANAGEMENT TO YOUTH WITH SERIOUS EMOTIONAL DISTURBANCE AND OBESITY

Katelynn A. Bourassa, M.S.¹, Thomas L. Wykes, PhD², Andrea E. Slosser, B.A.³, Kathryn A. Richardson, B.A.⁴, Christine L. McKibbin, PhD³

¹University of Wyoming Department of Psychology, Houston, TX; ²University of Wyoming Psychology Department, Cheyenne, WY; ³The University of Wyoming, Laramie, WY; ⁴The University of Wyoming Department of Psychology, Laramie, WY

Introduction. Youth with Serious Emotional Disturbance (SED) are at increased risk for overweight and obesity (OW/OB). Contributing factors may include psychotropic medication (e.g., Jerrell, 2010) and psychiatric symptoms (e.g., Davis, 2010). While community mental health providers may have the requisite skills to provide weight-related intervention (Barlow, 2007; Garland et al., 2010), little is known about the factors that influence their engagement in this behavior. The Theory of Planned Behavior (TPB; Ajzen, 1991) may guide the identification of variables influencing provider behavior. The purpose of the current study was to create a TPB-based measure to assess factors related to intention to provide weight-related intervention to youth with SED and OW/OB.

Methods. A TPB questionnaire was created from Salient Beliefs identified in a prior elicitation study and edited based on expert feedback. Then, community mental health providers serving youth with SED and OW/OB were recruited via electronic advertisement. A total of 101 providers participated. Participants completed a clinical practice survey and TPB questionnaire. Descriptive characteristics related to clinical practice were obtained. Psychometrics and a Confirmatory Factor Analysis (CFA) examined the properties of the TPB questionnaire. Hierarchical multiple linear regression assessed associations between TPB constructs and providers'; behavioral intentions.

Results. A majority of participants were Licensed Professional Counselors. Approximately 66% ($SD = 34.3$) of their caseload has SED. Participants identified a lack of training in weight-management techniques, and less than half reportedly provide weight-related intervention. The questionnaire showed adequate reliability ($\alpha = 0.72 - 0.84$) and CFA confirmed model fit (e.g., Standardized Root Mean Square Residual = 0.07). Several Direct Attitude constructs predicted intention to provide weight-related intervention. The overall regression model accounted for 67% of the variance in intention, with Subjective Norms ($B = .20$, $SE = .10$, $p < .05$), Perceived Behavioral Control ($B = .19$, $SE = .07$, $p < .01$), Role Beliefs ($B = .25$, $SE = .10$, $p < .01$), and Moral Norms ($B = .43$, $SE = .09$, $p < .05$) as significant individual predictors.

Conclusions. The TPB is a useful model from which to understand and augment provider attitudes toward weight management in the service of improving overall health and wellness of youth with SED and OW/OB.

RACIAL DIFFERENCES IN THE IMPACT OF INTERPERSONAL TRAUMA ON EATING DISORDERS, SUBSTANCE ABUSE, AND PTSD IN FEMALE VETERANS

Tanisha Thelemaque, M.S., Yongmei Li, Ph.D., Shira Maguen, Ph.D
San Francisco VA Medical Center, San Francisco, CA

Objective: Exposure to potentially traumatic events (PTEs) has been linked to deleterious impacts on health, both mentally and physically. PTEs of an interpersonal nature have been found to have profound impacts on well-being and health behaviors. The purpose of the present study is to examine the impact of interpersonal trauma (e.g., sexual and physical assaults) and self-identified race on eating, substance use, and PTSD-related behaviors in a sample of diverse women veterans.

Method: Participants were women veterans aged 18–70 who utilized VA medical center services, without psychotic disorders or suicidal ideation ($N = 407$). In a survey-based cross-sectional study, we used univariate descriptive statistics and logistic regression analyses to determine the associations between psychopathology, interpersonal trauma exposure, and race/ethnicity.

Results: Those with an experience of physical and/or sexual violence ($n = 154$) were compared to those without interpersonal trauma experience ($n = 253$). Both groups were diverse in terms of race/ethnicity with 40% identifying as non-White or Caucasian as well as military background. It was found that, compared with those who did not experience trauma, participants with interpersonal trauma exposure had a 4.34-fold increase in the odds (95% CI: 2.69–7.01) of meeting the criteria for PTSD diagnosis, and had a 2.39-fold increase in the odds (95% CI: 1.33–4.28) of having any eating disorder (e.g., bulimia, anorexia, binge eating disorder). Compared to White female veterans, Asian women had a 3.74-fold increase in the odds (95% CI: 1.38-10.16) of having any eating disorder. Experiencing interpersonal trauma was not associated with substance use disorders in the present sample.

Limitations: The current study utilized self-report and was cross-sectional. Additionally, the results may not be generalized to veterans who have not utilized VA medical center services.

Conclusions: Experiencing interpersonal trauma is associated with eating disorders and PTSD diagnoses, suggesting that targeted mental health screening efforts may be helpful. Consideration of racial/ethnic difference among female veterans seeking health care at the VA can also facilitate more targeted prevention and treatment services.

THE ASSOCIATION BETWEEN ASPECTS OF SOCIAL SUPPORT AND DEPRESSIVE SYMPTOMS AMONG PERMANENT SUPPORTIVE HOUSING RESIDENTS

Esther J. Holmes, MPH, CHES[®]¹, Scott T. Walters, PhD²¹UNT Health Science Center, School of Public Health, Fort Worth, TX; ²UNT Health Science Center, Fort Worth, TX

Background: Depression is a significant public health issue that disproportionately affects underserved and low-income populations. Previous research tends to show an association between social support and depressive symptoms. However, there are multiple aspects of social support, and the type of support that is associated with depression in underserved populations is unclear. Understanding the type(s) of social support associated with depression can help guide mental health interventions in this population. Therefore, the purpose of this study was to assess the association between three dimensions of social support (i.e., appraisal, tangible, and belonging) and depressive symptoms.

Methods: Baseline data was analyzed from 420 adults participating in m.chat, a technology-assisted health coaching program for people with mental health symptoms, residing in permanent supportive housing in Ft. Worth, TX. Social support was measured using a modified version of the Interpersonal Support Evaluation List (ISEL), and depressive symptoms were measured using the Patient Health Questionnaire (PHQ-9). Multiple linear regression was used to assess the influence of three aspects of social support (i.e., appraisal, tangible, and belonging) on depressive symptoms, adjusting for age, gender, ethnicity, marital status, diet, physical activity and smoking years.

Results: An increased sense of belonging was significantly associated with reduced depressive symptoms ($p = 0.0029$). However, there was not a significant association between appraisal ($p = 0.0846$) or tangible ($p = 0.3729$) social support and depressive symptoms.

Conclusions: Increasing perceptions of tangible (e.g., availability of help or assistance) and appraisal (e.g., availability of advice or guidance) dimensions of social support may have less influence on depressive symptoms. Mental health interventions among underserved populations may improve their effectiveness in reducing depressive symptoms by focusing on increasing a sense of belonging (e.g., group affiliation or inclusion) among participants.

PROGNOSTIC UNDERSTANDING: PERSPECTIVES OF ADVANCED CANCER PATIENTS

Melissa Masterson, MA¹, Barry Rosenfeld, PhD², Allison Applebaum, PhD³, Kara Buda, MA³, Sally Reisch, BA³¹Fordham University, New York, NY; ²Fordham University, Department of Psychology, Bronx, NY; ³Memorial Sloan Kettering Cancer Center, New York, NY

Background: Comprehensive health information is one of the most important decision-making tools that can be provided to advanced cancer patients. However, research shows that nearly 50% of cancer patients do not fully understand their prognosis. Lack of prognostic awareness has been linked to a range of psychosocial and medical outcomes including unnecessary and unwanted hospital admissions, deaths in acute care settings, late referral to palliative care services, poor symptom control, insufficient end of life planning, increased depression and anxiety, and ultimately reduced patient autonomy.

Despite the importance of prognostic understanding, research efforts have been hindered by the lack of a systematic, structured assessment of prognostic understanding. This study implemented a Thematic Content Analysis framework to characterize prognostic understanding in the advanced cancer setting.

Method: 28 advanced cancer patients participated in semi-structured interviews which focused on identifying the breadth of factors underlying prognostic understanding. Three independent raters utilized a Thematic Content Analysis framework for data reduction, to identify core themes that reflect unique aspects of prognostic understanding.

Results: Participants were 64% female ($n = 18$) and had a mean age of 59 ($SD = 13.1$). The sample was ethnically diverse: 36% Caucasian, 36% Hispanic, and 28% African American. 50% ($n = 5$) of the patients who identified as Hispanic were monolingual Spanish speakers. Thematic Content Analysis discovered 5 overarching themes related to prognostic understanding: understanding of current state of disease (100%), understanding of prognosis (100%), preferences for information (96%), communication (79%), and medical uncertainty (25%). Additionally, 21 specific facets of information were identified within each overarching theme. Patients most commonly reported the goal of their treatment (89%), the stage of their disease (75%), their treatment regimen (64%), their response to treatment (64%), and the importance of receiving prognostic information (64%).

Conclusions: Thematic Content Analysis results demonstrated 5 overarching themes and 21 specific facets of information related to prognostic understanding. These results illustrate the multidimensional nature of prognostic understanding and support the development of a comprehensive, multi-faceted assessment tool to assess this important construct. Future research initiatives should focus on the development and pilot testing of such a measure that can be utilized to better understand the phenomenology of prognostic understanding and its'; correlates in the context of advanced cancer.

AN EXAMINATION OF THE FULD OBJECT MEMORY EVALUATION IN ASSESSING EPISODIC MEMORY AND RETRIEVAL IN CHINESE ELDERLY

Rainbow T. H. Ho, Prof¹, Ted C. T. Fong, MPhil², Tiffany Hon, Ms³, Bing-yu Li, BSocSc⁴, Wai Chi Chan, Clinical Associate Professor⁵, Joseph SK. Kwan, Associate Professor⁶, Patrick Ka Chun Chiu, Honorary Clinical Associate Professor⁷, Linda Chiu Wa Lam, Professor⁸

¹Centre on Behavioral Health, The University of Hong Kong, Hong Kong, N/A, Hong Kong; ²Centre on Behavioral health, Hong Kong, N/A, Hong Kong; ³Centre on Behavioral Health, The University of Hong Kong, Hong Kong, Hong Kong, N/A, Hong Kong; ⁴Department of Social Work and Social Administration, Hong Kong, N/A, Hong Kong; ⁵Department of Psychiatry, The University of Hong Kong, Hong Kong, Hong Kong, N/A, Hong Kong; ⁶The University of Hong Kong, Hong Kong, N/A, Hong Kong; ⁷Department of Medicine, The University of Hong Kong, Hong Kong, Hong Kong, N/A, Hong Kong; ⁸Department of Psychiatry, The Chinese University of Hong Kong, Hong Kong, Hong Kong, N/A, Hong Kong

Introduction: Mild cognitive impairment (MCI) refers to an early but abnormal state of cognitive impairment between normal ageing and dementia (Petersen et al., 1999). Fuld Object Memory Evaluation (FOME) assesses the episodic memory functions of older adults across five recall trials and a delayed trial. Research Design: This study evaluated the psychometric properties of FOME in a sample of 204 Chinese older adults with cognitive impairments in Hong Kong. Discriminative power of FOME was inspected via receiver operating characteristic curve analysis.

Results: FOME showed good test-retest reliability and significant correlations with backward digit span, trail making and daily functioning. Total retrieval and verbal fluency significantly predicted lower likelihoods of dementia comparing to MCI, with optimal cut-off scores at 36 (75% sensitivity, 79% specificity) and 27 (91% sensitivity, 69% specificity), respectively.

Conclusions: The findings support FOME as a clinically valid assessment tool of various degrees of cognitive impairment in older Chinese adults. Future studies could further examine the predictive power of FOME in differentiating cognitively normal elderly from both MCI and dementia cases.

ASSESSING PHYSICAL ACTIVITY IN PEOPLE WITH MENTAL ILLNESS: VALIDATION OF THE SIMPLE PHYSICAL ACTIVITY QUESTIONNAIRE (SIMPAQ)

Simon Rosenbaum, PhD¹, Rachel Morell, AEP, B.ExPhys², Philip B. Ward, BMedSc, PhD³

¹UNSW Sydney, Sydney, New South Wales, Australia; ²UNSW Bondi Junction, New South Wales, Australia; ³UNSW Sydney, Liverpool BC, New South Wales, Australia

Background: Physical inactivity is a key contributor to the global burden of disease. However, insufficient physical activity disproportionately affects vulnerable populations such as those experiencing mental illness, despite increases in physical activity being associated with improvements in symptoms of mental illness in addition to a reduction of cardiometabolic risk. Ensuring valid and reliable clinical tools are available to assess physical activity within clinical mental health settings is of clear significance.

Methods: Between 2014 and 2016 the International Working Group developed the five-item SIMPAQ as an instrument to assess physical activity and sedentary behaviour among populations at risk of engaging in high levels of sedentary behaviour. During 2016/2017, 42 centres from 23-countries collected reliability and validity data on the SIMPAQ from patients with mental illness. Test-retest repeatability was assessed one-week apart. Criterion SIMPAQ validity was assessed against the Actigraph Gt3x accelerometer. Spearman's correlation coefficients will be reported.

Results: Data collection was completed in July 2017. N=1,059 participants were recruited from 42 centres across 23-countries including representation from lower-middle (India n=72, Nigeria n=10, Pakistan n=95), upper-middle (Brazil n=34; Iran n=47) and high-income countries (Australia n=150; Belgium n=35; Canada n=30; Chile n=18, Czech Republic n=8; Denmark n=23; Germany n=67; Hong Kong n=13; Ireland n=23; Italy n=117; Japan n=19; Netherlands n=20; Norway n=20; Portugal n=15; Spain n=36, Switzerland n=157; Taiwan n=37; USA n=13).

Conclusion: The validity and reliability of the SIMPAQ as a clinical measure to assess physical activity and sedentary behaviour among a diverse sample of people with mental illness will be reported.

COMPARING HEALTH BEHAVIOR RESEARCH FINDINGS FROM CONVENIENCE AND PROBABILITY SAMPLES

Michelle Jeong, PhD¹, Dongyu Zhang, ScM, MD¹, Jennifer C. Morgan, PhD², Jennifer Cornacchione Ross, PhD³, Amira Osman, PhD⁴, Marcella H. Boynton, PhD¹, Jennifer R. Mendel, MPH¹, Noel T. Brewer, PhD¹

¹University of North Carolina, Chapel Hill, NC; ²University of Pennsylvania, Philadelphia, PA; ³Wake Forest School of Medicine, Winston Salem, NC; ⁴University of North Carolina, Carrboro, NC

Background. Online convenience samples are a quick and low-cost way to study health behavior, but the comparability to findings from probability samples is not yet well understood.

Purpose. We sought to compare convenience and probability samples'; findings for experiments, associations, and prevalence in the context of health behavior research.

Methods. Participants were a probability sample of 5,014 US adults recruited by phone from September 2014 through May 2015 (cost ~ \$620,000 US) and an online convenience sample of 4,137 US adults recruited through Amazon Mechanical Turk (MTurk) in December 2014 (cost ~ \$17,000 US). Participants completed a survey with experiments, measures of tobacco product use, and demographic characteristics. We compared the statistical significance and direction of experimental findings, and statistically compared estimates for non-experimental associations and prevalence.

Results. MTurk convenience and probability samples showed the same pattern of statistical significance and direction in almost all experiments (19 of 22 analyses did not differ) and non-experimental associations (19 of 25 associations did not differ). Demographic characteristics of the samples differed substantially (1 of 17 estimates did not differ), with the convenience sample being younger, having more years of education, and including more Whites and Asians. Tobacco product use also differed substantially (1 of 22 prevalence estimates did not differ), with the convenience sample reporting more cigarette and e-cigarette use (median error 19%).

Conclusions. Using MTurk to recruit convenience samples can be a low-cost method that yields generalizable findings for experiments and association in the context of health behavior research. Prevalence estimates from MTurk convenience samples are likely to be over- or underestimates and should be interpreted with caution.

COMPARISON OF SINGLE AND DUAL FREQUENCY BIA WITH SKINFOLD CALIPERS FOR MEASUREMENT OF BODY COMPOSITION IN HISPANIC WOMEN

Jacob Szeszulski, MA¹, Elizabeth Lorenzo, BSN, RN¹, Anel Arriola, BS¹, Rebecca E. Lee, PhD²¹Arizona State University, Phoenix, AZ; ²Arizona State University, Phoenix, AR

Background: Bioelectrical impedance (BIA) is a common, convenient, and less invasive method to measure body composition (BC) compared with the more accurate and invasive method of skin fold testing. BIA measures BC by capturing the speed at which a current travels through the body. A single frequency (SF) current has been the industry standard, but more recently dual frequency (DF), which uses two currents at different speed, has become available. The purpose of this study was to examine the criterion validity of SF and DF BIA scales, with BC measured by skinfold calipers, among Hispanic women.

Methods: Hispanic mothers ($N=14$), age 30.8 ± 6.0 years old, with a mean BMI of $31.3 \pm 8.2 \text{ kg/m}^2$ (Range= 27.0 , min= 21.5 , max= 48.5), were measured twice consecutively by SF BIA, DF BIA, and skinfold calipers. Three site skinfold measures were taken (triceps, suprailliac, and abdominal) by trained assessors, and Hispanic specific BC equations were used to determine percent body fat. Intra-rater and inter-rater reliability were calculated between measures. Bland-Altman plots were used to examine agreement of each BIA measure with skinfold calipers.

Results: Intra-rater reliability was perfect between measurements of SF and DF BIA ($\alpha=1.0$), while sum of skinfolds was only slightly lower for triceps ($\alpha=.994$), suprailliac ($\alpha=.971$), and abdominal ($\alpha=.920$) sites. DF ($M=39.5 \pm 7.5$) and SF ($M=39.4 \pm 7.5$) measures were highly correlated ($r=.884$; $p<.001$) and had an absolute mean difference of $3.1 \pm 1.7\%$ (Range= 5.3 , min= $.7$, max= 6.0). Body fat caliper measures ($M=39.6 \pm 7.6$) were more strongly correlated with SF ($r=.889$; $p<.000$) measures than DF ($r=.830$; $p=.002$) measures and had a smaller absolute mean difference ($3.1 \pm 2.1\%$; Range= 6.35 , min= $.07$, max= 6.42 vs. $3.3 \pm 3.1\%$; Range= 8.71 , min= $.02$, max= 8.73). Bland-Altman plots revealed that SF BIA had a smaller confidence interval than DF (-5.5 through 8.7 vs. -7.8 through 10.0), but a less accurate point estimate (1.6 vs. 1.1).

Conclusion: Although the differences between SF and DF BIA appear to be small when compared with skin folding calipers, the SF BIA has stronger criterion related validity in Hispanic women and has similar measurement value compared to DF BIA, at a lower cost. We recommend further research investigate the value of DF BIA across other populations and compare with more precise measures of body composition (dual energy x-ray absorptiometry, underwater weighing) before researchers invest in DF technology.

6:30 PM-7:30 PM

EFFECTIVENESS OF SOCIAL MEDIA APPROACHES TO RECRUITING YOUNG ADULT LITTLE CIGAR SMOKERS

David N. Cavallo, PhD, MPH¹, Maria E. Pagano, PhD¹, Rock Lim, BS¹, Karen J. Ishler, PhD¹, Elizabeth Antognoli, PhD¹, Sarah Koopman Gonzalez, PhD¹, Erika Trapl, PhD¹, Susan Flocke, Flocke²¹Case Western Reserve University, Cleveland, OH; ²Susan, Cleveland, OH

Background: The popularity of social media (SM) among young adults suggests the use of these platforms for study recruitment of this age group. SM is used in large numbers by low-SES individuals and minorities, indicating it also may be an effective strategy for reaching individuals more difficult to recruit with traditional strategies. Previous studies have examined the use of SM for study recruitment, but few have compared recruitment rates across different platforms, and none to our knowledge have recruited little cigar and cigarillo (LCC) users.

Objective: To examine the effectiveness of different SM platforms and advertisement images for recruiting 14–28 year old LCC users to complete an eligibility screener for an LCC use survey.

Methods: We obtained data for advertisement impressions, costs, and engagements from Facebook and Twitter advertising management platforms for a two-month recruitment campaign in 2017. Advertisements were targeted to age group (14–28 years old), geography (Cleveland and Baltimore), and interests (e.g., Tobacco smoking). Advertisement effectiveness was defined as the percentage of completed screeners per impression. Chi-square tests were used to compare the rate of completed screeners per impression across social media platform and advertisement types.

Results: Screener completers ($n=1,913$) reported a mean age of 26 years. Of the screener completers who completed the LCC use survey ($n=393$), 51% identified as male, 34% as African American, and 8% as Hispanic. The campaign delivered 1,237,721 impressions with a cost of \$5.31 per completed and \$11.19 per approved screener. Advertisements delivered via Facebook/Instagram were more effective than Twitter (.19% vs. .14%, $\chi^2(1, N=1,237,721) = 41.22, p < .0001$). Across platforms, ads featuring exclusively an image of a little cigar were more effective (.39%) than ads with images of an individual smoking (.13%), an individual not smoking (.10%), or a group of individuals not smoking (.10%), $\chi^2(3, N = 1,237,721) = 886.80, p < .0001$.

Implications: The 2-month advertising campaign was effective in recruiting a diverse sample of young adults representative of racial/ethnic categories. Cost effectiveness of the campaign was similar to other tobacco SM recruitment campaigns, which have reported costs of \$8.80 per consent and \$4.37 per eligible participant. Advertisements on Facebook/Instagram were more effective than Twitter. Given our inability, however, to determine how many individuals in the sample use both, it may be that using multiple platforms remains the optimal recruitment strategy. Including a cigarillo image in advertisements was consistently the most effective advertisement design and should be considered by others recruiting LCC users via SM.

6:30 PM-7:30 PM

EVALUATING THE REPRODUCIBILITY OF AMBULATORY BLOOD PRESSURE VARIABILITY

Larisa Gavrilova, Doctoral Student¹, Matthew Zawadzki, Ph.D.¹, Tanya Spruill, Ph.D.²¹University of California, Merced, Merced, CA; ²New York University, School of Medicine, New York, NY

Ambulatory blood pressure (ABP) involves repeated measurements of BP in one's environment. Averages of these measurements predict cardiovascular disease and mortality. Yet, there is a growing recognition that oscillations in ABP – ABP variability – may be associated with cardiovascular risk independent of ABP mean. However, it is unclear if ABP variability is stable over time, which would help determine its importance as a risk factor and potential treatment target. The goal of the study was to examine the reproducibility of ABP variability across two observational, longitudinal studies. Participants were recruited from the New York City area. SpaceLabs ABP monitors were used to collect ABP readings over multiple 24-hour periods: three times, one month apart in Study 1; and twice, up to four months apart in Study 2. Readings were taken every 30 minutes in Study 1 and every 20 minutes in Study 2. Study 1 included 295 participants (55.3% female; $M \pm SD_{age} = 50.2 \pm 15.2$; 30.3% Black; 43% hypertensive). Study 2 included 282 participants (53.2% female; $M \pm SD_{age} = 39.3 \pm 11.2$; 56.6% Black; 4.2% hypertensive). ABP mean and variability (defined as the standard deviation) were calculated for daytime (6am-10pm) and nighttime (10pm-6am) periods. Bivariate and partial correlations (adjusted for age, sex, race, and body mass index) were conducted between each of the ABP sessions, separately for systolic BP (SBP) and diastolic BP (DBP). ABP mean was highly reproducible for daytime and nighttime SBP and DBP in both studies ($r_s > .66$). For variability, in Study 1, moderately strong relationships were found for daytime SBP and DBP ($r_s > .36$). Nighttime ABP variability sessions one month apart were related ($r_s > .45$), but the sessions two months apart did not have significant relationships. In Study 2, with sessions four months apart, no significant relationships were found for daytime and nighttime SBP and DBP variability, except daytime DBP ($r = .22$). Similar findings were observed in adjusted analyses. Results of the study are consistent with the evidence that ABP is consistent over time. Yet, ABP variability tended to be only reproducible with measurements closer in time, suggesting that ABP variability reflects changes in response to one's environment. These findings highlight the critical role of timing between the ABP measurement periods and support the notion that ABP variability is independent to ABP mean.

IDENTIFYING HEALTH BEHAVIOR CHANGE MECHANISMS: CHALLENGES FACED IN A META-REVIEW OF META-ANALYSES

Emily A. Hennessy, MPhil, PhD¹, Rebecca L. Acabchuk, PhD², Blair T. Johnson, PhD¹, Kiran McCloskey, BA Psychology, MSc Health Psychology³, Meiko Howell, M.A., Psy.S.⁴, Sahar Iqbal, Political Science, Health and Law⁵, Jania A. Stewart-James, N/A⁶, Kiiana A. McDavid, Bachelor of Science in Public Health⁷¹University of Connecticut, Storrs, CT; ²University of Connecticut, Hebron, CT; ³University of Connecticut, Mansfield Center, CT; ⁴University of Connecticut, Enfield, CT; ⁵University of Connecticut, Danbury, CT; ⁶University of Connecticut, Bridgeport, CT; ⁷University of Connecticut, Plantsville, CT

An overwhelming body of primary study and systematic review literature evaluates health behavior interventions. Meta-reviews (i.e., overviews), can synthesize this literature to improve its utility in basic and applied health sectors; yet, a synthesis is only useful if it identifies new themes across the literature that single reviews could not, by, for example, focusing on identifying effective components of behavioral interventions instead of simply validating intervention effectiveness. However, a limitation of overviews is that important nuances of behavior change interventions can be difficult to address, especially when seeking details from meta-analytic literature, which is once removed from the primary studies represented.

The aim of this presentation is to address the methodological challenges and opportunities involved in conducting a comprehensive and systematic overview of meta-analyses that have appeared since 2006 that examine self-regulation mechanisms driving behavior change interventions across a broad range of health behaviors linked to chronic diseases. Specifically, this overview seeks to identify tests of putative target mechanisms involved in health behavior change, permitting conclusions about whether an intervention is effective, as well as why it works, and at the same time documenting whether these conclusions rest on high quality review methods. By identifying key individual-level mechanisms of health behavior change, this overview promises to identify and evaluate the mechanisms by which interventions improve health behaviors, which ultimately should reduce the burden of chronic disease.

Due to the broad review scope, 12,326 abstracts from 7 electronic databases were identified as potentially eligible. The methodological challenges identified include: setting the review scope, developing and utilizing a logic model, selecting appropriate search terms and strings, and choosing literature sources. We discuss practical opportunities that emerge in addressing these challenges. Mechanisms addressed in a sample of the current review literature are presented to illustrate what to expect when conducting such a broad literature synthesis and how to use a logic model to guide the analysis and presentation of results (e.g., determining which domains of research are most in need of new, high-quality systematic reviews). The overview promises to leverage the extensive work that past meta-analysts have put into their systematic reviews.

ONLINE RECRUITMENT AND RETENTION METHODS FOR HIV PREVENTION RESEARCH AMONG ADOLESCENT MALES INTERESTED IN SEX WITH MALES (AMSM)

Kimberly Nelson, PhD, MPH¹, Jaime J. Ramirez, BA², Michael Carey, PhD¹¹Brown University, Providence, RI; ²Centers for Behavioral and Preventative Medicine, The Miriam Hospital, Providence, RI**BACKGROUND:** Adolescent males interested in sex with males (AMSM) are an important audience for HIV prevention interventions but they are difficult to reach due to their age and social stigma. We sought to identify efficient methods to recruit and retain AMSM in online research.**METHODS:** Interviews with AMSM ($N=16$; ages 14–18; 50% racial/ethnic minority; 69% gay-identified; 75% sexually active in the last year) were conducted at 2017 Pride events in Boston, MA and Providence, RI. Interviews took approximately 20 minutes and covered topics including social media website and phone application (“app”) use, where to advertise online, what to include in online advertisements, and potential methods to increase retention in longitudinal studies conducted online.**RESULTS:** AMSM participants reported that they used Facebook (94%), YouTube (88%), Snapchat (81%), and Instagram (81%). Instagram (75%), Snapchat (69%), and Facebook (63%) were identified as the best websites/phone apps to advertise on. Participants said online advertisements should include a brief description of the study with short phrases and bullet points (63%), colorful and bright pictures (56%), compensation details (56%), and familiar/comfortable words (50%). The majority (56%) would complete a 10–20 minute survey. Information about compensation (69%), the length of surveys (63%), and what kinds of questions would be asked (63%) were identified as important information to provide. The majority said that sending reminders between study activities (94%) and providing compensation (75%) would increase retention. Participants preferred an email gift card (69%). More than half (56%) said that \$10–\$20 is fair compensation for a 30 minute online survey.**CONCLUSIONS:** These results can inform recruitment and retention procedures in online HIV prevention research targeting AMSM. Designing procedures with the input of the target audience (i.e., AMSM) will increase the efficiency, reach, validity, and scientific yield of HIV prevention research. This yield, in turn, can facilitate the development of online HIV prevention interventions that address HIV disparities among this at-risk group.**CORRESPONDING AUTHOR:** Kimberly Nelson, PhD, MPH, Brown University, Providence, RI; kimberly_nelson_1@brown.edu

PICKING UP THE PACE: THE CASE FOR MIXED METHODS PSYCHOMETRIC RESEARCH IN PHARMACEUTICAL CLINICAL TRIALS

Jessica Markowitz, PhD¹, Antoine Regnault, PhD², Sophie Cleanthous, PhD, CPsychol³, Patrick Marquis, MD, MBA¹, Stefan Cano, PhD, CPsychol, AFBPsS³¹Modus Outcomes, Cambridge, MA; ²Modus Outcomes, Lyon, N/A, France; ³Modus Outcomes, Letchworth Garden City, N/A, United Kingdom

The patient perspective is now a central element in the evaluation of new therapies in pharmaceutical clinical trials. The increasing requirement of well targeted, fit-for-purpose patient-centered outcome measures (PCOMs) in a fast-moving industry has necessitated a rethink in methodology to develop and evaluate instruments.

Traditional psychometric research entails a three-step approach: item generation (usually involving qualitative research), followed by a first field test (to reduce the number of questions and form scales), followed by a second field test (to establish psychometric properties). The field tests are quantitative in nature. This linear approach usually takes a long time to complete and is risky. This is because qualitative methods alone cannot tell us about the extent to which concepts are measurable including: how well targeted the questions are to the type and range of issues experienced by patients; how well the questions work together as a set; and whether the response options are working as intended. Conversely, quantitative methods alone cannot tell us which concepts should be, and/or are purported to be, measured.

Mixed methods psychometric research provides an alternative approach to developing PCOMs. It requires an iterative, hypothesis-based, experimental approach to provide early empirical evidence about the relevance of the concepts under scrutiny, as well as the extent to which the questions are matched to the study sample, identify potential gaps in measurement, and provide key information about the adequacy of the response options. The synthesis of qualitative and quantitative data strengthens the development process and can lead to various actions such as revisiting the qualitative data, conducting more qualitative research, or providing confidence to take the next steps.

We illustrate these methods via a case study using the ABILHAND-56, a PCOM of manual ability, in a sample of patients with Multiple Sclerosis (MS, $n=118$). This mixed methods psychometric study focused on improving the targeting and sensitivity of the ABILHAND by adding new, targeted bolt-on items. Our findings suggested the ABILHAND provides better interpretable data when considered as a two-subscale instrument (i.e., Fine Motor and Power). Also, adding 20 additional items improved targeting, leading to a reduced ceiling effect, better precision, and therefore a more fit-for-purpose instrument to measure clinical change in future clinical trials.**CORRESPONDING AUTHOR:** Jessica Markowitz, PhD, Modus Outcomes, Cambridge, MA; jessica.markowitz@modusoutcomes.com

RESILIENCE RESOURCES SCALE (RRS): A NEW RESILIENCE MEASURE FOR ADOLESCENTS AND EMERGING ADULTS

Melissa Julian, B.A.¹, Alyssa C.D. Cheadle, Ph.D.², Robert M. Bilder, Ph.D.¹, Kendra S. Knudsen, B.S.¹, Christine Dunkel Schetter, Ph.D.¹¹University of California, Los Angeles, Los Angeles, CA; ²Hope College, Holland, MIResilience resources are defined as resources that promote the capacity to withstand and cope with demands while maintaining healthy functioning in various life domains. These resources are important to evaluate in the context of adolescence and emerging adulthood when navigating unique risks and new opportunities can have a significant impact on mental and physical health. Thus, it is crucial for researchers to be able to effectively assess the pertinent resilience resources during this developmental period. This study addresses the reliability, validity, and factor structure of the Resilience Resources Scale (RRS), a new 12-item self-report questionnaire briefly measuring multiple resources that contribute to resilience capacity. The scale's items assess self-esteem, mastery, optimism, familism, spirituality, and social support seeking skills which represent the majority of the most frequently cited resilience resources associated with both mental and physical health in adolescents and adults. The analytical sample included 295 undergraduate students who participated in the UCLA Stress and Resilience Assessment (SARA) Project. Participants either completed the RRS at one of two time points eight weeks apart ($n = 193$), or at both time points ($n = 102$). The factor analysis results provide evidence for a single factor structure and the scale's internal consistency was high ($\alpha = 0.90$). For the subset who took the instrument twice, the mean scores showed strong agreement with an intra-class correlation coefficient of 0.74 ($p < .001$, 95% CI [.64, .82]). Results indicated total scores on the resilience scale at the first time point were significantly correlated with standardized measures of life satisfaction ($r = .65$, $p < .001$), positive affect ($r = .64$, $p < .001$), depression ($r = -.64$, $p < .001$), anxiety ($r = -.39$, $p < .001$), and negative affect ($r = -.51$, $p < .001$) at the second time point as expected, indicating good predictive validity. In sum, the RRS has sound psychometric properties and can be used to evaluate core psychosocial resources that contribute to the construct of resilience in adolescence and emerging adulthood.**CORRESPONDING AUTHOR:** Melissa Julian, B.A., University of California, Los Angeles, Los Angeles, CA; mjulian@psych.ucla.edu

6:30 PM-7:30 PM

UNC PERCEIVED MESSAGE EFFECTIVENESS SCALE (UPMES): DEVELOPMENT AND VALIDATION OF A BRIEF SCALE

Sabeeh A. Baig, MS¹, Seth M. Noar, PhD¹, Nisha C. Gottfredson, PhD², Marcella H. Boynton, PhD¹, Kurt M. Ribisl, PhD¹, Noel T. Brewer, PhD¹

¹University of North Carolina, Chapel Hill, NC; ²UNC Gillings School of Global Public Health, Chapel Hill, NC

Introduction: Perceived message effectiveness (PME) is a common metric for identifying promising health messages, but standardized measures are few, lengthy, and assess constructs distal to behavior. We sought to establish the psychometric properties of the UNC Perceived Message Effectiveness Scale (UPMES) in the context of messages about the harms of chemicals in cigarette smoke.

Methods: Participants were a national convenience sample of 999 adults and national probability samples of 1,692 adults and 869 adolescents, recruited in 2015. Participants included smokers and nonsmokers who rated 10 brief messages. The UPMES has three items: “This message makes me concerned about the health effects of smoking”; “This message discourages me from wanting to smoke”; and “This message makes smoking seem unpleasant to me”. Response options ranged from “strongly disagree” to “strongly agree”.

Results: Results were similar across samples and messages. The UPMES was strongly unidimensional across the brief messages (all factor loadings ≥ 0.75). The scale had high reliability ($\alpha \geq 0.85$) over a large standardized range of PME scores (range $z = -3$ – 0.5), indicating a ceiling effect. The UPMES demonstrated convergent validity through very strong correlations with the established Davis Perceived Message Effectiveness Scale (average $r = 0.83$) and strong correlations with message credibility (average $r = 0.57$), and discriminant validity through a modest correlation with message reactance (average $r = -0.47$). The scale did not exhibit appreciable differential test functioning by education, sex, or smoking status (range Cohen’s $d = -0.1$ – 0.1).

Conclusions: The UPMES reliably and validly measures PME among adults and adolescents who differ on demographic characteristics that influence smoking disparities. The scale’s wording is general enough that it may be suitable for use in developing short messages for other risk behaviors.

VALIDITY OF THE DAILY MINUTES OF UNPROTECTED SUN EXPOSURE (MUSE) INVENTORY

Tammy Stump, PhD¹, Lisa G. Aspinwall, PhD², Nenita Maganti, BS³, June K. Robinson, MD⁴

¹Northwestern University, Chicago, IL; ²University of Utah, Salt Lake City, UT; ³Feinberg School of Medicine, Chicago, IL; ⁴Northwestern Univ Feinberg School of Medicine, Chicago, IL

Rates of skin cancer, including melanoma, continue to increase, indicating a need for more research and interventions targeting daily sun protection. To support these efforts, we developed the Daily Minutes of Sun Exposure (MUSE) Inventory. On the Daily MUSE, participants are asked to report their sun protection during specific self-reported activities. These responses yield several useful metrics on sun exposure, including total outdoor time, percentage of outdoor time particular sun-protection strategies are used, and, uniquely, duration of sun exposure received on various body sites, regardless of the method(s) of sun protection used. The present study provides initial validation data for the Daily MUSE among a sample of melanoma survivors who were asked to complete the daily MUSE for 10 consecutive days while wearing a UV sensor to objectively assess time outdoors. Following the 10-day study, participants completed the widely-used Sun Habits Survey.

On the Daily MUSE, participants ($N=31$, mean age=58.63, $SD=13.01$, 64.5% female) reported an average of 89.66 daily minutes outdoors ($SD=108.24$). Using multilevel modeling on the daily-level data, analyses showed that outdoor time reported in the Daily MUSE predicted outdoor time recorded by the UV sensor, $B=.54$, $p<.001$. Next, the percentage of outdoor time each particular sun protection habit was reported in the Daily MUSE during the 10-day study was calculated; a series of bivariate correlation analyses assessed the association between these MUSE percentages and corresponding items in the Sun Habits Survey. MUSE percentages were significantly correlated with the corresponding items from the Sun Habits Survey for wearing hats, sunscreen, a shirt with sleeves, and sunglasses, ($r_s=.53$ – $.90$, $p<.05$). MUSE percentage for shade use was not significantly associated with the Sun Habits measure of shade use, $r=-.01$, $p=.13$, which suggests that this sun protection habit may be more difficult to recall over a longer interval than at the end of the day. In summary, the Daily MUSE corresponds with an objective measure of exposure and a widely-used survey of sun habits, but differs from these measurement approaches because it will ultimately provide sun exposure scores which account for multiple, potentially overlapping methods of protection. We expect this new metric to be useful for both assessing and delivering feedback regarding change in sun exposure over time in melanoma survivors and other high-risk populations.

PREDICTORS OF DIET QUALITY AND PHYSICAL ACTIVITY IMPROVEMENTS IN A WEIGHT LOSS PROGRAM FOR OVERWEIGHT VETERANS WITH PTSD

Katherine D. Hoerster, PhD, MPH¹, Kristen E. Gray, PhD, MS², Tracy Simpson, PhD³, Jürgen Unützer, MD, MPH, MA⁴, Brian Saelens, Ph.D.⁵, Gayle Reiber, PhD⁶, Karin Nelson, MD, MSHS³

¹VA Puget Sound Healthcare, Seattle and University of Washington, Seattle, WA; ²VA Puget Sound Health Services Research & Development, Seattle, WA; ³VA Puget Sound Healthcare System, Seattle Division, Seattle, WA; ⁴University of Washington, Department of Psychiatry and Behavioral Sciences, Seattle, WA; ⁵University of Washington / Seattle Children's Research Institute, Seattle, WA; ⁶University of Washington School of Public Health, Seattle, WA

Background: Post-traumatic stress disorder (PTSD) is a risk factor for obesity. Because VA's weight loss program MOVE! is less effective for Veterans with PTSD, we developed MOVE!+UP, a 16-week weight loss program for Veterans with PTSD. MOVE!+UP is delivered in group and phone sessions by a peer support counselor. MOVE!+UP participants only lost an average of 1.8 pounds at 16 weeks. To inform changes that will help future MOVE!+UP participants lose weight, this study examines predictors of improved diet quality and physical activity among MOVE!+UP pilot participants.

Methods: We piloted MOVE!+UP among four cohorts of overweight Veterans with PTSD (12/2015–6/2017; N=34). Using established measures, we assessed diet quality and physical activity outcomes, and psychological (e.g., self-efficacy), behavioral (e.g., eating habits such as overeating), and social support predictors. We identified associations of baseline-to-16-week change in predictors with baseline-to-16-week changes in diet and physical activity. Associations ($p < .05$) in unadjusted linear regressions were included in multivariable linear regression models.

Results: Diet quality improved significantly but changes were modest (Mean improvement=2.6 (SD=3.7) on a 16-point scale). Conversely, physical activity changes were substantial (Mean increase=280 weekly minutes (SD=774)) but non-significant ($p = .09$). Improved self-efficacy for healthy eating, eating habits, perceived neighborhood support, using healthy eating behavioral strategies, and social support for healthy eating were associated with improved diet quality in unadjusted models. The latter two were independently associated with improved diet in multivariable analysis. Improved self-efficacy for physical activity, using physical activity behavioral strategies, and perceived neighborhood support were associated with improved physical activity in unadjusted models. None were independently associated with improved physical activity. We also found PTSD symptoms improved significantly at 16 weeks, by an average of 6.6 points, nearing the 10-point clinically meaningful threshold.

Conclusions: MOVE!+UP must be modified to better target activity and diet in order to help overweight Veterans with PTSD lose weight. Enhancing how MOVE!+UP targets self-efficacy, habits and behavioral strategies, and social support may improve weight loss outcomes produced by MOVE!+UP and other similar programs. Integrating MOVE!+UP into PTSD care may also help treat PTSD. Thus, if MOVE!+UP's effectiveness is optimized, this may be an efficient way of enhancing mental and physical health functioning among overweight Veterans with PTSD.

PRELIMINARY ANALYSIS OF THE IMPACT OF PROBLEM-SOLVING TREATMENT ON SUICIDAL IDEATION AMONG VETERANS WITH CHRONIC PAIN.

Lisa M. McAndrew, Ph.D.¹, Wilfred Pigeon, Ph.D.², Karen S. Quigley, Ph.D.³, David Litke, Ph.D.⁴, Shou-En Lu⁵, Joseph F. Rath, PhD⁶, Carmelen Chiusano, MPA⁷, Drew A. Helmer, M.D.⁴

¹War Related Illness and Injury Study Center, Veterans Affairs, New Jersey Health Care System; Department of Educational and Counseling Psychology, University at Albany, East Orange, NJ; ²Veterans Affairs, Canandaigua, NY; ³Edith Nourse Rogers Memorial VA Hospital, Bedford, MA, Bedford, MA; ⁴War Related Illness and Injury Study Center, Veterans Affairs, New Jersey Health Care System, East Orange, NJ; ⁵Department of Biostatistics, Rutgers School of Public Health, Piscataway, NJ; ⁶NYU Rusk Institute of Rehabilitation Medicine, New York, NY; ⁷VA NJHCS, War Related Illness and Injury Study Center, East Orange, NJ

Introduction: Every day 20 Veterans die from suicide. Suicide prevention treatments are primarily delivered in mental health care settings, and yet 70% of patients at high suicide risk do not seek mental health treatment. Patients with chronic pain (half of Veterans in the VA) have a 3-fold increased risk of attempting suicide and approximately 75% of male Veterans with chronic pain do not use mental health care, and yet are frequent users of primary care for their pain. This represents an unmet opportunity to integrate suicide prevention into chronic pain treatment.

Method: Problem-solving treatment is an evidenced-based behavioral therapy for chronic pain that teaches patients skills in finding solutions to difficult issues. We are currently conducting a randomized controlled trial of problem-solving therapy for Veterans with chronic pain with the goal to improve disability. Suicidal ideation was measured to characterize the sample. We conducted preliminary analysis to determine if there was evidence to support conducting a follow-up clinical trial to specifically target reduced suicidal ideation.

Results: Of the 193 enrolled Veterans, 110 have completed the 12 week assessment with 32 reporting passive ($n=27$) or active ($n=5$) suicidal ideation at either baseline or 12 weeks. Of these 32 Veterans, 88% had suicidal ideation at baseline. At the end of treatment, 40% ($n=6/15$) of Veterans receiving problem-solving treatment had suicidal ideation as compared to 65% ($n=11/17$) of Veterans in the control treatment ($\chi^2=4.03$, $p=.05$). Among the 32 Veterans with passive or active suicidal ideation at either baseline or 12 weeks, problem-solving treatment reduced the intensity of suicidal ideation. We found reduced intensity of suicidal ideation from 5.92 (SD=3.90) to 2.53 (SD=3.68) after 12 weeks, vs. reduction on the same measure in controls from 6.50 (SD=4.20) to 6.06 (SD=4.92) after 12 weeks, $t=2.3$, $p=.03$.

Conclusions: The findings suggest that problem-solving treatment for chronic pain may also decrease suicidal ideation. Chronic pain interventions are delivered in primary care, rehabilitation clinics and also delivered remotely. Integrating suicide prevention into chronic pain treatments increases points of access to suicide prevention treatment. Our findings suggest the need for a larger trial of problem-solving treatment for Veterans with chronic pain and active suicidal ideation.

BEHAVIORAL RESPONSES TO GULF WAR ILLNESS: IMPLICATIONS FOR REDUCING DISABILITY AMONG OUR VETERANS

Nicole Sullivan, Ph.D.¹, Lisa M. McAndrew, Ph.D.², Karen Quigley, Ph.D.³, Wilfred Pigeon, Ph.D.⁴, David Litke, Ph.D.¹, Fiona Graff, Psy.D.¹, L. Alison Phillips, B.A., M.A., Ph.D.⁵, Drew A. Helmer, M.D.¹

¹War Related Illness and Injury Study Center, Veterans Affairs, New Jersey Health Care System, East Orange, NJ; ²War Related Illness and Injury Study Center, Veterans Affairs, New Jersey Health Care System; Department of Educational and Counseling Psychology, University at Albany, East Orange, NJ; ³Interdisciplinary Affective Science Laboratory, Northeastern University; Department of Veterans Affairs, Bedford Memorial Hospital, Bedford, MA; ⁴Center of Excellence for Suicide Prevention, Canandaigua VA Medical Center, Canandaigua, NY USA, Canandaigua, NY; ⁵Psychology Department, Iowa State University; War Related Illness and Injury Study Center, Veterans Affairs, New Jersey Health Care System, Ames, IA

Background: Medically unexplained symptoms (MUS), including chronic pain and fatigue, are among the most prevalent conditions reported by our veterans. MUS are a particular concern for veterans who served in Operation Desert Shield/Operation Desert Storm, with 25–30% reporting chronic, medically unexplained symptoms collectively known as Gulf War Illness (GWI). This condition can be quite disabling. Behavioral treatments are the primary method to improve disability, however the effect size of these treatments is small to moderate suggesting opportunities to better understand the relationship of behavior to disability. In an effort to more fully examine this relationship, the present study assessed Gulf War veterans' behavioral responses to their GWI, and whether these responses were associated with disability.

Methods: 218 Gulf War veterans with GWI participated in a randomized control trial comparing Problem-Solving Treatment to Health Education. The current study analyzed data from the baseline assessment. Participants completed the Behavioural Responses to Illness Questionnaire (BRIQ) and the WHO Disability Assessment Schedule (WHODAS 2.0). The WHODAS 2 provides an overall disability score and 6 subscale scores.

Results: Participants reported that the most common behavioral responses to their GWI were limiting activity or all-or-nothing behaviors (e.g., pushing themselves until they crash). Few reported seeking emotional support. In terms of the relationship between behavioral responses and disability, regression analyses showed that limiting behaviors ($\beta = .265, p < .001$), all-or-nothing behaviors ($\beta = .189, p < .01$), and seeking practical support ($\beta = .225, p < .01$) were all related to overall disability. These three behaviors were related to higher disability for the subscales of cognition, mobility, engagement in daily activities, and participation in society. Limiting behavior was also associated with disability on the getting along with others subscale, and both limiting behaviors and practical support seeking were associated with greater disability on the self-care subscale.

Conclusion: These results highlight the relationship between behavior and disability among Gulf War veterans with MUS, and suggest that they may be responding to their illness in ways that promote further disability. This has implications for reducing disability among the Gulf War population by teaching veterans more adaptive behavioral responses to their symptoms to support more active engagement in life and society.

DELIVERING HEALTH BEHAVIOR CHANGE AT SCALE: THE HEALTH HABIT LAB MODEL

Ryan Kalpinski, Ph.D., Andrew Dunkle, Ph.D., Daniel Cassidy, Ph.D.

United States Air Force / Wilford Hall Ambulatory Surgical Center, San Antonio, TX

Introduction: Demand for the prevention and treatment of chronic health conditions related to lifestyle is prodigious and growing. Timely delivery of relevant services is both challenging and costly via traditional specialty behavioral health services. Less than 1% of patients for whom health behavior change consultation is appropriate are granted access to appropriate services. Consequently, 80% of the variance in health outcome available for influence by the health system is left unmanaged for a majority of patients. The desire to improve access to care assuming finite human resources gave rise to a Health Habit Lab (HHL) model which provides brief, targeted services that conventionally are available only through sub-specialty clinics.

Methods: The demand for health behavior change consultation was calculated from archival data and used to test candidate service delivery concepts for feasibility under real-world circumstances where consultative expertise is in limited supply. The model which emerged was subsequently subjected to proof-of-concept testing over a period of 8 months and competed against status quo service delivery.

Results: The mean demand for care associated with health behavior change in the family health and internal medicine clinics was observed at 844 appointments per month. Prior to the institution of the HHL, capacity for health-behavior related consultation averaged 169 per month, and evinced a sustained increase of 250% under the new model.

Discussion: Health service delivery in the 21st century is increasingly pressed to do more with less. Consequently, the efficient and effective delivery of the right package of care, to the right patient, at the right time is of paramount importance. The present study revealed a shocking degree of latent demand for health behavior change consultation, and the HHL concept demonstrated promise as a candidate solution to the challenge. As these results are both promising and also preliminary, future efforts to replicate the effect at scale are warranted.

EXTENDING THE REACH OF PSYCHOLOGY TO GASTROENTEROLOGY CLINICS: VETERAN INTEREST IN INTEGRATED CARE

Amitha P. Gumidyal, PhD¹, Jessica Lohnberg, PhD², Joseph Onyiah, MD¹, Virginia Morrow, MSN, ANP-C²¹VA Eastern Colorado Health Care System, Denver, CO; ²VA Palo Alto Health Care System, Palo Alto, CA

Background: Inflammatory bowel disease (IBD) is a chronic relapsing and remitting illness that can significantly impair quality of life (QOL) and increase psychological distress. Among Veterans receiving care at VA hospitals, the prevalence of IBD appears to be increasing. Given the complex medical and psychiatric presentation of many Veteran and IBD patients, VA GI clinics are especially suited for expansion of psychology services. Several studies have outlined potential models for integrated care, but little is known about Veteran interest in utilizing integrated care services.

Objective: This program evaluation activity had three aims: 1) to characterize outpatient GI clinics at two VA hospitals, 2) describe Veterans'; satisfaction ratings with their current GI care, and 3) to determine patients'; interest in having health psychology services available in their GI clinic.

Method: GI clinic patients diagnosed with IBD (N = 107) completed questionnaires reporting their perceived disease activity and satisfaction with their clinic experience. They were also asked if they would like to speak with a health psychologist during their visit and if this should be a service available to other Veterans.

Results: The sample was primarily male (88%), 61 years and older (48%), and white (56%). Fifty-seven percent of Veterans rated their perceived disease severity as moderate to severe while nearly two-thirds endorsed improved overall health and QOL following GI clinic care. Veterans were nearly split about their interest in speaking with a health psychologist at the time of their GI clinic visit, with 47% indicating that they were interested. Reasons for declining included not enough time, too many other health issues to discuss, no current issues, no interest, and current engagement in mental health services (28% of the sample). However, 87% of patients agreed that it would be beneficial to have a health psychologist available in the GI clinic for reasons including: help with managing stress, difficulty in managing a chronic illness and its effect on mood, adjusting after new diagnosis, and support in making lifestyle changes.

Conclusion: Access to psychological services within GI clinics is supported by Veterans and may help them better manage their chronic illness and related psychosocial distress. Given the potential negative impact of IBD on QOL and psychological functioning in Veterans, integrated psychology services in GI clinics should be considered.

MEDICAL-LEGAL PARTNERSHIPS CAN IMPROVE HOUSING AND PSYCHOSOCIAL OUTCOMES FOR VETERANS WITH MENTAL ILLNESS

Jack Tsai, PhD¹, Margaret Middleton, J.D.², Randye Retkin, J.D.³, Robert Rosenheck, M.D.¹¹Yale University School of Medicine and VA Connecticut Healthcare System, West Haven, CT; ²Connecticut Veterans Legal Center, West Haven, CT; ³New York Legal Assistance Group, West Haven, CT

Medical-legal partnerships—collaborations between legal professionals and health care providers that help patients address civil legal problems that can affect health and well-being—have been implemented at several Veterans Affairs (VA) medical centers to serve homeless and low-income veterans with mental illness. We describe the outcomes of veterans who accessed legal services at four partnership sites in Connecticut and New York in the period 2014–16. The partnerships served 950 veterans, who collectively had 1,384 legal issues; on average, the issues took 5.4 hours'; worth of legal services to resolve. The most common problems were related to VA benefits, housing, family issues, and consumer issues. Among a subsample of 148 veterans who were followed for one year, we observed significant improvements in housing, income, and mental health. Veterans who received more partnership services showed greater improvements in housing and mental health than those who received fewer services, and those who achieved their pre-defined legal goals showed greater improvements in housing status and community integration than those who did not. Medical-legal partnerships represent an opportunity to expand cross-sector, community-based partnerships in the VA health care system to address social determinants of mental health.

POSTTRAUMATIC GROWTH AMONG U.S. VETERANS OVER TIME

Jack Tsai, PhD, Robert Pietrzak, Ph.D.

Yale University School of Medicine and VA Connecticut Healthcare System, West Haven, CT

•Posttraumatic growth (PTG) has been found among many people who are exposed to traumatic events, but there have been few prospective studies of PTG, especially among U.S. veterans who are disproportionately exposed to trauma. This study aimed to 1) identify predominant PTG trajectories among veterans over a 4-year period; and 2) examine determinants of PTG trajectories among a comprehensive set of sociodemographic, military, clinical, and psychosocial variables. A total of 2,718 U.S. veterans in the National Health and Resilience in Veterans Study were assessed in 2011, 2013, and 2015. Weights were applied to represent the demographic composition of the U.S. veteran population. Three PTG trajectories were identified, labeled as Low and Decreasing PTG (74.0%), Consistently Moderate PTG (12.0%), and High and Increasing PTG (14.0%). Greater severity of posttraumatic stress disorder symptoms, specifically re-experiencing and avoidance symptoms, at baseline predicted Consistently Moderate and High and Increasing PTG trajectories. Compared to the Low and Decreasing PTG trajectory, the High and Increasing PTG trajectory scored higher on baseline measures of gratitude, purpose in life, spirituality, and social support. In conclusion, PTG is a dynamic process with divergent trajectories. Developing interventions that target certain psychosocial factors may help trauma survivors maintain PTG over time.

VETERANS LIVING WITH CANCER: DISTRESS AND SUICIDAL IDEATION

Patricia Cabrera-Sanchez, Ph.D., Kristin M. Phillips, Ph.D., Stephanie N. Miller, Ph.D.

James A. Haley VA Hospital, Tampa, FL

Background: Distress is considered the sixth vital sign in cancer care. It has been related to poor quality of life, treatment non-adherence, and suicidal ideation (SI). Little is known about distress experienced by Veterans with cancer. Due to the increased risk of SI among Veterans, research on factors related to distress and SI among Veterans with cancer is needed.

Objectives: (1) Identify factors associated with distress among Veterans with cancer. (2) Identify relationships between distress and SI.

Methods: Veterans with cancer (N = 111) who were referred for mental health evaluation completed clinical interview and measures of distress (Distress Thermometer and Problems List; DT), pain (Pain Numeric Scale; PNS), insomnia (Insomnia Severity Index; ISI), anxiety (Generalized Anxiety Disorder; GAD7), posttraumatic stress (PTSD Checklist; PCL), and depression (Patient Health Questionnaire; PHQ9).

Results: The most commonly endorsed problems were fatigue (73%), worry (70%), pain (67%), and sleep (67%). Overall, 83% of Veterans screened positive for distress (DT ≥ 4). Positive distress screen was associated with SI ($\chi^2 = 5.609$, $p < .001$). Of the domains on the Problems List, only Family Problems was associated with SI ($\chi^2 = 7.216$, $p = .007$). Positive distress screens were also associated with higher scores on mental health screening measures: PNS ($t = 5.99$, $p < .001$), ISI ($t = 4.43$, $p < .001$), PCL ($t = 4.68$, $p < .001$), GAD7 ($t = 6.84$, $p < .001$), and PHQ9 ($t = 5.42$, $p < .001$). To identify which factors accounted for the greatest proportion of variance in a positive distress screen, logistic regression was performed with PCL, PHQ9, GAD7, ISI, and PNS entered as predictors in separate blocks. Although the omnibus model was significant ($p < .001$), only PNS ($\beta = .288$, $p = .039$) and GAD7 ($\beta = .210$, $p = .049$) significantly contributed to the model.

Conclusion: While SI was associated with positive distress screening, it was the presence of Family Problems, not Emotional Problems, that differentiated those with and without SI. Furthermore, when measures of PTSD, depression, anxiety, insomnia, and pain were all entered in a model predicting positive distress screening, it was only anxiety and pain that remained significant. Although prior studies with Veterans have emphasized the importance of screening for PTSD and depression, current findings highlight the importance of using the DT and Problems List to screen for overall distress among Veterans with cancer.

6:30 PM-7:30 PM

ATTITUDES AND PREFERENCES TOWARDS CIVILIAN HEALTHCARE AMONG RESERVE SOLDIERS

Bonnie M. Vest, PhD¹, Jennifer Fillo, PhD², Jessica A. Kulak, PhD¹, D. Lynn Homish, BS¹, Gregory G. Homish, PhD¹¹University at Buffalo- State University of New York, Buffalo, NY; ²University at Buffalo, The State University of New York, Buffalo, NY

Background and Objective: Given that less than 50% of eligible veterans receive care through the Veterans' Health Administration (VA), civilian healthcare providers have been called upon to screen their patients for military service. However, there has been limited examination of veterans'; preferences for care in civilian healthcare settings. This study explored service members'; preferences for having their military-related health concerns addressed by civilian providers.

Methods: Data were drawn from Operation: SAFETY, an ongoing study examining health among US Army Reserve/National Guard Soldiers and partners. Participants reported attitudes and preferences for seeking healthcare in the civilian domain. The present sample included current or former male soldiers (N=246). Likert scale responses to attitudinal questions were categorized into *agree*, *disagree*, and *no opinion*. Multinomial logistic regression models examined relations between participants'; attitudes about these factors. Logistic regression models examined relationships between healthcare preferences (VA or civilian providers), and whether the service member believes their health problems are related to military service.

Results: Overall, 43% ($n=105$) of participants felt their health problems were related to their military participation and 35% ($n=66$) felt their doctor should ask about military status. However, among soldiers who attribute their current health concerns to their military service, only 39% have been asked by a provider about their military status. Believing health is related to military participation is marginally associated with lower odds of preferring a civilian healthcare provider (compared to the VA) for both physical (OR=0.57; 95% Confidence Interval (CI)=0.30, 1.06) and mental (OR=0.57; 95% CI=0.31, 1.06) health care. Further, those who attribute their health to military participation have higher odds of believing their healthcare provider understands military culture (OR=2.07; 95% CI=0.99, 4.33).

Discussion: Results revealed factors, such as beliefs about the relation between military service and health and providers'; military cultural competency, which may be important in influencing veterans'; healthcare preferences. Future work is needed to understand how these factors inform treatment seeking, adherence, and outcomes.

IDENTIFYING RESILIENCY FACTORS THAT PROTECT AGAINST SUBSTANCE USE AMONG PREVIOUSLY DEPLOYED SOLDIERS

Katelyn R. Benson, BS¹, D. Lynn Homish, BS², Gregory G. Homish, PhD²¹University at Buffalo, Buffalo, NY; ²University at Buffalo- State University of New York, Buffalo, NY

Identifying resiliency factors that protect against substance use among previously deployed soldiers

Background and Objectives: Soldiers who have been deployed to war zones are at an increased risk for negative health outcomes, including substance use. This study examined potential resiliency factors associated with decreased risk for illicit drug use and non-medical use of prescription drugs (NMUPD) among US Army Reserve / National Guard (USAR/NG) soldiers who have previously been deployed.

Methods: Data were drawn from Operation: SAFETY (Soldiers and Families Excelling Through the Years), an ongoing longitudinal study examining health among US Army Reserve/National Guard Soldiers and partners (N=411 couples). The present sample included 248 male soldiers who had previously been deployed. Unit support, deployment preparation, and support from family and friends were measured using the Deployment Risk and Resilience Inventory-2. At year one follow up, illicit drug use and NMUPD were assessed using the NIDA modified ASSIST. Logistic regression models were used to examine the influence of baseline unit support, deployment preparation, and support from family and friends on drug use at follow-up.

Results: 9% of participants reported current illicit drug use or NMUPD. Baseline reports of greater unit support were significantly associated with less likelihood of illicit drugs or NMUPD at year one follow up (OR = 0.96; 95% CI: 0.92, 0.99). Deployment preparation was not a significant predictor of current use of illicit drugs or NMUPD. Baseline reports of greater deployment support from friends and family were significantly associated with less likelihood use of illicit drugs or NMUPD at follow-up (OR = .94; 95% CI: 0.89, 0.99). In the adjusted model, which controlled for PTSD, the association between unit support and illicit drug use / NMUPD remained protective against drug use at follow-up (AOR = .96; 95% CI: 0.93, 0.99). Deployment preparation was not significantly predicting current drug use. There was some evidence suggesting that support of friends and family was protective against drug use at follow-up (AOR = .95; 95% CI: .90 - 1.00).

Discussion: Unit support and deployment support from family and friends were associated with lower odds of drug use. These findings suggest that among USAR/NG soldiers who have been deployed, various sources of social support are important protective factors against drug use. Post deployment resources should find ways to promote social support to offset possible negative health outcomes.

INSOMNIA, PTSD, AND MEDICATION USE IN OEF/OIF/OND VETERANS WITH TBI SYMPTOMS

Jenna Gress Smith, PhD¹, Julie Hurd, BA², Mary Lu Bushnell, PsyD³¹Phoenix VA Healthcare System, Gilbert, AZ; ²Arizona State University, School of Social and Behavioral Sciences, Phoenix, AZ; ³Phoenix VA Healthcare System, Phoenix, AZ

Studies estimate that up to 70% of Operation Enduring Freedom/Operation Iraqi Freedom/Operation New Dawn (OEF/OIF/OND) Veterans with traumatic brain injury (TBI) also have clinically significant sleep issues. Difficulty sleeping has been shown to be risk factors for, and associated with PTSD, suicidal ideation, and other detrimental health behaviors such as tobacco use and alcohol abuse in non-TBI samples (Germain et al, 2014). The combination of these factors can present significant clinical and treatment complexity accompanied by patient, provider, and system burden. However, treatment recommendations regarding the ineffectiveness of benzodiazepines and risks associated with chronic opioid use within this population are clear (Seal, et al., 2012; Watson, Ghani, & Correll, 2016). The current study sought to understand the prevalence and relationships among insomnia severity, PTSD, alcohol and tobacco abuse, in conjunction with opioids and benzodiazepines prescribed in a sample of OEF/OIF/OND Veterans with cognitive complaints who presented for the nationally mandated second level TBI evaluation in the Phoenix VA system. The sample included 137 (ages participants 95% male, 71% Caucasian, ages 21 to 58). Using the insomnia severity index (ISI), 21% of Veterans reported subthreshold insomnia, 39% reported moderate insomnia, and 28% had severe levels of insomnia. Fifty-six percent reported significant PTSD symptoms (PTSD-M \geq 50, PTSD Checklist, military version). Overall, 12% of Veterans were prescribed benzodiazepines and 14% opioids. As insomnia severity increased, so did the prevalence of opioid and benzodiazepine prescriptions such that 3% and 7% of Veterans with subthreshold insomnia were prescribed opiates and benzodiazepines, respectively. Whereas, 13% and 11% of Veterans with moderate insomnia, and 26% and 24% of Veterans with severe insomnia were prescribed opiates and benzodiazepines, respectively. PTSD and insomnia symptoms were significantly correlated ($r = .68$, $p < .001$), however, alcohol abuse and tobacco use were not correlated with insomnia, PTSD symptoms, or cognitive complaints, nor were cognitive complaints with PTSD or insomnia (all p 's $> .05$). The results of this study provide insight into current medication practices within OEF/OIF/OND Veterans, along with the need to provide more education and services for evidence based practices (e.g. CBT-I for insomnia) to improve future treatment.

MENTAL AND BEHAVIORAL HEALTH SEQUELAE OF VICARIOUS TRAUMA AMONG SPOUSES OF U.S. MILITARY SERVICE MEMBERS

Jennifer Fillo, PhD¹, Jessica A. Kulak, PhD², Bonnie M. Vest, PhD², D. Lynn Homish, BS², Gregory G. Homish, PhD²¹University at Buffalo, The State University of New York, Buffalo, NY; ²University at Buffalo- State University of New York, Buffalo, NY

Background: Emerging research has found links between service member/veteran Posttraumatic Stress Disorder (PTSD) and psychological distress among their spouses. This may be due to spouses internalizing the service member's traumatic experiences and/or the spouse's own life experiences. Whereas PTSD often co-occurs with mental and physical health outcomes, there is limited data on the extent to which vicarious trauma is a risk factor for similar comorbidities in military spouses. The present research examined the prevalence of vicarious trauma among civilian spouses of service members and the relations between vicarious trauma and spousal mental health, substance use, and relationship functioning.

Methods: Data were drawn from the baseline wave of Operation: SAFETY, an ongoing study examining health among U.S. Army Reserve/National Guard soldiers and their partners. The present sample included 344 civilian spouses (24 males, 320 females) with no prior military history. Vicarious trauma was defined as the presence of PTSD symptoms above an established cutoff for probable PTSD (scores \geq 31; Bovin et al., 2016) without ever experiencing a traumatic event. Among spouses without a prior traumatic event, regression analyses were used to examine relations between PTSD symptoms and mental health, substance use, and relationship functioning, controlling for spouse sex and service member PTSD symptoms.

Results: 9.09% of civilian spouses met criteria for vicarious trauma. Among civilian spouses without a prior traumatic event (N=132), their own PTSD symptoms were associated with poorer mental health [depressive symptoms ($b=0.31$, $p<.001$), anxiety ($b=0.38$, $p<.001$), anger ($b=0.31$, $p<.001$), emotional wellbeing ($b=-0.92$, $p<.001$)], greater likelihood of substance use [alcohol use (RR=1.02, $p<.01$), heavy drinking (RR=1.01, $p<.05$)], alcohol problems (RR=1.03, $p<.001$), current cigarette use (OR=1.04, $p<.05$)], and poorer relationship functioning [marital satisfaction ($b=-0.82$, $p<.001$)]. There were no relations between PTSD and any form of current/past illicit or non-medical prescription drug use.

Conclusions: Nearly 1 in 10 civilian spouses meet criteria for probable PTSD without having experienced a traumatic event. Further, civilian spouse PTSD symptoms were associated with negative mental health, substance use, and relationship functioning outcomes. Future research adopting dyadic approaches to examining the sequelae of military-related trauma may benefit both soldiers and their spouses.

6:30 PM-7:30 PM

THE EFFECTS OF THERAPY DOG INTERVENTION ON ANXIETY IN ADULT PATIENTS UNDERGOING DENTAL PROCEDURES: A PILOT STUDY

Doris K. Lam, D.M.D., M.S.¹, Andrew Avillo, DDS, MS², John E. Schmidt, PhD³¹U.S. Navy, New Orleans, LA; ²Naval Postgraduate Dental School, Bethesda, MD; ³Uniformed Services University of the Health Sciences, New Market, MD

Dental anxiety can be a significant barrier to dental care. Individuals suffering from dental anxiety often arrive late to or fail to keep dental appointments, which may lead to deteriorating dental problems and the need for more extensive and challenging dental interventions. The use of therapy dogs as an intervention to reduce anxiety has shown some efficacy in various patient populations, but has not been employed in adults with dental anxiety. This on-going pilot study is assessing the acceptability, feasibility, and effectiveness of reducing dental anxiety in adult patients by using a therapy dog intervention. Adult patients self-reporting dental anxiety were invited to participate in this study. After consent, participants were randomized into a therapy dog intervention group (DOG) or a standard care (SC) control group. A ten-minute intervention with a therapy dog was administered at the first two dental treatment sessions prior to the start of treatment for participants in the DOG group. Participants in the SC group spent ten minutes in the dental chair reading magazines or relaxing quietly. Study outcomes included psychological (e.g., anxiety) and physiological (e.g., heart rate variability) assessments, as well as adherence to dental appointments. Preliminary results suggest the therapy dog intervention is effective in reducing self-reported dental anxiety and resulted in an increase in comfort after dental treatment. Further, physiological data suggest the intervention may reduce physiological arousal prior to dental treatment. These initial findings show that adult patients with dental anxiety will benefit from therapy dog intervention. In previous studies, decreased anxiety is correlated with higher compliance to dental appointments, improved dental health, and overall higher satisfaction in dental care. A therapy dog intervention for adults with dental anxiety may be just as effective and less costly or risky compared to standard pharmacological interventions such as anxiolytics.

THE ROLE OF SOCIAL SUPPORT DURING POST-DEPLOYMENT RE-INTEGRATION IN THE ARMY NATIONAL GUARD (ARNG)

Magin Day, N/A¹, Virginia Gil-Rivas, Ph.D.², Dave Topp, PhD³, Shelley Macdermid Wadsworth, PhD³¹University of North Carolina at Charlotte, Charlotte, NC; ²UNC Charlotte, Charlotte, NC; ³Military Family Research Institute, West Lafayette, IN

Since September 11, 2001, the ARNG has experienced unprecedented operational stress. These soldiers experience post-deployment stressors unique to active components, including unit deactivation, unemployment, financial difficulties, and military-civilian role adjustments, putting ARNG members at high risk for mental health concerns. This study examined the buffering effects of civilian and military social support on the impact of reintegration stress on the mental health of ARNG members post-deployment.

Data were collected from 99 male, ARNG members. Inclusion criteria included return from deployment in support of OEF/OIF six months prior to participation.

Face-to-face structured interviews were conducted with ARNG members at six months post-deployment and hierarchical multiple regression analyses were conducted to assess the contribution of reintegration-related stress and trauma exposure on self-reported mental health and PTSD symptoms at six months post-deployment.

Regression analyses revealed reintegration stress ($b = -.59$; $p < .01$) and civilian social support ($b = 1.02$; $p < .01$) were associated with self-reported mental health during the post-deployment reintegration period. Contrary to expectations, neither civilian, nor military social support moderated the relationship between reintegration stress and self-reported mental health. A similar pattern emerged for PTSD symptoms. Specifically, civilian social support ($b = -0.42$; $p < .01$) was associated with lower levels of PTSD symptoms while trauma exposure ($b = 3.61$; $p < .01$) was associated with higher levels of symptoms. Contrary to expectations, social support (civilian and military) did not moderate the association between reintegration stress and PTSD symptoms.

The findings suggest that civilian social support is an important contributor to better mental health and lower levels of PTSD symptoms in this population. Social support from families and friends may be leveraged by programs aimed at serving ARNG members during reintegration. Clinicians are encouraged to evaluate civilian social support available to ARNG clients and consider ways in which these resources can be integrated in treatment efforts.

AN EXAMINATION OF OBESITY PROMOTING FOODS PRESENT IN THE HOME BASED ON BMI CATEGORY AND FOOD SECURITY

McKenzie Bourque, B.S.¹, Laura Aylward, M.S.², Kristin University, PhD³, Bradley Appelhans, PhD⁴¹Rosalind Franklin University of Medicine and Science, Lake Bluff, IL; ²Rosalind Franklin University of Medicine and Science, Chicago, IL; ³Rosalind Franklin University of Medicine and Science, North Chicago, IL; ⁴Rush University Medical Center, Chicago, IL

Individuals with food insecurity are at increased risk for developing obesity, but reasons remain unclear. This secondary data analysis evaluated whether BMI category (lean/overweight/obese) and food security are associated with the amount of obesity promoting foods in the home, independently and in interaction with one another.

Participants ($N=191$, 84% female, 65% non-white, 40% food assistance, 72% overweight/obese) were recruited for a study on food purchases. The household member who made 75% of purchases completed a demographic survey and the USDA Food Security Survey. Study personnel twice visited homes 2 weeks apart to complete an inventory including desserts, snacks, microwavable foods, sugary beverages, processed meat, cheese, yogurt, milk, and 'other dairy'; items (e.g. heavy cream). ANCOVA models tested associations between BMI and food security with the amount of foods, adjusting for food assistance and race. A Bonferroni correction resulted in p -value of .007.

BMI ($p=.01$) and food security ($p=.15$) were not associated with obesity promoting foods, but significant differences were found. The interaction between BMI and food security on processed meat was significant, $F(2,191)=5.64$, $p=.004$. In stratified analyses, BMI wasn't associated with processed meat in food secure homes, $F(2,65)=1.66$, $p=.199$, but was associated with more processed meat in food insecure homes, $F(2,126)=5.74$, $p=.004$, $\eta^2=.03$). In food insecure homes, individuals with obese BMI ($M=2.31$, $SD=1.43$) and overweight BMI ($M=2.39$, $SD=1.62$) had more processed meat compared to individuals with lean BMI ($M=1.19$, $SD=1.25$). BMI was associated with cheese, $F(2,191)=5.31$, $p=.006$, $\eta^2=.01$, individuals with obese BMI ($M=2.95$, $SD=1.53$) had more than individuals with lean BMI ($M=1.96$, $SD=1.36$). BMI was associated with 'other dairy'; $F(2,191)=5.12$, $p=.007$, $\eta^2=.02$, individuals with obese BMI ($M=1.18$, $SD=.95$) had more than individuals with a lean BMI ($M=.58$, $SD=.76$). Food security and BMI were not associated with other variables.

Contrast to studies that relied on self-report, these results do not support associations between BMI or food insecurity and obesity promoting foods in the home. Although there were significant associations involving processed meat, cheese, and other dairy, effect sizes were small. Future research should study the validity of self-report of home food environment. Future research should also examine why individuals with food insecurity are at increased risk of obesity.

EMPOWERING THE PCM TEAM: A BEHAVIORAL-SCIENTIFIC APPROACH TO WEIGHT-RELATED SERVICE DELIVERY

Andrew Dunkle, Ph.D.¹, Ryan Kalpinski, Ph.D.², Daniel G. Cassidy, Ph.D.², Abby Fields, Ph.D.¹¹United States Air Force/Wilford Hall Ambulatory Surgical Center, San Antonio, TX; ²United States Air Force, San Antonio, TX

Introduction: Whereas a majority of the US population now meets criteria for overweight or obesity, shockingly few referrals are made by primary care providers for the purpose of weight management. Resulting are complications expressed in terms of medical comorbidity and diminished health-related quality of life. The present study sought to increase the number of patients connected with weight management resources above the threshold below which the total population of persons overweight and obese would otherwise continue to grow. The resulting weight-specific referral system was subsequently evaluated for effectiveness and scalability.

Methods: Stakeholders from clinical health psychology, family medicine, internal medicine, endocrinology, health promotion, disease management, exercise physiology, and nutritional medicine collaboratively conceived of a 'referral hub'; concept through which to funnel weight-related courses of care. Historical baseline data were gathered for weight-related referrals, and the rate of referral was tracked over 20 months following implementation of a 'referral hub'; concept.

Results: The monthly referral rate at baseline ($M=3.83$; $SD=2.25$) was compared against data for nine months following implementation of the 'referral hub'; concept ($M=31.53$; $SD=9.97$). The observed increase in weight-related courses of care was substantial ($d=3.83$) and sustained for the duration of the study period.

Conclusion: The establishment of a purpose-built referral hub for weight management improved patient engagement substantially, and was well-tolerated by busy primary care providers. These data suggest that seemingly small efforts to increase the simplicity and ease with which such referrals are made can have dramatic and positive effects on provider behavior. In light of the overwhelming prevalence of overweight and obesity, future efforts should seek to increase the scale (e.g., group appointments) at which similar such referral hubs are designed to operate effectively.

USING MULTI-TASK LEARNING TO DEVELOP RISK PROFILES FOR REDUCING PRESCHOOL OBESITY HEALTH INEQUITIES

Elizabeth Towner, PhD, Lu Wang, Alex B. Hil, MA, Ming Dong, PhD, Dongxiao Zhu, PhD

Wayne State University, Detroit, MI

Background: The contributing factors to obesity-related health inequities during the preschool years are multi-faceted. While some factors may be shared amongst *all* preschoolers from low-income and minority backgrounds, others may be unique to each preschooler and/or subgroups of this population. Distinguishing shared and unique risk-factors is important to refining targets for public health versus individual-level prevention and intervention efforts. In this pilot study, we utilize multi-task learning (MTL) to develop individual and group risk-models for preschool obesity using formative data collected from low-income, primarily African-American families ($n=23$) in Detroit.

Methods: Height and weight measures were taken for preschoolers and caregivers to calculate BMI z-score and BMI, respectively. Caregivers reported family socio-demographic information and completed questionnaires on their feeding styles, impulsivity, depression, stress, social support, healthy literacy and numeracy, and food-related purchasing patterns, routines and resource management skills (e.g., budgeting). Observational coding data on the nutrition environment of primary food markets identified by each caregiver was also included. In total, 112 variables were examined as risk-factors of preschool obesity. MTL simultaneously and dependently generates individual risk-profiles for each participant in a particular data set. Subgroup/group models are then generated by identifying shared risk-factors amongst individual models. 10-item risk-profiles were generated for each preschooler and for the sample (group) as a whole.

Results: Variability was evident among individual risk-profiles. For the group model, 5 risk-factors (caregiver age, non-planning impulsiveness, combined motor + perseverance impulsiveness, total food market nutrition environment, and healthy food availability at food markets) were shared by all preschoolers and the additional 5 risk-factors (stress, control of feeding, attentional impulsiveness, SNAP dollars the family receives, and motor impulsiveness) were shared by 57–96% of preschoolers.

Conclusions: Providing strategies to aide caregivers in thinking before acting and resources for identifying and accessing food markets with healthy nutrition environments are important public health targets for our sample, but variability in individual risk-profiles suggests family-based intervention is also important for maximizing efforts to reduce preschool obesity in this high-risk group.

USING REINFORCEMENT LEARNING OPTIMIZATION TO ACHIEVE MAXIMUM COST-EFFECTIVENESS OF WEIGHT LOSS INTERVENTIONS

Evan Forman, Ph.D.¹, Stephanie Kerrigan, M.S.¹, Adrienne Juarascio, Ph.D.¹, Meghan Butryn, Ph.D.¹, Danielle M. Moskow, B.S.², Stephanie Manasse, Ph.D.¹¹Drexel University, Philadelphia, PA; ²Drexel WELL Center, Merion Station, PA

Gold standard behavioral weight loss interventions produce 5–10% weight loss (WL), but weight regain is typical. Providing intensive interventions in the very long-term is infeasible due to high financial cost and participant burden. Using remote coaching and digital monitoring represent innovative forms of ongoing intervention, but generally are either high cost and high accountability (e.g., phone calls from trained coaches) or low cost and low accountability (e.g., automated text messages). A particularly innovative solution to this tension would be to continuously vary the intensity-accountability balance of the intervention using the engineering principle of “reinforcement learning” in which a system tracks outcomes and continuously varies each participant’s intervention based on participant response. In Project ReLearn, the first use of a reinforcement learning project for WL, participants (n=51) completed a 1-month, group-based in-person behavioral WL intervention and then were randomly assigned to receive 3 months of twice-weekly interventions that were non-optimized (NO; 10-minute phone calls) or optimized (a combination of phone calls, text exchanges, and automated messages selected by an algorithm). The Individual Optimization (IO) algorithm selected interventions based on past performance of each intervention for each participant. The Group Optimized (GO) algorithm selected the best intervention for each group member that fit into a fixed amount of time (i.e., 1 hour). For this pilot trial, we evaluated feasibility of this new system and whether optimization would achieve equivalent benefit at a reduced cost. We hypothesized that at week 10 of remote coaching: (1) WL would be equivalent between all groups and (2) mean clinician time would be lower for both optimized groups. Results indicated that the system was feasible (successfully developed and deployed) though some technical and practical problems arose (e.g., clinician time management when participants fail to immediately respond), and that weight losses were equivalent (MNO= 4.71%, MIO=4.72, MGO=4.07). Yet, costs (in terms of hours of clinician time per participant) were vastly different: MNO= 4.00, MIO=1.47, MGO=1.48 hours. Thus, the optimized interventions yielded equivalent WL at roughly one third the cost. Overall, the reinforcement learning system demonstrated strong promise, but many improvements should be implemented before this system is implemented on a wider scale.

WHAT IS IN IT FOR ME? IMPACT OF SELF-EFFICACY ON SURGICAL WEIGHT LOSS DECISIONS

Andrea C. Johnson, MPH¹, Monique Turner, PhD¹, Paula Lantz, PhD, MS²¹George Washington University, Washington, DC; ²University of Michigan, Ann Arbor, MI

Background: Obesity is prevalent among a third of U.S. adults and a leading indicator for many chronic diseases. Those with higher BMI tend to value large weight reductions, especially for weight loss treatments such as bariatric surgery. Self-efficacy is important for non-surgical weight loss interventions but there is less information about the role of self-efficacy in the candidacy phase when there are discussions of side effects and decisions for uptake. The current study aimed to test if and how weight loss self-efficacy is associated with the risk one is willing to stake in order to achieve an ideal weight.

Methods: The study surveyed a national probability based sample of US adults ages 18+ with clinical obesity (BMI ≥ 30). A 2x3 repeated measures design was employed where participants answered their willingness to achieve different weight loss amounts within the context of bariatric surgery in varying risk scenarios. Scenarios included: weight loss conditions (1. Ten percent weight loss or 2. Percent for ideal weight loss) and side effect levels (1. Low (chronic diarrhea), 2. Moderate (severe infection), and 3. High (death)). This design was analyzed using a repeated measures linear mixed model.

Results: Results indicated participants were more likely to stake more risk for every unit increase they hypothetically achieved for an ideal weight ($\beta=11.2$, $p=0.04$). Yet, participants were more willing to stake risk under ideal weight loss conditions with the risk of death, only when they had higher weight loss self-efficacy ($\beta=1.20$, $p=0.05$). Follow-up margin predictions also demonstrated individuals with higher self-efficacy were more likely to stake risk. This trend was highest for those scenarios presenting one’s ideal weight as the bariatric surgery outcome.

Conclusions: Results from the modeling with the current sample indicate weight loss self-efficacy is a predictor of participants’ willingness to stake high risk to achieve one’s ideal weight after bariatric surgery. This indicates an opportunity for streamlining clinical assessments and shared decision making. Results also call for expanded partnerships in patient education interventions to bolster patients’ self-efficacy among those at high risk. Increasing self-efficacy among eligible patients has potential to increase uptake of bariatric surgery, enhance patient outcomes, and reduce the burden of obesity on the health care system.

ADHERENCE TO SELF-MONITORING PREDICTS WEIGHT LOSS AND WEIGHT REGAIN IN RURAL BREAST CANCER SURVIVORS

Stephanie Punt, B.S., Christie A. Befort, Ph.D.

University of Kansas Medical Center, Kansas City, KS

Background: Dietary self-monitoring is a cornerstone of behavioral strategies for weight loss and weight maintenance. Adherence to self-monitoring daily calories has been positively correlated with weight loss results, however, the impact of tracking the number of specific food items rather than calories has not been well investigated.

Objective: The study examines change in self-monitoring consistency (percentage of weeks number of specific food items of a structured diet, i.e. prepackaged entrees/shakes, fruits/vegetables, and unplanned snacks, were tracked ≥ 5 days) over time and the relationship between self-monitoring consistency and percent weight loss (first 6 months) and percent weight regain (months 6 to 18).

Methods: 210 rural breast cancer survivors ($M=58.0$ years, $SD=8.2$) with body mass index 27 to 45kg/m^2 ($M=34.0\text{kg/m}^2$, $SD=4.4$) participated in an intervention consisting of two phases: non-randomized 6-month weight loss followed by 12-month weight maintenance where participants were randomized to either continued bi-weekly conference calls or bi-weekly newsletters. The first 6 months, participants were instructed to consume 2 meal replacement shakes, 2 prepackaged entrees, 5 one-cup servings of fruit/vegetables, and to minimize snacks and meals out. During 6 to 18 months they were instructed to incorporate more home-prepared meals, maintain high fruit/vegetable consumption, and limit meals out. Dietary components were tracked daily via paper logs sent to interventionists via fax, email, or voicemail. Participants with weights available at all three time points were included in final analyses ($n=169$).

Results: Self-monitoring consistency was stable and highest during the first 6 months of the weight loss phase ($M=91.4\%$ of weeks, $SD=15.5$) and decreased during the weight maintenance phase ($M=67.5\%$ of weeks, $SD=37.1$, first quarter; $M=42.4\%$ of weeks, $SD=44.1$, last quarter). Higher self-monitoring consistency during weight loss phase was associated with greater weight loss at 6 months, $r(167) = -.39$, $p < .001$. Degree of reduced self-monitoring consistency during maintenance, predicted weight regain at 18 months after controlling for nonsignificant effects of percent tracking during weight loss, treatment arm, and interaction between treatment arm and percent reduced tracking during maintenance, $b = -.057$, $p < .001$.

Conclusion: Adherence to consistently tracking specific food items over time affects weight loss and weight regain. Strategies for maintaining self-monitoring are needed to promote weight maintenance.

AN ECOLOGICAL MOMENTARY STUDY OF PREDICTORS OF DAILY WEIGHING AND PHYSICAL ACTIVITY TRACKING AMONG YOUNG ADULTS

Brooke T. Nezami, PhD¹, Carmina G. Valle, PhD, MPH², Julianne M. Power, MS², Nisha C. Gottfredson, PhD³, Deborah F. Tate, Ph.D.²

¹UNC Chapel Hill, Chapel Hill, NC; ²University of North Carolina at Chapel Hill, Chapel Hill, NC; ³UNC Gillings School of Global Public Health, Chapel Hill, NC

Adherence to self-monitoring predicts weight loss success, but declines over time. Predictors of lapses in self-monitoring are not well known. The goal of the current study was to use ecological momentary assessment (EMA) to explore behavioral and psychosocial predictors of lapses in daily weighing and wearing activity trackers.

Using the study's smartphone application, 20 young adults ($M = 27.1 \pm 4.7$ years; $M_{\text{BMI}} = 25.3 \pm 3.2 \text{ kg/m}^2$, 70% female, 70% non-Hispanic white, 25% undergraduates and 75% college graduates) completed EMA survey sets 3 times per day for 30 days. Survey sets included 3–8 questions from a pool of 34 items assessing self-reported facilitators and barriers to weighing/tracker wear, intentions, mood, stress, dietary intake, self-reported physical activity, and sleep. All participants were provided a Wi-Fi scale and used a Fitbit to track activity. Participants were told of the benefit of daily weighing and tracker wear for weight maintenance, but were not given specific goals. Objective Fitbit data was used to determine the daily outcomes of weighing (yes/no) and wearing a tracker (yes/no). Weight change from the prior weight observation, minutes of moderate-to-vigorous physical activity (MVPA), and steps were also explored as potential predictors of weighing/tracker wear. Missing EMA data was imputed using multilevel multiple imputation. Separate generalized linear mixed models modeled the effect of each predictor on the probability of weighing and tracker wear.

Participants completed 81% of the surveys. There were a total of 366 weigh days and 492 tracker wear days (out of 600). The median number of weigh and tracker wear days were 21 (IQR=10–28) and 23 (IQR=16–26), respectively. Objectively measured weight change and minutes of MVPA did not predict weighing or wearing a tracker the next day. However, each 1000-step increment on the prior day was associated with 4% greater odds of tracker wear the next day (95% CI: 1.01, 1.08). Participants were less likely to weigh on a given day if they self-reported that their weight had stayed the same or gone up (vs. declined; OR=0.16 [95% CI: 0.06, 0.45], OR=0.27 [95% CI: 0.09, 0.79], respectively), and were less likely to weigh if they were planning to engage in usual activity compared to less than usual (OR=0.55, 95% CI: 0.30, 0.99). Higher ratings of happiness predicted higher odds of tracker wear the next day (OR=1.51, 95% CI: 1.06, 2.14). Self-reported PA, dietary intake, sleep, stress, intentions, and other mood ratings did not predict either outcome.

On average, adherence to weighing and tracker wear was high. The findings suggest that self-reported judgments of behavior and psychosocial factors may be more associated with adherence than actual weight change and activity behaviors. The results highlight the need to explore additional factors that might be time-varying predictors of lapses in self-monitoring.

ASSOCIATIONS BETWEEN PARENTAL MONITORING AND ADOLESCENT WEIGHT STATUS: MEDIATING VIA DIETARY INTAKE AND PHYSICAL ACTIVITY

Kay W. Kim, B.A.¹, Jan Wallander, PhD², John Felt, MA¹¹University of California, Merced, merced, CA; ²University of California, Merced, MERCED, CA

Objective: We examined how parental monitoring is associated with adolescents' concurrent and subsequent weight status and how this may be mediated through health-promoting behaviors, such as healthy eating and physical activity, and health-risk behaviors, such as unhealthy eating and sedentary activity. Also we examined whether these relationships differ among racial/ethnic groups using multigroup structural equation modeling.

Method: Data came from 4,088 Black, Latino, and White students assessed in 7th and 10th grades. Parental monitoring was assessed by adolescents' reporting on their parents' monitoring behavior. Dietary Intake was assessed by adolescents' self-report using items adapted from the School Based Nutrition Monitoring questionnaire. Physical activity was assessed using items adapted from the PACE+ screening measure for physical activity on a 7-day recall. Sedentary behavior was assessed using items where adolescents reported time spent using the computer and watching television per week.

Results: Parental monitoring was not directly related to adolescents' weight status, but positively associated with adolescents' healthy eating and physical activity and negatively with sedentary behavior similarly across three groups. Parental monitoring was negatively associated with unhealthy eating only among Latino.

Conclusion: Parental monitoring is a salient dimension of authoritative parenting, a parenting style that is generally associated with positive child and adolescent development. Here it is demonstrated that those positive effects also extend to important health-related behaviors. These findings suggest that programs aimed at improving dietary intake and physical activity in adolescents should incorporate parents and address their parenting approach.

ATTITUDES TOWARD WEIGHING: LINKING AFFECT, BEHAVIOR, AND WEIGHT IN THE PERINATAL PERIOD

Susan D. Brown, PhD¹, Michaela Kiernan, PhD², Ai-Lin Tsai, M.A., M.S.³, Assiamira Ferrara, MD, PhD⁴¹Kaiser Permanente Northern California, Oakland, CA; ²Stanford University School of Medicine, Stanford, CA; ³Kaiser Permanente, Oakland, CA; ⁴Kaiser Permanente Division of Research, Oakland, CA

Weighing oneself regularly is widely recommended in behavioral interventions to treat and prevent obesity. It may also be important in the perinatal period, when managing weight gain has implications for maternal and infant health. Yet weighing may not be perceived as pleasant, especially for those who struggle with weight management—the very adults who may benefit from the feedback this behavior provides. We aimed to examine the reliability and validity of a concise self-report measure of affective attitudes toward weighing, and its relation to perinatal weight. Within the *Pregnancy Environment and Lifestyle Study* (PETALS), an ongoing pregnancy cohort in an integrated healthcare delivery system, we examined a subset of participants who completed a survey during pregnancy and subsequently delivered an infant between March and August 2017 ($N = 138$; $M \pm SD$ age = 30.9 ± 5.4 , range 18.8 - 45.3 years; 39% Latina, 30% White, 18% Asian, 9% African American/Black, 5% other). In the survey, participants completed a novel scale assessing affective attitudes toward weighing (3 items) and established scales assessing affective attitudes toward physical activity and healthy eating (4 items each), with higher scores indicating more positive attitudes; and reported how often they weigh themselves. We extracted pre-pregnancy body mass index (BMI) and total gestational weight gain (i.e., weight change from pre-pregnancy to delivery) from electronic health records. Overall, pregnant women reported moderately positive attitudes toward weighing (2.8 ± 1.1 on the 5-point Likert scale). Cronbach's alpha, an estimate of internal consistency reliability, was .74. Supporting criterion validity, attitudes were more positive among the 30% who weighed daily/weekly vs. the 70% who weighed less than weekly (3.1 ± 0.9 vs. 2.7 ± 1.2 ; $p = .04$); and among the 8% who weighed daily vs. the 92% who weighed less than daily (3.6 ± 1.0 vs. 2.8 ± 1.1 ; $p = .02$). Supporting discriminant validity, positive attitudes toward weighing modestly correlated with positive attitudes toward physical activity ($r = .24$, $p = .004$) and healthy eating ($r = .25$, $p = .003$). Positive attitudes toward weighing correlated with lower pre-pregnancy BMI ($r = -.41$, $p < .0001$; sample mean 27.0 ± 6.2 kg/m²), and a trend emerged such that attitudes were more positive among the 52% of participants who met national guidelines for appropriate gestational weight gain vs. the 48% who exceeded them (3.0 ± 1.1 vs. 2.6 ± 1.1 ; $p = .08$). Results indicate that affective attitudes toward weighing can be assessed with a scale that is brief, easily administered, reliable, and valid. Affective attitudes may influence weight management before and during pregnancy, and should be examined in future studies.

6:30 PM-7:30 PM

CARDIOMETABOLIC RISK IN YOUNG ADULTS: DO PERCEPTIONS MATCH REALITY

Meghan Mavredes, MPH¹, Loretta DiPietro, PhD, MPH¹, Laura L. Hayman, PhD, MSN, FAAN², Melissa A. Napolitano, PhD³¹The George Washington University, Washington, DC; ²College of Nursing & Health Sciences, UMass Boston, Boston, MA; ³The George Washington University, Washington, DC, DC

Background. Metabolic syndrome (MetS) is becoming more prevalent in younger populations. Those with components of MetS (i.e., increased abdominal adiposity, high fasting blood glucose, blood pressure, and triglycerides, and low high-density lipoprotein cholesterol) are at an increased risk for diabetes, cardiovascular disease, and stroke. Understanding young adult risk and perceptions and knowledge of risk can serve to inform improvements in patient-health care provider conversations.

Purpose. We examined the perception of metabolic risk and MetS status in a sample of young adults with Body Mass Index (BMI) values in the overweight or obese range.

Methods. Young adults aged 18–35 (N=351; 79.8% female; 57% Caucasian; M age 23.21 ± 4.31 years; M BMI 31.36 ± 4.2 kg/m²) enrolled in a healthy body weight randomized controlled trial completed the following measurements and measures: anthropometric, blood pressure, fasting blood draw, and a 5-item questionnaire assessing knowledge of and self-perception of metabolic risk including knowledge of blood glucose, cholesterol, and blood pressure.

Results. The majority of participants (n=237; 68.1%) did not have knowledge of the term metabolic risk, while 62.4% (n=216) met at least one MetS criteria. The majority also reported never having their blood glucose tested (n=191; 54.9%) even though 13.7% (n=45) and 17.3% (n=55) had a fasting glucose and fasting hemoglobin A1c (HbA1c) levels in the pre-diabetes range, respectively. No differences were observed in blood glucose and HbA1c between those who reported testing and those who didn't. Approximately 32% (n=110) reported not knowing their blood pressure, with 16.8% (n=59) having an elevated blood pressure. Blood pressure levels did not differ significantly by self-reported knowledge of blood pressure. There were significant differences in systolic blood pressure (p<0.001) and abdominal circumference (p<0.001) by sex, systolic blood pressure by race (p=0.005), and diastolic blood pressure (p<0.001) and abdominal circumference (p<0.001) by BMI.

Conclusions. A disconnect exists between actual metabolic risk and understanding/perception of risk in young adults in a population where the majority is already meeting at least one criteria for MetS. Implications will be discussed in context of informing patient-provider conversations and educational programs for young adults about metabolic risk and the importance of maintaining healthy lifestyles across the life course.

EFFECTS OF BEHAVIORAL WEIGHT-LOSS TREATMENT ON FOOD ADDICTION SYMPTOMS AND FRUIT INTAKE AMONG ADULTS WITH OBESITY

Eliza L. Gordon, M.S.¹, Aviva Ariel-Donges, M.S.², Vivian Bauman, B.S.³, Abraham Eastman, M.A.², Brittney N. Dixon, M.P.H.², Kathryn M. Ross, Ph.D. M.P.H.², Michael G. Perri, PhD²¹University of Florida, Gainesville, FL; ²University of Florida, Gainesville, FL; ³University of Florida, Clinical and Health Psychology, Gainesville, FL

Introduction: A significant subset of adults with obesity report problems with "food addiction" (FA; the compulsive consumption of certain foods despite adverse consequences), yet little is known regarding treatment. This study evaluated the effects of behavioral weight-loss treatment on FA and identified its associations with weight change and fruit intake.

Methods: The sample included 31 adults (87.1% women, 83.9% Caucasian; M±SD: age=54.4 ± 10.2 years, BMI=37.6 ± 3.8 kg/m²) who met criteria for FA based on the Yale Food Addiction Scale (YFAS; ≥3 symptoms plus distress/impairment) and completed the 4-month behavioral weight-loss program. The YFAS, a self-report questionnaire based on DSM-IV substance dependence criteria, was administered pre- and posttreatment. Fruit intake was measured by the Rapid Eating Assessment for Participants-Shortened Version.

Results: Treatment produced significant reductions in FA symptom count (M±SD: -2.4 ± 1.8 of 7 symptoms, p=.001) and weight (M±SD: -8.3 ± 5.4% body weight, p<.001), with a trend toward increased fruit intake (McNemar's chi-square=194.5, p=.065). Increased fruit consumption (r=-.466, p=.008) and decreased weight (r=.451, p=.011) were significantly associated with reduced FA symptoms. Similarly, participants who reported eating ≥2 servings of fruit/day at 4-months had significantly greater reductions in FA (-3.2 ± 1.6 vs. -1.7 ± 1.7 symptoms, p=.030) and larger weight losses (-12.1 ± 5.8% vs. -6.8 ± 4.5% body weight, p=.010) compared to participants who ate less fruit.

Conclusions: Behavioral weight-loss treatment led to significant improvements FA symptoms among adults who met YFAS criteria, and greater improvements in FA were associated with increased fruit intake and larger weight loss. Increasing fruit consumption within the context of a behavioral weight-loss program may be an effective approach to improving FA symptoms in this population.

ENGAGEMENT AND WEIGHT LOSS IN A WEB AND MOBILE PROGRAM FOR LOW-INCOME POSTPARTUM WOMEN: FITMOMS/MAMÁSACTIVAS

Julianne M. Power, MS¹, Suzanne Phelan, PhD², Karen E. Hatley, MPH³, Anna Brannen, MS⁴, Karen Christian, Associate Professor⁵, Maria Ruano Legato, California⁶, Deborah F. Tate, Ph.D.¹

¹University of North Carolina at Chapel Hill, Chapel Hill, NC; ²cal poly, SLO, CA; ³UNC Chapel Hill, Chapel Hill, NC; ⁴California Polytechnic State University, Nipomo, CA; ⁵California Polytechnic State University, San Luis Obispo, CA; ⁶California Polytechnic University, San Luis Obispo, San Luis Obispo, CA

Greater engagement with technology-based health interventions is often associated with improved outcomes. To better understand predictors of engagement among multicultural, low-income women, this paper reports on patterns of engagement with the Fit Moms/Mamás Activas website, a 12-month post-partum weight loss intervention that resulted in significantly greater weight loss among postpartum women in the Special Supplemental Nutrition Program for Women, Infants, and Children (WIC) relative to standard WIC. Engagement metrics included the percentage of participants who logged in at least once per month, use of 19 intervention features characterized by the proportion of total page views per feature, and exploration of patterns of use based on total logins. Four user groups were established (N = 174): non-users (NU: 0–11 log-ins, 26.4%), low-engaged (LE: 12–47 log-ins, 32.8%), high-engaged (HE: 48–96 log-ins, 17.2%), and super-users (SU: 97+ log-ins, 23.6%). Log-in rates were initially high and decreased over time. More than three-quarters (82.2%) of participants initiated the web program, almost half (47.1%) logged in during month 6, and 17.2% logged in during month 12. The most utilized intervention features were related to self-monitoring behaviors and lesson content. A one-way ANOVA revealed a significant effect of user type on average days tracking weight ($F(3,168)=70.5$, $p=0.000$), diet ($F(3,168)=30.2$, $p=0.000$), and physical activity ($F(3,168)=43.8$, $p=0.000$). Super-users had significantly more tracking days compared to all other user types, and comprised half (49.8%) of all lesson page views. There was a significant effect of user type on percent weight loss from baseline to 12 months ($F(3,148)=5.15$, $p=0.002$) among completers (87%). Super-users had significantly greater percent weight loss than LE and non-users, but not HE users (SU -7.15% +6.67, HE -5.25% + 6.42, LE -3.02% + 7.68, NU -1.31% + 6.77). Non-users were more likely to be employed, ($\chi^2=13.08$, $p=.004$), however no other associations between user type and demographics were found. Low income post-partum mothers engaged primarily with the lessons and self-monitoring features of the Fit Moms/Mamás Activas website. Usage was associated with weight change; user groups who logged in more frequently (>1 per week on average), approximately 40% of the sample, had average weight losses of 5–7% at 1 year. Promoting frequent (>1/week) engagement with web and mobile programs may produce clinically meaningful weight losses in low-income postpartum women.

EXPLORATION OF FACTORS RELATED TO OBESITY AND SEXUAL FUNCTION

Torianne Ipema, MS¹, Katherine Elder, PhD², Jennifer Antick, PhD²

¹Pacific University, San Francisco, CA; ²Pacific University, Hillsboro, OR

Objectives: The growing prevalence of obesity worldwide and its negative health consequences are well documented, with a particular focus on physical conditions associated with excess adiposity (World Health Organization, 2000). An accumulating body of research has been focused on the psychosocial consequences of being overweight or obese, such as depression and binge eating (Luppino et al., 2010; Yanovski, 2003). The purpose of this study is to contribute to this body of research in the topic areas of negative body image, internalized weight stigma, depression, and sexual functioning in overweight and obese individuals.

Method: Participants completed questionnaires online assessing for body image dissatisfaction (Body Shape Questionnaire; BSQ), internalized weight stigma (Weight Bias Internalization Scale; WBIS-11), depression (Patient Health Questionnaire; PHQ-9), and sexual functioning (Changes in Sexual Functioning Questionnaire; CSFQ-14). Both participant-entered body mass index (BMI) and waist circumference (WC) were utilized to categorize participants in normal weight (BMI between 18.5 to 24.9), overweight (BMI between 25.0 to 29.9), and obese (BMI over 30.0) categories. One hundred and twenty participants above the age of 18 were included in the analyses assessing for the relationships among the aforementioned variables.

Results: Of the 120 participants, 42 were cisgender male (35%), 75 were cisgender female (62.50%), and two were gender fluid/non-binary (1.70%). Mean scores on the measures were as follows: BMI M= 27, SD= 7.38; WC M= 33.24, SD= 7.55; BSQ M= 84.82, SD= 34.40; WBIS-11 M= 37.72, SD= 12.65; PHQ-9 M= 6.93, SD= 5.98; CSFQ-14 M= 42.88, SD= 10.63. The overweight group reported greater impairment in sexual functioning than obese and normal weight participants as evidenced by lower total scores on the CSFQ-14, $p = 0.03$. A significant relationship was demonstrated between the sexual desire subscale of the CSFQ-14 and waist circumference, $p = 0.04$. Depression scores were a significant predictor of sexual satisfaction scores, a question created to use in adjunct with the CSFQ-14, $p = 0.00$. Finally, a significant relationship was demonstrated between internalized weight stigma and sexual satisfaction, $p = 0.05$.

Conclusions: The relationship between weight, shape, psychosocial well-being, and sexual functioning is complex. In an effort to better serve overweight and obese populations in a healthcare setting, practitioners should consider body image, weight stigma, mood, and sexual function as important aspects of quality of life in their assessment and treatment of these individuals.

Relevance to conference theme: *Extending our reach* as health professionals by considering all aspects of quality of life, including sexual function, in overweight and obese patients in a sensitive and health-centric manner.

FAMILY ENTROPY: A SYSTEMATIC REVIEW OF ORGANIZATION OF THE FAMILY HOME ENVIRONMENT AND CHILD OBESITY

Carolyn Bates, M.A.¹, Joanna Buscemi, Ph.D.², Laura M. Nicholson, BA¹, Molly Cory, B.S.², Anjana Jagpal, BA², Amy Bohnert, Ph.D.³

¹Loyola University Chicago, Chicago, IL; ²DePaul University, Chicago, IL; ³Loyola University of Chicago, Chicago, IL

High rates of child overweight and obesity place youth at risk for a multitude of short- and long-term health consequences (Biro & Wein, 2010). To inform effective prevention and intervention, it is essential to identify risk and protective factors in children's primary environments, including the home (Davison et al., 2012). The level of organization is a studied, but not well specified aspect of the family home environment that may impact child weight. Prior research on organization within the home environment has included an array of constructs, such as family routines (Fiese et al., 2002), limit setting (Fiese, Rhodes, & Beardslee, 2013), household chaos (Weisner, 2010), crowding (Evans, Lepore, Shejwal, & Palsane, 1998), and the broad home environment (Bradley et al., 2001). The current study proposes a conceptual model depicting relations between the organization of the home environment and child weight, and evaluates support for this model among children ages 2–12 in the existing literature.

Six hundred thirty-seven studies were independently reviewed by four coders for eligibility. Coders assessed the studies for the following inclusion criteria: (i) presented original research (e.g., no review articles, letters, or commentaries) (ii) included individuals between ages 2–12, (iii) measured overweight, obesity, or body mass index (BMI) zscore (zBMI) as a dependent variable, and (iv) measured family organization, disorganization, chaos, routines, limit setting, or crowding as an independent variable. Thirty-one studies were included in the final synthesis.

The conceptual model was supported by the literature, with 75% of studies evidencing statistically significant inverse relations between the organization within the family home environment and child weight. Studies provided compelling evidence across numerous indicators of organization, including family routines, limit setting, crowding, and the broad home environment, suggesting that the relevance to child weight extends beyond a single indicator of home organization. Drawing on these results, the study concludes by proposing a new overarching construct, family entropy, which integrates existing constructs and represents the total organization/disorganization across the home environment. There are numerous directions for future work exploring relations between family entropy and child weight, including (i) examining the mediating role of health behaviors, (ii) examining the moderating role of socioeconomic factors, (iii) broadening evidence across cultures and nationalities.

IS WEIGHT LOSS SUCCESS A MATTER OF INCREASING ADHERENCE FOR THOSE WITH ADHD?

Doris E. Ogden, BS, MS, Jean Harvey, PhD, RD

University of Vermont, Burlington, VT

BACKGROUND: Adherence to attendance and self-monitoring is associated with treatment success in behavioral weight loss programs. Adults with ADHD are more likely to be obese and less likely to experience weight loss success yet reasons why are largely unexplored. Therefore the aims of this study were to explore adherence and weight loss patterns between adults with and without ADHD.

METHODS: This retrospective analysis examined weight loss results and treatment engagement of participants with and without ADHD from identical 24 week behavioral interventions. Data from iReach (a large multi-center clinical trial) and Focus (a smaller trial including only adults with ADHD) were evaluated to better understand differences. Data from the online and hybrid conditions of iReach were analyzed (n=312) and compared to in-person treatment data from the two conditions of FOCUS (n=37). Both studies shared all materials and a number of the same therapists.

Adherence measures included attendance at weekly classes and submission of self-monitoring journals. Weight loss was expressed as % of baseline weight lost at 6 months. Comparisons were made before and after dividing subjects from each trial into high, moderate and low weight-loss tertiles. Variables were then examined by weight loss tertile.

RESULTS: High, moderate and low iReach tertiles lost 11.7, 5.5, and .2% of baseline respectively, while high, moderate and low Focus tertiles lost 7.9 and 1.9, and gained 1.3%.

Attendance was higher in both iReach conditions (76% and 73%) vs. both conditions of Focus (53% and 58%). Self-monitoring was also higher in iReach (71% in both conditions) vs. Focus (50% and 54%).

CONCLUSIONS: The disparity between level of adherence and weight loss between those with ADHD and those without is striking given that in-person groups (FOCUS) tend to do better with weight loss than online groups (iReach). Since adherence was far lower in the Focus study, research is needed on improving treatment engagement, particularly dietary self-monitoring, in populations with ADHD.

LIFE EVENTS, PHYSICAL ACTIVITY, AND WEIGHT LOSS MAINTENANCE: DECOMPOSING MEDIATING AND MODERATING EFFECTS ON HEALTH BEHAVIOR

Kara L. Gavin, PhD, MPH¹, Julian Wolfson, PhD², Mark Pereira, PhD, MPH², Nancy E. Sherwood, PhD³, Jennifer A. Linde, Ph.D.²

¹Northwestern University Feinberg School of Medicine, Chicago, IL; ²University of Minnesota, Minneapolis, MN; ³School of Public Health, University of Minnesota, Minneapolis, MN

Introduction: Although adherence to high levels of moderate to vigorous physical activity (MVPA) has been associated with better weight loss maintenance, this analysis attempted to clarify the individual and joint effects of MVPA in concert with significant life events (e.g. divorce, marriage, job change or loss, death of a relative, etc.) on weight following a behavioral weight loss intervention.

Methods: Data from the Tracking Study weight loss trial were utilized. Men and women residing throughout the Minneapolis-St. Paul, MN metropolitan area were recruited, randomized, and followed from July 2012 to September 2015. A four-way decomposition model was used to examine the effect measure modification and mediation of life events by MVPA achievement on 24-month weight. The model analyzed four components: the controlled direct effect (CDE) estimated the portion of the effect of life events on weight controlling for MVPA, the reference interaction (INT REF) estimated the interactive effect of life events and high MVPA on weight, the mediated interaction (INT MED) estimated the portion of the effect of life events and high MVPA on weight that was both mediated and moderated, and the mediated main effect or pure indirect effect (PIE) estimated the effect of life events on weight that was mediated through reported MVPA. These four components were summed to give the total effect. Independent variables were occurrence of life events (≥ 1 vs. 0) reported at 12 months and MVPA achievement (low = 2500 kcal) reported at 18 and 24 months. The outcome was weight measured at 24 months.

Results: The total effect of life events and MVPA on weight was estimated to be 1.36 kg (95%CI= 0.01, 2.70 $p=0.05$) when using 18-month MVPA and 1.63 kg (95%CI= 0.30, 2.96 $p=0.02$) in the model using 24 month MVPA. The CDE of life events on 24-month weight was larger than the estimated total effect in models accounting for 18-month MVPA ($\beta = 2.39$ kg 95%CI= 0.31, 4.48) and 24-month MVPA ($\beta = 2.31$ kg 95%CI= 0.29, 4.33). All other interaction and mediation estimates were not statistically significant.

Conclusion: This decomposition offers new potential for examining the effects of health behaviors that may act as both mediators and effect modifiers of health outcomes in the same analysis. Although little can be said about the interaction of life events and MVPA achievement on weight loss maintenance, our findings help to rule out mediation. These findings suggest that life events and MVPA should be considered for their unique effects on weight loss maintenance. However, simultaneous consideration of joint pathways affecting weight loss maintenance when designing interventions to prevent weight regain is important.

PERCEIVED MEDIA PRESSURE PREDICTS EATING PATHOLOGY IN YOUNG ADULT WOMEN WITH OVERWEIGHT/OBESITY WHO USE SOCIAL MEDIA

Sylvia Herbozo, PhD¹, Lilit Hovsepian, MA², Amanda Suplee, PhD³, Serena D. Stevens, PhD⁴, Abigail Alido, MA²

¹University of Illinois at Chicago, Chicago, IL; ²Loma Linda University, Loma Linda, CA; ³Valley's Children Hospital, Madero, CA; ⁴Cleveland Clinic, Cleveland, OH

The negative effects of media on disordered eating are well-documented. Recent studies have focused on social media given the significant increase in social media use among young adults over the past decade. There is initial evidence that social media use is associated with body dissatisfaction and eating pathology in young adult women. However, this research has primarily focused on young adult women of average weight, despite the prevalence of overweight/obesity during young adulthood. The current study investigated social media use and perceived media pressure as predictors of eating pathology in young adult women with overweight/obesity who use social media. Participants were 231 young women aged 18 to 29 ($M = 19.27$, $SD = 1.53$) with a body mass index (BMI) of 25 or greater ($M = 30.71$, $SD = 6.45$). The Sociocultural Attitudes Towards Appearance Questionnaire-4, a social media questionnaire, and the Eating Disorders Examination-Questionnaire were administered. All participants reported using at least one social media site. Approximately 91% of the participants used Facebook, 91.7% used Instagram, 64.8% used Twitter, and 61.0% used other social media sites. Results indicate that 54.7%, 57.1%, 34.4%, and 34.4% of participants used Facebook, Instagram, Twitter, and other social media sites for one hour or more per day, respectively. A multiple regression analysis was used to determine the influence of social media use and perceived media pressure on eating pathology. Overall, the regression model accounted for a significant proportion of the variance in eating pathology, $R^2_{adj} = .185$, $F(2,219) = 26.14$, $p < .001$. We found that perceived media pressure significantly predicted eating pathology such that a 1 unit increase in perceived media pressure was associated with a 0.57 unit increase in eating pathology ($b = .573$, 95% CI [.405, .741], $p < .001$). The amount of time spent on social media did not significantly predict eating pathology ($p > .05$). Results indicate that those who report feeling pressure from the media to achieve societal standards of attractiveness may be more likely to engage in eating pathology. Study findings regarding perceived media pressure support prior research with young adult women of average weight and highlight the importance of examining the manner in which media exposure is experienced rather than only the frequency of media use. Future research should examine the roles of thin ideal internalization and appearance comparison on the relationship between social media use and negative outcomes. This research could inform intervention efforts for reducing the potential harmful effects of media in young adult women with overweight/obesity.

PREVENTING DIETARY LAPSES IN SOCIAL SITUATIONS: THE POWER OF A JUST-IN-TIME ADAPTIVE INTERVENTION FOR WEIGHT LOSS

Gerald Martin, B.A., Stephanie Goldstein, MS, Meghan Butryn, Ph.D., Adrienne Juarascio, Ph.D., Evan Forman, Ph.D.

Drexel University, Philadelphia, PA

Adherence to dietary prescriptions is vital for success in behavioral weight loss treatments (BWL). BWL targets many of the factors that influence lapses from those diets, but the socializing around food (SAF) continues to be a common trigger for dietary lapses, indicating the need for treatments that can more effectively target those settings. The current study sought to examine the ability of just-in-time adaptive interventions (JITAI) to reduce the number of lapses triggered by SAF in a weight loss seeking population. We hypothesized that opening JITAI specifically targeting SAF would reduce the likelihood of lapsing at the subsequent prompt. Second, we hypothesized that receiving JITAI would moderate the relationship between SAF and lapsing. Overweight/obese participants (n=35) followed the weight watchers diet for 8 weeks while using an app called OnTrack. OnTrack utilizes ecological momentary assessment (EMA) and machine learning to predict dietary lapses and delivers behaviorally-based JITAI to help participants avoid lapsing. After two weeks of use OnTrack predicts when lapses may occur, and sends JITAI for 6 weeks based on those predictions. Effectiveness of JITAI was determined by comparing the likelihood of successfully avoiding a lapse after receiving a JITAI to lapse rates during the first two weeks of the study. Lapses were considered successfully avoided if a participant received and opened an intervention related to SAF and did not report lapsing by the time of their next EMA prompt (~3 hours). Participants received an average of 5 (SD=3.77) JITAI related to SAF over the 6 week period. Approximately 80% of the alerts were opened by participants. Generalized estimating equations revealed that opening a JITAI related to SAF reduced the likelihood of lapsing at the next prompt by 59% ($p=.076$) compared to the rate of lapses prior to receiving JITAI. Receiving JITAI moderated the relationship between SAF and lapsing at the trend-level ($p=.078$), such that there were less reported lapses related to SAF in the 6 weeks when JITAI were sent. These results indicate that interventions related to SAF reduced lapses in participants found to be at risk of lapsing. Although these trends did not reach statistical significance, these findings provide further evidence that JITAI may be a viable remote treatment method to target common triggers of dietary lapses such as SAF. Limitations of this study include sample size, and the assumption that all SAF related JITAI were predicted correctly. Similar trials with larger sample sizes are warranted to further examine this trend, as well as further development of JITAI treatments such as smartphone applications.

RELATIONSHIP BETWEEN CHANGES IN WEIGHT, PHYSICAL ACTIVITY & EXECUTIVE FUNCTION

Diane Radler, PhD¹, Rachel Griehs, MS¹, Andrea Banu, BS², Christopher J. Brush, B.S.³, Peter J. Ehmann, B.A.⁴, Brandon L. Alderman, Ph.D.⁵

¹Rutgers, The State University of New Jersey, Newark, NJ; ²Rutgers, The State University of New Jersey, New Brunswick, NJ; ³Rutgers, The State University of New Jersey, Somerset, NJ; ⁴Rutgers, The State University of New Jersey, Long Valley, NJ; ⁵Rutgers, The State University of New Jersey, Hightstown, NJ

Uninterrupted sitting time (ST) poses a threat to the health and wellness of all adults. However, it is unclear to what extent adults with overweight and obesity can successfully use activity monitors with cognitive behavioral therapy strategies to change physical activity (PA) and ST in an attempt to reduce body weight. Additionally, the exploration of potential behavioral and neurocognitive factors (e.g., executive function) may further explain variability reported in the change in PA and ST.

Purpose: To determine the relationships between change in weight and changes in PA and ST after a 12-week intervention among adults with overweight or obesity. A secondary aim was to examine baseline and change in executive function as predictors of weight loss across the intervention.

Methods: Adults (n=58) aged 18–65 years with a BMI between 25–50 kg/m² received a FitBit® Charge HR monitor and set daily PA goals with a registered dietitian (RD) at baseline; they received weekly dietary and PA education during an in-person class or via an online platform for 12 weeks. Outcomes included ST, PA (steps/day), and weight (pounds, lbs). Executive function was assessed at baseline and after the intervention at week 12 using the Sternberg and Wisconsin Card Sorting tasks. Weight change was defined as participants either losing (>0.0 lbs) or gaining (≤0.0 lbs) weight from baseline to week 12. Descriptive statistics were used to characterize the sample; GLM and regression analyses were used to assess change in outcome variables.

Results: Participants were primarily female (n=54; 93%), White (n=42; 72.4%), and were 45.7 ± 12.0 years with a baseline BMI of 32.1 ± 5.1 kg/m². From baseline to week 12, ST decreased from 545.2 ± 164.8 to 456.5 ± 171.1 min/day (p) and mean weight change among all participants was -1.5 lbs (p=.09); 31 participants lost weight (mean loss -4.8 ± 5.3 lbs) while 21 participants gained or had no change in weight (mean gain 3.4 ± 3.9 lbs). Those who lost weight significantly increased PA (8641 ± 3679 steps) versus those who gained weight over the 12 weeks (6657 ± 2503 steps; $F(1,47) = 4.11, p = .048$). Change in executive function, but not baseline cognitive performance, was a significant predictor of overall weight loss, $F(1, 49) = 7.3, p = .01$.

Conclusion: The findings of this study support the relationship between weight loss with PA, and highlight the importance of examining individual characteristics, such as executive function, that may help to explain behavioral response to PA and weight loss interventions.

SELF-WEIGHING: AN ECOLOGICAL MOMENTARY ASSESSMENT (SW EMA): DESIGN AND ACCEPTABILITY

Carly R. Pacanowski, PhD RD¹, Gregory M. Dominick, Ph.D.¹, Jennifer A. Linde, Ph.D.², Scott Engel, PhD³, Ross D. Crosby, Ph.D.³¹University of Delaware, Newark, DE; ²University of Minnesota, Minneapolis, MN; ³Neuropsychiatric Research Institute, Fargo, ND

Background: Daily self-weighing (SW) is a promising strategy for weight management in emerging adults. EMA enables psychological and behavioral data to be collected remotely and in real time. However, EMA protocols tend to be burdensome for participants, resulting in greater attrition and missing data. Moreover, no studies to date have used EMA to test the psychological and behavioral consequences of daily SW. This abstract describes the design and acceptability of a pilot RCT testing the psychological and behavioral effects of daily SW.

Methods: Participants were college-aged women, screened for eating disorders, and randomly assigned to daily SW or an active control (daily temperature-taking; TC). Baseline measures included height, weight, and a psychological survey that was repeated weekly for the first month. Participants were required to complete their assigned behavior every day for 3 months. EMA was purposefully front-loaded at the beginning of the intervention (month 1 only), in which participants were asked to respond to 6 signals daily (weeks 1 and 4) and complete 1 assessment at end of day (weeks 2 and 3). Surveys were administered weekly during the first month. Data from the intervention behaviors were wirelessly transmitted to a database that enabled frequent monitoring for adherence.

Results: (month 1 only). Ninety-five interested individuals contacted the study group; 61 received the first screening email and of these, 16 were ineligible (due to not passing eating disorder screening, time commitment or lack of response). Out of 15 who met inclusion criteria, consented, and were randomized, 1 dropped before starting the intervention due to Wi-Fi issues, 1 withdrew in the 4th week, and 1 was noncompliant with the study protocol in the 1st week. Twelve participants (6 in each group) successfully completed the required protocol. Cumulatively, over the first month, compliance rates were 94.6% for EMA1, 86.3% for daily behavior, 88.7% for EMA2, 86.9 for EMA3, 77.4% for EMA4, 83.3% for EMA5, and 67.6% for EMA6. All weekly surveys (48/48) were completed.

Conclusion: Despite challenges of adhering to and completing the rigorous protocol, results suggest this study design was acceptable for college women and effective in mitigating attrition during month 1 and throughout the 3-month study period. Moreover, EMA response rates were acceptable, resulting in a robust and more complete dataset. These findings informed a larger RCT currently underway.

STRESS IS ASSOCIATED WITH REDUCED EXECUTIVE FUNCTION, GREATER DISINHIBITED EATING, AND HIGHER BMI

Jessica O'Neill, MPH¹, Heather Orom, PhD²¹University at Buffalo, The State University of New York, Buffalo, NY;²University at Buffalo, Buffalo, NY

Background: While stress can sometimes reduce appetite, it is also associated with unhealthy food choices, disinhibited eating, and obesity. Resisting the temptation to eat is difficult in an obesogenic environment, and the challenge increases under conditions of stress-induced cognitive load. The specific executive functions and behavioral mechanisms that mediate the effect of stress on obesity are not well understood.

Purpose: The purpose of this study was to identify executive functions that may mediate the association between stress and obesity in women.

Methods: Participants were 249 female Amazon Mechanical Turk workers recruited to be part of a larger study (median education=bachelor's degree; 83% white; mean age=37.2 (SD=11.9)). Stress was measured with Cohen's Perceived Stress Scale (short form). Executive function was assessed with the Behavior Rating Inventory of Executive Function for Adults (BRIEF). We analyzed scales from Roth et al.'s 3-factor solution: metacognition (MI) (problem-solving via planning/organization, utilizing working memory), emotional regulation (ER) (control of emotions, cognitive flexibility), and behavioral regulation (BR) (inhibitory control, monitoring of social behavior). Disinhibited eating was assessed with the Three Factor Eating Questionnaire. Body mass index (BMI) was calculated from self-reported height and weight. We used multivariable linear regression to examine associations between stress, BRIEF, disinhibited eating, and BMI and bootstrap estimates to test for indirect effects of stress on disinhibited eating through each BRIEF factor as well as indirect effects of BRIEF on BMI through disinhibited eating (6 models total). We controlled for age, income, and education in all analyses.

Results: Greater stress was associated with worse executive function on BRIEF MI (B=2.368, p<0.0001), ER (B=1.142, p<0.0001), BR (B=0.599, p<0.0001) as well as greater disinhibited eating (B= 0.246, p=0.001) and higher BMI (B=0.294, p=0.043). There was a significant indirect effect of stress on disinhibited eating through BRIEF MI (indirect effect=0.163, 66.1% of total effect) and ER (indirect effect=0.172, 69.8% of total effect), but not BR. There was a significant indirect effect of BRIEF MI, but not ER or BR, on BMI through disinhibited eating (indirect effect=0.061, 87.2% of total effect).

Discussion: People with high stress may engage in disinhibited eating due to reduced cognitive control or emotional regulation; however, disinhibited eating does not appear to be due to failure to monitor social appropriateness of behavior. Many pathways causing weight gain are possible, including attention bias towards unhealthy food, eating to regulate emotions, failure to monitor intake, or difficulty adhering to nutrition planning goals. Interventions that modulate these may mitigate the effect of stress on weight gain.

THE CLINICAL UTILITY OF WEIGHT-RELATED TERMS: EFFECTS OF WEIGHT LABELS AND INTERNALIZED WEIGHT BIAS ON TREATMENT INITIATION

Christina M. Hopkins, BS, Gary Bennett, PhD

Duke University, Durham, NC

Weight bias contributes to avoidance of health behaviors, engagement in weight gain behaviors, and poorer functioning of metabolic and regulatory systems. Physicians are routinely implicated as sources of weight bias, in part due to poor patient-provider communication. Patient preferences for words used to describe weight have been measured, yet the effect of these terms on treatment initiation has not been tested. This study examines the effect of four commonly-used terms on psychological precursors to treatment initiation, and assesses the effect of internalized weight bias.

Using Amazon's Mechanical Turk (mTurk), 436 adults with BMI > 25 reported baseline internalization of weight bias. Participants then read vignettes describing common experiences at a doctor's office wherein the term used to describe weight was randomly varied (i.e., "weight", "fat", "obesity", or "BMI"). Participants then rated self-efficacy for health behavior change and risk perception of obesity.

Participants were, on average, male (53%), white (75.7%) 35 ± 9.6 years old, with a BMI of 33.9 ± 7.5 kg/m². 80.3% of participants reported at least experiencing at least one form of weight based teasing, discrimination, or harassment.

There were significant effects of the terms "obesity" and "fat". Exposure to the term "obesity" resulted in greater perceived control over obesity ($M_{diff} = 1.4$, $p = .004$) and greater self-efficacy for diet change ($M_{diff} = 10.4$, $p = .007$). Exposure to the term "fat" resulted in decreased understanding of obesity ($M_{diff} = 1.01$, $p = .004$). There were no effects of "weight" nor "BMI".

Baseline internalized weight bias (IWB) moderated the association between term and self-efficacy or risk perception. The main effect of term on illness coherence was moderated by baseline IWB ($p = .03$), such that those with higher IWB reported lower illness coherence after exposure to the term "fat". Internalized weight bias also significantly affected self-efficacy; for those exposed to all four terms, higher IWB was associated with lower self-efficacy ($p < .001$). There was no moderating effect of experienced weight bias.

The words used to describe body weight differentially affect common precursors to treatment initiation. "Obesity" may result in greatest risk perception of obesity and self-efficacy for behavior change in most adults. Internalized weight bias moderates the effect of the term "excess fat"; it may serve as a neutral term for most adults, but has negative effects for those with internalized weight bias. Future research should identify the clinical significance of these effects to inform treatment guidelines and medical training.

WELLNESS TEAM STABILITY AND LOCAL WELLNESS POLICY IMPLEMENTATION: A LONGITUDINAL STUDY

Carolyn McIlree, MD, MA¹, Hannah Lane, PhD, MPH², Yan Wang, PhD², Caroline Greene, MPH³, Erin Hager, PhD²

¹University of Maryland Baltimore, Baltimore, MD; ²University of Maryland School of Medicine, Baltimore, MD; ³Maryland Department of Health, Baltimore, MD

Wellness Team Stability and Local Wellness Policy Implementation: A Longitudinal Study

Introduction: Local Wellness Policies (LWP) are school-district documents containing goals for nutrition and physical activity in schools. Cross-sectional studies suggest that schools with wellness teams are more likely to implement LWPs. This study uses a prospective cohort design to examine whether wellness team stability over time is associated with change in LWP implementation in a large, state-wide sample of schools.

Methods: School administrators/school wellness leaders in Maryland responded to a biennial online survey (Time 1, 2012–2013; Time 2, 2014–2015 school years). 17-items on implementation of wellness policies and practices in a Likert scale (fully=3, partially=2, under development=1, not implemented=0) were summed at Time 1 and 2, and a change score was calculated. "Wellness team stability" was categorized into four groups according to wellness team presence at two time points: "established" (both timepoints, 35%), "new" (Time 2 only, 22%), "discontinued" (Time 1 only, 13%), and "never" (neither timepoint, 30%). Paired t-tests compared wellness implementation between two times within each stability group; multi-level regression models compared LWP implementation across groups, accounting for clustering within school districts and adjusting for school demographics.

Results: Of 1349 eligible schools, 744 had complete Time 1 data (55%), 799 Time 2 (59%), and 441 both (34.2%). Schools were: 69% Elementary, 56% suburban, 35% of student body was majority (≥75%) African American/Hispanic, and 28% majority (≥75%) low-income. Time 1 mean (SD) implementation score for wellness teams was 32.0 (11.5) "established," 17.6 (11.4) "new," 28.3 (11.4) "discontinued," and 15.4 (10.7) "never." At both time points, "established" teams maintained high LWP implementation, and "never" teams maintained low implementation with no significant change over time ($p > 0.05$). Compared to "never", "new" schools experienced a greater increase in LWP implementation ($B=9.9$, $p<0.001$), "discontinued" schools decreased LWP implementation over time ($B=-10.8$, $p<0.001$).

Conclusions: Compared to schools that never had a wellness team, schools with new teams improved LWP implementation, and schools with discontinued teams declined. Schools with established teams maintained a high level of implementation. Forming and maintaining wellness teams encourages LWP implementation, and should be considered an evidence-based strategy for school wellness promotion.

WHAT DOES “DIETING” REALLY MEAN? A DAILY DIARY STUDY OF BEHAVIOR

Elizabeth McLaughlin, PhD¹, Jane E. Smith, PhD², Kelsey Serier, MS², Jamie Smith, MS², Jerry Simmons, MS³¹VA Connecticut Healthcare System, New Haven, CT; ²University of New Mexico, Albuquerque, NM; ³University of New Mexico, Albuquerque, NM

Dieting is often considered, by professionals and laypeople alike, to be a means of weight control or weight loss. Thirty to fifty percent of women report that they are dieting at any given time. Dieting is often recommended as a means of weight loss for the two-thirds of Americans who are overweight. Yet research consistently shows that self-reported dieting does not result in sustained weight loss. Understanding what “dieting” means in terms of behavior is crucial to resolving this discrepancy. However, the literature on an operational definition of dieting remains somewhat unclear. This study contributed to this literature by assessing the *daily* weight control strategies and dietary intake of people who self-identify as dieting. College women ($N = 266$) provided reports of their current eating pattern(s) (dieting, “watching what you eat,” and/or “eating healthy”) followed by three daily diaries (24-hour recalls of dietary intake and weight control strategies) elicited from them on randomly selected days during a one-month period. At baseline, 55 individuals endorsed current dieting, current “watching,” and current “eating healthy,” with 122 individuals endorsing only current “watching” and current “eating healthy,” but not dieting. Just 3 individuals endorsed current dieting only, and 31 endorsed no eating pattern. “Dieters” were participants who endorsed dieting, plus “watching” and “eating healthy,” while “non-dieters” were participants who endorsed “watching” and “eating healthy” but not dieting. The dieters’ group mean BMI was in the overweight range; the non-dieters’ was in the normal weight range. Those who were dieters at baseline did not consistently endorse dieting across daily diaries. Nevertheless, dieters reported fewer daily calories, and more overall weight control strategies, including more *healthy* weight control strategies, than non-dieters. Across groups, participants’ weights did not change significantly during the one-month study. This study’s daily diary methodology was uniquely suited to the question of what dieters typically do to influence their weight. Dieters do appear to engage in weight control strategies which could result in weight loss; however, their reports of whether they are dieting are inconsistent across days, suggesting that difficulty in sustaining behavior impedes effective weight control. These results have clinical and research implications in the area of weight loss.

ACUTE EFFECTS OF INTERRUPTING SITTING ON DISCOMFORT AND ALERTNESS OF OFFICE WORKERS

Roberto Benzo, M.S.¹, Nicholas Kruse, Ph.D.², William Hughes, M.S.¹, Darren Casey, Ph.D.¹, Lucas Carr, Ph.D.¹¹University of Iowa, Iowa City, IA; ²Uni, Iowa City, IA

Introduction: Sedentary behavior has been associated with impaired musculoskeletal discomfort and fatigue. Sedentary office workers sit as much as 75% of work time placing them at increased risk for discomfort and impaired alertness. Little is known on the acute effects of sedentary behavior on such outcomes and/or whether interrupting sedentary behavior prevents impairments in discomfort and alertness. The aim of this study was to compare the effect of four hours of uninterrupted sitting against four hours of sitting interrupted with 10 minute hourly bouts of standing or pedaling on perceived alertness and discomfort among sedentary office workers.

Methods: Fifteen middle-aged (age 36.7 ± 5.5 years) sedentary workers completed three conditions: (1) four hours of uninterrupted sitting; (2) four hours of sitting interrupted with 10 minutes of standing each hour; and (3) four hours of sitting interrupted with 10 minutes of pedaling each hour. Measures of alertness (Stanford Sleepiness Scale) and discomfort (General Comfort Rating Scale) were collected four times each hour for four hours. Within- and between-group differences in comfort and alertness were evaluated using linear mixed effects regression models. Tests of simple effects and pairwise comparisons were used for post-hoc analyses of interaction (condition x time).

Results: Discomfort significantly increased over time in all three conditions. However, the increased discomfort observed in the uninterrupted sitting was significantly greater compared to both the standing ($p < 0.001$) and pedaling ($p < 0.001$) conditions. There were no between-group differences in alertness over time. However, short-lived improvements in alertness were observed immediately following the 10-minute standing and pedaling interruptions.

Conclusions: Interrupting sedentary work with brief bouts of standing and pedaling had a positive impact on both discomfort and alertness. Further research is needed to determine the minimum dose (frequency, intensity, time and type) of sedentary interruptions necessary to support optimum health and work productivity of highly sedentary employees.

K-STATE MOVEMENT CHALLENGE: ENHANCING THE REACH AND IMPACT OF A WORKSITE PHYSICAL ACTIVITY INTERVENTION

Rebecca Gasper, B.S., Stacy Divine, BBA, Amanda D. McDiffett, PHR, SHRM-CP, Emily L. Mailey, PhD

Kansas State University, Manhattan, KS

Purpose: The worksite is an ideal place for interventions to increase physical activity since it is where many individuals spend most of their day. The Movement Challenge is one such program that was started at Kansas State University in 2015. The purpose of this study is to evaluate the successes of the program in the first few years and identify areas for improvement to increase participation across campus in upcoming years.

Methods: Faculty and Staff from all departments were invited to register for the challenge. This was structured as a competition between departments for who could log the most steps. Human Capital Services started this initiative in 2015 with minimal funds, and formed a partnership with the Kinesiology Department after the initial year. Before the second year of the program, an evaluation was conducted to identify areas to improve the program to increase participation from K-State employees across campus.

Results: The evaluation results led to multiple changes being made, including: recruiting Captains from each department, issuing weekly challenges, disseminating a weekly newsletter, expanding the challenge from four to six weeks, modifying the step-reporting process, and adding a leaderboard for percentage of employees participating. Total participation in the program at any time increased by 38% from Year 1 to 2, with 646 new participants who did not participate the previous year. Departments with Captains also reported higher participation in the program, and the number of Departments with Captains increased from 17 to 57 from year 1 to year 2, and preliminary data from year 3 indicates that number has now increased to 77. The number of departments with any participation has also increased from 87 in the initial year to 140 in year 2 and 150 in the current year. Areas identified for future change include engaging more male employees and incorporating additional recognitions for people who meet their individual step goals.

Conclusions: Forming a partnership between two groups on campus to sponsor the K-State Movement Challenge increased the impact and reach of the program. These results suggest that regular evaluation of worksite interventions is key to improving their quality and impact for the employees. K-State will continue to evaluate on an annual basis and modify the program to meet the needs of our employees and ensure faculty and staff from across the campus are reached.

PREDICTING POST-TRAUMATIC STRESS DISORDER: A MACHINE LEARNING APPROACH

Dejan Magoc, Ph.D.¹, Tanja Magoc, Ph.D.², Joe Tomaka, Ph.D.³, Stormy Monks, Ph.D.⁴

¹Stetson University, DeLand, FL; ²University of Florida, GAINESVILLE, FL; ³New Mexico State University, Las Cruces, NM; ⁴Texas Tech University, El Paso, TX

Introduction: Post-Traumatic Stress Disorder (PTSD) is an anxiety disorder that involves a specific set of symptoms which develop after experiencing, witnessing, or confronting stressful and traumatic events. With repeated exposure to such traumatic events, firefighters are at great risk for developing post-traumatic-stress (PTS) symptoms and related problems such as alcohol misuse, especially if they use alcohol as means of coping with stress. The purpose of our study was to build an automated predictor of PTSD in municipal firefighters, using three machine learning algorithms.

Methods: 740 municipal firefighters completed assessments of PTS symptoms, alcohol consumption, alcohol problems, drinking motives, and coping with stress as part of a larger study. We used data on PTS symptoms and alcohol related outcomes to train and test the machine learning algorithms, including Neural Network (NN), Naïve Bayes Method, and Decision Tree, to build and validate the automated predictor of PTSD in municipal firefighters.

Results: The results of this study indicated that the automatic predictors can successfully predict PTSD with the accuracy of 88.65% using Naïve Bayes and 91.76% using both NN and Decision Tree.

Conclusions: Even though the results are not 100% perfect, they are highly promising and show a great potential for quick and early identification of firefighters susceptible to PTSD and potentially alcohol related problems, which could help focus on less intense interventions among firefighters, such as education and simple advice rather than counseling, diagnostic evaluation, and treatment in more severe cases when firefighters with health related problems are identified in later stages.

ASSESSING SEVERITY OF ADVERSE CHILDHOOD EXPERIENCES IN CHRONIC PAIN PATIENTS

Eric Kruger, DPT/M.S.¹, Deborah Helitzer, Sc.D.², David A. Graeber, MD³, Robert Rhyne, Vice Chair for Research⁴, Kevin Vowles, PhD¹¹University of New Mexico, Albuquerque, NM; ²Arizona State University, Phoenix, AZ; ³Phoenix VA Health Care System, Scottsdale, AZ; ⁴University of New Mexico School of Medicine, Albuquerque, NM

Chronic pain, pain lasting greater than 3 months, is one of the most prevalent and costly conditions in US health care—afflicting 35% of the population and costing greater than \$635 billion dollars annually. Chronic pain is also associated with psychosocial comorbidities, such as depression and anxiety. Adverse childhood experiences (ACE) is a known factor that increases the likelihood of developing psychological dysfunction in adulthood. Children exposed to these events have poorer health in adulthood and are more likely to report headaches and other chronic pain syndromes. The aim of this study was to evaluate the association of pain related constructs (pain intensity, interference, affective pain and pain catastrophizing) and physical and mental health functioning with a new instrument for recording ACE experiences: The Brief Adverse Childhood Events Survey (BRACES), which evaluates exposure to six types of ACE (physical abuse, sexual abuse, emotional abuse, emotional neglect, physical neglect and witnessing parental violence). In total, 129 individuals with chronic pain (65.9% female) completed the BRACES while presenting for a treatment appointment. Participants were dichotomized into two groups: those that reported no ACE events and those that reported any ACE event (68% reported any ACE). No significant differences in pain intensity, interference, catastrophizing and affective pain (higher emotional ratings of pain) were found between groups. Those that answered yes to any ACE event were further analyzed via an index of severity of abuse (this index was calculated by averaging responses about severity for each type of ACE). Using hierarchical regression, the ACE severity index provided significant incremental prediction of affective pain ($p < .001$, $\Delta R^2 = 0.07$), psychological distress ($p < .001$, $\Delta R^2 = 0.17$) and mental health functioning ($p < .001$, $\Delta R^2 = 0.05$) when controlling for baseline pain and demographics.

Conclusions: In this sample, a simple dichotomization of those reporting no ACE or any ACE was not sufficient to discriminate scores on pain, physical and mental health constructs. However, the severity of the reported ACE experiences in childhood was associated with increased pain and psychological dysfunction in adulthood—this is consistent with the literature on ACE and psychological functioning and pain. The BRACES instrument provides a unique tool for assessing severity of ACEs.

e-health programs carry promise to support self-management of chronic illness, including chronic pain. Whether such programs succeed depends not only on patients' acceptance and adherence, but also on health care providers'; attitudes and willingness to support the use of such programs. Health care providers working with chronic pain have a focal role in supporting patients'; coping with pain, and their input is therefore essential for the development and utility of any tool in management of chronic pain.

Using service design methods, the present study seeks to: 1) explore health care providers'; experiences and challenges in chronic pain management, and 2) identify health care providers'; needs, requirements and potential challenges to usage of a chronic pain e-health program.

Semi-structured individual interviews were conducted with healthcare providers (N=12; i.e., an anaesthesiologist, general practitioners, psychologists, a psychiatrist, physical therapists, a registered nurse and an occupational therapist) across health service levels, all working within chronic pain management.

The interviews provide insight into health care providers'; challenges and unmet needs in management of chronic pain, as well as their prerequisites and necessities for making a chronic pain e-health program usable and efficient. The interviews reveal that health care providers often feel at a loss due to the complexity of the many challenges presented by chronic pain patients. Findings indicate a need for a common explanatory model for chronic pain across health care providers. Findings also underline lack of time to explain and provide a biopsychosocial understanding of pain for patients, and to guide the promotion and acquisition of appropriate pain coping strategies. The results emphasize the utility and potential benefit of an e-health program in a) structuring treatment and follow-up of chronic pain patients in health care practices, and b) identifying important aspects of self-management of chronic pain. Health care providers'; preferences for the intervention's content, context of use, and platform type are identified, as well as potential challenges and obstacles for implementation and use of such a technological program in health care practices.

In conclusion, findings present valuable guidance from health care providers to be considered in building, prototyping and testing a chronic pain e-health self-management program.

DECREASES IN PAIN CATASTROPHIZING AND INCREASES IN PAIN RESILIENCE ARE RELATED TO BETTER PAIN REHABILITATION OUTCOMES

Christopher R. France, Ph.D.¹, Peter Max Slepian, MS², Douglas John. French, Ph.D., L.Psych.³, Thomas Evans, MD³¹Department of Psychology, Ohio University, Athens, OH; ²Ohio University, Athens, OH; ³Atlantic Pain Clinic, Moncton, NB, Canada

Although reductions in pain catastrophizing have been related to better treatment outcomes for individuals with chronic pain, to date these effects have not been examined alongside simultaneous changes in pain resilience. Forty-four women and 45 men underwent an 8-week interdisciplinary functional restoration program and completed the following measures at admission and discharge: Pain Catastrophizing Scale, Pain Resilience Scale, Quebec Back Pain Disability Scale, and the Short Form Health Survey (SF-36). Separate hierarchical linear regressions were conducted to predict discharge ratings on the Quebec Back Pain Disability Scale and the SF-36 subscales. For each analysis, baseline (admission) score on the relevant outcome measure was entered into the first block. In the second block, (discharge minus admission) changes in catastrophizing and resilience were offered as potential predictors using a stepwise procedure. Results of the analyses indicated that: 1) improvement in SF-36 mental health scores were significantly related to increases in pain resilience ($\beta = 0.236$, $p = 0.034$), but not to changes in pain catastrophizing, and 2) reductions in back pain disability were significantly related to decreases in catastrophizing ($\beta = 0.177$, $p = 0.013$) and marginally related to increases in resilience ($\beta = -0.13$, $p = 0.068$). This study supports the growing body of literature that highlights the importance of targeting both catastrophizing and resilience in the treatment of chronic pain.

EXPERIENCES OF DISCRIMINATION IN HEALTHCARE AND PAIN COPING AND INTERFERENCE AMONG AFRICAN AMERICANS WITH OSTEOARTHRITIS

Ida Griesemer, BA¹, Liubov Arbeeva, MS², Kelli Allen, PhD³¹University of North Carolina at Chapel Hill, Carrboro, NC; ²Thurston Arthritis Research Center, Chapel Hill, NC; ³University of North Carolina at Chapel Hill, Chapel Hill, NC

Introduction: Social Stress Theory posits that coping resources may buffer the association between prejudice-related stress and negative health outcomes, but little work has been done to understand the relationship between discrimination and coping in the context of pain. This study explores how experiences of discrimination in healthcare settings relate to participants'; rumination and perceptions of pain interference.

Methods: Participants ($n=62$) were a subset of adults enrolled in a clinical trial of Pain Coping Skills Training for African Americans with Osteoarthritis (OA) who had completed variables included in these analyses to date. We conducted independent t-tests to assess differences between participants who reported any past experiences of racial discrimination in healthcare on the Personal Discrimination Multi-item measure ($n=24$, 38%) versus those who reported none on two pain coping and perception variables: ruminating on one's pain and pain interference (the degree to which one's pain interferes with daily activities). Rumination was assessed with a subscale of the Coping Strategies Questionnaire, and pain interference with the PROMIS 6-item short form; higher scores indicate more rumination and interference. We then used ANCOVA to examine group differences while controlling for lower extremity pain severity.

Results: There was a significant difference in rumination scores between those who reported past discrimination ($m=6.33$, $sd=4.00$) and those who did not ($m=8.67$, $sd=4.38$), $p=.04$. The trend remained present when controlling for pain severity ($adj\ m=6.67$ and 8.28 , respectively), $p=.15$. There was also a significant difference in pain interference between those who reported discrimination ($m=60.75$, $sd=7.31$) and those who reported none ($m=64.95$, $sd=6.39$), $p=.02$. The trend remained when controlling for pain severity ($adj\ m=62.06$ and 63.79 , respectively), $p=.16$.

Discussion: African Americans with OA who reported past experiences of discrimination in healthcare reported less use of rumination and less pain interference, as compared to those who reported no past discrimination experiences. These findings suggest that resilient responses to discrimination in healthcare may shape individuals'; pain coping and perception, making them less likely to ruminate and to view their pain as interfering with daily activities. Future research should continue to explore the links between discrimination, resilience, and pain coping and interference.

FEELING THE PRESSURE TO BE PERFECT: LINKS BETWEEN PERFECTIONISM, SOMATIZATION, AND PAIN IN A NON-CLINICAL SAMPLE OF ADOLESCENTS

Edin Randall, PhD¹, Lea Ventura, PhD², Kelly Smith, BA³¹Boston Children's Hospital, Brookline, MA; ²University of Illinois Chicago, Chicago, IL; ³Boston Children's Hospital, Waltham, MA

Introduction: Research indicates that perfectionism is associated with indicators of psychological adjustment among adolescents; however, perfectionism's links with physical health outcomes (e.g., pain and somatization) is less clear. The paucity of research is surprising given the well-established relations between psychological factors/personality traits and physical health outcomes and the mounting clinical evidence of perfectionistic tendencies among youth with chronic pain. This cross-sectional study examines links between several forms of perfectionism [self-oriented perfectionism (SOP; perfectionism pressures directed toward oneself), socially prescribed perfectionism (SPP; perfectionism pressures experienced from one's environment), effortless perfectionism (EP; pressure to appear perfect without seeming to exert effort)], somatization, and chronicity of pain in a non-clinical sample and considers gender differences.

Method: Participants included 9-12th graders (52% female; $Age=15.94$; $SDage=1.07$). Of the total sample, $n=60$ (60% female; $Age=15.95$; $SDage=1.10$) reported pain in the last month and were included in analyses. Participants completed the Child-Adolescent Perfectionism Scale [CAPS;subdomains=SOP, SPP], Effortless Perfectionism Scale (EP), and Child Somatization Inventory (CSI). Participants reported whether they experienced pain in the last month and whether pain initiated "less than 3 months" ago (acute) or "3 or more months" ago (chronic).

Results: The SPSS PROCESS dialog was used to investigate moderation models [95% bias-corrected bootstrap confidence intervals ($k = 5000$)]. Higher levels of SPP ($B = 1.04$, $SE = .47$, $p = .03$) and EP ($B = 1.57$, $SE = .73$, $p = .03$) was associated with more somatic complaints for the overall sample. For females only, SOP was linked to more somatic complaints ($B = .08$, $SE = .18$, $p = .00$) and chronic pain ($B = -9.43$, $SE = .388$, $p = .02$) while higher levels of EP was linked to acute pain among males ($B = 6.63$, $SE = 2.59$, $p = .01$).

Discussion: Findings indicate that certain types of perfectionism are differentially linked to physical outcomes based on gender. Intra-personal forms of perfectionism (SOP) are particularly salient for females and linked to more somatic complaints and chronic pain. Alternatively, interpersonal forms of perfectionism (SPP, EP) were linked to more somatization and shorter duration of pain in males. It is possible that females tend to internalize perfectionistic tendencies and associated emotional struggles which may result in physical manifestations of chronic stress. Alternatively, males may be more susceptible to external pressures to be perfect and focused on making it look easy; this tendency may be exacerbated in the context of a struggle such as acute pain. However, longitudinal studies are required to determined causal relations.

MIGRAINE SELF-MANAGEMENT ACTIVITIES AND THE RELATIONSHIP BETWEEN LOCI OF CONTROL, AND PHYSICIAN MIGRAINE MANAGEMENT.

Caitlin Kienzler, B.S. Psychology¹, Trelsie Sadler, MA², Amrita Bhowmick, MPH³, Amy Wachholtz, PhD¹¹University of Colorado Denver, Denver, CO; ²University of Colorado Denver, Boulder, CO; ³Health Union, LLC, Chapel Hill, NC

Introduction: Few research studies examine the link between avoidance of migraine triggers and patient feelings regarding internal (migraine self-management) and external loci of control (perception of physician treatment). We hypothesized that both internal and external loci, as rated by participants, would be significantly related to whether or not a migraineur reported taking active steps to avoid migraine triggers.

Method: 4,502 U.S. adult migraine participants completed the 2015 Migraine.com survey. 4,341 participants identified specific migraine triggers and steps in migraine self-management (e.g. make lifestyle/diet changes, actively seek out information on migraine medications). Locus of control ratings were assessed across multiple questions using a 7-point Likert scale.

Results: Chi square tests on migraine self-management and perceived internal locus of control ($X^2(24)=43.3$, $p < .05$), showed a significant relationship to whether a participant took active steps to avoid specific migraine triggers. However, the items related to external (physician) locus of control (e.g. physician evaluation and treatment of symptoms) did not show a significant relationship with active migraine self-management ($X^2(24)=23.9$, $p > .05$).

Discussion: Avoidance of migraine triggers and migraine self-management showed a relationship with feelings of internal loci of control but did not show a relationship with feelings of external loci of control. Further examination of perceptions of loci of control may provide intervention points to help providers encourage patients to take more active steps in preventing and reducing their migraines through self-management.

PRELIMINARY RESULTS OF A VIRTUAL PERSPECTIVE-TAKING INTERVENTION TO REDUCE RACE AND SES BIASES IN PAIN TREATMENT DECISIONS.

Adam T. Hirsh, PhD¹, Tracy Anastas, B.A.¹, Megan M. Miller, M.S.¹, Nicole Hollingshead, Ph.D.²¹Indiana University - Purdue University Indianapolis, Indianapolis, IN; ²Dept of Family Medicine / The Ohio State University, Columbus, OH

Black and low SES patients are less likely to receive guideline-concordant pain care than White and high SES patients, respectively. We developed a novel provider-focused intervention to reduce these disparities. Physician residents/fellows were recruited for this randomized controlled trial that assessed treatment biases at baseline (T1) and one-week post-intervention (T2). Physicians who were biased at T1 - i.e., showed systematic differences in their treatment decisions across patient race (Black/White) and/or SES (low/high) - were randomized to an individually-tailored perspective-taking intervention or control condition. The intervention provides personalized feedback about physicians' biases, dynamic interactions with computer-simulated patients tailored to physicians' unique biases, and videos depicting how pain has impacted the patients' lives. We are currently in year 4 of a 5-year trial testing the intervention in a large national sample. We present preliminary results characterizing the study sample, extent and nature of treatment biases at T1, and demographic and clinical characteristics of physicians who were biased at T1. Five hundred and two physicians (55% male, age = 29.7 ± 3.1 years) have completed the study. Most identified as non-Hispanic (90%) and White (64%) or Asian (25%). Most were in residency training (75%) with a moderate amount of clinical experience with pain (mean = 41.39 ± 23.93 [0–100 scale]). Over one-third (n=191) of the sample demonstrated a race and/or SES bias when making treatment decisions at T1. The "bias" group had a larger proportion of White physicians than the "no-bias" group (72% vs. 64%). Of those in the "bias" group, 121 (63%) demonstrated a race-x-SES bias, 45 (24%) a race-only bias, and 25 (13%) an SES-only bias. A higher proportion of male physicians demonstrated race-x-SES (64% male) and SES-only (56% male) biases, whereas a higher proportion of female physicians demonstrated a race-only bias (47% male). No differences were observed in the distribution of physicians by ethnicity (Hispanic vs. non-Hispanic) or race (White vs. non-White) across the bias categories. These preliminary results highlight the feasibility of our novel methods and suggest that patient race and SES have unique and interactive effects on physician decisions for pain care. These results also suggest that physician demographic characteristics are important considerations when assessing and intervening on pain treatment biases.

REDUCING DISTRESS IN PATIENTS WITH CHRONIC PAIN: IS THE PAIN TOLERANCE INDEX A USEFUL MEASURE?

Frances Deavers, PhD¹, Olufunke O. R. Awosogba, PhD², Paul Sloan, PhD³¹Michael E. DeBakey VA Medical Center, Houston, TX; ²University of Texas Southwestern Medical Center, Dallas, TX; ³Michael E DeBakey VA Medical Center, Houston, TX

As it is often impossible to alleviate chronic pain completely, patients are routinely asked about the highest acceptable or tolerable level of pain to help establish treatment goals. There is an underlying assumption that reducing pain to an acceptable level should help alleviate distress. This is reasonable, given that there is a strong association between pain and distress, such that more severe pain predicts greater distress. The pain tolerance index (PTI) is a measure of how much a patient's pain needs to change in order to be tolerable. Theoretically, a lower PTI should be linked to lower distress. However, this has yet to be empirically tested. The current study aims to establish that 1) a lower PTI predicts less distress and 2) this relationship remains significant, even when accounting for current pain level. Veterans with chronic pain (N = 205; 76.6% male) participated in a six-week pain management group. At the end of each session, participants rated their current pain, current distress, and highest tolerable pain on a Likert scale ranging from 0–10, with higher numbers representing greater pain and distress. The PTI was calculated by taking the difference between current pain and highest tolerable pain for each participant. Regression analysis of data derived from week six (post-treatment) indicated that a lower PTI significantly predicted less distress, accounting for 8.5% of the variance in distress. However, when current pain was added to the model, PTI was no longer significantly related to distress. Once current pain is taken into account, PTI does not significantly explain variability in distress among patients with chronic pain. Though PTI may be helpful for setting pain management goals in other contexts (e.g., cancer-related pain), these results suggest that attempting to decrease pain to an acceptable level may not be an effective technique for reducing distress in patients with chronic pain. Implications of these results will be discussed including 1) the need for operational definitions of acceptable or tolerable pain and 2) alternative targets for decreasing distress among patients with chronic pain.

RELATIONSHIP BETWEEN SELF-COMPASSION AND PAIN RESILIENCE IN THE CONTEXT OF ACUTE EXPERIMENTAL PAIN

France Talbot, Ph.D., L.Psych.¹, Dominique Basque, B.A.¹, Douglas John French, Ph.D., L.Psych.²¹Université de Moncton, Moncton, NB, Canada; ²Atlantic Pain Clinic, Moncton, NB, Canada

Self-compassion involves self-kindness, mindfulness and a recognition that inadequacies and suffering are shared human experiences. Cross-sectional studies have revealed that higher levels of self-compassion have been associated with greater adaptive pain coping, higher pain acceptance and less pain-related disability. The relationship between self-compassion and pain-specific resilience has yet to be examined. This study aims to assess the extent to which self-compassion relates to pain resilience and the relative contribution of these so-called protective factors to the prediction of pain catastrophizing and pain intensity in the context of experimental pain. Fifty-eight undergraduate students (53 = females; 5 = males) underwent an acute experimental pain induction using the cold pressor task. The Pain Resilience Scale and the Self-Compassion Scale-Short Form were completed prior to the cold pressor task while the Pain Catastrophizing Scale and a NRS measure of pain intensity (0 = no pain; 100 = maximum pain) were completed immediately afterward. Correlational analyses and standard multiple regression analyses were conducted. Higher levels of self-compassion were moderately related to higher levels of pain resilience ($r = .31$, $p = .02$). Neither self-compassion nor pain resilience predicted pain intensity. Self-compassion did not predict pain catastrophizing, but pain resilience was a significant predictor ($\beta = -.33$; $p = .017$). Higher levels of pain catastrophizing were moderately related to higher pain intensity ($r = .43$; $p < .001$). These findings suggest a possible mediational model in which self-compassion would relate to pain resilience which, in turn, would contribute to lower levels of pain catastrophizing which would relate to lower pain intensity. This proposed model remains to be tested among a larger sample. Interventions aiming to increase self-compassion may prove to be helpful within programs targeting pain-specific resilience as part of clinical pain management.

Background: A growing body of evidence supports the efficacy of eHealth interventions in coping with a variety of illnesses and disorders, including short- and long-term pain conditions. The efficacy and continued use of eHealth treatment programs depend not only on content and technology but also on the patients'; motivation, acceptance and adherence. Despite interest from patients, existing chronic pain eHealth studies have experienced high attrition rates. New interventions are necessary, focusing specifically on patients'; needs, perspectives, expectations and context of use.

Aim: The present study seeks to identify the unmet informational and support needs of patients with chronic pain, and to investigate how an eHealth intervention can be designed to address these needs. In doing this, caregivers experiences and needs are included. Users'; requirements for functionality and design are also explored.

Method: Individual interviews were conducted with patients living with different chronic pain conditions (N=16; e.g., neuropathic pain, musculoskeletal pain and rheumatic pain). Treatment backgrounds varied, ranging from general practitioners'; visits and physical therapy in primary health care to more specialized treatments in secondary health care. Caregivers (N=5) were also interviewed to provide insight into caregivers'; experiences, needs and perspectives and to gain a deeper understanding of the patient group.

Results: Interviews provided insight into needs and wishes of patients and their caregivers living with chronic pain related to everyday life and coping. The need for mastery, normalization and activity pacing were highlighted. Furthermore, the need for a positive distraction, especially in relation to high pain levels, stressful situations and struggles with sleep were expressed by both groups. Preferences as to design of an eHealth tool, type of platform and privacy issues were identified, showing accessibility to be a key factor for user adoption.

Conclusions: The study provides important knowledge about the everyday needs of patients with chronic pain and their preferences in relation to a digital pain management intervention. Possible areas where an eHealth intervention might support existing treatments, such as learning and mastery courses, are also identified. Results give direction for further development and prototyping of an intervention that will ultimately be tested in a randomized controlled trial.

PATTERNS IN MODE OF PHYSICAL ACTIVITY AND DIABETES RISK AMONG LATINOS IN THE U.S.

Anna Divney, DrPH¹, Tailisha Gonzalez, MPH, MS², Sandra E. Echeverria, MPH, PhD³

¹CUNY School of Public Health, New York, NY; ²CUNY Graduate School of Public Health and Health Policy, Brooklyn, NY; ³CUNY Graduate School of Public Health and Health Policy, New York, NY

Latinos are disproportionately affected by type 2 diabetes mellitus. Randomized clinical trials indicate that increasing physical activity among those with diabetes can improve glucose and lipid levels, insulin resistance, and weight reduction goals. While these studies have demonstrated that more active living can reduce chronic health disease risk, most of the research has focused on leisure-time physical activity. Little empirical evidence exists documenting if the same health-enhancing effects is evident across distinct modes of physical activity. Understanding the impact of other modes of physical activity (PA), such as transportation and work physical activity, on health may be especially important among racially/ethnically diverse populations who may have less time for leisure time physical activity given these groups, on average, are more socially disadvantaged than non-Latino whites. In prior studies from our research team (under review), we showed that vigorous work physical activity made up a significantly higher proportion of all modes of physical activity among foreign-born Latinos (19.51%) compared to U.S.-born Latinos (13.03%) and non-Latino whites (15.03%) and were significantly more likely to meet physical activity guidelines through transportation physical activity. The present study builds on this earlier work and examines how leisure, work, and transportation physical activity, are independently associated with diabetes prevalence among Latinos participating in the 2007–10 NHANES. The weighted means and percentages of key sociodemographic characteristics and prevalence of each PA outcome and diabetes status will be presented and log binomial models fit to examine associations between each mode of PA and diabetes adjusting for relevant covariates. We hypothesize that diabetes prevalence will differ across each mode of physical activity, but will show higher diabetes prevalence among those engaged in the lowest levels of all modes of physical activity. Investigating patterns in physical activity and diabetes for Latinos compared to non-Latino Whites could shed light on acculturation-related processes related to changes in health status and health behaviors for immigrant-origin populations.

A QUALITATIVE STUDY EXPLORING PERCEPTIONS SURROUNDING PHYSICAL ACTIVITY MONITORS IN USERS AND NON-USERS

Natalie Golaszewski, MA¹, Katie Burford, B.S.², John Bartholomew, PhD³

¹University of Texas, Austin, Austin, TX; ²University of Texas at Austin, Austin, TX; ³The University of Texas at Austin, Austin, TX

Introduction: Wearable physical activity monitors are gaining popularity and use in health behavior research. However, the general perceptions of these monitors is unclear. Therefore, the purpose of this study is to qualitatively explore the perceived psychological constructs and health benefits of wearable physical activity devices.

Methods: Participants were 21 adults (24 - 60 years; 57.1% female; 95.2% non-Hispanic/Latino; 85.7% white). All engaged in moderate to high levels of physical activity. Six focus groups were conducted with 3 - 5 exercisers, with half composed of those who used wearable monitors and half composed of non-users. Each focus group lasted between 30 and 60 minutes. Each focus group was audio recorded, transcribed, and analyzed using an iterative approach creating first-level descriptive codes followed by second-level analytic codes. A combination of these codes allowed for generating broader themes.

Results: *General perceptions.* Non-wearable users described wearable monitors to be costly and inaccurate. In addition, they viewed users as being overly responsive to popular trends, and materialistic. Wearable users valued these devices for tracking activity, personal accountability, goal setting, and validation. Despite this, wearable users expressed a cyclical relationship between using their monitors to help achieve goals, then reducing use before returning to the monitors. *Psychological constructs.* Non-wearable users expressed a number of positive feeling towards wearable activity monitors as they provide a sense of achievement, pride, and happiness. On the other hand, they described these devices as bringing added stress, dependency, and reflecting attention seeking behaviors. While wearable users had positive emotional reactions towards their devices, they also mentioned feelings of co-dependence on their device eliciting anxiety, guilt, and added stress.

Health benefits. If characteristics of wearable devices changed (i.e., user friendliness and more affordable), non-wearable users might be motivated to use them to engage in more physical activity, but still questioned the sustainability of this use. Both wearable and non-wearable users supported the use of devices in the medical field as they would be helpful for providers and patients – if they could be more affordable.

Conclusion: Both users and non-users held a number of positive opinions with regard to wearable activity monitors. Users emphasized the benefits for motivation and accountability, while non-users emphasized high cost, poor accuracy and stigmas for use. Interestingly, both groups were concerned that the devices would invoke feelings of guilt and dependence. These data suggest a number of areas for further investigation to better leverage activity monitors to increase physical activity behavior.

A RANDOMIZED STUDY TESTING INCREMENTAL VERSUS ADAPTIVE GOAL SETTING USING AN INCENTIVE-BASED MHEALTH APP

Lauren White, MSc¹, Marc Mitchell, PhD²¹Carrot Insights, Toronto, ON, Canada; ²Western University, London, ON, Canada

Objective: The Carrot Rewards application ('app;') was developed as part of a novel public-private partnership to reward Canadians with loyalty points (e.g., groceries) for walking more. The purpose of this study was to examine different methods of setting daily step goals (i.e. incremental vs. adaptive goal setting).

Methods: A 26-week randomized study was conducted in which 1,722 participants were enrolled in the Carrot Rewards walking program between November 1st and 14th, 2016. During the two-week baseline period, mean steps/day were calculated for each participant. Thereafter, participants earned incentives (\$0.04 Cnd) every day they reached their baseline mean (i.e. level of first daily step goal). Participants earned additional points (worth \$0.40 Cnd) for meeting their step goal 10 out of 14 days. Upon meeting the 10-day contingency, participants could increase their daily goal by 500 steps, with the objective of gradually increasing their number of steps by 3,000 each day ('incremental goal setting'). At Study Week 15, about one out of every eight users was randomly selected to continue with the incremental goals approach for 12 more weeks. The remaining users were exposed to the new, adaptive goal setting approach. With the adaptive goal setting, daily step goals were *re-calculated monthly* (i.e. mean steps/day from the past 30 days) to better reflect recent activity patterns (e.g., with changing seasons, injury, etc.). The primary study outcome was the difference in mean steps/day between the two groups at Study Week 26, and was analyzed using independent t-tests.

Results: Among users enrolled in the Carrot Rewards walking program, 655 had complete data sets (4 valid days at baseline, Study Week 3 and 26; 38%). Participants were predominantly female (64%) and aged 35 years. At Study Week 15, 90 users (14%) continued with incremental goal setting, while 565 received adaptive goals. While there was no statistically significant difference between the groups at Study Week 26 (difference = 514 steps/day, $p = .213$), users receiving adaptive goals walked more steps per day from the baseline period to Study Week 26 (766 steps/day) compared to those in the incremental goal group (230 steps/day).

Conclusions: While promising, the adaptive goal setting approach did not increase physical activity to a greater extent than the incremental approach. Future research should focus on the differential effects over longer periods.

COMPARISON OF PHYSICAL ACTIVITY AND OUTDOOR PLAY ENVIRONMENTS OF FAMILY CHILDCARE HOMES AND CENTERS IN NEBRASKA

Danae Dinkel, PhD¹, Dipti Dev, PhD², Yage Guo, MS³, Emily Hulse, MS⁴, Zainab Rida, PhD, RD, LMNT⁵, Ami Sedani, MPH⁶, Shane Warehime, MS⁷, Brian Coyle, MPH⁶

¹University of Nebraska Omaha School of Health & Kinesiology, Omaha, NE; ²University of Nebraska at Lincoln, Lincoln, NE; ³University of Nebraska Lincoln, Lincoln, NE; ⁴Children's Hospital & Medical Center - Center for the Child & Community, Lincoln, NE; ⁵Nebraska Department of Education, Lincoln, NE; ⁶Nebraska Department of Health and Human Services, Lincoln, NE; ⁷University of Nebraska at Omaha, Omaha, NE

Purpose: Since 2010, Nebraska state and local partners have collaborated to offer the Nutrition and Physical Activity Self-Assessment for Childcare (Go NAP SACC) to family childcare homes (FCCH) and childcare centers (CCC) across the state. However, FCCHs and CCCs have unique characteristics that may impact the type of physical activity environment they offer to the children they serve. For example, CCCs usually have bigger facilities and more staff compared to FCCHs. To date, no research has examined differences that may exist in the physical activity environments between FCCHs and CCCs in Nebraska. Identifying these differences is critical to understanding how to best support each setting to achieve best practices. Therefore, the purpose of this study was to assess and compare differences in the physical activity environment of FCCHs and CCCs in Nebraska.

Methods: FCCHs ($n = 201$) and CCCs ($n = 102$) participated in the Go NAP SACC pre-evaluation during 2014–2016. This study examined the results from 2 of the 5 Go NAP SACC self-assessments: Infant and Child Physical Activity and Outdoor Play and Learning. Answers were coded as 1 = barely met, 2 = met, 3 = exceeded, and 4 = far exceeded childcare standards based on Go NAP SACC recommended best practices. Multivariate analyses were conducted to evaluate differences.

Results: The result indicated that FCCHs and CCCs both performed significantly better than their counterparts on several items. FCCHs reported higher ratings in respect to the following items: 1) the amount of time providing for children's indoor and outdoor physical activity ($p < .01$); 2) offering tummy time to non-crawling infants (.028); 3) the amount of adult-led physical activity provided to children each day ($p < .01$); 4) the time limit that children were asked to remain seated ($p = .044$); 5) covering a variety of physical activity topics during professional development ($p = .003$); and 6) the amount of shade provided outdoors ($p = .012$). CCCs reported higher ratings in: 1) provision of outdoor play ($p = .015$); 2) the amount of time providing for outdoor play each day ($p = .032$); 3) the use of the outdoors for a variety of activities (free play, structured learning; $p = .03$), and 4) the number of play areas in outdoor play spaces (sand box, swings; $p = .036$). Both providers FCCHs and CCCs scored relatively lower on education and professional development and policy dimensions across physical activity and outdoor play practices.

Conclusions: Interestingly, FCCHs showed significantly higher achievement of childcare standards in relation to infant and child physical activity in general whereas CCCs reported higher scores in regards to outdoor play and learning. Future research should examine if there are ways FCCHs and CCCs can learn from each other in order to continue to improve quality in these areas.

DEVELOPMENT OF SMART WALK: A CULTURALLY RELEVANT SMARTPHONE-BASED PHYSICAL ACTIVITY PROGRAM FOR AFRICAN AMERICAN WOMEN

Rodney P. Joseph, PhD¹, Barbara Ainsworth, PhD, MPH², Steven P. Hooker, Ph.D.¹, Marc A. Adams, PhD, MPH¹, Sonia Vega-López, Ph.D.¹, Glenn Gaesser, PhD¹, Michael Todd, PhD¹, Colleen Keller, PhD¹

¹Arizona State University, Phoenix, AZ; ²College of Health Solutions, Arizona State University, Phoenix, AZ

Background. African American (AA) women perform low physical activity (PA) levels (i.e., 36% achieve the national aerobic PA guidelines) and experience a high burden of associated cardiometabolic disease conditions (i.e., 82% are overweight/obesity, 48% have cardiovascular disease, and 10% have type 2 diabetes). To address these PA and cardiometabolic disease health concerns, our research team has developed Smart Walk, a culturally relevant, Social Cognitive Theory-based smartphone-delivered intervention designed to increase PA and reduce cardiometabolic disease risk among AA women aged 24–49. The Smart Walk smartphone application includes 4 key features to promote PA: 1) Multi-media PA promotion modules delivered on a weekly basis in the form of 3–7-minute videos and electronic text with images, 2) discussion boards for participants to discuss the weekly PA modules and give/receive social support, 3) a PA self-monitoring/tracking tool, and 4) brief PA promotion messages delivered 3 times per week via push notifications. The purpose of this presentation is to describe the development process of the Smart Walk program.

Methods. Development has followed a 4-phase process. Phases 1–3 are complete. Phase 4 is ongoing with completion scheduled for March 2018. **Phase 1** used a series of focus groups (n=9) with 25 AA women (*M* age = 38.5 years, *M* BMI = 39.4 kg.m²) to identify essential theoretical and cultural factors associated with PA. In **Phase 2**, qualitative data collected during Phase 1 were analyzed using NVivo qualitative data analysis software and findings were used to enhance the theoretical fidelity and cultural relevance of the PA program. In particular, intervention materials were designed to target five Social Cognitive Theory constructs (i.e., self-efficacy, self-regulation, social support, behavioral capability, and outcome expectations) and were culturally tailored to address three cultural characteristics of African American women (i.e., collectivism/ethic of care, racial pride, and physical appearance norms). **Phase 3** focused on technical development of the PA promotion materials. For this phase, we partnered with a copy editor to ensure all text-based intervention materials were written at < 8th grade reading level and a local photographer/videographer to create professional photos and video vignettes for the PA program. For **Phase 4**, the research team is collaborating with software engineers to develop the Smartphone app used to deliver the Smart Walk program.

Results. The development process described is designed to maximize usability, cultural relevance, and impact of a smartphone-based PA program for AA women. The program is scheduled to be tested in an 8-month randomized controlled pilot trial beginning Fall of 2018.

Conclusions. The Smart Walk intervention has the potential of promoting PA and reducing cardiometabolic disease risk among AA women.

DO DOG WALKERS ACCUMULATE MORE MODERATE PHYSICAL ACTIVITY MINUTES THAN NON-DOG WALKERS?

Katie Becofsky, PhD¹, Brittany Mastellar, MS¹, Connor Saleeba, N/A¹, Alec Shostek, N/A²

¹UMASS Amherst, Amherst, MA; ²University of Massachusetts Amherst, Amherst, MA

There is growing interest in the health benefits of dog ownership, including the role of dogs in promoting regular physical activity (PA). Research suggests that dog walking can help owners meet PA guidelines, but few studies have used accelerometers to verify that self-reported dog walkers engage in more moderate PA than non-dog walkers. It is plausible that dog walking replaces other PA and/or that dog walking falls below moderate-intensity.

PURPOSE: To examine accelerometer-measured PA levels among dog owners that report regularly versus never walking their dog.

METHODS: Forty-two dog owners who reported exercising ≤ 3 d/week were enrolled in a stealth health intervention involving dog obedience training. Participants wore an Actigraph GT3X on their right hip and recorded all dog walking activity for 7d at baseline. We examined average min/d of moderate PA among regular dog walkers (≥ 4 d/wk) compared to non-dog walkers (0d/wk) and summarized self-reported dog walking behavior using descriptive statistics.

RESULTS: Twenty participants (80% female; mean age 35 ± 10 years) were included in analyses; seven reported walking their dog ≥ 4 d/wk and thirteen reported walking their dog 0d/wk. Dog walkers reported 20 ± 11 min/d of dog walking (range 10–43 min/d). Dog walkers averaged 31.4 ± 13.0 min/d of moderate PA compared to 16.2 ± 9.3 min/d among non-walkers ($p=0.007$).

CONCLUSION: This investigation is consistent with previous literature suggesting that owners that walk their dog accumulate more health-promoting PA than owners that do not walk their dog. More research is needed to verify the intensity of dog walking in general and across dog sizes and breeds. Novel interventions that promote dog walking among inactive dog owners may have significant public health benefit given that millions of American households own dogs.

DOSE RESPONSE ASSOCIATION OF OBJECTIVE PHYSICAL ACTIVITY WITH MENTAL HEALTH IN A REPRESENTATIVE NATIONAL SAMPLE OF ADULTS

Paquito Bernard, Pr¹, Isabelle Doré, PhD², Ahmed-Jerome Romain, PhD³, Gabriel Hains-Monfette, Baccalaureate⁴, Catherine Sabiston, PhD⁵

¹Université du Québec à Montréal, montreal, PQ, Canada; ²University of Toronto, Montreal, PQ, Canada; ³University of Montreal Hospital Research Centre (CRCHUM), Montreal, PQ, Canada; ⁴Université du Québec à Montréal, Montréal, PQ, Canada; ⁵University of Toronto, Toronto, ON, Canada

Objectives: Although higher physical activity (PA) levels are associated with better mental health, previous findings about the shape of the dose–response relationship between PA and mental health are inconsistent. Furthermore, these associations may differ according to sedentary levels. We investigated the cross-sectional dose-response associations between objectively measured physical activity and mental health in a representative national sample of adults. We also examined whether sedentary time modified the PA - mental health association.

Methods: Physical activity and sedentary were measured using accelerometry in Canadians aged 20 to 69 years. Using data from Canadian Measures Health Survey (n=8150), generalized additive models with a smooth function (adjusted-for socio-demographic and health behavioral factors) were fitted to examine associations between moderate and vigorous PA (MVPA), light PA (LPA) (minutes/day), daily steps (combined or not with sedentary) and self-rated mental health.

Results: A curvilinear relationship between average daily minutes of MVPA ($p < 0.001$) and mental health was observed, with benefits until 50 min/day. For LPA, a more complex shape (monotonic and curvilinear) was found ($p = 0.003$). For daily steps, inverted U-shaped curve suggested increasing benefits until 5000 steps ($p < 0.0001$). The tested PA-sedentary combinations showed that increasing sedentary time buffered the positive PA-mental health associations.

Conclusion: Non-linear dose-response patterns between the PA characteristics and mental health were observed. Our empirical findings make a unique contribution in the literature by providing a new understanding of PA-sedentary interplay with mental health, using objective measures and population-level data. From a public mental health perspective, four messages can be drawn from this: every daily MVPA minutes until 50 minutes are positively associated with mental health; every daily steps are positively associated with mental health and more than 5000 are associated with benefits; when LPA is combined with MVPA, greater benefits for mental health might be achieved and the “move more and sit less” strategy might also apply to mental health.

EFFICACY OF CLINIC-BASED TREADMILL WALKING IN CREATING BEHAVIORAL CHANGE IN OVERWEIGHT AND OBESE ADULTS WITH BIPOLAR I DISORDER

Jacob Poynter, M.D. Candidate¹, Alessandro Cuomo, MD², Suzanne Havstad, MS³, Anne Germaine, PhD⁴, Andrea Fagiolini, MD⁵, Ellen Frank, PhD⁶, David J. Kupfer, MD⁶, Carol Janney, PhD⁷

¹Michigan State College of Human Medicine, Midland, MI; ²Division of Psychiatry, Department of Molecular Medicine University of Siena School of Medicine, Siena, N/A, Italy; ³Henry Ford Health System, Detroit, MI; ⁴Associate Professor of Psychiatry and Psychology, University of Pittsburgh School of Medicine, Pittsburgh, PA; ⁵Division of Psychiatry, Department of Molecular Medicine University of Siena School of Medicine, Siena, N/A, Italy; ⁶Department of Psychiatry, University of Pittsburgh School of Medicine, Pittsburgh, PA; ⁷Michigan State University College of Human Medicine, Midland, MI

Objective: To determine the efficacy of in-clinic treadmill walking as part of a weekly behavioral intervention program among overweight and obese adults with bipolar I disorder (BD).

Design: Randomized clinical trial; Reducing Medical Risk in Individuals with BD (MEDRISK) Study: baseline data collected 2009–2011.

Setting: Depression, Mania-Depression Prevention Program, University of Pittsburgh Medical Center, Pittsburgh, PA, USA

Participants: Overweight and obese ($BMI \geq 25 \text{ kg/m}^2$) adults (18–55 years) diagnosed with BD in remission (Hamilton Rating Scale 2510, Young Mania Rating Scale8, Clinical Global Impression-Bipolar

Methods: The IRRi behavioral intervention consisted of 15 weekly sessions (focusing on improving sleep/wake disturbances, social rhythms, nutrition and physical activity (PA) to reduce medical comorbidities and improve psychiatric and functional outcomes) delivered by a lifestyle coach trained as a health educator in a private office. Optional in-clinic treadmill walking protocol consisted of walking for 10 min for the first session with 5 min increases/session to a maximum of 45 min of treadmill walking/session. Daily PA (total and aerobic steps) was estimated using Omron pedometer at baseline, 4- and 6- month follow-up. Valid monitoring days defined as total steps/d > 500 and pedometer worn > 8 hrs/d. Paired t-tests used to detect step differences from baseline to follow-up.

Results: Optional clinic treadmill walking was offered to 37 of the 50 (74%) IRRi participants and 54% (n=20) expressed interest in treadmill walking. At baseline, participants averaged 5075 ± 2128 total steps/day. On average, participants walked on the treadmill for 29 ± 9 min, 1.4 ± 0.5 miles, 3 mph, 8 ± 6 (62%) of sessions. Treadmill walkers (n=16) increased PA by an average of 857 steps/day ($p=0.11$) and 5690 aerobic steps/wk ($p=0.04$) from baseline to 4-month follow-up (end of weekly in-clinic treadmill walking sessions). At 6-month follow up, neither in-clinic treadmill walkers ($p=0.62$) nor non-treadmill walkers (n=17, $p=0.83$) had a statistically significant change in daily steps compared to baseline.

Conclusion: Weekly in-clinic treadmill walking with a lifestyle coach facilitates PA in adults with BD. However, less frequent sessions (monthly or longer) with a lifestyle coach or programs of inadequate duration may not be sufficient to sustain behavioral change in this high-risk population.

EXPLORING PHYSICIANS' INTENTION TO PROVIDE EXERCISE COUNSELING TO PATIENTS IN TAIWAN USING THE THEORY OF PLANNED BEHAVIOR

Jiun-Hau Huang, S.M., Sc.D., An-Min Lynn, M.D., M.P.H., Chia-Hsien Hsu, B.S.

National Taiwan University College of Public Health, Taipei, Taipei, Taiwan (Republic of China)

Background: Overweight/obesity and chronic diseases could largely be attributed to lack of physical activity (PA). Lately, increasingly more clinical guidelines have recommended that physicians should provide patients with exercise counseling (EC) to help increase their PA, through which the patients could not only improve their lifestyle but also enhance their treatment effects. However, little is known about the current situation of physicians'; intention to provide EC for outpatients in Taiwan. Hence, this study aimed to examine physicians'; intention to provide EC and their associated factors using the Theory of Planned Behavior (TPB).

Methods: Using the TPB as a theoretical framework, a quantitative questionnaire was developed, including the single-item measures and multiple-item scales of TPB constructs—Attitude Toward the Behavior (ATB), Subjective Norm (SN), and Perceived Behavioral Control (PBC). A total of 27 individual TPB items were factor-analyzed to form 5 multiple-item scales (i.e., ATB about positive and negative outcomes, general SN, and PBC under facilitating and constraining conditions), which demonstrated satisfactory psychometric properties. Survey responses from 1,016 physicians were included in the multivariate logistic regression analyses to examine the TPB-based factors related to higher EC intention.

Results: Only 42.8% of the physicians were classified as having higher intention to provide EC. Regarding the single-item measures of the TPB constructs, physicians perceiving positive ATB (AOR=3.28), supportive SN (AOR=3.73), and high PBC (AOR=4.24) reported higher intention to provide EC. As for the multiple-item scales of the TPB constructs, perceiving neutral (AOR=2.14) and positive (AOR=4.40) ATB about positive outcomes was linked to higher intention to provide EC. When perceiving neutral (AOR=2.21) and supportive (AOR=3.62) general SN, physicians were more likely to have higher intention to provide EC. Physicians perceiving high PBC under facilitating conditions (AOR=1.54) were more likely to have higher intention to provide EC.

Conclusions: Less than half of the physicians in this study had higher intention to provide EC. The study also showed that the higher the level of these main TPB constructs, namely, ATB about positive outcomes, general SN, and PBC under facilitating conditions, the higher the intention of physicians to provide EC for outpatients. These findings can inform future research and clinical practice.

FEASIBILITY AND EFFECT OF A PEER MODELING WORKPLACE PHYSICAL ACTIVITY INTERVENTION FOR WOMEN

Sheri Rowland, PhD, MSN, APRN-BC

Univeristy of Nebraska Medical Center, Omaha, NE

Purpose: Work, marriage, and children have a greater negative influence on healthy physical activity (PA) behavior in women compared to men. The purpose of this study was to evaluate the feasibility and effect of a 12-week workplace, peer modeling intervention on cardiorespiratory fitness and cardiovascular risk in working women.

Theoretical Framework: Social cognitive theory (self-efficacy) and social comparison theory support the peer modeling intervention. Skills and new patterns of behavior can be developed through observation of and self-comparison to, a model successful with a health behavior.

Methods: A randomized, two-group, pretest-posttest design was used. Inactive women 19 to 65 years of age were recruited from employees of a Midwestern health system. Participants were randomized to either the attention control group (ACG) (n = 26) or the intervention group (IG) (n = 26). Both groups met every other week for six lunch and learn presentations. The ACG received general health information. The IG participated in six group sessions with an active peer model, received an exercise prescription, and PA information. Pre and post measures were: PA (ActiGraph), Estimated VO_{2max} (cycle ergometer), resting heart rate (HR), fasting glucose and lipids, and lifetime cardiovascular risk. Data analysis was completed using hierarchical linear modeling.

Results: Thirty-nine women completed both pre and post testing (ACG n = 22; IG n = 17). No significant group by time interaction effects were found. Although both groups increased their PA levels over time (F [df = 1] = 11.4, p = .002), primary outcomes that favored the IG were estimated VO_{2max} (IG = 6.7%; ACG = 4.2%) and resting heart rate (IG = -5.3%; ACG = -1.0%). Secondary outcomes that favored the IG were lifetime cardiovascular risk (IG = -13.0%; ACG = -3.2%), total cholesterol (IG = -3.1%; ACG 1.3%), triglyceride (IG = 6.6%; ACG = 30.6%) and LDL (IG = -2.7%; ACG = 0.3%).

Conclusions: A workplace peer modeling intervention was feasible although there was greater drop-out in the IG compared to the ACG. Although PA increased in both groups, the IG had greater improvements in fitness (VO_{2max} , HR) and cardiovascular risk (total cholesterol, triglyceride, LDL, calculated risk score) compared to ACG. Results support repeating the intervention in a fully powered study.

6:30 PM-7:30 PM

FEASIBILITY OF AN ACCEPTANCE-BASED INTERVENTION TO PROMOTE ADOLESCENT PHYSICAL ACTIVITY

Amanda Woodworth, N/A¹, Margaret Schneider, Ph.D.²¹University of California Irvine, Irvine, CA; ²University of California, Irvine, Irvine, CA

Background: Most adolescents do not meet the recommended 60 minutes of physical activity (PA) per day. Moreover, school-based interventions have shown little to no impact on increasing PA. Unlike most PA interventions, acceptance-based behavioral treatments (ABT) encourage individuals to adopt new behavior patterns by accepting internal experiences (emotions, urges, physiological sensations) rather than working to change them. To date, interventions to promote increased adolescent PA using ABT have not been tested. This study reports on the feasibility of such an intervention.

Methods: A pilot study was conducted with 9 middle-school students to examine the feasibility of delivering 12 weekly behavioral counseling sessions combined with activity monitoring. Interviews were conducted during sessions 6 and 10 to elicit adolescents' thoughts about wearing the Fitbit Flex activity monitor daily for 12 weeks and attending weekly behavioral counseling sessions during the PE period. Qualitative analysis of interview responses was conducted using ATLAS.ti 8.0 to code responses and identify themes.

Results: Three participants (2 control and 1 intervention) were dropped from the study due to noncompliance with assessments ($N = 1$) or injury ($N = 2$). At least 3 weekly sessions had to be rescheduled for 8 participants (range = 3 to 8), and all participants completed all 12 sessions. Perceptions of the Fitbit were overwhelmingly positive, with all participants reporting it was a helpful reminder to meet their activity goals and most participants commenting that it was natural or comfortable to wear. All students reported that they noticed at least one positive change, including having more energy ($N = 6$), trying harder in PE ($N = 5$) and being more focused ($N = 3$). Negative comments related to the Fitbit were primarily related to the need to charge the device every 5–7 days, and negative comments about study participation related primarily to the cardiorespiratory fitness test or missing specific preferred activities during the PE period. Four out of the nine participants were able to report using an acceptance-based skill when asked. Most of the participants perceived they were now being more active or involved during PE, and four out of the nine students reported that they were spending more time engaged in PA.

Conclusions: A 12-week-school based intervention incorporating activity monitoring with weekly behavioral counseling is feasible and was received overwhelmingly positively by middle-school students. As a whole, the students liked wearing the Fitbits and reported experiencing positive changes over the course of the intervention. Reported utilization of the acceptance-based skills was modest, suggesting that the guided monitoring of activity levels may have been the more influential component of the intervention.

I THINK THEREFORE I AM? EXAMINING THE RELATIONSHIP BETWEEN EXERCISE IDENTITY AND EXERCISE IN BEHAVIORAL WEIGHT LOSS TREATMENT

Leah Schumacher, M.S., Stephanie Kerrigan, M.S., Christine C. Call, A.B., Jocelyn Remmert, B.A., Fengqing Zhang, Ph.D., Meghan Butryn, Ph.D.

Drexel University, Philadelphia, PA

Exercise identity (EI), or the degree to which one identifies as an exerciser and incorporates exercise into his or her self-concept, has been hypothesized to promote continued engagement in exercise. However, research on EI is limited by frequent use of self-report measures of exercise, cross-sectional designs, and research in convenience and/or physically active samples (vs. key populations for increasing exercise, such as individuals with obesity). This study examined: (1) demographic and anthropomorphic predictors of EI at the beginning of behavioral weight loss (BWL) treatment, (2) the relationship between EI and engagement in objectively-measured moderate-to-vigorous activity (MVPA) at the start of treatment, (3) change in EI during the first 6 months of treatment, as the exercise prescription increased, and (4) the relationship between change in EI and MVPA at 6 months. Participants ($N=320$) were adults with overweight or obesity ($M_{BMI}=35.1 \text{ kg/m}^2$) who received 16 sessions of group-based BWL over 6 months. The exercise prescription increased from 0 to 250 minutes of MVPA per week during this time. EI was measured with the Exercise Identity Scale at 0 and 6 months; MVPA per week was measured by waist-worn accelerometers at both times points. BMI was negatively correlated with baseline EI ($b=-0.05$, $p=0.003$), and identifying as non-White (vs. White) predicted greater baseline EI ($b=-0.38$, $p=0.04$). Controlling for these variables, baseline EI was significantly and positively associated with baseline MVPA ($b=0.20$, $p<0.001$). EI increased substantially from 0 to 6 months ($p<0.001$; partial $\eta^2=0.15$), but change in EI from 0 to 6 months did not predict MVPA at 6 months ($b=-.002$, $p=.76$) when controlling for baseline MVPA, baseline EI, and relevant demographic variables. These findings support the relevance of EI to exercise behavior among BWL participants at the start of treatment, and demonstrate that EI increases during BWL treatment. However, the hypothesis that increases in EI would translate into greater MVPA was not supported. This may be due to differing motivations for exercise across participants; for example, EI may be less predictive of MVPA among individuals with a high level of external motivation for exercise. Future research should examine whether factors such as motivation moderate the relationship between EI and MVPA, as well as whether increases in EI during BWL confer benefit for exercise maintenance after program contact reduces or ends.

INITIAL VALIDATION OF A NEW THREE PHASE HABIT MEASURE IN THE PHYSICAL ACTIVITY DOMAIN

Cassandra J. Husband, BSc, Dr. Ryan E. Rhodes, PhD

University of Victoria, Victoria, BC, Canada

Background: The benefits of physical activity (PA) have been well-established, yet most of the population is inactive. A sound understanding of PA antecedents is likely to improve intervention success. Most PA research has focused on conscious, reflective determinants (e.g., attitudes, intentions), yet emerging research suggests that reflexive factors such as habit may also determine PA. Habit is an automatic behavioral response triggered by a stimulus. Due to the complexity and duration of PA behavior, habit may be most important during the initiation of PA and less relevant during its execution. However, the effect of habit in multiple phases on PA performance (preparation, initiation, execution) requires continued investigation. Additionally, habit research has relied primarily on results from the Self-Report Habit Index (SRHI), which has been criticized for under-representation of the stimulus-response aspects of habit formation and an over-reliance on behavioral frequency, which may or may not be reflective of habit. Alternative measures of PA habit would be useful. The purpose of this study was to examine the validity and reliability of a short-item measure of PA habit, and whether the three phases of habit contribute to explaining levels of PA.

Methods: Undergraduate students at the University of Victoria completed an online survey including the SRHI, the alternative habit measure (with item content covering automaticity, absence of will-power, cues, and thoughts other than PA), exercise intentions, and current exercise participation.

Results: We received 609 responses (29.6% male, mean age=21.51; SD=4.70). Reliability of the five-item short form habit measure was adequate for preparation (.72), initiation (.76), and execution (.77) phases of PA. The SRHI was significantly ($p < .01$) associated with the phases of preparation ($r = .73$), initiation ($r = .78$), and execution ($r = .53$) in the instrument. Correlations with PA were also significant ($p < .01$) for preparation ($r = .34$), initiation ($r = .51$), and execution ($r = .29$), yet only initiation habit was independently associated with PA in multiple regression analysis [$F(3, 459) = 54.64$; $p < .01$]. Finally, both initiation habit ($\beta = .37$; $p < .01$) and intention ($\beta = .31$; $p < .01$) were significant independent predictors of PA explaining 33% of its variance [$F(3, 460) = 53.81$; $p < .01$].

Conclusion: The three phases of habit had acceptable reliability and were associated with PA and the SRHI, which supports the validity of the new measure. This test also supports past research and theory that initiation habit may be the crucial phase for PA. Habit formation promotion may have utility in PA intervention independent of more standard intention promotion approaches.

OSTEOPATHIC MEDICAL STUDENTS' KNOWLEDGE AND ATTITUDES TOWARD EXERCISE PARTICIPATION, RECOMMENDATIONS, AND COUNSELING

Emily Guseman, PhD¹, Jonathon Whipps, MS², Elizabeth A. Beverly, PhD³

¹Ohio University Heritage College of Osteopathic Medicine, Athens, OH; ²Ohio University, Athens, OH; ³Ohio University Heritage College Osteopathic Medicine, Athens, OH

Current guidelines recommend that primary care physicians provide physical activity (PA) counseling as part of routine preventative healthcare. However, specific education regarding PA recommendations is typically not included in medical school curriculum and it is unclear whether future physicians are prepared to offer effective counseling in this area.

PURPOSE: The purpose of this study was to describe first year medical students' personal knowledge and attitudes toward the importance of PA for themselves and their future patients.

METHODS: An electronic anonymous survey was distributed to all first-year osteopathic medical students enrolled at an osteopathic medical school in the Midwestern US. The survey, designed specifically for this study, assessed health-related knowledge, beliefs, and behaviors.

RESULTS: A total of 144 students (mean age 24.1 ± 2.0 y; 52.8% female, 71.3% white) completed the survey. Most students (91.0%) indicated that living a healthy lifestyle was "extremely important" or "very important" to them, while 86.9% prioritized PA at least "moderately". Over half exercised for at least 30 minutes on at least 3 of the last 7 days, but only 29.5% reported doing so on at least 5 days. Nearly all of the students (95.5%) indicated that exercise is "extremely important" or "very important" for their future patients, 72.9% indicated feeling at least "moderately comfortable" counseling patients, and 84.3% desire to include counseling in their practice. However, only 59.7% indicated that they are aware of current PA recommendations for American adults.

CONCLUSIONS: Although participants prioritized exercise for themselves and their future patients and indicated a desire to include exercise counseling as part of routine clinical care, the majority were unaware of the current PA recommendations for American adults. Thus, there is a need to specifically address PA recommendations as part of the medical school curriculum.

PERSONALITY PROFILES, EXERCISE TRIAL ATTRITION AND ADHERENCE: DO THE BIG FIVE MATTER?

Daniel Palac, MA¹, Jason D. Cohen, B.S.², Tiffany Bullard, B.S.³, Arthur Kramer, PhD⁴, Edward McAuley, PhD³, Sean P. Mullen, PhD³¹University of Illinois at Urbana-Champaign, Champaign, IL; ²University of Illinois at Urbana-Champaign, Champaign, IL; ³University of Illinois at Urbana-Champaign, Urbana, IL; ⁴Northeastern University, Boston, MA

The relationship between personality and exercise self-regulation is unclear. There is reason to believe that profiles of personality traits may exist (unobserved, empirically derived subgroups, i.e. “latent classes”) that lend themselves to more favorable outcomes regarding exercise behavior. To date, research has mostly focused on conscientiousness (*C*) and neuroticism (*N*), as these traits are associated with occupational success and life satisfaction. The purpose of this study was to test whether inter-individual differences in the Big Five (BF) personality traits were associated with exercise behavior in the context of a randomized controlled trial involving a multicomponent cognitive training (CT) program (vs. an attention-control involving health education video-viewing) designed to increase exercise self-regulation. Participants completed the BF Inventory at baseline ($n=133$), one-month (post-CT; 6% missing), and 5-month follow-up (21% missing). Data were analyzed using general mixture modeling with a robust maximum likelihood estimation to handle missing data. A 3-class solution was selected based on the lowest Bayesian Information Criteria ($BIC=3521.53$) and bootstrap likelihood ratio test= 29.24 , $p<.01$; entropy=.74). There were no significant group differences in BF trait levels at baseline. With the exception of attrition during CT, baseline profiles of BF traits were not associated with the trial’s primary outcomes (adherence, dropout). To explore personality change as a function of CT, we modeled all five BFI difference scores that revealed two distinct classes but no statistically significant differences across primary outcomes. Finally, we examined group effects on *C* and *N* scores, in isolation, via growth mixture modeling. A 3-class solution was selected based on theory and model fit indices for both *C* and *N* and each trait’s trajectory reflected temporally-stable means (high/moderate/low). There were also no significant associations between empirically-estimated latent class assignment and any behavioral outcome data within the *N* model. Interestingly, the CT group were 3.3x more likely to be empirically-assigned to the low *N* class. Similar to *N*, there was no change in *C* from baseline. However, results revealed that those who were consistently high in *C* attended more exercise classes than those who were moderate in *C* ($p<.05$). In the *C* model, the CT group was also 1.4x and 1.7x more likely than the control group to be assigned to the high or low-moderate *C* classes, respectively. In the context of a novel multicomponent CT program, these results provide limited evidence supporting the role of conscientious in exercise adherence.

PHYSICAL ACTIVITY AND SEDENTARY BEHAVIOR PREDICT INTRAINDIVIDUAL AFFECTIVE VARIABILITY AMONG OVERWEIGHT AND OBESE ADULTS

Stephanie Kerrigan, M.S., Leah Schumacher, MS, Stephanie Manasse, PhD, Meghan Butryn, Ph.D., Evan Forman, Ph.D.

Drexel University, Philadelphia, PA

Adults who are overweight/obese engage in less physical activity (PA) and more sedentary behavior (SB) than normal-weight peers. Affective consequences of PA/SB contribute to future decisions about activity, and affective variability is related to physical and psychological outcomes. However, little work has been done to evaluate within-person variability in negative affect resulting from PA/SB. Participants ($n=140$) completed one week of assessment at month six (when the PA prescription had reached the maximum) of a year-long behavioral weight loss (BWL) treatment. Individuals were asked, each day, to complete six semi-randomly timed prompts assessing mood states and to wear a waist-worn accelerometer for all waking hours. Affective variables assessed were: loneliness, anger, boredom, sadness, and stress. Intraday affective variability was calculated for each participant using mean squared successive difference (MSSD). Analyses examined whether: 1) a bout of PA predicted next-day MSSD; 2) a bout of morning PA predicted same-day MSSD; 3) a bout of early morning SB predicted same-day MSSD. PA bout occurrence predicted lower next-day variability in loneliness (estimate = -0.09 , $t = -2.17$, $p = .03$), anger (estimate = -0.21 , $t = -2.13$, $p = .03$), and stress (trend-level; estimate = -0.15 , $t = -1.95$, $p = .05$); no relationships were observed between PA and next-day variability in boredom, sadness, or stress. No relationships were observed between morning PA and same-day affective variability. A bout of morning SB predicted higher same-day variability in boredom (estimate = 0.08 , $t = 1.97$, $p = .049$) and stress (estimate = 0.15 , $t = 2.25$, $p = .02$); no relationships were observed between morning SB and variability in loneliness, anger, or sadness. Results indicate that PA and SB predict subsequent variability in affect among adults engaging in BWL. Notably, although engaging in a bout of PA reduced affective variability (specifically for loneliness, anger, and stress) on the next day, no effects were observed on the same day, indicating that there may be a delayed impact of PA on regulating negative affect. Delayed benefits are less likely to reinforce behavioral engagement than more immediately salient benefits. Engaging in SB early in the morning is associated with variability in boredom and stress on that day. Future research should examine whether PA/SB are also predicted by affective variability, as it is likely that these relationships are bidirectional.

RESIDENTIAL SEGREGATION AND DISPARITIES IN EXERCISE AMONG A NATIONAL SAMPLE OF LATINOS AND WHITES

Hope Landrine, PhD, Irma Corral, PhD, MPH, Yongping Hao, PhD, Jukelia Bess, BA
Brody School of Medicine, East Carolina University, Greenville, NC

Latinos exhibit significantly lower levels of exercise than Whites. Many have theorized that this is because Latino neighborhoods are 8.6 times more likely than White ones to lack recreational facilities; 82% of Latino (vs. 38% of White) neighborhoods have none. This suggests that Latino residential segregation may contribute to or account for ethnic disparities in exercise. We explored these possibilities for the first time by analyzing data on the 82,487 White and 8,785 Latino adults in the 2000 Behavioral Risk Factor Surveillance System (BRFSS), a random, nationwide telephone health survey. BRFSS data on exercise (Any exercise in the past month? Yes/No) were linked to 2000 census data on the Segregation (Hispanic Dissimilarity Index) and Poverty (% Below) levels of all metropolitan statistical areas (MSAs) in the BRFSS. If segregation accounts for (fully explains) disparities in exercise, then Latinos in high-segregated areas will exercise less often than Whites whereas those in low-segregated/integrated areas will not differ from Whites. If segregation contributes to disparities, then Latinos in both high and low segregated areas will exercise less often than Whites, with disparities greater for high-segregated Latinos vs. Whites. Multi-level modeling revealed that Whites were 1.6 times more likely than Latinos to have exercised in the past month. After controlling for age, education, gender, and MSA-Poverty, Latinos residing in high and in low segregated MSAs were 41.6% and 31.9% (respectively) less likely than Whites to exercise. These findings suggest that Latino segregation contributes to but does not account for exercise disparities. The study is limited by measuring segregation and poverty at the MSA level. Census tract (CT) level measures of neighborhood influences are more sensitive and predictive than MSA-level measures, and CTs (not MSAs) constitute neighborhoods. Hence, the segregation effect found here is surprising given the MSA level of analysis and no doubt underestimates segregation's role. Research at the CT-level is needed to clarify the role of segregation in Latino disparities in exercise and highlight the possible need to expand the reach of behavioral interventions to segregated areas to reduce Latino disparities in exercise.

RESULTS OF A 12-WEEK FITBIT INTERVENTION ON CHANGES IN DAILY STEP COUNTS IN LOW-INCOME MOTHERS

Gregory M. Dominick, Ph.D., Carly R. Pacanowski, PhD RD

University of Delaware, Newark, DE

Background: While 50% of U.S. mothers with young children do not engage in regular physical activity (PA), rates are disproportionately lower for mothers living at or below the federal poverty level. Wearable PA monitors such as Fitbit have the potential to influence PA, yet the efficacy of a Fitbit-only intervention to increase PA in low-income mothers is unknown. This pilot study examined the temporal impact of using a Fitbit to increase daily steps over 12-weeks.

Methods: Participants (N=13) were insufficiently active, low-income mothers receiving assistance from the Delaware Women, Infants, and Children (WIC) program. Baseline measures included demographics, body mass index (BMI), PA self-efficacy, and average 7-day step counts, measured with ActiGraph GT3X accelerometers. Participants received a Fitbit Charge device to wear during all waking hours over 12-weeks. Daily Fitbit step counts were obtained through a third-party server (Fitabase). At posttest, participants completed the same measures administered at baseline, plus a Fitbit Satisfaction questionnaire. Paired t-tests were used to examine changes in mean weekly step counts, BMI, and PA self-efficacy (baseline and 12-weeks). Trajectories of daily Fitbit step counts were tested using linear mixed models with fixed and random effects for time.

Results: Compared to baseline, no statistically significant changes were found at 12-weeks for mean weekly step counts (8,710.17 ± 10,650.58 and 8,305.33 ± 8204.05), BMI (31.24 ± 5.31 and 31.40 ± 5.10), or PA self-efficacy (2.75 ± 0.94 and 2.95 ± 0.71), all $p > 0.05$. There was a significant, positive effect of time for increasing average daily Fitbit step counts during week 1 only, controlling for baseline steps ($\beta = 770.87 \pm 355.94$, $p = 0.034$). Baseline PA self-efficacy and posttest Fitbit satisfaction scores were independently associated with a significant increase in daily Fitbit step counts over the 12 weeks ($\beta = 1,254.24 \pm 295.80$; $p = 0.00$) and ($\beta = 2,795.12 \pm 683.41$; $p = 0.00$), respectively.

Conclusions: Impact of a stand-alone Fitbit intervention to increase daily step counts in low-income mothers was limited to week 1 only, suggesting an initial novelty effect that is not sustained over time. However, higher baseline PA self-efficacy and greater Fitbit satisfaction scores were associated with an increase in average daily steps taken over 12 weeks. Study findings highlight the need for personally tailored PA interventions in this at-risk population.

SOCIAL COGNITIVE DIFFERENCES BETWEEN ADULT EXERCISERS EFFICACIOUS TO MANAGE EXERCISE AND CONCURRENT LEISURE GOALS

Jocelyn E. Blouin, MSc, Nancy C. Gyurcsik, PhD

University of Saskatchewan, Saskatoon, SK, Canada

Adults often set multiple concurrent goals, including exercise, which they plan to pursue in their leisure time. Unfortunately, most adults do not pursue exercise often enough to obtain health benefits. Prior research has shown that self-regulatory efficacy to concurrently manage multiple goals is associated with more frequent exercise. Social cognitive theory (SCT) contends more frequent exercisers hold stronger perceptions that positive exercise outcomes are highly valued and likely to occur. Although SCT contends that managing exercise with other goals may be easier the more mutually facilitative the goals are, no research has examined whether adults with varying levels of efficacy differ in their levels of intergoal facilitation. The study purpose was to examine whether adults ($N = 119$; $M_{age} = 30 \pm 12$ years) who reported pursuing one exercise and one non-exercise goal and who had varying levels of efficacy beliefs differed in intergoal facilitation, outcome expectations, and exercise. An online survey assessed goals, efficacy, facilitation, outcome expectations (likelihood and value) and past month exercise. Higher ($n = 36$), moderate ($n = 44$), and lower ($n = 39$) efficacy groups were identified and then compared using MANOVA. Facilitation, outcome expectations, and exercise were the dependent variables. The overall MANOVA was significant, ($p < .01$, $\eta^2_{partial} = .10$). Follow-up ANOVAs revealed that the higher efficacy group reported significantly higher intergoal facilitation and outcome likelihood (p 's $< .05$; $\eta^2_{partial} = .10$ and $.07$) than the moderate and lower efficacy groups. Outcome value and exercise did not significantly differ between groups. Across all groups, value exhibited a near ceiling effect and all groups were highly active, with means ranging from 296 to 358 minutes/week of exercise. Findings contribute novel information that higher efficacy is a key differentiating social cognition associated with higher intergoal facilitation and outcome likelihood. Future research should examine whether more efficacious individuals set concurrent goals that are more facilitative, than conflicting, in nature. Future research should also recruit a diverse sample of participants with varying exercise levels (e.g., initiates, insufficient, and sufficient exercisers). Such research will provide valuable information that should help adults better manage and pursue health promoting exercise, while also pursuing non-exercise goals in their leisure time.

TARGETING AUTONOMY, COMPETENCE, AND RELATEDNESS IN A WEIGHT LOSS PROGRAM FOR KNEE REPLACEMENT PATIENTS

Sara M. Rothberger, PhD¹, Kenzie A. Cameron, PhD, MPH², Christine Pellegrini, PhD¹¹University of South Carolina, Columbia, SC; ²Northwestern University Feinberg School of Medicine, Chicago, IL

The majority of knee replacement patients are overweight/obese before surgery. Despite functional improvements after surgery, most patients gain additional weight. Based on patient and stakeholder input, we developed the 14 session Patient-Centered Weight Loss Program (PACE). Guided by the Self-Determination Theory (SDT), PACE aimed to promote patients'; autonomy, competence, and relatedness by eliciting patients'; perspectives, providing options and encouragement, and supporting choices. Sixteen patients were randomized to start ≤ 6 weeks before surgery (PACE) or 12 weeks post-op (Delayed PACE). We hypothesized that increases in autonomy (assessed via the Health Care Climate Questionnaire) and competence (Perceived Competence Scale) as well as higher levels of relatedness (Intrinsic Motivation Inventory [IMI] relatedness subscale) would be associated with increased intrinsic motivation (IMI) and program engagement (# of calls completed). Autonomy and competence were assessed at baseline (pre-op), 12, and 26 weeks after surgery; relatedness was assessed at 12 weeks for PACE and 26 weeks for Delayed PACE. Repeated measures ANOVAs were used to examine changes in SDT constructs over time and group, and Pearson correlations were used to explore relationships between SDT constructs and program enjoyment. Sixteen participants (mean \pm SD 63.3 \pm 7.5 yrs, 69% female, 69% White, BMI 36.3 \pm 5.1 kg/m²) were randomized. Retention was 69% and 63% at 12 and 26 weeks respectively, with no differences between groups. Delayed PACE (-10.5 \pm 4.1%) lost significantly more weight than PACE (-4.3 \pm 1.5%, $p < 0.05$) at 26 weeks. Participants completed 9.6 \pm 2.2 coaching sessions. Perceived competence increased from 4.1 \pm 0.9 at baseline to 5.5 \pm 5.5 at 26 weeks ($F(2,20) = 8.03$, $p < 0.003$, $\eta^2 = 0.445$); but no differences emerged between groups. Similarly, no changes across time or differences between groups were seen with autonomy or relatedness. Motivation was similar across groups (5.6 \pm 1.4) and neither motivation nor program enjoyment were related to SDT constructs. Despite attempts to target SDT constructs, PACE only increased perceived competence. Although the small sample size may be contributing to the lack of hypothesized effects in this study, the results suggest other mechanisms are likely contributing to the significant weight losses observed. Future studies are needed to better understand the mechanisms underlying the short- and long-term weight changes among knee replacement patients.

THE SELF-EFFICACY REBOUND DURING AN INTERVENTION TO PROMOTE MODERATE EXERCISE IN ADOLESCENTS

Brian Hartz, PhD¹, Rick Petosa, PhD²¹Denison University, Coulumbus, OH; ²The Ohio State University, Columbus, OH

Health education in schools remains a powerful means of improving the health of adolescents. Physical activity promotion before and after school have demonstrated promising effects. These interventions are theory based but few actually assess changes in theoretical constructs during the intervention. Self-efficacy has consistently been associated with adolescent exercise. But studies have revealed that self-efficacy is relatively resistant to change. Effective strategies to build self-efficacy among adolescents are needed. The purpose of the study was to test the ability of a Social Cognitive Theory (SCT) based intervention to impact self-efficacy and moderate exercise during and after the intervention in rural adolescents. A quasi-experimental design was used to compare the treatment and comparison group. Three rural high schools in Ohio agreed to have their health classes participate in the study N=200 subjects in the intervention group and N=95 subjects in the comparison group. Students in each group were exposed to similar health education curricula, however the experimental group students received an additional 10 lesson intervention focused on behavioral skill building exercises. Measurements were collected at pre-test, 5 weeks and 2 weeks post intervention. Previously validated measures were used for exercise, and self-efficacy. At posttest the intervention group reported an increase from 1 to 3 days per week of moderate-intensity exercise ($p = .001$). There was a significant treatment interaction with self-efficacy ($p = .001$). The intervention group reported statistically significant decreases in self-efficacy at midpoint in intervention. However, by the end of the intervention there was a significant increase relative to baseline levels. This data demonstrates that self-efficacy for exercise may drop while engaging in SCT based behavioral skill building interventions, but can recover as students become more proficient with the behavior changes necessary for successful of exercise adherence. This study is one of just a few projects demonstrating how self-efficacy changes during a SCT based intervention. This study reinforces that self-efficacy can be one SCT variable that is amenable to change by a SCT intervention and this can result in a positive effect on leisure time physical exercise behavior. Short term behaviorally based health education programs could produce transient declines in self-efficacy.

USING NEIGHBORHOOD HEALTH PROMOTION ACTIVITIES TO ASSESS BEHAVIORS, PERCEPTIONS, AND INTENT RELATED TO PHYSICAL ACTIVITY

Megan Knapp, MPH¹, Jeanette Gustat, PhD, MPH², Keelia O'Malley, MPH³, Naomi King Englar, BA⁴, Carolyn C. Johnson, BA, MS, PhD; LPC, NCC²

¹Tulane University, New Orleans, LA; ²Tulane University School of Public Health and Tropical Medicine, New Orleans, LA; ³Tulane Prevention Research Center, New Orleans, LA; ⁴Tulane School of Public Health and Tropical Medicine, New Orleans, LA

Introduction: Neighborhood health promotion activities can provide interactive environments in which to connect and communicate with community members about health-related behaviors while also serving as a resource for data collection and neighborhood program recruitment. Through *Movin'*; for LIFE (Lasting Improvements for Fitness and Energy), a program that works to develop a model of healthy living for residents of an urban, under-resourced, predominately black community, a family health promotion festival was implemented and data were collected regarding behaviors, perceptions, and intent related to physical activity (PA).

Methods: The Family Fun Fest (FFF), a one-day weekend event, included 5 activity stations that focused on PA and provided information about opportunities to engage in PA, such as neighborhood walking clubs. Trained staff conducted intercept interviews with attendees. Questions included demographic characteristics, current PA behaviors, perceptions about neighborhood conduciveness to PA, and interest to engage in more PA. Participants were also asked about their interest in joining neighborhood walking clubs.

Results: A total of 156 individuals attended the FFF, 63 were eligible for intercept interviews, and 58 completed them. Interview participants were primarily black (96.6%) and female (79.3%). The average age was 49 (SD=17.2). Most (70.7%) reported engagement in regular PA with walking indicated as the most popular activity (85.4%) among the physically active. The majority (91.4%) of participants were interested in walking more to increase their PA, and 60.3% signed up to join a neighborhood walking club. Of those who reported no regular PA (n=17), 64.7% signed up for the walking clubs. A significant relationship was found between self-reported regular PA and neighborhood perceptions. Those who agreed that their neighborhood encouraged PA were 4.32 times more likely to report regular PA than those who did not agree (95%CI: 1.32–15.11).

Conclusions: Neighborhood health promotion activities can be a useful tool for collecting information on current behaviors and recruiting potential participants in neighborhood-based programs, such as walking clubs. They may also motivate community members to change behavior as over half of those who reported no regular PA registered to join a walking club. Future research should examine whether intent to participate translates to actual participation.

AWARENESS OF CHRONIC DISEASE RISK IS LOW AMONG BURMESE REFUGEES

Heather Orom, PhD¹, Kellie Schmit, BA², Alexandra Judelsohn, MUP³, Amanda N. Sosnowski, N/A⁴, Aye Bay Na Sa, N/A¹, Isok Kim, PhD LCSW², Roberto Diaz Del Carpio, MD, MPH⁶, Samina Raja, PhD¹

¹University at Buffalo, Buffalo, NY; ²University at Buffalo, Grand Island, NY; ³University at Buffalo, State University of New York, Buffalo, NY; ⁴University at Buffalo, Amherst, NY; ⁵University at Buffalo - The State University of New York, Buffalo, NY; ⁶University at Buffalo, Buffalo, NY

Background. Approximately a quarter of the over 60,000 refugees who resettle in the U.S. each year are from Burma. As has been the case for many other immigrant groups, as the Burmese acculturate, it is expected that they will experience declines in health, including increased incidence of chronic disease. In order to target health messaging to Burmese communities, a baseline understanding of their awareness of, and perceptions of risk for common illnesses is needed.

Purpose. The purpose of our study was to explore perceptions held by refugees from Burma about risk for common diseases (diabetes, heart disease, cancer).

Method. We conducted semi-structured interviews with 28 refugees from Burma (ages 23–72, 79% female; no education – college) who had resettled in a mid-sized Northeastern U.S. city (1–10 years in the U.S.). Interview topics included perceptions of risk for heart disease, diabetes, and cancer, and attributions for these perceptions. Open-ended questions were coded by teams of at least two coders who resolved discrepancies via discussion.

Results. Most participants were either uncertain about or thought they were not at risk for heart disease (85%), diabetes (87%), and cancer (91%). Lack of awareness about heart disease and cancer was common. Many had not discussed the diseases with a health care provider. The few participants who did rate their risk often attributed their level of risk to factors also noted in studies of risk perceptions in U.S. born samples (eating high sugar and fat foods vs a diet rich in vegetables; inadequate physical activity; genetics/family history; smoking; physical signs and symptoms). They also made attributions less commonly reported (e.g., belief in fate or that thinking about a disease might increase the likelihood of getting it; belief that stress, negative emotions, and trauma cause heart disease).

Discussion. Given low disease awareness, it seems many refugees from Burma have yet to be reached by mainstream chronic disease risk messaging. Also, in most cases, health care providers were not communicating these messages or were not doing so in a way that was understood by the participants. A few recognized that adopting an American diet and sedentary lifestyle might be unhealthy, but this was relatively uncommon. Community-based messaging efforts to promote healthy aspects of Burmese and American cultures might be an innovative path forward for these communities.

DIAGNOSING AUTISM: WHAT LATINO PARENTS AND CAREGIVERS KNOW AND BELIEVE

Lucía I. Floríndez, MA, Daniella C. Floríndez, MPH

University of Southern California, Burbank, CA

Background: Of the 1 in 68 children diagnosed with autism spectrum disorders (ASD) in the United States (CDC, 2014), the prevalence varies significantly across racial and ethnic groups. Documented disparities exist regarding autism diagnosis for Latino children. When compared to White children, previous research has shown that Latino children are diagnosed at a later age (Mandell, Listerud, Levy, & Pinto-Martin, 2002), are less likely to be diagnosed even when meeting autism criteria (Mandell et al., 2009), and more likely to be misdiagnosed (Mandell, Ittenbach, Levy, & Pinto-Martin, 2007). Given these issues surrounding accurately diagnosing Latino children with ASD, it is necessary to explore what Latino parents, caregivers, and community members understand about ASD diagnosis.

Purpose: The purpose of this study is to investigate what 18 Latino families know and believe about diagnosing autism, and the factors that inform their health beliefs.

Methods: Narrative interviews with 18 Latino families (8 families with a typically developing child aged 6–12 and 10 families with a child with ASD aged 6–12) were conducted to identify the factors that impact their in-home oral care routines, including how the presence of ASD may alter their habits. Family units consisted of at minimum, the primary caregiver, and included other family members who provided care for the enrolled child. Each family was interviewed twice in their native language (Spanish or English) for approximately 1–2.5 hours each session. As a secondary line of questioning, families were probed to discuss their perceptions of ASD. Interviews were transcribed verbatim and thematically analyzed by 3 coders.

Results: Five themes pertaining to where parents obtained their knowledge and details about their beliefs about ASD diagnosis were identified. The first, *Misconceptions*, explained the various fallacies perpetuated about ASD. The second theme, *Parents as students and teachers*, described how parents had to learn about their child's diagnosis to then be able to educate others. Next, *Role of Family* was related to the influence of family members on sharing information and opinions. Following, *Outside influence* clarified the information provided by non-family members, including health care providers, community members, or social network connections. The last theme, *Cultural Stigma*, focused on information that originated from the family's cultural background, situating the ASD diagnosis within Latino culture.

Conclusions: Researching how Latino parents, caregivers, and community members perceive Autism diagnosis will help illuminate how health information is communicated within this at-risk population, and inform the development of future targeted education and intervention programs.

DO ANXIETY SYMPTOMS MEDIATE THE RELATIONSHIP BETWEEN FAMILISM AND HEALTH OUTCOMES AMONG LOW INCOME HISPANIC AMERICANS?

Elizabeth J. Wilson, B.A.¹, Kadie M. Harry, M.A.¹, Kalon R. Eways, M.A.¹, Jillian M. R. Clark, Ph.D.², Ricardo M. Marte, Ph.D.³, Kymberley K. Bennett, PhD¹

¹University of Missouri-Kansas City, Kansas City, MO; ²VA Center of Excellence for Stress and Mental Health, VA San Diego Healthcare System/University of California, San Diego, San Diego, CA; ³Department of Psychology, University of Missouri-Kansas City, Kansas City, MO

Low socioeconomic status (SES) is a well-established risk factor for poor health outcomes and is associated with engagement in fewer health behaviors relative to higher SES. Hispanic Americans are more likely to be of low SES relative to Whites; however, while there are noted disparities in some health outcomes, Hispanic Americans have better mortality outcomes than other minorities. This apparent contradiction has been termed the Hispanic Paradox. The Reserve Capacity Model proposes that cultural resources buffer the detrimental effects of poverty on health. In particular, elements of the reserve capacity lead to reduced psychological distress, which results in better health behaviors and outcomes. Familism, or the primacy of the family unit, is one such value seen in many Hispanic cultures that may protect against the negative effects of poverty on health. Thus, the current study tested whether anxiety symptoms mediate relationships between familism and mental health-related quality of life (MHR-QoL), physical health-related quality of life (PHR-QoL), and engagement in health behaviors.

Participants of Hispanic descent were recruited from a holiday assistance program at a Salvation Army in the Midwest ($N = 133$); all participants had annual incomes below federal poverty guidelines. The sample was largely female (89.3%) and uninsured (77.5); mean age was 36.4 years ($SD = 9.2$). Participants were asked to complete the survey in English or Spanish, and most completed it in Spanish (79%). In addition to familism, the survey measured anxiety symptoms and three health outcomes (MHR-QoL, PHR-QoL, and engagement in health behaviors).

Mediation analyses were conducted using the Hayes'; PROCESS Macro. Results showed that anxiety did not significantly mediate relationships between familism and MHR-QoL, PHR-QoL, and engagement in health behaviors. However, there was a significant direct effect from familism to anxiety symptoms $b = -0.16$, $t(102) = -2.15$, $p = .03$. This result lends partial support to the hypothesis that cultural reserves are related to psychological processes. Other significant direct effects included anxiety predicting MHR-QoL and PHR-QoL, $b = -0.61$ $t(98) = -7.64$, $p < .001$ and $b = -0.35$, $t(95) = -2.33$, $p = .02$, respectively. Taken together, these results, while not fully supporting the hypothesized associations, do suggest that cultural values may affect intermediate psychological mechanisms that, in turn, affect health behaviors and outcomes.

ETHNIC IDENTITY MODERATES THE RELATIONSHIP BETWEEN STRESS AND CO-OCCURRING ADVERSITIES AMONG BLACK WOMEN

Idia B. Thurston, Doctorate, Kathryn H. Howell, PhD
University of Memphis, Memphis, TN

Background: The co-occurrence of three epidemics (Substance Abuse, Violence, and AIDS/HIV, i.e., SAVA) has been termed a syndemic (Singer, 1996). Syndemic theory explains how social determinants of health (such as minority stress) drive health disparities in certain communities, including among racial/ethnic minorities, individuals living in poverty, and people in urban settings. While increased stress has been associated with experiencing more SAVA epidemics, less is known about how protective factors might mitigate this risk. The current study examined whether ethnic identity serves a protective role in the relationship between stress and SAVA in Black women.

Method: Participants included 129 Black women ($M_{age}=34.8$, $SD=8.6$) in the U.S. Mid-South. Most women (79%) had a yearly income \leq \$20,000 and 61% had completed high school or less. Women were recruited from community organizations and completed hour-long interviews about life stressors (*Life Events Checklist*), perceived socio-economic status (SES), and ethnic identity (*Multigroup Ethnic Identity Measure-Revised*). SAVA was assessed based on report of illicit substance use in the past 6 months (*WHO Alcohol, Smoking, and Substance Involvement Screening Test*), physical/sexual violence with a partner in the past 6 months (*Revised Conflict Tactics Scale*), and ever testing positive for HIV. Endorsement of each SAVA was summed for a total score ranging from 0–3. SPSS PROCESS was used to examine the relationship between life stress and SAVA (accounting for age and SES) as moderated by ethnic identity.

Results: Controlling for age and SES, the moderation model was significant, $F(5, 123) = 6.74$, $p < .001$, $R^2 = .17$. Moderation was supported as the interaction between life stress and ethnic identity was associated with SAVA adversities ($\beta = .01$; $p < .05$). Specifically, the conditional effect of life stress on SAVA at differing levels of ethnic identity was significant at high levels of ethnic identity ($\beta = .06$; $p < .001$), but not at low or average levels of ethnic identity.

Conclusions: Findings confirm the positive association between life stress and SAVA; however, our results advance this knowledge by showing that Black women with high levels of ethnic identity appear to be protected from this cumulative risk trajectory. Thus, interventions for Black women experiencing SAVA should explore strategies for increasing ethnic identity exploration and commitment to enhance wellbeing.

PRELIMINARY EVALUATION OF ATLANTA YOUTH PARTNERSHIP: ENGAGING AFRICAN-AMERICAN ADOLESCENTS IN CBPR HEALTH OUTCOMES RESEARCH

Jessica Sales, PhD, Leah Powell, MPH, Merete Tschokert, Mag.a pharm, Ashley Phillips, MPH, Erin Bednarczyk, BS, Ilyssa Tamler, BA, Kenyana Weaver, BBA
Rollins School of Public Health, Emory University, Atlanta, GA

Background: African-American (AA) adolescents experience multiple health disparities impacting numerous health outcomes (e.g., HIV, unintended pregnancy, obesity, asthma). Yet, in health outcomes research, adolescents are typically only study participants, potentially limiting the design, implementation, participation in and uptake of research findings in real-world settings. To fill this gap, the Atlanta Youth Partnership (AYP) engages AA youth as key stakeholders in health outcomes community-based participatory research (CBPR) to improve its reach and translatability.

Methods: In the 18-month AYP initiative, our team utilizes a youth development framework to provide developmentally tailored training and support to the AYP Youth Board. This approach engages adolescents in CBPR by acknowledging the unique structural support necessary for them to meaningfully engage and sustain their involvement in youth-driven research. Weekly 2 hour trainings equip youth with basic health research skills and foster leadership capabilities, as per the youth development CBPR process. An Adult Advisory Board comprised of local youth-serving professionals serves in a supportive capacity for the Youth Board. We collected data on youth meeting attendance and participation to assess engagement. At 6 months, we surveyed the youth to ascertain perception of voice in decision-making, presence of supportive adult relationships, and confidence in leadership and teamwork ability.

Results: Through an application process we recruited 12 AA high school students and 6 adult professionals in Atlanta to serve on the AYP Youth and Adult Advisory Boards. From Feb-Aug 2017, we held 18 Youth Board training sessions and 4 joint Youth/Adult meetings. The average youth attendance rate was 87.96% ($SD=7.68\%$), all youth facilitated at least one activity during joint meetings, 83.3% reported AYP increased their confidence talking in groups, 75% reported increased confidence working with adults, and 67% felt more confident working with a team. Youth strongly endorsed having a voice in decision-making ($M=4.73$, $SD=.46$) and the presence of supportive adult relationships ($M=4.78$, $SD=.20$; range:1–5).

Conclusions: Preliminary evaluation of AYP indicate high levels of sustained engagement and participation by youth. Thus far, our youth-development approach to CBPR has successfully provided youth with supportive adult relationships while allowing youth decision-making authority in the research process.

QUALITATIVE EXPLORATION OF FAMILY INFLUENCES ON PHYSICAL ACTIVITY AND NUTRITION BEHAVIORS IN LATINO HOUSEHOLDS

Larkin L. Strong, PhD MPH¹, Lorna McNeill, PhD, MPH², Susan M. Schembre, MS, PhD, RD³, Belinda Reininger, DrPH, MPH⁴¹University of Texas MD Anderson Cancer Center, Houston, TX; ²UT Texas MD Anderson Cancer Center, Houston, TX; ³The University of Texas MD Anderson Cancer Center, Houston, TX; ⁴University of Texas School of Public Health, Brownsville Regional Campus, Brownsville, TX

Background: Despite widespread recognition of the need to address physical activity (PA) and nutrition behaviors among U.S. Latinos, current knowledge regarding effective approaches remains limited. Latino culture places great emphasis on the family, yet research is needed to better understand how to build support within the family for healthy changes. This study qualitatively explored family influences on PA and nutrition behaviors in dyads of adult Latino family members to inform the adaptation of a family-focused community health worker-delivered intervention to promote healthy eating and PA in Latino households in Houston, TX.

Methods: In-depth interviews and brief surveys were conducted with 20 adult Latino family dyads (n=40 individuals) who resided in the same household to assess current PA and nutrition behaviors, family influences, and social support within the family for healthy behaviors. Interviews were audio-recorded, transcribed, and translated, as needed. Qualitative analysis involving inductive and deductive coding with NVivo 11 is ongoing.

Results: Participants were predominantly women (67%) and from Mexico (57%) with a mean age of 39 years (range 18–65). The most common relationship was husband-wife (44%) followed by mother-daughter (28%). Participants reported low levels of education (e.g., 44% ≤ 8 years) and acculturation (89% low acculturation), and nearly half (47%) reported low food security. Approximately 43% reported meeting PA recommendations, and 6% reported consuming ≥5 FV daily. Family influences on nutrition and PA behaviors centered on family health concerns that motivated positive lifestyle changes, household decision making that determined the types of food/drink purchased and prepared, and household knowledge and norms related to PA and nutrition behaviors. For example, some participants described how food preferences of the breadwinner dictated family meal choices, and how the sedentary lifestyle of household members limited motivation for PA. Participants also emphasized the positive effects of family members' modeling of healthy behaviors and the sharing of knowledge related to PA and nutrition.

Conclusions: Preliminary results yield insight regarding how family members may influence PA and nutrition behaviors in the home, intentional or not. Findings point to the need for interventions to engage multiple family members to promote increased awareness, motivation, and support for healthy lifestyles within the home.

LONGITUDINAL TRAJECTORIES OF SUBJECTIVE STRESS AMONG DEMENTIA CAREGIVERS

Lauren Bangerter, PhD¹, Yin Liu, Ph.D.², Steven H. Zarit, Ph.D.³¹Mayo Clinic, Rochester, MN; ²Utah State University, Logan, UT; ³Penn State University, University Park, PA

Subjective stressors are critical to the caregiver stress process, yet little work has examined resources that contribute to longitudinal changes in subjective stressors. The present study examines a variety of factors that contribute to changes in subjective stressors across time. Dementia caregivers (N=153) completed an in-person interview and 8 daily telephone interviews at baseline, and follow up interviews at 6 and 12-months. Growth curve analyses examine how care- and non-care stressors, respite, dyadic relationship quality, family support/conflict and care transitions (e.g., nursing home placement) are associated with changes in role overload and role captivity across 12 months. Caregivers who transitioned out of their role had higher overload and captivity at baseline. Among caregivers who transitioned out of caregiving, higher captivity at baseline was associated with declines in captivity and overload; more non-care stressors at baseline was linked to increased captivity and greater overload across time. Adult day service use and family support were associated with lesser captivity over time; taking more breaks from caregiving was linked to lower overload. Higher dyadic relationship quality was associated with lower captivity and overload. Findings contribute to caregiver intervention efforts by highlighting important resources associated with subjective stressors across time.

ENGAGING FAMILY CAREGIVERS INTO HEALTHCARE DELIVERY: BARRIERS, FACILITATORS, AND BEST PRACTICES

Joan M. Griffin, PhD¹, Lauren Bangerter, PhD², Robin K. Matsuyama, PhD³, Courtney van Houtven, PhD⁴¹Mayo Clinic, Rochester MN, MN; ²Mayo Clinic, Rochester, MN; ³Virginia Commonwealth University, Richmond, VA; ⁴Durham VA and Duke University, Durham, NC

Families can directly and indirectly affect adult patient health and reduce costs to health care systems, yet there is no consensus on the best practices for integrating caregivers into the healthcare experience. Research on how clinical practitioners can effectively integrate family into patient disease management, rehabilitation, or symptom control has lagged far behind the research on developing patient-centered care. To address this issue, we present barriers and facilitators to engaging families and caregivers into healthcare delivery. We draw on data from two qualitative studies in order to explicate challenges of two different clinical populations; caregivers of persons with Alzheimer's disease, and caregivers of persons with heart failure. Drawing on the experiences of these two different caregiver groups, we explore the major barriers to being fully integrated into the healthcare of the care-recipient (e.g., legal/privacy concerns; maintaining patient autonomy and dignity; lack of training in managing complex family dynamics) and potential "best practices" (e.g., establishing trust with caregivers; identification of caregivers in the medical record; routine assessment of caregiver health; clarification of roles on healthcare team). We also present potential methods for measuring best practices, including new survey assessments of caregiver engagement in healthcare practices. Finally, we present opportunities and challenges for studying the role of caregivers in the healthcare setting (e.g., charting, role definition, and better partnerships with social services). This work is foundational to developing future evidence-based, feasible strategies for caregivers to improve patient outcomes and maintain their caregiver health.

ARE COUPLES WHO PARTICIPATE IN RESEARCH TOGETHER HEALTHIER AND MORE SATISFIED IN THEIR RELATIONSHIP?

Sydneyjane Varner, MA, Krista Ranby, PhD, Richard Hayes, Psychology BA
University of Colorado Denver, Denver, CO

Intimate partners affect individual's daily and long term health behaviors and influence the progression and outcomes of many chronic diseases (e.g. cancers and chronic pain). As such, couples-based interventions to affect positive health behavior change and improve disease outcomes are gaining attention from researchers. The nature of dyadic research, however, poses many challenges which often make recruitment of both partners difficult, prompting questions regarding whether there are systematic differences in couples that choose to participate and what effect those differences may have on the external validity of couples-based research. The aim of the current study is to determine if couples where both partners choose to participate in a couples' health study systematically differ from those where only one partner chooses to participate. Participants were recruited from a Bridal Expo and Facebook in a two-stage process; initial participants first completed an online survey and provided their partner's email address, then their partners were invited, via email, to complete the same online survey. Nearly all (88%) initial participants provided email addresses for their partners. Participants were surveyed about their own and their partner's health habits, mental and physical QOL, health status, and relationship quality. Data were used from the initially recruited partner in a total of N=847 unique couples; of the total sample, one third (N=286) were individuals whose partners also participated in the study (i.e. complete couples) and two-thirds (N=561) were individuals whose partners did not participate (i.e. incomplete couples). Complete and incomplete couples were compared using reports from the initially recruited partner. ANOVA and crosstabulations indicate significantly poorer health status, health habits and relationship quality within incomplete couples compared to complete couples. The majority of differences between groups were observed in reports from the participant about their partner. These health and relationship quality differences have several important implications for couples-based health research including the possibility that couples participating in health research together might be more similar to one another and may have better behaviors and relationships than couples choosing not to participate together. Ways in which this potential recruitment bias may affect study design, recruitment efforts, and couples-based intervention needs will be discussed.

ATTACHMENT AND CHRONIC STRESS AS A PATHWAY FROM ADVERSE CHILDHOOD EXPERIENCES TO PHYSICAL SYMPTOMS

Ruichen Sun, N/A, Jefferson Singer, PhD
Connecticut College, New London, CT

Background: It has been repeatedly reported that adverse childhood experiences (ACEs) predict worse health outcomes in adulthood. One of the pathways proposed is that ACEs are linked to higher level of stress, which then has implications for health through altering HPA axis activities, autonomic system functioning, and immune profile. Additionally, individuals who are insecurely attached are more prone to stress reactivity. The present study proposed an integrated model in which ACE exerts its power on lifelong health through exacerbating attachment insecurity, which predisposes individuals to chronic stress. Elevated stress level then increases the risk for a host of physical problems. In addition, lack of perceived social support would mediate ACE's influence on attachment, and health anxiety would partially account for attachment anxiety's effect on physical symptoms.

Method: 205 participants were recruited on Amazon Mechanical Turk (51.2% female, 79% white, mean age=36.8). They completed a battery of questionnaires on ACEs, attachment anxiety and avoidance (Experience in Close Relationship, ECR-R), perceived chronic stress (Perceived Stress Questionnaire, PSQ), physical symptoms (Patient Health Questionnaire Physical Symptoms, PHQ-15), health anxiety (Health Anxiety Inventory, HAI), depressive symptoms (Patient Health Questionnaire Depression Scale, PHQ-8), and perceived social support (Social Provision Scale, SPS) during childhood.

Results: A path analysis was conducted to evaluate the hypothesized model. ACE had a direct (Beta= .145) and indirect effect (through social support, Beta's = -.443 and -.406) on attachment anxiety; attachment anxiety had an indirect effect on physical symptoms through perceived chronic stress (Beta's = .495 and .434) and health anxiety (Beta's = .430 and .353); health anxiety had a direct effect on chronic stress (Beta = .358) and indirect effect on physical symptoms through chronic stress (Beta's = .358 and .434). The Comparative Fit Index (CFI) for the model was .941.

Conclusion: The findings provided preliminary support for our hypothesized model from ACE to attachment insecurity, to chronic stress, and finally to physical symptoms. Limitations include reliance on retrospective self-report and lack of biological measures. Future research is needed to investigate the mechanisms behind early adversity, attachment, and stress physiology, and to ultimately inform interventions for ACE survivors that focus on fostering attachment security.

BIOPSYCHOSOCIAL CORRELATES OF DISCRIMINATION IN DAILY LIFE

Lindsey Potter, M.P.H.¹, Elizabeth Brondolo, Ph.D.², Joshua M. Smyth, PhD³¹The Pennsylvania State University, University Park, PA; ²St. John's University, Jamaica, NY; ³Pennsylvania State University, University Park, PA

Discrimination is associated with negative mental, physical, and behavioral indicators of health and may contribute to health disparities. The literature on the relationship of discrimination to health has largely relied on retrospective reports, with much less known about the real-time within-person association between discrimination and biopsychosocial processes. Intensive longitudinal methods (e.g., ecological momentary assessment [EMA] and daily diaries) may capture perceived experiences of, and responses to, discrimination in daily life and clarify the temporal sequence of events, thus helping to elucidate potential mechanisms linking discrimination to poor health. This review identified studies of discrimination related to race, sex, weight, and sexual orientation, and examined the prevalence and frequency of discrimination in daily life, its psychosocial and contextual correlates, and moderators of the effects of discrimination on health. EMA and daily diary data suggest that discrimination may occur more frequently than is clear from survey research (e.g., due to weight, nearly once per day; due to race, up to twice daily; due to sexual orientation, up to twice weekly; due to sex, up to three times daily). Discrimination is enacted by a variety of perpetrators (e.g., friends, teachers), through various means (e.g., verbal expressions, overt behavior), and across a range of settings (e.g., medical, employment, educational, and social settings). Perceived discrimination was reliably associated with poorer mental health (e.g., negative affect, rumination, depressive symptoms) in daily life. Among some stigmatized groups (e.g., sexual minorities) discrimination was related to social isolation and lower quality social support, whereas among others (e.g., overweight/obese individuals) discrimination was related to decreased motivation to enact positive health behaviors such as diet and exercise. This review also highlights the need for, and potential benefit of, relating momentary experiences of discrimination with health behaviors (e.g., physical activity) and biomarkers (e.g., cortisol, inflammatory cytokines) in daily life, as these may be proximal mediators of the relationship between discrimination and health outcomes. EMA studies are also important for the development of just-in-time or tailored interventions for coping with discrimination and may inform best practices in clinical settings to improve patient outcomes and reduce health disparities.

DATING, HEALTH BEHAVIOR, AND FITBITS: RELATIONSHIP STATUS IMPACTS HEALTH BEHAVIORS IN YOUNG ADULTS

Brittany E. Canady, Ph.D., ABPP, Briana V. McCoy, MA, Christina Lawrence, MA

Marshall University, Huntington, WV

Introduction: Long-term romantic relationships are widely recognized as impacting the health and well-being of the individuals engaged in the relationship. In addition to provision of social support and enhancement of coping, engagement in health behavior is one way in which relationships are hypothesized to impact health. However, while some research has indicated that romantic partners actively influence partners' behaviors (e.g., Canady, Lawrence, & McCoy, 2017; Vilchinsky et al., 2011), and partners' health behaviors grow more similar over time (e.g., Ask et al., 2012, Homish & Leonard, 2008), studies have generally occurred in the context of long-term romantic relationships. The current study explores differences in health behaviors which occur during shorter-term dating relationships.

Method: Participants were 19 female college students who enrolled in a two-semester prospective study. Participants completed online questionnaires via Qualtrics biweekly evaluating relationship status and frequency of engagement in a variety of both health-promoting and health-compromising behaviors (alcohol use, tobacco use, fruit/vegetable consumption, exercise, binge eating, purging, restricting calorie intake, and tanning), and wore a Fitbit throughout the study to provide a biometric measure of activity level.

Results: Participants reported having been in a romantic relationship for 120 out of a total of 231 two-week time periods for which data on relationship status was available. Profile analysis was used to evaluate similarities and differences in health behaviors for periods participants were in or out of relationships. While the overall profile remained similar, participants' amount of engagement in health behaviors differed depending on relationship status ($F(8, 117) = 12.035, p < .001$), such that participants who reported current involvement in romantic relationships engaged in higher amounts of the behaviors measured, whether health-promoting or health-compromising, than participants who reported no involvement in a romantic relationship.

Conclusion: These results suggest that some health behaviors may change as relationship status changes. More research is needed to determine potential reasons for these changes, which may vary by specific health behavior. Further evaluating the impact of dating relationships can provide key information regarding the development and maintenance of health behaviors in young adults as well as better target health behavior interventions in this population.

DIVERSE PERCEPTIONS OF ACCESSING REPRODUCTIVE HEALTH CARE ON THE US-MEXICO BORDER: A QUALITATIVE PERSPECTIVE

Elizabeth S. Valdez, MPH¹, Martha Miker, PhD², Rosi Andrade, PhD³¹University of Arizona, Tucson, AZ; ²El Colegio de la Frontera Norte, Tijuana, Baja California, Mexico; ³The Southwest Institute for Research on Women, Tucson, AZ

Background: In a five year period (2005–2010) the border city of Nogales, Sonora (Son), MX experienced a population increase of 30,000 inhabitants due to changing migration flows to the U.S., increased border security, and the *maquiladora* industry and the subsequent migration of people from other states. This population boom has resulted in urban disorder and deficits in education, health, and public services. Due in part to socioeconomic and sociocultural factors and the lack of comprehensive sexual and reproductive health education, the rate of adolescent pregnancies is on the rise in the city of Nogales, Son.

Objective: Our qualitative study queries local community members and key stakeholders about the perceived barriers and solutions facing immigrant women in need of reproductive health care, and how that influences adolescent pregnancy at the US-Mexico border.

Methods: We formed a binational research team to interview community leaders, health care providers, mothers of adolescent parents, and adolescent mothers to explore (1) perceived barriers and solutions to accessing reproductive health care on the border, and (2) how these factors influence adolescent pregnancy rates on the border.

Results: Participants reported structural and sociocultural barriers to accessing reproductive health care. Despite free and available contraception, misinformation about sexual and reproductive health is pervasive. Lack of access to reproductive health care, sociocultural factors, and sexual violence play a role in the high rates of adolescent pregnancy in the city of Nogales, Son.

Discussion: Qualitative findings are described, as well as current binational research strategies to address barriers to access to care on the U.S.-Mexico border. Increased communication between mothers and their children about sexual and reproductive health may be a strategy for increasing use of reproductive health care resources among adolescents and reducing the rate of adolescent pregnancy.

DYADIC EFFECTS OF DISCRIMINATION ON DAILY HEALTH BEHAVIORS AMONG SAME-SEX MALE AND FEMALE COUPLES

Nicholas Perry, M.S.¹, Brian R. W. Baucom, Ph.D.², David M. Huebner, Ph.D.³¹Brown University, Providence, RI; ²University of Utah, Salt Lake City, UT; ³George Washington University, Washington, DC

Among sexual minority couples, discrimination is a unique form of stress that can impact both partners. Minority stress theory posits that discrimination negatively impacts personal health, but has not been well-articulated or studied interpersonally within same-sex couples. However, the effects of stress on health can spill over across romantic partners, and health behaviors are also known to play out interdependently within romantic relationships. The current study aimed to expand our understanding of the influence of minority stress on health into a dyadic context in romantic relationships. Studies of minority stress also have typically focused on high-risk behaviors (e.g., condomless sex, drug use), and less on daily health behaviors that affect health cumulatively. The current study focuses on whether discrimination negatively impacts sleep, diet, and exercise among same-sex couples in line with minority stress theory.

Sixty same-sex couples (30 male, 30 female) completed an online observational study, including standardized self-report measures of discrimination, sleep disturbance (i.e., quality, depth, restoration), poor diet (e.g., soft drinks, fried food), healthy diet (e.g., fruits, vegetables), and physical exercise (e.g., cardiovascular, strength). 30.8% of participants identified as a racial or ethnic minority. The average age of participants was 30 years (SD = 10) and the average relationship length was 5 years (SD = 6 years; mode = 1.75 years). Actor-partner interdependence models for indistinguishable dyads tested associations between one's own discrimination and one's own health behaviors (i.e., actor effect), as well as one's partner's discrimination with own health behaviors (i.e., partner effect). Exploratory analyses tested interactions by couples' sex (i.e., male vs. female).

One's own discrimination affected own sleep problems ($B=.18, p<.05$). In addition, one's partner's discrimination affected own sleep disturbance ($B=.13, p<.05$). Own discrimination was also positively associated with own poor diet, but not partner's diet ($B=.06, p<.05$). No actor or partner effects were significantly associated with healthy diet or exercise ($p's>.05$). No effects varied across couples' sex (all interaction $p's>.05$).

Findings indicated that discrimination appears to impact some daily health behaviors of sexual minority individuals and their romantic partners, particularly sleep. These results are among the first to document the cross-over effects of sexual minority stress on one's own and one's partner's daily health. The interpersonal impact of discrimination on same-sex relationships should be considered in both prevention studies and public policy.

EXAMINATION OF THE RELATIONSHIP BETWEEN IN-STORE ENVIRONMENTAL FACTORS AND FRUIT AND VEGETABLE PURCHASING AMONG HISPANICS

Jennifer Sanchez-Flack, PhD MPH¹, Julie Pickrel, MPH², George Belch, PhD³, Shih-Fan Lin, DrPH⁴, Cheryl Anderson, PhD⁵, Maria Martinez, PhD⁶, Elva Arredondo, PhD³, Guadalupe X. Ayala, PhD MPH³

¹University of North Carolina Asheville, Asheville, NC; ²Institute for Behavioral and Community Health, San Diego, CA; ³San Diego State University, San Diego, CA; ⁴Institute for Behavioral and Community Health, San Diego, CA; ⁵UC San Diego, La Jolla, CA; ⁶UC San Diego, LA JOLLA, CA

Retail food environments have received attention for their influence on dietary behaviors and for their nutrition intervention potential. To improve dietary behaviors, such as fruit and vegetable (FV) purchasing, it is important to examine its relationship with in-store environmental characteristics. This study used baseline data from the *El Valor de Nuestra Salud* study to examine how in-store environmental characteristics such as product availability, placement and promotion were associated with FV purchasing among Hispanic customers in San Diego County. Mixed linear regression models indicated that greater availability of fresh FVs was associated with a 0.36 dollar increase in FV purchasing ($p=.01$). Placement variables, specifically each additional square foot of display space dedicated to FVs ($p=.01$) and more fresh FV displays ($p=.01$), were associated with a 0.02 dollar increase and -0.29 dollar decrease, respectively, in FV purchasing. Introducing FV promotions in the final model was not related to FV purchasing. Exploratory analyses indicated that men reported spending 3.69 fewer dollars on FVs compared to women, controlling for covariates ($p=.02$). These results can help inform interventions targeting in-store environmental characteristics to encourage FV purchasing among Hispanics.

EXPLORING SOCIAL AND ENVIRONMENTAL INFLUENCES ON DIETARY BEHAVIORS OF URBAN, MINORITY PREADOLESCENTS

Nina F. Killie, BS¹, Ellen Huang, RD², Katrina F. Mateo, MPH³, Melissa Fuster-Rivera, PhD⁴, May May Leung, PhD, RDN⁵

¹CUNY School of Urban Public Health at Hunter College, Ridgfield, CT; ²CUNY Hunter College, Forest Hills, NY; ³CUNY Hunter College / CUNY School of Public Health, New York, NY; ⁴CUNY-Brooklyn College, Brooklyn, NY; ⁵Hunter College, City University of New York, New York, NY

Background: Disproportionately high rates of childhood obesity exist in Latino, African American (AA)/Black, and low-income, urban populations. Among preadolescents, an understudied population, influences on dietary behaviors begin to expand beyond the home environment as food decisions become more independent. Although it is well-established that child dietary behaviors affect obesity risk, it is less clear how social and physical environments affect food choices, particularly within preadolescent minority populations. The purpose of this study is to identify and explore these influences.

Methods: Latino and AA/Black parents ($n=20$) and children ($n=32$) age 9–12 years from low-income neighborhoods in Northern Manhattan, New York City area participated in focus groups (4 child-only, 3 parent-only) or interviews (6 parent-child dyads), which addressed dietary knowledge, attitudes, and practices. Sessions were recorded and transcribed. Inductive and deductive processes were used to code and analyze transcripts in order to identify and categorize social and/or physical environmental influences related to child dietary behaviors.

Results: Parents and children both had high levels of dietary knowledge, especially of what constituted healthy dietary behaviors. Social interactions and their effects on child dietary behaviors were identified and categorized into three settings: child's home, other people's homes, and school. Within the home, mothers were the primary purchasers and preparers of food for their children. Mothers laid out specific restrictions and rules for their children to follow. When children stepped out of their home environment, these rules were more likely to be ignored. In peers'; homes, children frequently chose foods they saw their friends consuming, which were less likely to be healthy. In regards to the school environment, mothers frequently packed their children lunches to bring to school. However, children still emulated peer food selection within the school environment, which were also less likely to be healthy.

Conclusions: Dietary behaviors among Latino and AA/Black youth are influenced by peer food choices and maternal feeding practices, often tied to specific settings such as the home and school. Developing interventions that encourage healthy eating through the unique social influences within specific physical environments may improve dietary behaviors within this at-risk population and, thus, decrease obesity risk.

PREDICTING BINGE DRINKING TRAJECTORIES AND THEIR INFLUENCE ON IMPAIRED DRIVING AMONG COLLEGE STUDENTS

Shiran Bord, MPH, PhD¹, Assaf Oshri, PhD², Matt Carlson, MS²

¹University of Haifa and The Max Stern Yezreel Valley College, Haifa, N/A, Israel; ²University of Georgia, Athens, GA

Background: Alcohol impaired driving (AID) and binge drinking are major health concerns among college students. Although the link between binge drinking and AID is well established, knowledge regarding binge drinking patterns, the factors influencing binge drinking, and the associations between consumption patterns and alcohol related risk behaviors is lacking.

Aims: To examine heterogeneous trajectories of binge drinking during college and tests factors that might predict class membership as well as class membership outcomes.

Methods: Data were obtained from a sample of 1,265 college students ($M_{age} = 18.5$, $SD = .66$) as part of the Longitudinal Study of Violence Against Women ($N = 1,265$; 59.3% female; 69.2% white). Analyses were completed in three stages. First, a growth curve analysis was conducted to identify trajectories of binge drinking over time. Second, growth curve mixture modeling analyses were pursued to assess unobserved growth trajectories of binge drinking without predictors. Lastly, parental drinking variables were added to the model as predictors of class membership, and AID and being a passenger of a drunk driver were added to the model as outcomes.

Results: Three binge drinking trajectories were identified: *high-convex*, *medium-concave* and *low-increasing*. Parental drinking was associated with being in *high-convex* and *medium-concave* classes. Compared to the *low-increasing* class, the *high-convex* and *medium-concave* classes reported more AID and being a passenger of a drunk driver more frequently.

Conclusions: Parental drinking may affect children's later engagement in AID. Efforts should focus on parents' education regarding the consequences of parental modeling of alcohol consumption.

PREDICTORS OF EARLY CANCER DETECTION BEHAVIOR AMONG BLACK MALES

Darlingtona Atakere, MS, Tamara Baker, Ph.D.

University of Kansas, Lawrence, KS

With significant medical improvements and early detection, there has been an overall decrease in mortality and morbidity rates resulting from a cancer diagnoses. Despite this improvement in national and global health status, Black males continue to be diagnosed at a later stage, with a more aggressive disease state. To contribute to our understanding of the complexity of incidence and mortality due to cancer, adult Black males ($N=222$) 30–63 years of age were surveyed to determine the implication of demographic (age, education), social (self-esteem, cancer beliefs) and psychosocial characteristics (perceived vulnerability to cancer diagnoses, illness attitude) on early cancer detection behaviors. Results showed age ($b = -.21$, $pb = .18$, $pb = -.55$, $p=.00$), and illness attitude ($b = 2.44$, $pM = 8.16$, $SD = 3.9$) and younger ($M = 8.43$, $SD = 4.6$) participants; $t(146) = 220$, NS). Focusing exclusively on Black males enhances our understanding of this adult population, and data from this study holds promise in informing health messages that may reduce deleterious health behaviors and outcomes among this marginalized population.

PRESENCE OF SUPPORT DURING STRESSFUL/UPLIFTING EVENTS PREDICTS CARDIOVASCULAR OUTCOMES

Ashley Peak, M.S., Mariam Ter-Petrosyan, M.S., Luci Martin, Ph.D.

University of La Verne, La Verne, CA

Social relationships or interactions are a well-known marker of physical health (i.e., Holt-Lunstad, Smith, & Layton, 2010) and have been tied to healthier physiological profiles (Uchino, 2006); however, not all social relationships are health-promoting (i.e., Uchino, 2013). The current study is a re-analysis of an archival dataset that was collected across two phases: Phase 1 included a self-report survey and Phase 2 included a physiological assessment ($n = 305$; 73% female; mean age 21.59, $SD = 5.15$). Fifty-nine percent of the sample self-identified as European American, 18% African American, 11% Latino(a), and 12% as Asian, Native American, or other ethnicity. In the survey, participants were asked to describe three stressful and three uplifting events they had experienced throughout their lives and whether support was present during these events. Sixty-eight percent of the sample endorsed others being present during all uplifting events, while 49% endorsed others being present during all stressful events. Results indicated that greater presence of social support was negatively associated with cardiovascular health, such that a higher presence of support was associated with higher diastolic blood pressure (DBP) ($r = .12$, $p = .04$) and lower heart rate variability ($r = -.14$, $p = .02$). Further, presence of support ($t = 2.46$, $p = .02$) was still a significant predictor of DBP when adjusting for age, sex, and race ($R^2 = .14$, $F(8, 281) = 5.47$, $p < .001$). These findings demonstrate that mere presence of support during important life events (whether stressful or uplifting) may not be health promoting. The mechanisms by which support is health promoting need to be better understood in order to inform relationship science and interventions that promote support to improve quality of life and health.

REGIONAL HEALTH DISPARITIES AMONG OLDER ADULTS IN THE UNITED STATES

Jacquelyn Minahan, MA, Esmeralda Valdivieso, MA, Tamara Baker, Ph.D.

University of Kansas, Lawrence, KS

Unequal access to social, financial and educational services cause differences in the mental and physical health of older adults. This study investigated health disparities of older adults in the United States using the 2014 Behavioral Risk Factor Surveillance System published by the CDC. Respondents selected were 65 years and older, and analyzed variables included: general health status, BMI, physical and mental health status, exercise, history of depression and cognition. When compared with other regions, the southern U.S. had the highest percentage of individuals endorsing poor perceptions of health (27.3%), a lifetime prevalence of depression (16.3%) and trouble with cognition (11.0%). Of those who reported a lower quality of health in last month, individuals from the South indicated the highest average of days of poor physical and mental health (14.6 and 12.0, respectively). With respect to health behaviors, this same region demonstrated the lowest percentage of individuals participating in physical activities (67.0%). Obesity was found to be highest in the Midwest (29.1%) and South (27.3%). Difference in health indicators between U.S. regions are interpreted using the social determinants perspective and fundamental cause of health inequalities. According to the 2014 U.S. Census, the southern region has the highest percentage of older adults living below the poverty line, as well as the lowest household annual income and education rate. Differences in social capital and unavailable resources shape older adults' health behaviors by determining their lifestyle choices, and ultimately influence their physical and mental health.

ROMANTIC RELATIONSHIP SATISFACTION AND AMBULATORY BLOOD PRESSURE DURING SOCIAL INTERACTIONS

Talea Cornelius, PhD, MSW¹, Jeffrey L. Birk, Ph.D.², Donald Edmondson, PhD, MPH², Joseph E. Schwartz, PhD³¹Columbia University, New York, NY; ²Columbia University Medical Center, New York, NY; ³Stony Brook University, Stony Brook, NY

Background. Mechanisms linking high-quality romantic relationships and improved cardiovascular health, including lower blood pressure (BP), are not fully understood. It may be that people experience lower BP specifically when interacting with a romantic partner. This study parsed the effects of different types of social interactions on ambulatory BP (ABP) and tested whether romantic relationship satisfaction moderated these effects. We hypothesized that participants who were more satisfied with their romantic relationship would have reduced BP during partner interactions. Additionally, we explored whether any BP reduction due to high satisfaction extended to other social interactions (e.g., friends, coworkers).

Methods. Participants ($N=594$) were drawn from a larger study on lab BP/ABP and cardiovascular health. Mean age was 46.5 ± 9.3 . Participants were 57.4% female and 65.1% were married. Participants reported on romantic relationship quality and completed 24 hours of ABP monitoring. At each reading, participants also reported on whether or not they had just had a social interaction and with whom. Multilevel models were used to account for nesting of data over time.

Results. Relationship satisfaction ($M=108.2 \pm 9.0$) significantly modified the effect of social interactions on systolic and diastolic BP (SBP, DBP). Participants with high (+1SD) relationship satisfaction had significantly decreased SBP during interactions with a romantic partner, $B=-0.77$, $p=.02$; low satisfaction (-1SD), $B=.59$, $p=.14$. This pattern also emerged for DBP: high satisfaction, $B=-.19$, $p=.14$; low satisfaction, $B=1.01$, $p<.01$.

Participants'; satisfaction with their romantic partner also modified SBP response during interactions with a friend such that SBP was elevated only if satisfaction was low, and DBP response when interacting with an "other" such that DBP was elevated only if satisfaction was high.

Conclusion. In support of study hypotheses, this large and ecologically valid study found that participants with high levels of romantic relationship satisfaction experienced significantly lower BP during social interactions with their partner. Effects were largely restricted to romantic interactions, yet there was some evidence for spillover to other types of relationships. Studies are needed to determine whether interventions to improve satisfaction within couples might additionally benefit BP and long-term cardiovascular health.

THE EFFECT OF MARITAL SATISFACTION AND NEUROTICISM ON AMYGDALA ACTIVATION

Erin T. Kaseda, N/A¹, Zachary J. Blackhurst, MS², Sean C. Aaron, MS², Malia Anderson, PhD³, C. Brock Kirwan, PhD², Wendy C. Birmingham, PhD²¹Brigham Young University, Draper, UT; ²Brigham Young University, Provo, UT; ³Utah Valley University, Provo, UT

Background: The relationship between amygdala activation and processing aversive stimuli and negative emotions has been well established. The amygdala is an important component of emotional processing relevant to maintaining long-term relationships, which provide emotionally complex interactions, but its role in processing positive and ambiguous stimuli is unclear. Multiple studies have established that neuroticism consistently predicts lower marital satisfaction, though the underlying mechanisms are not well understood. We hypothesized that marital satisfaction would be associated with neuroticism and amygdala activation when married individuals were exposed to emotionally complex conflict discussions.

Method: 49 married participants aged 22–42 (M=28; N=24 female) completed the Couples Satisfaction Index and the Neuroticism Subscale of the Big 5 Personality Inventory and participated in a video-recorded discussion conflict task with their spouse. Functional MRI data was obtained as each subject watched a video of the discussion task spliced with neutral visual and auditory stimuli in rotating 30 second segments. Exclusionary criteria included health factors that may have altered neural activation patterns.

Results: Participants were mostly educated, middle-income, and white (88%). In an ROI analysis of the amygdala we found significantly increased functional activation in both the left ($p=.03$) and right amygdala ($p=.04$) while viewing the recording conflict discussion in individuals with greater marital satisfaction. Higher neuroticism was similarly correlated with increased right amygdala activation ($p=.05$) during the conflict task.

Conclusions: Unlike the majority of research on the processing of emotions which focused on the impact of negative stimuli on amygdala activation, the present study focused on ambiguous stimuli. Highly satisfied couples had higher amygdala activation which may have been due to experiencing conflict as emotionally complex whereas couples with lower relationship satisfaction may have experienced simple processing of conflict discussions that were congruent with their generally negative evaluation of their marriages. Also, those with high neuroticism may process emotions effortfully which is associated with amygdala activation. This finding suggests that both the right and left amygdala are involved in the processing of more complex emotions for married individuals.

THE INVESTIGATING NETWORK SUPPORT IN GAPS IN HEALTH AND TREATMENT IN BREAST CANCER (INSIGHT-BC) STUDY

Candyce Kroenke, ScD, MPH¹, Elaine Kurtovich, MPH², Alyce Adams, PhD², Veronica Shim, MD³, Lawrence Kushi, ScD²¹Kaiser Permanente Northern California, Oakland, CA; ²Kaiser Permanente Division of Research, Oakland, CA; ³Kaiser Permanente, East Bay, Oakland, CA

Background: Once diagnosed, African-American (AA) women have a 40–70% higher risk of breast cancer (BC) mortality compared with non-Hispanic white (NHW) women. Treatment differences have been implicated but there has been little investigation of the causes of these differences. While women with larger personal social networks generally have better BC survival, it is unclear how the social environment differs by race in BC survivors and how this might help explain disparities in treatment and survival. Our goal is to understand how race differences in social networks influence variation in decisions about and follow-through with treatment.

Methods: In the Investigating Network Support In Gaps in Health and Treatment in Breast Cancer (INSIGHT-BC) mixed-methods study, we will recruit a purposive sample of 30 women of AA and NHW women with stage II-III invasive BC who received treatment at the Kaiser Permanente Northern California (KPNC) Oakland Medical Center for semi-structured interviews about their social networks and perceived effects on BC treatment. Women will be selected based on differences in chemotherapy treatment status (without delays in chemotherapy, with delays, and without recommended treatment) (6 race x treatment groups of 5 women each). Participants will be frequency matched on age, stage, BC subtype, and education. We will collect egocentric social network data in in-person interviews using EgoWeb 2.0 social network software. This produces visualizations of the participant's social network which can stimulate insights about how social relationships affect their ability to manage treatment.

In quantitative analyses of 3,782 newly diagnosed women from the Pathways study and in additional women recruited from the KPNC Oakland Medical Center, we will examine race differences in social network characteristics (e.g., size, types and diversity of ties, levels of social support and burden) and will further evaluate, in analyses of the joint effects of race and social network size, associations between social networks, treatment, and breast cancer outcomes, and whether associations differ by race.

Results: In preliminary results, adjusted for education and stage, AA women had smaller networks than did NHW women ($p<0.001$). They were less likely to be married ($p<0.001$) or have large (\geq median=10) friend/relative networks ($p=0.007$), though they were more likely to participate in religious organizations ($p<0.001$). AA and NHW women reported similar overall levels of social support but AA reported lower positive social interaction ($p=0.003$), lower support from friends ($p=0.06$), less time spent with friends ($p=0.02$), and greater distance in relationships ($p<0.001$). Additional results will be presented.

Conclusion: Social network characteristics differ in AA vs. NHW women. This study will help to evaluate the role of social networks in disparities in breast cancer treatment and outcomes.

WORKPLACE-BASED EDUCATIONAL INTERVENTION IMPROVES LATINOS' KNOWLEDGE OF AND ADHERENCE TO CANCER SCREENINGS

Echo Warner, MPH¹, Laura Martel, BS², Judy Ou, PhD¹, Gina Nam, MPH³, Sara Carbajal-Salisbury, BS in Business⁴, Anne Kirchoff, PhD, MPH⁵, Deanna Kepka, PhD, MPH¹

¹Huntsman Cancer Institute/University of Utah, Salt Lake City, UT; ²Huntsman Cancer Institute, Salt Lake City, UT; ³Huntsman Cancer Institute, Salt Lake City, UT, Los Angeles, CA; ⁴Alliance Community Services, Murray, UT; ⁵University of Utah, Salt Lake City, UT

Background: Latinos'; higher age-adjusted mortality from cancer and lower socioeconomic status compared to Non-Hispanic Whites makes them a priority population for testing workplace-based educational interventions. Nationally more Latinos are employed in service and manual labor jobs compared to other racial/ethnic groups. Targeting low-income Latinos through workplace-based initiatives may be a strong approach to improving cancer screening knowledge and adherence.

Methods: Latinos ages 18 and older in Utah participated in a workplace-based educational intervention from January 2015-February 2016 designed to improve knowledge and adherence of breast, cervical, and colorectal cancer screenings. We assessed the effectiveness of this intervention at baseline and follow-up among a sample of N=265 Latinos using McNemar's, univariate regression, and multivariable regressions.

Results: Knowledge of the recommended age for cervical, breast, and colorectal cancer screenings improved from baseline to follow-up (cervical=65.1% to 77.7%, breast=67.2% to 81.7%, colorectal=49.8% to 80.7%, all $p < 0.01$). Knowledge of the recommended frequency for cervical and colorectal cancer screenings increased from baseline to follow-up (cervical=34.0% to 46.5%, colorectal=72.8% to 83.8%, both $p < 0.01$). Insured participants had improved knowledge of breast cancer screening compared to uninsured participants (OR=5.28, 95% CI 1.39–20.04). Adherence to cervical, breast, and colorectal cancer screening increased from baseline to follow-up, but only increases in Fecal Immunochemical Tests (FIT) for colorectal cancer were significant (13.8% to 56.9%, $p < 0.001$). Male participants were more likely to improve in FIT adherence compared to females (OR=2.95, 95% CI 1.08–8.05). Part-time/temporary (OR=0.27, 95% CI 0.10–0.75) and unemployed/retired (OR=0.30, 95% CI 0.09–0.99) participants had lower odds of improving in FIT adherence compared to full-time employees. Participants with annual incomes \geq \$25,000 had 10.2 times (95% CI 2.75–37.95) the odds of improving in FIT adherence compared to those earning $<$ \$10,000 annually.

Conclusions: Interventions that target service industry and manual labor employees through partnerships with employers and community based organizations provide a viable intervention model for strengthening community capacity and supporting employees in improving breast, cervical, and colorectal cancer knowledge and adherence of screening among Latinos.

APPLICATION OF INTEGRATIVE BEHAVIOR MODEL IN UNDERSTANDING DRINKING BEHAVIOR AMONG BINGE DRINKERS AND SOCIAL DRINKERS

Amir Bhochohoy, PhD, CHES¹, Paul Branscum, PhD, RD²

¹University of South Carolina, GREENWOOD, SC; ²Miami University, Oxford, OH

Binge drinking is arguably the single most important preventable cause of morbidity and mortality among college students. Understanding the nature of binge drinking among college students is complex. While colleges typically provide standardized health education interventions to prevent binge drinking, interventions may be more effective if they were tailored to reflect students'; drinking status. For example, for students who already binge drink, tertiary prevention efforts to stop binge drinking is warranted. While for students who drink socially, primary and secondary prevention efforts to monitor their alcohol intake and prevent them from becoming binge-drinkers is warranted. The purpose of this study was to explore psychosocial determinants of binge drinking behaviors among two distinct groups of students. First, we evaluated factors that would help binge drinkers to stop binge drinking, and second, we evaluated factors that would prevent social drinkers from binge drinking in the future. This was a prospective study, whereby undergraduate students ((n=233; binge drinkers (n=161); social drinkers (n=72)) from the large Southwestern University completed an on-line survey evaluating factors associated with binge drinking, and a month later binge drinking status was evaluated. Regression models showed that attitudes, perceived norms and perceived behavioral control (PBC) predicted 48.1% of the variance of intentions to stop binge drinking for binge drinkers, and 60.7% of the variance of intention to continue to not binge drink for social drinkers. Similarly, logistic regression models showed intentions, PBC, and skills predicted 16.6% of behavior for stopping binge drinking among binge drinkers and 30.9% of the behavior for continue not to binge drinking among social drinkers. The results from this study suggested attitude, especially experiential attitude, was the strongest predictor of intentions towards binge drinking for both groups. This study shows the IBM is a promising model for predicting and explaining binge drinking behavior among college students and provides more specificity towards predictive factors to design effective interventions.

FUTURE-SELF CONTINUITY PREDICTS LOWER ALCOHOL ABUSE

Bryan Ross, B.A.¹, Hal Hershfield, Ph.D.², Abraham Rutchick, Ph.D.³

¹California State University, Northridge, woodland hills, CA; ²University of California, Los Angeles, Los Angeles, CA; ³California State University, Northridge, Northridge, CA

Continuous identity across time is a defining feature of the self. However, there is variability in the extent to which people subjectively experience a sense of connection with their future selves ("future self-continuity"). If people feel more connected to their future selves, they should be more likely to engage in behaviors that benefit those selves (i.e., behaviors that promote long-term benefit rather than immediate gratification). Indeed, future self-continuity has been shown to be associated with a variety of adaptive behaviors. For example, greater future self-continuity is correlated with more retirement savings, and increasing future self-continuity induces increases in saving behavior. Analogous effects have been found in diverse domains such as academic procrastination, ethical behavior, and suicidality. A recent study revealed a correlation between future self-continuity and self-reported general health, and showed that manipulating future self-continuity (using an intervention in which participants wrote letters to their distant future selves) led to increased exercise behavior. The current study examined the relation between future self-continuity and alcohol abuse. Given that future self-continuity has been associated with adaptive health behaviors, we hypothesized that greater levels of FSC would predict lower scores on an alcohol screening test. A sample (N=243) recruited from Amazon's Mechanical Turk took a survey in which they completed a measure of future self-continuity and the Short Michigan Alcohol Screening Test (S-MAST). Greater future self-continuity significantly predicted lower alcohol abuse scores ($b = -.241, p < .001$). Furthermore, the relationship held after controlling for age and gender. These initial findings suggest that people who feel more similar to their future selves show fewer tendencies for alcohol abuse. In future research, we will manipulate future self-continuity using a writing task intervention and prospectively assess alcohol consumption.

PROJECT PAN: RELATIONSHIP BETWEEN PSYCHIATRIC CORRELATES AND NON-SUICIDAL SELF INJURY

Alex Jaffe, B.A., Pierre A. Leon, M.A., Samantha Weiss, Undergraduate, Larissa Thiele, Undergraduate, Anthony Eldridge, Master's Student, Georita Frierson, PhD
Rowan University, Glassboro, NJ

Background: Non Suicidal Self-injury (NSSI) is the deliberate act of harming oneself with no suicidal intent. Many undergraduates partake in this behavior, with prevalence rates as high as 35%. This population may also engage in negative health behaviors, including smoking and drinking. Studies have shown these behaviors co-occur with NSSI, but there's a dearth of health psychology literature on whether or not negative health behaviors predict / correlate with engagement in NSSI. Increased research in this area could help clarify multiple health behaviors in the NSSI population.

Purpose: The present study explored the relationship between health behaviors and engagement in NSSI.

Methods: Two hundred nineteen undergraduate students aged 18–35 ($M=20.09$; $SD=2.29$, 74% female) completed an online survey at a public university in Southern New Jersey. Participants were recruited using an IRB-approved flyer, an undergraduate psychology pool, and through class presentations.

Results: A logistic regression was conducted to predict the relationship between health behaviors and engagement in NSSI. Results indicated that individuals who partake in negative health behaviors are more likely to engage in NSSI ($OR=0.475, p<0.05$). Two point-biserial bivariate correlations were computed to assess the relationships between negative health behaviors (smoking, drinking) and NSSI. Results indicated there were no significant correlations ($r_{pb(215)}=-0.046, -0.011, ps>0.05$).

Conclusions: Participants who engage in negative health behaviors compared to their counterparts perform NSSI, irrespective of negative health behavior type.

Implications: Results indicate those who don't perform negative health behaviors are less likely to engage in NSSI. Tertiary prevention methods may need to also address (negative) health behaviors to provide comprehensive psychoeducational interventions for persons who self-report NSSI.

UNDERSTANDING THE RELATIONSHIP BETWEEN TRAUMA, ALCOHOL AND OTHER DRUG USE AND VIOLENT CRIME.

Siobhan Lawler, BA Psych (Hons)¹, Lexine A. Stapinski, PhD, M.ClinPsych, BPsych(Hons)², Emma L. Barrett, PhD³, Maree Teesson, BSc Psych(Hons), PhD⁴

¹National Drug & Alcohol Research Centre, University of New South Wales, Sydney, New South Wales, Australia; ²University of New South Wales, Sydney, Australia, Sydney, New South Wales, Australia; ³NHMRC Centre of Research Excellence in Mental Health and Substance Use, Sydney, New South Wales, Australia; ⁴UNSW Sydney, Sydney, New South Wales, Australia

The majority of young people in custody have drug and alcohol related problems, with 78% classifying as risky drinkers and 89% having used illicit drugs. Furthermore, there is strong evidence of an association between substance use and violent offending specifically, with many of these young offenders also reporting significant trauma histories. The current study seeks to examine the relationship between substance use, trauma and violence in the judicial context and contemplate judge's aims in sentencing. A cross sectional analysis of sentencing remarks from courts in New South Wales, Australia was conducted. Between 2015 and 2016, a total of $N = 221$ remarks sentencing serious violent offences were available. Not surprisingly, substance use involvement was identified as an offence characteristic in three-quarters of violent offence cases ($n = 186$). A subsample of these remarks sentencing offenders aged between 18 and 25 ($n = 38$) were then exported for further review.

Among young adult offenders, robbery and assault were the most common offences, and methamphetamine and alcohol were the most commonly involved substances (43% and 29% of cases, respectively). One in four offenders had a diagnosis of Post-Traumatic Stress Disorder, over half (61%) had a history of trauma and 39% had two or more co-occurring mental health disorders. Alcohol and other drug treatment was a common goal in sentencing and addressing substance use dependence was seen as key in the offender's successful rehabilitation in the majority of cases. The analysis indicated that alcohol and other drug use were commonly implicated in violent crime and violent offending was linked to the offenders substance use, particularly in the context of the use of methamphetamine.

USING THE INTEGRATIVE BEHAVIOR MODEL AND THEORY OF PLANNED BEHAVIOR TO PREDICT DRINKING BEHAVIOR: A SYSTEMATIC REVIEW

Amir Bhochohiboya, PhD, CHES¹, Paul Branscum, PhD, RD²

¹University of South Carolina, GREENWOOD, SC; ²Miami University, Oxford, OH

Alcohol is the third leading lifestyle-related cause of death in the US. The Theory of Planned Behavior (TPB) has been extensively used in understanding and predicting health-related behavior, and now, the researcher uses the Integrated Behavior Model (IBM), an updated version of the TPB. The purpose of this study is to systematically review the literature on studies that have applied the IBM and TPB towards understanding and predicting alcohol consumption behavior, to identify modifiable targets for public health promotion interventions and campaigns. Eligibility criteria for the studies included full-text English language peer-reviewed article published between 2011 and 2016. Six databases, (i.e. ERIC and Medline) were used to identify relevant articles. The Boolean search strategy was selected with the combination of keywords: alcohol, binge drinking, and heavy drinking, Integrated Model, IBM, and TPB. Eleven articles were included in the final review. Each article was thoroughly read to extract the following variables: purpose, participants, research design, measures, results, and outcomes. Of the 11 studies identified, 2 used the IBM and 9 used the TPB. Similarly, 8 studied "binge-drinking", 1 studied "heavy-drinking", 1 studied overall alcohol consumption, and 1 studied drinking behaviors among pregnant women. Attitudes emerged as the strongest determinant of intentions and behavior followed by the perceived norms for the alcohol consumption behavior. The core constructs of IBM/TPB predicted a significant amount of variance for intentions (45% to 55%) and the drinking behaviors (26% to 46%). Evidence from this review also suggests that self-efficacy should replace the construct perceived behavioral control. In conclusion, practitioners should operationalize behavior change techniques and strategies to modify individual's attitudes and norms to help reduce drinking behaviors. An outcome of this review can inform the future studies and intervention.

ARE PTSD SYMPTOMS ASSOCIATED WITH ENGAGEMENT AND RESPONSE TO ALCOHOL CARE MANAGEMENT FOR VA PATIENTS WITH HIGH RISK DRINKING?

Theresa E. Matson, MPH, Evette J. Ludman, PhD, Katharine A. Bradley, MD, MPH
Kaiser Permanente Washington Health Research Institute, Seattle, WA

Introduction: Posttraumatic stress disorder (PTSD) may create important barriers to engagement in alcohol use disorder (AUD) care management. This study tested whether having PTSD, compared with not having PTSD, (1) interfered with engagement in AUD care management and (2) was associated with more heavy drinking days at 12-month follow up, among a sample of Veteran Affairs (VA) patients randomized to receive care management for AUD.

Methods: VA patients from three primary care sites were eligible for the Choosing Healthier Drinking Options In Primary Care (CHOICE) trial if they reported high-risk drinking (≥ 4 drinks/day for women; ≥ 5 for men, two times per week or once per week if any prior AUD treatment). This observational sub-study was interested only in patients randomized to receive AUD care management and who completed baseline screening for PTSD ($n=147$). Adjusted generalized linear regression models with Poisson and binomial distributions were used to assess the relationship between baseline PTSD and the number of nurse care visits at 12 month follow up as well as the number of heavy drinking days in past 28 days at 12 month follow up, respectively.

Results: Participants with and without PTSD did not differ significantly on baseline sociodemographic characteristics or baseline percent heavy drinking days. After adjusting for potential confounders, PTSD was *not* significantly associated with the number of visits with the CHOICE nurse ($p=0.94$). Participants with PTSD had significantly lower odds of heavy drinking days at 12 month follow up than participants without PTSD ($OR=0.77$; 95% CI: 0.65, 0.92; $p<0.01$).

Conclusions: VA patients who were at risk for heavy drinking and had PTSD were no less likely than those without PTSD to engage in AUD care management and were more likely to reduce their drinking. These findings suggest future primary care interventions for AUD should not exclude patients with PTSD or dissuade providers from treating patients with high-risk drinking on the basis of having PTSD.

DRINKING MOTIVES AND ALCOHOL-RELATED CONSEQUENCES AMONG LATINO DAY LABORERS

Vanessa N. Torres, MPH, India J. Ornelas, MPH, PhD

University of Washington, Seattle, WA

Background: Latino day laborers may engage in unhealthy alcohol use as a way of coping with immigration-related stressors, which can ultimately lead to negative health and social consequences. Interventions to reduce unhealthy alcohol use focus on weighing the pros and cons of drinking. The purpose of this study is to describe Latino day laborers' motives for drinking, as well as their alcohol-related consequences in order to inform interventions to reduce unhealthy alcohol use.

Methods: As part of the Vida PURA study, we recruited 181 Latino immigrant men from a day labor worker center to complete interviewer-administered surveys. Eligible participants had Alcohol Use Disorders Identification Test (AUDIT) scores ≥ 6 . Surveys included measures of alcohol use, drinking motives, alcohol-related consequences, and demographic characteristics. We measured alcohol use using the AUDIT and alcohol-related consequences using the 15-item Short Inventory of Problems (SIP) to calculate lifetime consequences score. We assessed differences in drinking motives and lifetime consequences by level of AUDIT risk (scores 0–7 indicate low risk or abstinence, scores 8–15 suggest unhealthy alcohol use, scores 16–19 indicate harmful and hazardous drinking and scores 20–40 suggest alcohol dependence) using chi-square tests of independence and two-sample tests of proportions.

Results: The most commonly reported drinking motives were to cope with anxiety, to enhance feelings of fun, and to socialize. However, those men with higher AUDIT scores (20–40) compared to those with lower AUDIT scores (6–19) reported higher mean levels of anxiety, enhancement, and social motives. Men with higher AUDIT scores reported an average of twelve alcohol-related consequences, while men with lower AUDIT scores reported an average of six alcohol-related consequences.

Conclusions: Initial results demonstrate that those men who are alcohol dependent as indicated by AUDIT scores ≥ 20 face additional alcohol-related consequences and have more anxiety-related motives to drink compared to those men with lower AUDIT scores. These findings suggest that brief interventions should consider using Motivational Interviewing (MI), which is a client-centered counseling style for eliciting behavior change by helping participants to explore motives and consequences of drinking. More research is needed to determine if MI is effective in reducing alcohol consumption among this population.

HIGH-INTENSITY DRINKING: PREVALENCE RATES ACROSS ADULTHOOD BY GENDER AND RACE/ETHNICITY

Ashley Linden-Carmichael, Ph.D., Stephanie T. Lanza, Ph.D.

The Pennsylvania State University, University Park, PA

Individuals who engage in heavy episodic drinking, or consuming 4+/5+ drinks in one sitting for women/men, are at heightened risk for experiencing alcohol-related harms. An emerging body of research has found that many drinkers far exceed heavy episodic drinking cutoffs. Such "high-intensity drinking", or drinking at twice the level of a heavy episodic drinker (8+/10+ drinks for women/men), is linked with numerous harms, including alcohol use disorder. Limited attention thus far has been devoted to identifying individuals most at risk. Such information is critical for informing prevention efforts. Using a nationally representative sample of adults, the current study modeled age-varying prevalence rates of high-intensity drinking across adulthood by gender and by race/ethnicity. Data were from the National Epidemiologic Survey on Alcohol and Related Conditions (NESARC-III). Individuals who were between ages 18 and 64 and reported any alcohol use in the past year were included in study analyses ($n = 22,776$). Intercept-only time-varying effect models (TVEMs) were used to estimate the prevalence of high-intensity drinking across continuous age separately as a function of gender and race/ethnicity (White vs. Black vs. Hispanic). High-intensity drinking was generally more prevalent among men than women, with peak prevalence at approximately age 25 (40%) for men. Peak prevalence of high-intensity drinking was observed for women at age 18 (25%). High-intensity drinking prevalence steadily declined across age, with approximately 11% of men and 5% of women engaging in high-intensity drinking at age 64. Notably, confidence intervals overlapped for men and women at age 18, indicating that prevalence rates were equal for men and women at this age. In terms of race/ethnicity, rates were lowest for Black adults (14%) and remained steady from ages 18 to 64. For both White and Hispanic adults, age trends were characterized by peaks occurring around age 21 followed by steady declines, with White adults having a slightly higher rate than Hispanic adults. Findings highlight several ages at which disparities in high-intensity drinking were most prominent across both gender and race/ethnicity. Results suggest that White and Hispanic adults and men are key targets for intervention throughout young adulthood. In addition, as women peak in high-intensity drinking at age 18, prevention efforts may be warranted in late adolescence for this subgroup.

INVESTIGATING ETHNIC DIFFERENCES IN MARIJUANA USE AMONG HAWAII YOUTH: 2011 - 2015

Allison Wagner, M.A.¹, Danilyn Goya, MPH¹, Claudio Nigg, Ph.D.²¹University of Hawai'i at Manoa, Honolulu, HI; ²University of Hawaii, Honolulu, HI

Background: Youth marijuana use remains a concern nationally, with much research devoted to understanding the risk and protective factors related to use. Modeling these factors using an ecological model necessitates that research attempt to integrate multiple levels of influences on use (i.e., self, family, community, society). One step in understanding cultural influences on youth marijuana use is to first investigate disparities in use amongst ethnic groups, especially in Hawaii which comprises of several ethnic groups.

Purpose: To examine youth marijuana use in Hawai'i across different ethnic groups.

Methods: The marijuana-related use indicators from the Youth Risk Behavior Survey – Hawai'i for years 2011, 2013, and 2015 were examined. Rates are presented for youth in grades 9 through 12.

Results: In 2015, Native Hawaiian youth endorsed higher rates of lifetime marijuana use (47%; 95% CI: 43.2 – 50.8) than all ethnic groups other than Other Pacific Islander students (37.4%; 95% CI: 30.1 – 44.6), and was higher than the national rate (38.6%). This was also true in 2013, and in 2011, Native Hawaiian youth had significantly higher rates than all other ethnic groups measured (51.1%; 95% CI: 46.9 – 55.3).

In 2015, Native Hawaiian (28.8%; 95% CI: 24.9 – 32.7), Caucasian (22.9%; 95% CI: 19.4 – 26.3), Other (22.5%; 95% CI: 19.9 – 25.1), and Other Pacific Islander (22%; 95% CI: 15.8 – 28.2) students had the higher rates of current marijuana use than Filipino (11.6%; 95% CI: 7.6 – 15.7), Japanese (10.1%; 95% CI: 4.6 – 15.6), and Other Asian (5.4%; 0.6 – 10.2) students, and was again higher than the national rate (21.7%)

A similar pattern emerged for early use, such that Native Hawaiian (17.4%; 95% CI: 14.6 – 20.2), Other Pacific Islander (13.9%; 95% CI: 8.5 – 19.3), and Other youth (10.1%; 95% CI: 7 – 13.3) more frequently endorsed use before age 13 than did Filipino (5.5%; 95% CI: 3.6 – 7.4), Japanese (3.5%; 95% CI: 1.2 – 5.9), and Other Asian youth (2.6%; 95% CI: 0.5 – 4.8). The national rate for 2015 was 7.5%.

Conclusions: Overall, it appears that Native Hawaiian, Other Pacific Islander, Caucasians, and Other students had the highest lifetime, current, and early use between 2011 – 2015. Culturally appropriate and evidence-based programs are suggested to target groups with consistently higher rates of use. Additional research to understand the levels of influence on youth in these groups is needed to design such prevention and intervention efforts.

LINKING AND SYNCING STAKEHOLDERS - ADDRESSING THE PRESCRIPTION OPIOID CRISIS IN HAWAII

Michelle H. Tong, BA¹, Emilee H. Turner, BA², Tammie Healan Hoapili Smith, MPH³, Daniel Galanis, Ph.D.⁴, Therese Marie Argoud, MPH⁵, Edward Mersereau, LCSW, CSAC⁶, Claudio Nigg, Ph.D.⁷¹University of Hawaii at Manoa, Honolulu, HI; ²University of Hawai'i at Mānoa, Honolulu, HI; ³State of Hawaii Department of Health, Honolulu, HI; ⁴Hawaii Department of Health, Honolulu, HI; ⁵Department of Health, EMS and Injury Prevention System Branch, Honolulu, HI; ⁶Department of Health, Alcohol and Drug Abuse Division, Kapolei, HI; ⁷University of Hawaii, Honolulu, HI

Opioid misuse is becoming the leading cause of poisoning deaths nationwide. From 2010–2014, prescription opioids contributed to 35% (270) of the 778 drug overdose deaths in Hawaii. In response, the Data-Driven Prevention Initiative (DDPI), funded by the CDC, collaborated with the State Targeted Response to the Opioid Crisis (STR) funded by the SAMHSA, by launching the Opioid Abuse Initiative. This fostered interagency networks amongst stakeholders to identify the concerns, resources, and gaps that exist to inform a statewide Strategic Plan. A critical component of the DDPI and STR Projects is a needs assessment consisting of a stakeholder survey, environmental provider map, literature review, existing database scan, and legislative policy summary. The number of respondents from each stakeholder group were: prevention (69), treatment (35), medical providers (including physicians, nurses, pharmacists, dentists, and veterinarians) (1,266), policymakers (7), law enforcement (42), and insurance (17). Survey results revealed promising areas of policy, education, and data-sharing approaches to combat the local prescription opioid crisis. In response and under directive from the Governor and Director of Health, in 2017, two committees were created with representation across sectors to coordinate the Strategic Plan. The Executive Steering Committee on Substance Use (ECSU) provides support and direction for implementation. Under the ECSU is the Opioid Abuse Prevention Strategic Planning Committee (OPSPC), which focuses on development. The OPSPC further breaks down into workgroups that concentrate on specific aims rooted in best practices areas of the opioid issue as supported from national recommendations, the literature, and the needs assessment survey. The workgroups are: Treatment Access; Prescriber Education & Pain Management Practices; Data-Informed Decision Making; Prevention & Public Education; Protocols for Opioid Prescription; and Support for Law Enforcement & First Responders. Organizational categories represented include: State Departments; Coalitions; Police; Insurance agencies; University; Legislators; Prevention and Treatment agencies, and Medical Providers. Currently, the Hawaii statewide Strategic Plan against prescription opioid abuse is being developed with implementation planned for mid-2018.

NARCISSISTIC GRANDIOSITY AND RISKY HEALTH BEHAVIORS IN COLLEGE STUDENTS

Sulamunn R. M. Coleman, M.S.¹, Michael J. Bernstein, Ph. D.², Jacob A. Benfield, Ph. D.², Joshua M. Smyth, PhD³¹The Pennsylvania State University, State College, PA; ²Penn State University Abington, Abington, PA; ³Pennsylvania State University, University Park, PA

Narcissism is a generally maladaptive aspect of personality characterized, in part, by an overriding need for recognition and admiration in order to maintain an inflated sense of self (i.e., grandiosity). Grandiosity encompasses related, yet theoretically distinct components, such as leadership and authority striving (e.g., to demonstrate one's superiority and willfulness), exhibitionism, and a general willingness to take advantage of others to meet entitled expectations. In medical patient populations, grandiosity has been associated with behavioral processes known to influence health outcomes, including high-risk substance use and sexual behavior. Evidence also documents rising rates of grandiosity in college students, highlighting the importance of examining the relationship of grandiosity to the health and well-being of college students: in particular, the tendency to engage in risky health behaviors. In this study, college men and women ($n=122$; $M_{age}=19.51$, $SD=1.70$, 75.2% women) completed self-report measures of grandiosity and specific grandiose traits (i.e., "leadership/authority," "grandiose exhibitionism," and "entitlement/exploitativeness"), problematic alcohol consumption, and number of sex partners over the last three months. Grandiosity was positively associated with problematic alcohol consumption ($\beta = .33$, $p = .05$), and gender moderated a positive association between grandiosity and number of recent sex partners: compared to college women high in grandiosity, college men high in grandiosity reported having more sex partners during the last three months ($\beta = -.41$, $p = .05$). A similar gender by entitlement/exploitativeness interaction was observed for number of recent sex partners ($\beta = -.45$, $p < .01$). Overall, these results suggest college students higher in grandiosity may be at increased risk for a variety of poor health outcomes associated with problematic alcohol consumption (e.g., accidental injury, liver disease) and having multiple concurrent sex partners (e.g., contracting STIs). As such, increasing prevalence rates of grandiosity among college students may warrant increased concern for their long-term health and well-being. By extension, colleges may benefit from developing and testing treatments to reduce health behavior risks associated with grandiosity.

PREDICTORS OF ALCOHOL USE AMONG AN AFRICAN AMERICAN CHURCH POPULATION: THE ROLE OF RELIGIOSITY

Kelsey Christensen, MA¹, Jannette Berkley-Patton, PhD, MA, BSEE², Alexandria Bauer, MA¹, Carole Bowe-Thompson, BS¹, Nia Johnson, BA³, Sheila Lister, B.S.¹, Natasha Aduloju-Ajijola, PhD, MPH, CHES⁴¹University of Missouri-Kansas City, Kansas City, MO; ²University of Missouri-Kansas City, School of Medicine, Kansas City, MO; ³University of Missouri Kansas City, Kansas City, MO; ⁴University of Missouri-Kansas City, School of Medicine, Kansas City, MO

Although African Americans (AAs) are more likely to abstain from alcohol and report drinking less often than Whites, they are at greater risk for disease (e.g., liver cirrhosis), death, and social consequences (e.g., arguments/fights, work difficulties, legal problems) due to alcohol use – even at low levels of consumption. Additionally, studies suggest AAs may be less likely to initiate and engage in treatment for alcohol-use disorders than Whites. Studies indicate AAs tend to be highly religious and suggest that religious involvement may be a protective factor against alcohol-related problems. Given these disparities, further understanding of sociodemographic factors related to alcohol consumption among AA church-affiliated populations may assist in informing faith-based, early intervention efforts. The present study examined potential predictors (e.g., gender, religiosity, perceived stress, sleep, violence exposure, cigarette use, overall health) of alcohol consumption using baseline survey data from Project Faith Influencing Transformation (FIT), a diabetes/heart disease prevention intervention piloted in six AA churches and their community outreach ministries (e.g., food/clothing programs). Church and community participants ($N=352$) were predominantly female (68%) and had an average age of 54 ($SD=13$). Results indicated that the majority of participants (78%) reported consuming alcohol very seldom or never, and the remaining participants (22%) reported consuming alcohol several times per month or more. Preliminary analyses indicated that there were significant negative relationships between alcohol use and age ($r = -.1$, $p = .07$), gender ($r = -.09$, $p = .09$), sleep ($r = -.11$, $p = .06$), religious engagement ($r = -.22$, $p < .001$), and collaborative religious coping ($r = -.10$, $p = .06$). There were significant positive relationships between alcohol use and self-directive religious coping ($r = .10$, $p = .06$) and tobacco use ($r = .25$, $p < .001$). Education, perceived stress, violence exposure, past mental health diagnosis, overall health, and passive religious coping were not significantly related to alcohol use. A p -value of .1 was utilized to determine which variables to include in the regression analysis. In the linear regression model, religious engagement negatively predicted alcohol use ($\beta = -.18$, $p = .01$) and tobacco use positively predicted alcohol use ($\beta = .16$, $p = .01$). Age, gender, sleep, collaborative religious coping, and self-directive religious coping were not significant predictors of alcohol use. Findings of the present study suggest that given the high co-occurrence of alcohol and tobacco use, future intervention efforts should consider addressing both as well as targeting individuals with lower levels of religiosity (e.g., community members served through outreach ministries) who may be more at-risk for alcohol-related consequences.

READINESS FOR IMPLEMENTING WEB-BASED INTERVENTIONS FOR THE PREVENTION OF RISKY SUBSTANCE USE AT GERMAN UNIVERSITIES

Claudia Pischke, PhD¹, Frauke Wichmann, N/A², Thomas Ganz, N/A³, Thomas Heidenreich, N/A⁴, Hajo Zeeb, N/A⁵

¹Leibniz-Institute for Prevention Research and Epidemiology - BIPS, Bremen, Bremen, Germany; ²Leibniz Institute for Prevention Research and Epidemiology-BIPS, Bremen, N/A, Germany; ³University of Applied Sciences Esslingen, Germany, Esslingen am Neckar, Baden-Württemberg, Germany; ⁴Hochschule Esslingen, Esslingen, Baden-Württemberg, Germany; ⁵Leibniz Institute for Prevention Research and Epidemiology - BIPS, Bremen, Bremen, Germany

Background: Web-based programs for the prevention and/or reduction of risky substance use appear to be appropriate for reaching a broad spectrum of university and college students. However, little is known about effective strategies for scaling these programs up in the university context. The aim of the DIOS-project was to assess readiness to implement web-based interventions at ten universities using an adapted version of the community readiness assessment in order to prepare scale-up.

Methods: Forty qualitative interviews with stakeholders at ten universities were conducted. The Community Readiness Assessment (CRA) by Stanley (2014) was translated into German, adapted to the German university context, and included questions addressing five dimensions: (1) existing knowledge among students about campus-wide interventions/efforts, (2) key persons/organizations in the setting promoting or implementing programs/strategies, (3) perceived university climate towards promoting or implementing programs/strategies, (4) existing knowledge of students regarding the issue, and (5) existing resources put into preventive programs. The transcripts of the interviews were scored by two independent researchers, using pre-defined scoring rules. For each university, a score ranging between 1 (no awareness) and 9 (community ownership) was determined.

Results: Overall, readiness for implementing web-based interventions across universities was rather low with universities rarely reached levels beyond a score of three. Looking at the scores for the individual dimensions, scores ranged from 1 (no awareness) - 4 (preplanning). On average, universities displayed the following scores for the individual dimensions: 2.4 (range: 1–4) for dimension (1), 3.8 (range: 2–5) for dimension (2), 4.0 (range: 3–5) for dimension (3), 3.8 (range: 3–4) for dimension (4), and 4.4 (range: 3–5) for dimension (5).

Conclusions: The adapted CRA was useful for determining different levels of implementation readiness at German universities. Universities included in this study displayed low levels of readiness for implementing web-based programs for the prevention and/or reduction of risky substance use. Based on the results of the assessment, universities received feedback on how to take the necessary steps to increase readiness and to prepare for program implementation. Whether scale-up at these universities will be successful, will be the subject of future research.

SMOKELESS TOBACCO USE AND LOW BIRTH WEIGHT CHILD AMONG WOMEN IN A RURAL SETTING OF INDIA.

Delfin Lovelina Francis, MDS

Dr MGR Medical University, Chennai, Tamil Nadu, India

Introduction: Low birth weight and preterm birth are powerful determinants of morbidity and mortality in newborn babies and infants. It has been known for more than 40 years that babies born to mothers who smoke weigh less than babies whose mothers don't smoke. Smoking during pregnancy also increases the risk for preterm delivery. In South East Asia smoking among women may be rare, but use of smokeless tobacco is common. There are indications that using smokeless tobacco could be as detrimental to fetal health as cigarette smoking.

Aim: To study the effect of using smokeless tobacco during pregnancy on babies' birth weight at birth.

Materials and Methods: A prospective cohort study was carried out in a teaching hospital in a rural setup among 54 pregnant women who had used smokeless tobacco product at least once a day for the past six months. The frequency of use was categorized as light (one to four times per day) or heavy (five or more times per day). Commonly used forms of tobacco was betel quid (paan) with tobacco, gutka, and paan masala are chewed and generally retained in the mouth for longer periods. They were followed for a period of seven months and birth weight of the newborn was measured.

Results: Smokeless tobacco use was associated with an average reduction of 105 g in birth weight (95% confidence interval 30 g to 181 g). The odds ratio for low birth weight was 1.6 (1.1 to 2.4), adjusted by logistic regression for maternal age, education, socioeconomic status, weight, anaemia, antenatal care, and gestational age. The adjusted odds ratio for preterm delivery (< 37 weeks) was 1.4 (1.0 to 2.1); for delivery before 32 weeks it was 4.9 (2.1 to 11.8) and before 28 weeks it was 8.0 (2.6 to 27.2).

STRUCTURAL AND SOCIOCULTURAL BARRIERS TO ALCOHOL ABUSE TREATMENT SEEKING: A QUALITATIVE STUDY WITH MEXICAN-ORIGIN MALES

Luis A. Valdez, PhD, MPH¹, Scott Carvajal, PhD, MPH², John M. Ruiz, Ph.D.², Eyal Oren, PhD, M.S.³, David O. Garcia, PhD⁴¹The University of Arizona, Tucson, AZ; ²University of Arizona, Tucson, AZ; ³San Diego State University, San Diego, CA; ⁴The University of Arizona / Mel and Enid Zuckerman College of Public Health, Tucson, AZ

Background: Research suggests that Mexican origin (MO) men experience disproportionate levels of adverse health and social consequences of alcohol abuse when compared to non-Hispanic whites (NHW). Despite the disparate burden of alcohol-related consequences, MO men face greater barriers than their NHW counterparts in accessing, engaging, and completing alcohol abuse treatment services. Little is known about how individual (E.g. knowledge) and sociocultural (E.g. cultural norms) factors interact with the social context (E.g. neighborhood disadvantage) to influence treatment seeking behaviors among MO males.

Purpose: To examine MO male perspectives regarding the influential factors of alcohol abuse treatment-related behaviors that can lead to disparate treatment engagement and completion rates.

Methods: Twenty semi-structured interviews were completed with MO men (age: 44.6 ± 11.3 years), 50% of whom had limited English language proficiency. We conducted a thematic analysis using a hybrid deductive-inductive analysis strategy centered in an *a priori* developed codebook that was supplemented with iterative analysis of interview transcripts.

Results: Findings suggest the presence of a complex relationship between structural-, sociocultural-, and individual-level factors related to treatment seeking. Structural barriers were related to lack of insurance and high costs hindering successful treatment. Moreover, dissatisfaction with treatment was centered in; 1) disapproval of treatment created by poor experiences resulting in distrust of sliding-scale and free programs; and 2) inadequacy of communication between patient and provider due to poor language and cultural responsiveness. Sociocultural factors were related to difficulties problematizing alcohol abuse due to cultural normalization of consumption, and societal stigmatization of treatment. Individual factors were related to *machismo*-bound pride as well as lack of knowledge.

Conclusion: There is a need for culturally and linguistically responsive dissemination of accurate information about treatment availability, eligibility, and process. Awareness building efforts also need to target the Hispanic male community regarding the detrimental effects of alcohol-related problems and treatment, in order to diminish associated stigma. Lastly, increased or redistributed funding for linguistically and culturally responsive programs is also needed in communities with large Hispanic populations in order to meet a growing demand for services.

VARIABILITY IN POSITIVE AFFECT, ALCOHOL CONSUMPTION AND MENTAL HEALTH AMONG MOTHERS

Jaclyn P. Maher, Ph.D.¹, Chaelin Ra, PhD², Adam Leventhal, PhD³, Donald Hedeker, Ph.D.⁴, Jimi Huh, PhD⁵, Chih-Ping Chou, Ph.D.⁵, Genevieve F. Dunton, PhD, MPH⁵¹University of North Carolina at Greensboro, Greensboro, NC; ²University of Southern California, Pasadena, CA; ³Usc, Los Angeles, CA; ⁴University of Chicago, Chicago, IL; ⁵University of Southern California, Los Angeles, CA

Affective volatility (i.e., variability) is typically conceptualized as a marker of poor behavioral and psychological health. However, whether variability in affect is detrimental to health may depend on one's usual or average level of affective experience. Amongst individuals who experience low average positive affect, greater vacillation between bouts of joy and anhedonia may be associated with better health outcomes relative to experiencing a restricted range of positive affect. This study therefore tested the hypothesis that mean levels of positive affect captured via an 8-day intensive repeated Ecological Momentary Assessment (EMA) would moderate the association of EMA-measured positive affect variability with behavioral and psychological health outcomes amongst mothers (N = 202; M_{age} = 41 years, Range = 24–57; 49% Hispanic) with young children. Mixed Effect Location Scale Modeling parsed variance in subject-level means and variances for positive affect, and these random effects were subsequently entered in subject-level regression models predicting with alcohol use (i.e., frequency of consumption, binge drinking), depressive symptoms, and anxiety assessed through a baseline questionnaire. Subject-level mean positive affect moderated the associations of subject-level variability in positive affect variability with alcohol consumption frequency (Interaction: $\beta = .22, p = .02$) and depressive symptoms (Interaction: $\beta = .20, p = .02$). More positive affect variability was associated with greater alcohol consumption and depressive symptoms at higher positive affect mean levels, whereas more positive affect variability was associated with less alcohol consumption and depressive symptoms at low mean positive affect. Such interactions were not significant for anxiety and binge drinking. Results from this study reveal that positive affect volatility is not unilaterally associated with poor behavioral and psychological health. Also, intensive longitudinal modeling of interactions of subject-level mean and variability may provide incremental information in psychopathology research and a nuanced perspective on the role of positive affect variability in the tailoring of clinical services for mothers.

THE NIH SOBC RESEARCH NETWORK: EXTENDING THE REACH OF BEHAVIOR CHANGE SCIENCE

Jennifer A. Sumner, PhD¹, Jun Ma, MD, PhD², Joshua M. Smyth, PhD³, Donald Edmondson, PhD, MPH⁴, Susan M. Czajkowski, Ph.D.⁵, Sherri Sheinfeld Gorin, PHD⁶

¹Center for Behavioral Cardiovascular Health, Columbia University Medical Center, New York, NY; ²University of Illinois at Chicago, Chicago, IL; ³Pennsylvania State University, University Park, PA; ⁴Columbia University Medical Center, New York, NY; ⁵National Cancer Institute, National Institutes of Health, Bethesda, MD, MD; ⁶Columbia University, New York, NY

Unhealthy behaviors—including smoking, overeating, medication nonadherence, and physical inactivity—contribute to negative health outcomes and chronic disease. Unfortunately, it is extremely difficult to initiate and maintain lasting healthy behavior changes. The NIH Common Fund's Science Of Behavior Change (SOBC) program brings together researchers across disciplines to address these challenges and develop a more unified science of behavior change. The program aims to improve our understanding of mechanisms of behavior change by supporting cross-cutting research that integrates basic and translational science. In 2015, the SOBC Research Network was formed, bringing together eight interdisciplinary research teams to employ a mechanism-focused, experimental medicine approach to behavior change research. These researchers are developing measures of putative intervention targets related to common mechanisms of behavior change, including self-regulation, stress reactivity and resilience, and interpersonal and social processes. The teams then engage these targets through experimentation and/or intervention and examine subsequent behavior change. In this symposium, two members of the SOBC Research Network will provide examples of this mechanism-focused, experimental medicine approach to behavior change research. One project representing self-regulation and one project representing stress reactivity and resilience were selected; researchers will present initial findings from their projects and share information regarding measures of their relevant mechanisms. Next, a representative from the SOBC Research Network Resource and Coordinating Center will introduce the SOBC Measures Repository, a web-based resource featuring behavioral science measures that have been (or are in the process of being) validated based on the SOBC experimental medicine approach. The symposium will conclude by having an NIH representative review the implications of the SOBC approach and Measures Repository for basic and translational research and discuss how initial findings have the potential to influence prevention and treatment strategies.

Symposium 1A

UNDERSTANDING TREATMENT RESPONSE TO INTEGRATED BEHAVIOR THERAPY FOR COMORBID OBESITY AND DEPRESSION IN PRIMARY CARE

Jun Ma, MD, PhD

Background: Comorbid obesity and depression exacerbates morbidity and disability. Integrated therapy for patients with both disorders are lacking in primary care; variability in treatment response is unknown.

Methods: Obese depressed adults (n=409) from 8 primary care clinics were randomized to usual care or Integrated Coaching for Better Mood and Weight, which combines problem-solving therapy for depression and a patient-directed diabetes prevention program for weight loss, plus as-needed antidepressant medication management. We used polynomial regression to model individual treatment response trajectories with serial Patient Health Questionnaire (PHQ9) and weight data over 1 year. We then conducted disjoint cluster analysis on the intercept, linear and quadratic coefficients of individual trajectories for PHQ9 and weight separately, and compared clusters (ANOVA, χ^2) on baseline characteristics and intervention adherence.

Results: Improved PHQ9 and weight loss were related ($r=0.17$, $P=0.04$), with 3 clusters for each, but the 2 sets of clusters were not significantly correlated. **PHQ9** clusters differed in baseline symptoms and trends of improvement. **Cluster 1** (27% of participants) had milder baseline symptoms and steady improvement [intercept $\beta_0=5.80$ ($P<.001$), linear $\beta_1=-0.08$ ($P=0.003$), quadratic $\beta_2=0.001$ ($P=0.11$)], and **cluster 2** (47%) had moderate baseline symptoms and then improvement [$\beta_0=10.21$, $\beta_1=-0.26$, $\beta_2=0.004$ (all $P<0.001$)]. **Cluster 3** (15%) had the worst baseline symptoms that improved but then rebounded [$\beta_0=14.54$, $\beta_1=-0.56$, $\beta_2=0.01$ (all $P<0.001$)]; they also had the highest baseline anxiety and post-traumatic stress, most negative problem-solving orientation, worst disability and quality of life, most early intervention dropouts, poorest weight and physical activity self-tracking. **Weight change (%)** clusters ($\beta_0=0$ for all) differed in patterns of initial decline and later regain. **Cluster 1** [24%; $\beta_1=-0.05$ ($P=0.003$), $\beta_2=0.0003$ ($P=0.63$)] had steady but the least weight loss, and less self-tracking (v. cluster 2). Weight loss was moderate in **Cluster 2** [31%; $\beta_1=-0.36$, $\beta_2=0.006$ (both $P<0.001$)] and the most in **cluster 3** [12%; $\beta_1=-0.70$, $\beta_2=0.01$ (both $P<0.001$)], with modest regain in both.

Conclusions: These results have important implications for early identification of targeted interventions. This experimental medicine approach will lead to improved understanding of the mechanisms of varied treatment responses in order to optimize individualized treatment.

Symposium 1B

EVERYDAY STRESS RESPONSES AND HEALTH BEHAVIORS

Prof. Joshua M. Smyth, PhD

Our project applies the SOBC approach by examining the association of ecologically valid stress response components to sleep and physical activity. We use repeated measures from everyday life to examine within-person fluctuations in specific components of stress responses (reactivity, recovery, and pile-up/frequency) as potentially unique predictors of sleep and activity. Five independent data sets from diverse samples were used: 3 Ecological Momentary Assessment (EMA) and 2 Daily Diary (DD) studies. Participants (N range across studies: 117–2022, range of mean age: 41–56, range of % female: 51–74) completed momentary surveys 5/day for 2–14 days in EMA, or an evening survey in DD for 7–14 days, asking about stressors and indicators of stress response. Subsets of sleep variables (reported sleep quality, difficulty falling asleep, sleep duration) were collected daily across the 5 studies, and device-assessed physical activity data was collected in 2 EMA studies. Indicators of reactivity (initial rise in response to stressor), recovery (degree of return to baseline following stress response), and pileup (number of stress responses) were used as prospective predictors of sleep indicators (day level) and activity (over the upcoming 2hrs) in multilevel models. Higher within-person stress reactivity was prospectively associated with lower sleep quality; individuals reported poor sleep quality following days with higher than average levels of stress reactivity. Difficulty falling asleep, measured in only one study, was higher following days with higher than average stress reactivity. There were no systematic relationships between stress recovery and sleep. Stress response pile-up was associated with poorer sleep quality, more difficulty falling asleep, and reduced sleep duration. Stress reactivity and recovery did not predict device-assessed physical activity. Stress response pileup prospectively predicted lower activity counts. By applying the SOBC approach across multiple independent data sets we show that naturalistic stress responses are important predictors of enacting sleep and activity behaviors; additionally, that components of the stress response are uniquely related to specific aspects of health behaviors. Understanding such associations helps advance our understanding of the dynamics of stress responses, of health behavior enactment in everyday life, and can form the basis for interventions that are dynamically tailored to promote specific health behaviors.

Symposium 1C

THE SOBC MEASURES REPOSITORY: AN ONLINE SEARCHABLE HOME FOR DOWNLOADING MEASURES OF BEHAVIOR CHANGE MECHANISMS

Donald Edmondson, PhD, MPH

Supported by the National Institutes of Health (NIH) Common Fund, the Science of Behavior Change (SOBC) program seeks to improve the understanding of mechanisms underlying human behavior change by applying an experimental medicine approach to behavior change research. By using this common method, SOBC researchers aim to reveal how and why people make and sustain healthy behaviors, which will inform the development of more reliable, efficient, and effective behavioral interventions. This presentation will describe the experimental medicine approach, and introduce a new resource for behavior change researchers.

This August, SOBC launched an internet-based measures repository where researchers can learn about and download measures of key behavior change mechanisms. This repository on the SOBC website is a unique resource that offers a way to advance, and engage with, behavior science research tools that have been tested using the experimental medicine approach to identifying mechanisms of behavior change.

Research funded during stage one of SOBC (2009–14) identified three broad classes of intervention targets that are highly relevant to the mechanisms underlying behavior change: self-regulation; stress reactivity and stress resilience; and interpersonal and social processes. This aided the development of a reliable and valid way to measure engaged targets through experimental manipulation or interventions. This measurement focus has been the foundation for the current stage two phase of the SOBC Research Network (2015–present).

Initial findings from stage one have informed the population of the SOBC measures repository. An essential and unique feature of the repository is the documentation of a measure's status through the three steps of the SOBC experimental medicine approach: (1) Identify, (2) measure, and (3) influence. First, researchers identify a hypothesized mechanism that drives behavior change. Next, they develop valid measures of the target mechanism. Researchers then influence the target mechanism with experimental methods. Measures are ultimately validated or not validated based on whether a change in a measure relates to a change in behavior.

This presentation will walk attendees through the measures repository, and highlight its value for the field.

Symposium 2

8:00 AM-9:15 AM

UNPACKING SEDENTARY BEHAVIOR REDUCTION: INTERVENTION APPROACHES AND OUTCOMES IN POPULATIONS WITH CHRONIC CONDITIONS

Dori E. Rosenberg, PhD, MPH¹, Laura Ellingson, PhD², Dale S. Bond, PhD³, Lucas Carr, PhD⁴

¹Kaiser Permanente Washington Health Research Institute, Seattle, WA; ²Iowa State University, Ames, IA; ³The Miriam Hospital/Brown Alpert Medical School Weight Control and Diabetes Research Center, Providence, RI; ⁴University of Iowa, Iowa City, IA

There has been rapid development of interventions to reduce sedentary behaviors as the epidemiologic evidence has grown to suggest that sedentary time is associated with health detriments. Populations who are less likely to meet physical activity guidelines (e.g. older adults, people with obesity) could be particular candidates for interventions to reduce sedentary time as they may have difficulty engaging in moderate-to-vigorous physical activity. However, strategies for reducing sedentary behavior (defined as activities done while sitting or reclining at low energy expenditures) can focus on many different target behaviors. Approaches include targeting increases in bouts of standing time, breaks from sitting, and light intensity physical activity. Populations may vary in which of these approaches best fits their lifestyle. The presentations in this session will present results of experimental studies seeking to uncover the effectiveness and feasibility of different approaches to reducing sedentary time. Presentations will describe the strategies used to create the desired changes in sedentary behaviors and the behavioral outcomes of the interventions. The discussant, Dr. Lucas Carr, will provide a synthesis of the findings presented and make suggestions for future research on sedentary behavior reduction in populations with chronic conditions.

Symposium 2A

HOW DOES A SITTING REDUCTION INTERVENTION ALTER SEDENTARY, STANDING, AND ACTIVE TIME IN OLDER ADULTS WITH OBESITY?

Dr. Dori E. Rosenberg, PhD, MPH

Background: While studies suggest that reducing sedentary time among older adults is feasible, there is little data on which aspects and patterns of behavior change with sedentary time reduction. We aimed to examine how an intervention to reduce sedentary time alters various aspects of sedentary and physical activities. The study targeted older adults with obesity, a population at high risk for low physical activity and high sedentary time for whom alternative health-promoting strategies are needed.

Methods: We conducted a randomized controlled pilot trial (N = 60; mean age = 67, mean BMI = 36). Intervention participants (termed I-STAND; N = 29) received a Jawbone UP band to prompt breaks from sitting, feedback on sitting time from wearing an activPAL device, educational materials, and 6 brief health coaching sessions over 12 weeks. Control participants (N = 31) received healthy living information through a self-study program. Outcomes were assessed with the activPAL device worn for 7 days at baseline and at 12 weeks and included mean wake time spent: sitting, standing, engaging in prolonged bouts of sitting for 30 minutes or more, taking breaks from sitting, and stepping. We also examined average daily step counts. Linear regression models adjusted for baseline measures were conducted.

Results: I-STAND participants had decreases in sitting time (-70 mins/day), increases in standing time (+51 mins/day), and reductions in prolonged sitting bouts (-2.5/day) compared to controls (+7 mins/day sitting, -3 mins/day standing, +0.1 prolonged bouts; all p's < .01). There were no significant changes in breaks from sitting, stepping time, or steps.

Conclusions: Older adults with obesity are able to reduce their sitting time. Sitting time was primarily displaced with increases in standing time. Additionally, prolonged bouts of sitting were significantly reduced. However, sitting reduction did not impact sitting breaks and physical activity. Our approach can inform future interventions seeking to relate changes in sitting patterns with health outcomes.

Symposium 2B

USING FITNESS TRACKERS TO IMPROVE ACTIVE AND SEDENTARY BEHAVIORS AND SYMPTOMS IN PATIENTS WITH CHRONIC LOW BACK PAIN

Dr. Laura Ellingson, PhD

Background: Chronic low back pain (CLBP) is a debilitating condition experienced by more than 10% of the US population. Evidence demonstrates that increasing physical activity (PA) is one of the few efficacious treatments for CLBP. However, patients with CLBP have high sedentary time (ST) and encouraging PA is challenging. Wearable fitness trackers have shown promise for improving PA in patient populations, but their effectiveness in CP patients is largely unexplored.

Methods: Patients with CLBP (N=57; mean age: 43.5) were randomly assigned to receive a Fitbit Charge alone (FB; N=17) or in combination with motivational interviewing (FBMI; N=19) or a waitlist control condition (WLC; N=21) for three months. Patients receiving Fitbits were encouraged to utilize them as they saw fit to “move more and sit less”, and received monthly calls to address any issues with the trackers. Those receiving MI additionally had three sessions (1 in-person, 2 via phone) with a trained health coach to discuss motivation for change and self-selected behavioral goals. PA, ST, and symptoms were assessed at baseline and 3-months using the ActiGraph, activPAL, and validated questionnaires (SF-36, SF-MPQ, CLBP Minimal Dataset). Changes in all outcomes were examined using 3 (groups) x 2 (time points) repeated measures ANOVA and effect size calculations (Cohen’s d).

Results: Results showed a trend towards a group by time interaction for ST ($p=0.06$; $d=0.61$) and light PA ($p=0.07$; $d=0.60$). Participants in FB and FBMI groups showed small decreases in ST (16.5 mins/day) and increases in light PA (13.5 mins/day), while WLC participants had increases in ST (43.5 mins/day) and decreases in light PA (40.7 mins/day). Time spent in higher intensity PA remained stable over the intervention ($p>0.05$). Across groups, pain symptoms significantly improved over the trial (p)

Conclusions: Wearable trackers show promise for positively influencing PA and ST patterns in patients with chronic pain. Decreasing ST and increasing light PA improved pain symptoms in the absence of changes in higher intensity PA and could be a viable target for future interventions in this population.

Symposium 2C

A JITAI APPROACH TO BREAKING UP PROLONGED SEDENTARY BEHAVIOR WITH LIGHT-INTENSITY WALKING IN ADULTS TREATED FOR OBESITY AND CARDIOVASCULAR DISEASE

Dale S. Bond, PhD

BACKGROUND: Individuals with obesity and/or cardiovascular disease perform high levels of sedentary behavior (SB), which hinders total physical activity (PA) participation. Interrupting and replacing SB with PA is challenging. As SB is highly habitual, involves minimal awareness, occurs frequently, and is more reinforcing than PA, the vigilance, motivation, and effort necessary to monitor, interrupt, and replace SB can exceed available energy, time and resources. We developed and pilot-tested a mobile Just-in-Time Adaptive Intervention (JITAI) that automatically monitors SB/PA and intervenes only when it is likely to have the greatest health impact to avoid participant fatigue and frustration with self-monitoring or receiving interventions at irrelevant times or locations.

METHODS: We pilot-tested our JITAI in 2 studies. In Study 1, adults with obesity ($n=30$) were randomized to 3 conditions each lasting 7 d involving smartphone prompts for walking breaks of (1) 3-min after 30 SB min; (2) 6-min after 60 SB min; and (3) 12-min after 120 SB min. Study 2 randomized cardiac rehabilitation (CR) patients ($n=16$) to CR+JITAI (smartphone prompts for walking breaks of 6-min after 60 SB min and increasing bouted moderate walking to 30 min/d) or CR only. Participants’ SB and PA were measured via the SenseWear Armband monitor for 7 d at baseline and after each of the 3 conditions (Study 1) or 12-week post-intervention (Study 2). Within- and between-subject changes in % time spent in SB and PA were compared.

RESULTS: In Study 1, all 3 conditions decreased % time in SB and increased % LPA relative to baseline ($ps<.005$). The 3-min condition was superior to the 12-min condition for decreasing SB and increasing LPA ($ps<.05$). In Study 2, CR+JITAI produced improvements in % SB time (-2.3% vs. +6.5%) and bouted moderate-to-vigorous PA (MVPA: +13.3 vs. 4.1 min/d) that were clinically (but not statistically) significant and of a medium effect size (Cohen’s $d=.54$ and $.69$).

CONCLUSIONS: For individuals with chronic conditions at high risk for excessive SB, this JITAI offers a promising strategy to 1) facilitate adherence to SB change via individual tailoring and minimizing burden, and 2) effectively break up prolonged SB with brief light-intensity PA.

Symposium 3

8:00 AM-9:15 AM

INCREASING OUR IMPACT: HOW 3 SBM MEMBERS DEVELOPED AND DISSEMINATED HIGH IMPACT HEALTH POLICY BRIEFS

Joanna Buscemi, Ph.D.¹, Akilah Dulin-Keita, PhD², Tracy Trevorrow, Ph.D.³, Alicia Kaye Matthews, Illinois⁴, Marian L. Fitzgibbon, IL⁴

¹DePaul University, Chicago, IL; ²Brown University School of Public Health, Providence, RI; ³Chaminade University, Honolulu, HI; ⁴University of Illinois at Chicago, Chicago, IL

The Society of Behavioral Medicine’s (SBM’s) Health Policy Committee (HPC) provides structured and guided opportunities for SBM members and SBM special interest groups (SIGs) to increase the impact of their work through the development and dissemination of health policy briefs. The purpose of this symposium is to 1) present four of the health policy briefs that have been developed in the past year and 2) provide members with “lessons learned” and tips for writing and disseminating the briefs. First, Dr. Akilah Dulin-Keita will discuss two health policy brief related to diet and disease prevention. The first highlights the importance of sugary drink taxes and the second focuses on increasing funding for fruit and vegetable production in the reauthorization of the Farm Bill. Dr. Trevorrow will then describe a health policy brief about the importance of later school start times on student health and learning. Next, Dr. Matthews will describe a brief focused on supporting policies to reduce smoking disparities for sexual and gender minorities. The discussant and Chair of the Health Policy Committee, Dr. Joanna Buscemi, will close with remarks on key strategies for developing authorship teams, engaging organizational partners, and increasing the reach of briefs through broad dissemination. Dr. Marian Fitzgibbon, Chair of the Health Policy Council, will serve as Chair for the symposium.

Symposium 3A

PREVENTING CHRONIC DISEASE THROUGH POLICY: SUPPORTING SUGARY DRINK TAXES AND FRUIT/VEGETABLE PRODUCTION IN THE FARM BILL

Dr. Akilah Dulin-Keita, PhD

Objective: Present SBM's policy briefs advocating for improved dietary quality (i.e., sugar sweetened beverage excise tax and increasing fruit and vegetable production and intake in The Farm Bill reauthorization) and provide an overview of "lessons" from writing these briefs.

Background: In the United States (U.S.), poor dietary quality is a significant public health problem. Despite a recent decline, sugar intake still exceeds federal recommendations. Sugar sweetened beverages (SSBs) are the largest source of added sugars and account for almost half of added sugars consumed. Consumption of SSBs increases risks for chronic diseases such as obesity, type 2 diabetes, coronary heart disease, and fatty liver disease. Inadequate fruit and vegetable (FV) intake is also of great concern. Low FV intake is associated with cardiovascular disease, stroke, and some forms of cancer; and with all-cause mortality. In 2013, approximately 12% to 17% of all deaths in 2013 were attributable to inadequate FV intake. However, analysis of the U.S. Department of Agriculture's databases indicate that the availability of FV in the food supply are at half or less than half of what is needed to meet federal dietary recommendations. In response to the mounting research evidence that suggests a causal link between poor diet quality and chronic diseases, policy makers in some countries and U.S. states have implemented taxes on SSBs and some FV programs. *While the aforementioned policies and programs are promising, we must create and support national policies that prioritize SSB taxes and increase FV production and intake.*

Approach: We will present an overview of the sugar sweetened beverage policy brief and The Farm Bill policy brief. We will describe how we worked with the Health Policy Committee to identify authors who are SBM members and non-members. The authorship teams used an iterative process to arrive at the final drafts of the policy briefs. The presentation will review the process of conceptualizing ideas, arriving at suggestions for tax implementation, and countering beverage industry arguments with available evidence. With regard to The Farm Bill, we will also describe summarizing complex ideas in a meaningful way and how we introduced potentially controversial ideas tactfully. We will also describe the process for engaging stakeholders (both internal and external to SBM) and will discuss how we leveraged existing evidence to arrive at our policy recommendations.

CORRESPONDING AUTHORS: Daniel Taber, PhD, University of Washington; dtaber47@uw.edu; Joanna Buscemi, PhD, DePaul University; JBUSCEM2@depaul.edu; Lisa Quintiliani, PhD, Boston University; Lisa.Quintiliani@bmc.org

Symposium 3B

STARTING SECONDARY SCHOOLS AT 8:30 A.M. OR LATER PROMOTES STUDENT HEALTH AND LEARNING

Dr. Tracy Trevorrow, Ph.D.

Objective: To present SBM's policy statement advocating for later start times for secondary schools to promote health and learning and share the lessons learned in its development.

Background: As a consequence of puberty, teenage students are biologically driven to have later sleep and wake-up times than younger children. Most secondary schools in the US start too early to accommodate for this shift in sleep patterns resulting in inadequate sleep, psychological and physical health problems, and reduce students' ability to learn. Barriers to later school start times include conflicts with after school programs, staff and teacher schedules, and school busing costs. Schools that have delayed start times have not reported significant problems with their new schedules and have shown improvements in students' sleep, daytime alertness, academic achievement, school attendance, and driving safety. Educators should adopt a policy that ensures secondary schools start at 8:30 a.m. or later. This standard has been advocated by numerous professional organizations. A systematic and nationwide delay in start times for secondary schools can be accomplished by lobbying members of school boards, state departments and legislators, and providing healthy sleep education campaigns to educators, school counselors, students and their families.

Approach: We will provide an overview of the significance of school start times on students' health and learning and how our school start time position statement was developed. We will share lessons learned regarding writing a brief lobbying document as well as a more detailed statement for journal publication. Frequent consultations with SBM leaders were required to appreciate the structure and voice of these documents and the many steps of review. We found it challenging to adopt an advocacy voice which contrasts with our typical approach to scholarly writing. We sought advice from multiple sources and integrated feedback over multiple iterations. As scientists and clinicians we were unaccustomed to developing specific strategies which would result in policy changes. Doing this may be our greatest contribution to this issue as specific action plans appear lacking in other position statements addressing school start times.

Symposium 3C

REDUCING SMOKING DISPARITIES FOR SEXUAL AND GENDER MINORITIES

Dr. Alicia Kaye. Matthews, Illinois

Background: Smoking remains the leading preventable cause of death and disease in the United States, and each year more than 480,000 people die prematurely from smoking or secondhand smoke exposure. Sexual and gender minorities are at elevated risk for tobacco-related death and disease due to disproportionately high rates of tobacco use. The reasons for this difference likely stem from discrimination, stigma, targeted marketing by the industry, and normalization of tobacco in community spaces and organizations. Despite these disparities, gender and sexual minorities are not systematically included in tobacco prevention and control efforts. Little is known about if evidence-based tobacco control interventions improve or exacerbate disparities for sexual and gender minority populations. National recognition of the problem exists and in the Fall of 2016, the National Institutes of Health (NIH) designated the LGBT community as a health disparity population. These combined factors underscore the importance of advocating for the inclusion of sexual and gender minority persons in tobacco prevention and control efforts now. Specifically, we must support the inclusion of gender and sexual minorities (e.g., people identifying as lesbian, gay, bisexual, and transgender [LGBT]) in all local, state, and national tobacco prevention and control activities including surveillance of tobacco use and cessation activities, targeted outreach and awareness campaigns, increasing access to culturally appropriate tobacco use dependence treatments, and restricting disproportionate marketing to LGBT communities by the tobacco industry, especially for mentholated tobacco products.

Approach: We will provide an overview of smoking related disparities based on sexual orientation and gender identity and the implications for smoking cessation research and policy following the NIH designation of LGBT as a health disparity population. Next we will provide an overview of the LGBT smoking disparities policy brief and key recommendations. We will discuss the process of engaging stakeholders from across multiple stakeholder groups including smoking cessation researchers, national advocacy groups, grass-roots organizations, health care providers and professional organizations, and policy groups; the process of conceptualizing the multi-factorial approaches required to address the problem; and the use of traditional and emerging outlets for dissemination processes.

Symposium 4

8:00 AM-9:15 AM

TRANSLATING EVIDENCE-BASED BEHAVIOR CHANGE INTERVENTIONS INTO MOBILE APPLICATIONS

Ellen Beckjord, PhD, MPH¹, Amber Blackwood, MPH, CHES², Elaine Fath, MA³, Sherry Pagoto, PhD⁴

¹UPMC, Pittsburgh, PA; ²UPMC Health Plan, Pittsburgh, PA; ³Schell Games, Pittsburgh, PA; ⁴University of Connecticut, Storrs, CT

A behavioral scientist, a game designer, and a health coach walk into a bar... or, in our case, into a white board-lined conference room, joined by experience designers, health educators, and systems analysts, and after 19 months of focused work, translated three workbook-based behavior change interventions into mobile applications that function as just-in-time adaptive interventions (JITAs). In this symposium, we will describe the process we used for creating stress management, weight management, and smoking cessation JITAs, including what worked well and what challenges we encountered. Our first presentation will detail the codesign methods used to foster creative thinking within the group, to level the playing field for professionals from different disciplines, and to enable broad participation in decision making while respecting the subject matter expertise of each participant. Next, we will discuss how health behavior theory was used to guide the selection of functional capabilities for the delivery of intervention content. Our Discussant will consider this process in the context of the broader field of digital health; offer her perspective on what makes for the successful translation of evidence-based behavior change interventions into digital assets; and discuss how behavioral medicine professionals can leverage specific processes and collaborations in the service of scaling their interventions via digital health.

Symposium 4A

HOW BEHAVIORAL THEORY GOT ITS GROOVE BACK: GAME DESIGN MEETS BEHAVIORAL CONSTRUCTS IN THE CODESIGN OF A MOBILE BEHAVIOR CHANGE APP

Amber Blackwood, MPH, CHES

Is there a place for the traditional behavioral change theories that we know and love in a new age of sexy and innovative digital health technology? We think the answer is yes. Our team of health coaches, public health practitioners, behavioral scientists, and game designers developed an interactive digital habitat where a user can work their way through a journey of lifestyle transformation, picking up lessons and tools along the way. Each feature they encounter is laden with core constructs from health behavior theories disguised as just another engaging element of a transformational game. We will reflect on how both behavioral theory and the iterative process used to generate content influenced the development of content delivery vehicles within the app. We will also review how we used a diverse blend of chatbots, tailored feedback, wizards, and just-in-time-adaptive-interventions (JITAI) to model behavior, prompt reflection, set goals, and build self-efficacy. We will cover the insights gleaned from ongoing user testing and how they continuously informed edits to past content as well as the direction of future content generation. Our development of three engaging, evidence-based mobile behavior change apps illustrates the value of collaborative industry partnerships in harnessing related expertise in a creative and complimentary way. When considering ways to extend the reach of current behavioral change programs with digital technology, industry partnerships should be leveraged to optimize engagement.

Symposium 4B

THE CODESIGNER'S TOYBOX: USING A BROAD RANGE OF TOOLS FROM MULTIPLE DISCIPLINES TO HELP DIVERSE TEAMS COLLABORATE CREATIVELY

Elaine Fath, MA

If you're involved with app development, you're working with a diverse set of experts with very different schemas; ways of talking about problems; with their own way of creating work, generating ideas, and making decisions. It can sometimes feel difficult or impossible to keep everyone on the same page and excited about what is being created. The concept of iterative, collaborative design across disciplines exists in Education, User Experience Design, Game Design, Service Design, Codesign, and numerous other disciplines. And yet, because the vocabulary for describing this practice can vary so widely from field to field, it can be hard to know the breadth of tools and methods at a multidisciplinary team's disposal when preparing to codesign. This presentation will describe codesign methods used for creating a series of just-in-time adaptive interventions for health behavior change. We used a blend of methods from different disciplines and have emerged from the process with a list of "do's" and "don'ts" for teams attempting to foster creative co-development and shared participation of design in multidisciplinary teams. We will discuss suggestions for getting everyone generating and participating in active meetings, developing a shared language between teams, avoiding "design by committee," developing a clear shared understanding of a design, as well as common pitfalls that emerge when designing with a multidisciplinary group and how to mitigate. Participants will walk away with a sense of what to try and what to avoid, along with a set of references and resources from disciplines as broad as Education and Game Design in order to delve deeper into how to prepare for their own active codesign meetings that respect the expertise of each participant while allowing for broad participation in the decision-making and design process.

Symposium 5

8:00 AM-9:15 AM

FEASIBILITY OF EHEALTH AND MHEALTH APPROACHES FOR CANCER CARE AND SURVIVORSHIP

Lisa M. Quintiliani, PhD¹, Jennifer Huberty, PhD², Cynthia C. Forbes, PhD³, Elizabeth J. Lyons, PhD, MPH⁴

¹Boston University, Boston, MA; ²Arizona State University, Phoenix, AZ; ³Dalhousie University, Halifax, NS, Canada; ⁴The University of Texas Medical Branch, Galveston, TX

Advances in detection and treatment of cancer have led to an increasingly large cohort of survivors. Modification of health behaviors and addressing symptom control and other psychosocial supportive care needs has the potential to increase quality of life, prevent future cancer recurrence and increase long-term health among cancer survivors. However, translating these recommendations into population-wide, inexpensive, sustainable programs for cancer survivors has, to date, proven largely unrealized. There is great promise of mobile health (mHealth) and electronic health (eHealth) tools that are mobile, simple, and embedded into daily life routines. This symposium presents innovative research of three separate studies in early stages that are focused on examining the feasibility of approaches for health promotion among multiple cohorts of cancer survivors using mHealth and eHealth strategies. We will present baseline data and preliminary results; each will describe the mHealth or eHealth strategy used, the rationale for selecting each cancer survivor population targeted, study design, and preliminary evidence of feasibility. Investigators will also detail how they would refine their studies in the future to take advantage of new or emerging technologies. Dr. Lisa Quintiliani will present qualitative data collected using a modified Delphi approach from a cohort of breast cancer survivors from underserved populations describing which features (based on the behavior change technique taxonomy) of a mHealth app would be important to them. Dr. Jennifer Huberty will describe the results of two feasibility trials of home-based on-line yoga for patients with myeloproliferative neoplasms. Dr. Cynthia Forbes will present a review of feasibility, acceptability, and efficacy of online supportive care interventions targeting prostate cancer survivors. We will close with a discussion, Dr. Elizabeth Lyons who will comment on the commonalities and differences among the studies with implications for use of mHealth and eHealth strategies in future studies among cancer survivors.

Symposium 5A

DEVELOPMENT OF AN MHEALTH APP FOR WEIGHT MANAGEMENT AMONG BREAST CANCER SURVIVORS FROM UNDERSERVED POPULATIONS

Dr. Lisa M. Quintiliani, PhD

Background: Advances in detection and treatment of breast cancer has led to a large cohort of cancer survivors who may have an increased awareness of health promotion; mobile health (mHealth) technologies have the potential to deliver effective behavioral interventions in a format suited to everyday life. Ownership of smartphones is now 77%, with similar ownership rates between gender and racial/ethnic groups. However, the features that should be included in mHealth interventions for cancer survivors have not been well specified, particularly among those from low income or racial/ethnic minority groups. Therefore, the objective of this study is to identify evidenced-based features that breast cancer survivors from underserved populations would find important to include in a mHealth application (app) to improve weight management.

Methods: We examined the systematic review by Hoedjes and colleagues and identified 19 techniques from the Behavior Change Technique (BCT) Taxonomy version 1 that were present 2 or more times in interventions shown to be effective in weight-related trials among cancer survivors. We then developed a presentation that depicted each BCT along with accompanying pictures depicting how each could be incorporated into a mHealth app. Next, female breast cancer survivors were recruited from a large safety net hospital to participate in a focus group. During the group, participants were shown the BCT presentation and asked to rate how important each feature would be from 1 (not at all important) to 9 (very important). Using a modified Delphi method, each participant was then asked to re-rate the features after seeing their own rating compared to the group rating. Participants also answered open-ended questions about their perceptions of mHealth apps.

Results: Seven women participated in 1 of 2 focus groups. Mean age was 60 years; the majority received public health insurance and were African American or Black (85% for both). All were overweight or obese. Scores ranged from 5–9 for all features. Most did not change their ratings after being shown the group ratings. Lower rated features included the need for specifying credible sources; higher rated features included demonstration on how to perform behavior (e.g., stretching exercises). Participants valued apps that are easy to navigate, tailored to their habits, and convenient to use on their schedule.

Conclusion: Breast cancer survivors from underserved populations were able to identify important features to include in a mHealth app and to elaborate on preferred app design characteristics. Future research will involve additional focus groups and the development of a mHealth app for usability testing among the same population, ultimately resulting in a mHealth app ready for efficacy testing in a larger trial.

Symposium 5B

FEASIBILITY OF ONLINE YOGA FOR MYELOPROLIFERATIVE NEOPLASM PATIENTS: COMBINED DATA FROM MULTIPLE STUDIES

Jennifer Huberty, PhD

Introduction: Myeloproliferative neoplasms (MPNs) are a hematological cancer with a chronic symptom burden not entirely resolved with current medical therapy. Fatigue is the most common contributor to a reduced quality of life (QoL) experienced by up to 84% of MPN patients. Yoga successfully improves fatigue and QoL in other cancer patients. Here we present the combined feasibility data for two home-based online yoga studies in MPN patients.

Methods: An online yoga feasibility study was completed in 2016 and a pilot study in 2017. The methods described herein were the same for both studies. MPN patients were recruited nationally via internet-based strategies. Participants enrolled in a 12-week (60 min/wk) online yoga intervention and completed self-report questionnaires assessing symptom burden at baseline (wk 0), mid-point (wk 7), post-intervention (wk 12), and follow-up (wk 16). Satisfaction was measured post-intervention. Weekly participation was tracked objectively using an online web analytics software. Feasibility was defined as: (a) *acceptability*: >70% satisfied with online yoga and >70% intent to continue participating in yoga, (b) *demand*: >70% completed 42 min/wk of yoga (70% of prescribed minutes), and (c) *practicality*: >70% completed questionnaires. Pilot study participants received a blood draw at baseline and post-intervention from a certified phlebotomist at a Quest Diagnostics Patient Center. Feasibility (i.e., acceptability) of the blood draw was defined as ≥70% completion rate at both time points.

Results: Across both studies, 504 MPN patients completed eligibility, 89 completed an informed consent, 24 dropped out, and 65 completed the intervention. *Acceptability*: A total of 74% participants were satisfied/very satisfied and 53% were likely/very likely to continue participating in online yoga. *Demand*: Yoga participation averaged ~42 min/week across the 12-wk study, with 20% (n=13/65) averaging ≥60 min/wk (≥100% prescribed minutes) and 43% (n=29/65) averaging ≥42 min/wk (70% of prescribed minutes). *Practicality*: A total of 100% of baseline, 86% of mid-point, 78% of post-intervention, and 72% of follow-up questionnaires were completed. In the pilot study, ~93% of blood draws were completed at baseline and ~71% at post-intervention.

Conclusion: Both online yoga and remote blood draws are feasible in MPN patients. Future RCTs are needed to examine the efficacy of online yoga and to determine the effects that online yoga has on blood biomarkers.

Symposium 5C

A SYSTEMATIC REVIEW OF FEASIBILITY, ACCEPTABILITY, AND EFFICACY OF ONLINE SUPPORTIVE CARE INTERVENTIONS FOR PROSTATE CANCER

Dr. Cynthia C. Forbes, PhD

Background: A large proportion of men with prostate cancer have functional and psychosocial supportive care needs; many of which are going unmet. Men appear to approve of supportive care interventions but are reluctant to take part in face-to-face, one-on-one, or group counselling sessions. It has been suggested that utilizing online delivery may help circumvent this barrier. This review aims to examine the feasibility, acceptability, and efficacy of online supportive care interventions targeting prostate cancer survivors (PCS).

Methods: Studies were primarily identified through a structured search of the following databases: PubMed, Embase and PsycINFO, in addition to forward and backward citation searches. Studies were eligible for inclusion if they: 1) examined feasibility, acceptability, or efficacy of an online intervention designed to improve supportive care outcomes for PCS as a major part of the study; 2) presented outcome data collected from PCS separately (if mixed cancer groups); and, 3) evaluated efficacy outcomes using a randomized trial design or feasibility/acceptability using a single-arm or randomized trial design. Two authors reviewed abstracts and extracted data; four authors performed methodological reviews.

Results: 16 studies met inclusion criteria. Overall, 2441 men (average age 64 years) were included in this review. Seven studies were classified as randomized controlled trials (RCTs); though, three of these were small pilot RCTs designed to test feasibility, acceptability, and preliminary efficacy of the intervention. Studies reported on the following outcomes: feasibility and acceptability of an online intervention (e.g. patient support, online medical record or follow-ups, or decision aids); reducing decisional conflict or distress; improving cancer-related distress and health-related quality of life; and satisfaction with cancer care.

Conclusion: There appears to be good preliminary evidence for online supportive care among PCS, but not much high level evidence yet. Overall, the sample sizes are relatively small and not representative. Further, inadequate acceptability measures in most studies made it difficult to determine actual PCS acceptability and satisfaction, and lack of a control group precluded strong conclusions regarding efficacy. Translation also appears minimal, with few interventions made publically available post evaluation. Larger trials with appropriate control groups and greater emphasis on translation of effective interventions is recommended.

PROCESSES, OUTCOMES, AND PRODUCTS TO MAKE DESIGNING FOR DISSEMINATION POP!

Amy G. Huebschmann, MD, MS¹, Phoutdavone Phimphasone-Brady, PhD², Bethany M. Kwan, PhD, MSPH¹, Jodi Summers. Holtrop, PhD¹, Natalia Loskutova, MD, PhD³, Borsika Rabin, M.P.H., Ph.D., Pharm. D.⁴

¹University of Colorado School of Medicine, Aurora, CO; ²University of Colorado, Anschutz Medical Campus, Aurora, CO; ³American Academy of Family Physicians, Kansas City, MO; ⁴University of California San Diego, La Jolla, CA

Experts estimate it takes an average of 17 years for only 14% of all evidence-based studies to be translated into clinical practice. To expand the reach of behavioral medicine, it is critical for researchers to begin with the end-goal of dissemination in mind. For these reasons, dissemination and implementation (D&I) researchers have begun developing frameworks to measure the different facets required to Design for Dissemination (D4D). These D4D facets may be organized conceptually as Processes, Outcomes, and Products (POP). D4D processes include engaging a range of relevant stakeholders from beginning to end of a project and identifying relevant models and communications channels for dissemination. D4D outcomes include assessments of readiness for dissemination such as pragmatic outcome measures and data on impact and cost that may convey return on investment information to future adopters of the program, as well as measures of actual dissemination to other systems and settings. D4D products include dissemination toolkits and dissemination strategies. This symposium will highlight the different roles of D4D processes, outcomes, and products across studies that represent a range of D4D stages—from early formative stakeholder engagement work for cultural tailoring to the lessons learned from a large-scale dissemination. The first presenter will compare and contrast the D4D Processes of stakeholder engagement with standard community-based participatory research approaches in her work to culturally adapt an evidence-based weight loss program for a population of Latino women with binge eating disorder. The second presenter will present D4D POP examples from an observational study of primary care practices utilizing care management, including a D4D Product: a guide on how to successfully integrate care managers into practices. The third presenter will present D4D POP examples from a study developing mobile health applications for patients and practices use to identify resources tailored to patients, including a D4D product of specific messaging that resonates with patients and clinical providers. The fourth presenter will present D4D POP examples from a large-scale dissemination program that distributed dementia toolkits for family practice clinicians across the United States. Our discussant will identify themes across studies and elaborate on the future potential and challenges of the D4D field.

Symposium 6A

MAKE IT COUNT TWICE: STAKEHOLDER ENGAGEMENT TO INFORM CULTURAL ADAPTATIONS AND IDENTIFY IMPLEMENTATION STRATEGIES

Dr. Phoutdavone Pimphasone-Brady, PhD

Background: Despite national efforts to disseminate effective weight management interventions to reduce the high prevalence of obesity, such interventions are not broadly implemented and disseminated among Latina women with binge eating disorder (BED), a subgroup of Latinas who are less likely to seek treatment for BED. Innovative strategies within the community are needed in order to engage this vulnerable subgroup. The objectives of this study were to interview Latinas with BED (i.e., key stakeholders), in order to learn how to culturally adapt an evidence-based behavioral weight loss (BWL) program and to determine successful strategies to implement this program in the future with community health advisors.

Methods: To effectively reach Latinas with BED, several strategies were used, including building long-term relationships with two community organizations that serve Latino families. Participants who met inclusion criteria were invited to focus groups and interviews to suggest how to culturally adapt an evidence-based BWL program. Qualitative analysis by the constant comparative method identified surface and deep level themes.

Results: Our community relational strategies yielded interviews with 20 Latinas with BED (*Age* = 30 ± 9.87 years, *Body Mass Index* = 34.40 ± 6.64 Kg/m², *Binge eating episodes/month* = 4 ± 4.92 [data shown as mean ± SD]) who provided input on the program's acceptability and sustainability. Surface level themes to improve program acceptability were: reduce overly repetitive lesson content, deliver health information with culturally relevant examples, and organize self-monitoring forms to improve ease of use. Deep level themes to address program sustainability were: 1) present shared cross-cultural health-related values, 2) discuss Latina health beliefs and expectations, and 3) emphasize the influence of individual's contextual factors that influence treatment engagement and success. Also, eight of the twenty participants recruited (40%) were previously trained as community health advisors and recommended avenues for future program dissemination (e.g., community health clinics).

Conclusion: Our findings illustrate the benefit of developing ongoing relationships with community organizations, in order to engage with key stakeholders who can improve interventions' acceptability and sustainability for culturally distinct groups. When designing for dissemination, stakeholder engagement from project beginning to end is critically important.

Symposium 6B

USER-CENTERED DESIGN OF A DIGITAL BEHAVIORAL HEALTH RESOURCE MATCHING APPLICATION

Dr. Bethany M. Kwan, PhD, MSPH

Background: Many patients with behavioral health needs benefit from community resources outside of the clinic environment. A digital application ("app") could help patients and their care teams identify appropriate, accessible behavioral health resources in their community. To ensure the app has the potential for wide-scale dissemination and reach, it must first be adopted by end-users. Developing with end-users in mind improves adoption rates. Potential end-users include patients with behavioral health needs, family members, care team members including patient navigators, and resource representatives. We used a user-centered design (UCD) process to identify app features end-users would endorse as valuable, engaging, and likely to be disseminated.

Methods: A phased approach to UCD included: a) initial engagement of patients with behavioral health needs and clinicians to identify the scope of resource needs, b) wireframe and iterative prototype development, and c) prototype demonstration and interviews with 22 representative end-users (patients, clinicians, social workers). Through participation in the National Institutes of Health Innovation Corps (iCorps) program, we formulated a business model that specified value propositions, dissemination channels, customer segments, revenue streams, and cost structures.

Results: UCD informed design and development of a functional prototype that end users endorsed as important, innovative, and useful. A social worker noted the app was "wildly helpful, wildly appropriate, and needed." The value proposition for patients was summarized as, "This app helps find the right health and wellness resources for you – faster than a web search!" The value proposition for clinicians was, "This app helps empower your patients to change behavior, meet social needs, saving time for limited care management resources to work with high-need patients." For resources, the value proposition was, "This tool finds qualified and motivated customers, resulting in more revenue and visibility for your organization." Dissemination channels identified include direct marketing to health systems, payers, and resources.

Conclusion: End-user engagement and iterative development methods are key steps in the UCD process. Value propositions and business models are key products of digital health tools designed for dissemination. Future work includes testing the app for usability, effectiveness, and likelihood of dissemination.

Symposium 6C

CARE MANAGEMENT IMPLEMENTATION: SETTING IT UP MATTERS IN HOW IT WORKS

Dr. Jodi Summers, Holtrop, PhD

Background: Due to the increasing prevalence of chronic disease, care management of patients with these conditions is becoming increasingly common in primary care practice. Care management is a patient-centered approach to “assist patients and their support systems in managing medical conditions more effectively,” and includes patient education, goal setting and self-management support. The objective of this study was to examine models of care management delivery and identify differential features to successful implementation.

Methods: Descriptive study using multiple methods including social network analysis (SNA; on data from written questionnaires to all practice members) and qualitative comparative analysis (QCA; on data from practice member interviews and shadowing of care managers). Participants included 24 primary care practices in Michigan (16) and Colorado (8).

Results: Three structures for care management delivery were identified based on the care manager work location and employer: embedded, co-located and off-site. SNA revealed that embedded care managers were both more likely to be in the core of communication within the practice regarding chronic disease management than off-site care managers (42% v. 18% v. 0%; $p=.01$) and have higher in-degree centrality (Median 19 v. 10 v. 0; $p=.002$). In-degree centrality is a value describing the amount to which information flows into one individual. Embedded and some co-located care managers had rich network connections with practice members of all types. A logic model driven two-level QCA revealed that a rich, accurate, shared mental model of care management and buy-in to team-based care should produce high quality well implemented care management (Y) [Coverage = 0.944; Consistency = 0.921]. These factors should in turn result from role changes, physician buy-in, good coordination, and logistical efficiency [Coverage = 0.901; Consistency = 0.801]. Qualitative examination indicate that these factors are more likely to occur in embedded and co-located care management.

Conclusions: How a care management program is structured can have significant implications regarding how much and how well it is used. Based on these findings, a care management implementation guide was developed and disseminated to primary care practices to assist in the early decision-making stages regarding setting up a care management program.

Symposium 6D

DESIGNING FOR DISSEMINATION TO IMPROVE DEMENTIA MANAGEMENT: STARTING EARLY AND THINKING BIG

Natalia Loskutova, MD, PhD

Background: Despite substantial evidence about the appropriate management of dementia, only 35% of recommended care processes for patients with dementia are delivered in primary care. Several reasons for this gap include: 1. dementia management research interventions have not always addressed the needs of end users – clinicians and patients; 2. funding opportunities for evidence-based dementia care implementation research are limited; 3. deliberate dissemination efforts to relevant end users by researchers are lacking. Addressing these concerns, the American Association of Family Practice (AAFP) National Research Network conducted a mixed methods implementation and dissemination study to develop and broadly disseminate a dementia care toolkit for practices (AAFP Cognitive Care Kit).

Methods: We used a stakeholder engagement process with AAFP members to develop the toolkit content and format (web-based). We developed an intentionally broad dissemination plan at the time of the research proposal development that included: 1. traditional academic dissemination through peer-reviewed publications and conferences; 2. clinical review journal articles targeting non-academic primary care providers; 3. marketing and communications strategies via AAFP communications channels; 4. education sessions during the AAFP annual member conference. The AAFP utilized web analytics and user feedback data to evaluate the reach, of the dissemination plan and to assess end-user engagement with the toolkit.

Findings: To date, the Cognitive Care Kit has been delivered through AAFP marketing strategies and the AAFP member conference. Of national AAFP users who have received the AAFP marketing strategies to date, 9% ($n = 2,399$) have accessed the Cognitive Care Kit, with over half of those who accessed it visiting sections on cognitive evaluation, prevention and/or late-stage dementia management. Also, $n = 1,695$ of the AAFP clinicians at the 2017 AAFP conference attended planned education sessions. The overall user feedback has been positive “The Care Kit seems to be just about right”.

Implications for Designing for Dissemination: Research projects that address important clinical gaps need to deliberately consider development of dissemination plans early in the project development, and should plan broad dissemination opportunities to reach end-users via their preferred communication channels. Additionally, requesting user feedback during the dissemination process may further optimize the dissemination plans.

Symposium 7

8:00 AM-9:15 AM

ASSESSING THE BEHAVIORAL HEALTH NEEDS OF TRANSGENDER AND GENDER NON-CONFORMING INDIVIDUALS

Nadav Antebi-Gruszka, PhD¹, Demetria Cain, MPH, CPH², Michael E. Newcomb, Ph.D.³, Kristi E. Gamarel, PhD⁴

¹City College of New York, New York, NY; ²Hunter College at City University of New York/ CHEST, New York, NY; ³Northwestern University, Chicago, IL; ⁴University of Michigan, Ann Arbor, MI

Transgender and gender nonconforming (TGNC) individuals are disproportionately affected by significant health disparities compared to cisgender (non-transgender) individuals, including higher HIV and STI prevalence rates, higher rates of depression, more alcohol and drug use, and more reported suicide attempts. TGNC are also more likely to be discriminated against when trying to access health services. Experiences of discrimination, along with related social and economic stressors contribute to these health disparities. Yet, research into these factors is limited, culturally appropriate interventions are underdeveloped, and much remains to be done to extend the reach of behavioral health research toward TGNC individuals. This symposium seeks to provide an overview of the unique needs of this vulnerable population by examining several health outcomes in various gender identity subgroups. The first talk will present findings from a U.S. national cohort of transgender men (individuals assigned female at birth whose gender identity or expression is male) who have sex with men, about the prevalence of HIV and bacterial/viral STI testing in this population, and factors associated with this prevalence. The second talk will present on the transgender women (individuals assigned male at birth whose gender identity or expression is female) and the association between transgender stigma, depression, and negative consequences from alcohol and drug use. The third talk compares TGNC youth assigned female at birth with TGNC youth assigned male at birth on depression and suicidality, violence and victimization, and alcohol and drug use. Together, these presentations highlight the importance of examining health disparities among gender minorities and the need for transgender-specific or multilevel interventions. Discussion will be led by a researcher in the field of public health, substance use, and gender minorities, and will focus on the overall implications of this research, goals for future investigation, and intervention development.

Symposium 7A

FACTORS ASSOCIATED WITH HIV AND STI TESTING UPTAKE IN A U.S. NATIONWIDE SAMPLE OF TRANSGENDER MEN WHO HAVE SEX WITH MEN

Dr. Nadav Antebi-Gruszka, PhD

Introduction: HIV and sexually transmitted infection (STI) screening is critical for HIV/STI prevention and care. Transgender men—individuals assigned female at birth whose gender identity or expression is male—report relatively low HIV/STI testing prevalence compared to cisgender (non-transgender) men. Within this population, transgender men who have sex with men (TMSM), and especially those having sex with cisgender men, are at risk of being affected by HIV and bacterial/viral STIs. Yet, research about the prevalence of HIV/STI testing and factors related to lower testing in this population is scarce. To address this gap, we examined the associations between sociodemographic and behavioral indicators and HIV/STI testing (previously identified in the testing literature) in a U.S. national sample of TMSM.

Methods: Using data from a convenience sample of 203 TMSM recruited online, four multivariable logistic regression models were fit for lifetime HIV testing, past year HIV testing, lifetime bacterial STI testing, and lifetime viral STI testing.

Results: The majority of TMSM reported lifetime testing for HIV (72.4%), bacterial STIs (67.5%), and viral STIs (70.9%), and 61.6% of TMSM received HIV screening in the past year. Overall, 49.3% of TMSM reported engaging in HIV transmission risk behavior, defined as condomless vaginal/anal sex with a casual male sexual partner who was of a known discordant or unknown HIV status. Being gay/queer, residing in the South, having fewer than 5 casual male sexual partners (compared to more than 5 partners), and engaging in HIV transmission risk behavior in the past six months were associated with lower lifetime and past year HIV testing prevalence. Furthermore, having fewer than 5 casual male sexual partners was related to lower prevalence of lifetime bacterial STI testing. Lastly, TMSM who were recruited from a social networking website, had 1–4 casual male sexual partners, and had not used drugs in the previous 6 months were less likely to be ever tested for viral STIs.

Conclusions: HIV and STI testing uptake among TMSM was suboptimal, and similar to those found in previous studies with cisgender MSM samples. Efforts to increase HIV/STI testing among TMSM who engaged in condomless sex are warranted. Specialized TMSM-specific services may be needed to extend our reach and increase HIV/STI testing uptake in this vulnerable population.

Symposium 7B

TRANSGENDER STIGMA, DEPRESSIVE SYMPTOMS, AND NEGATIVE CONSEQUENCES FROM ALCOHOL AND DRUG USE AMONG TRANSGENDER WOMEN

Ms. Demetria Cain, MPH, CPH

Introduction: Research shows that alcohol and substance use is extremely prevalent among LGB individuals relative to their heterosexual counterparts, in particular the negative consequences from use. These health disparities are largely explained through the effects of experiencing stigma, internalizing negative stereotypes, and higher depressive symptomatology. Transgender women (TW) face increased rates of discrimination as gender minorities. Yet, these associations are understudied within this vulnerable population. TW may be experiencing problems from alcohol and drugs use related to coping with social and economic stressors associated with transgender stigma. This study seeks to examine the association between anticipated transgender stigma, internalized transphobia, depression and negative consequences from alcohol and drug use.

Methods: The sample included 212 transgender women in New York City recruited through online and community outreach. We ran descriptives, correlations and a negative binomial regression model to examine factors associated with higher scores on the Short Inventory of Problems-Alcohol and Drugs (SIP-AD).

Results: The mean age was 34 years old with 23% percent reporting heavy drinking and 17% reporting cocaine, crack, ecstasy, GHB/GHL, or methamphetamine use at least once a week in the past 2 months. Mean SIP-AD was 8.25 (SD = 9.71), 20.99 (SD = 11.56) for depressive symptomatology, 15.19 (SD = 4.11) for anticipated transgender stigma, and 20.74 (SD = 6.34) for internalized transphobia. A negative binomial log link regression controlling for race, age, transition age, education, and income found higher depression (ARR = 1.04, $p = .03$) associated with higher SIP-AD. Internalized transphobia was not associated (ARR = 1.02, $p = ns$) with SIP-AD.

Conclusions: Negative consequences from alcohol and drug use are prevalent among TW and associated with depressive symptoms and anticipated transgender stigma, yet not associated with internalized transphobia. TW may not be internalizing negative stereotypes about being a gender minority in ways that impact their health. These findings suggest a need for culturally appropriate interventions to address alcohol and drug use and to extend intervention development beyond the individual to address structural level factors.

Symposium 7C

PREVALENCE OF HEALTH OUTCOMES AND RELATED BEHAVIORS IN A SAMPLE OF TRANSGENDER AND GENDER-NONCONFORMING YOUTH

Michael E. Newcomb, Ph.D.

Background: An emerging body of literature has documented that transgender and gender-nonconforming (TGNC) individuals experience profound disparities relative to their cisgender peers across various health domains, including depression and suicidality, violence and victimization, and alcohol and drug use. These analyses aimed to examine prevalence of various health outcomes and related behaviors in a diverse sample of TGNC youth, as well as differences in these outcomes based on sex assigned at birth.

Method: Data were collected between 2015 and 2017 as part of two ongoing longitudinal studies of LGBTQ youth in the Chicago area. RADAR is a cohort of LGBTQ youth assigned male at birth ($N = 1047$), and FAB 400 is a cohort of LGBTQ youth assigned female at birth ($N = 438$). These analyses utilized data from the baseline assessment for all participants who identified as TGNC in RADAR ($N = 80$) and FAB 400 ($N = 119$), for a total analytic sample of 199 TGNC youth.

Results: For the sample as a whole, depressive symptoms were common; past 6 month suicidal ideation and suicide planning was reported by 28.1% and 10.6%, respectively. Past 6 month gender identity-based victimization was also common, with the majority of the sample reporting recent verbal or physical harassment. With regard to substance use, 21.1% reported alcohol use in the moderate- to high-risk range for an alcohol use disorder, and 22% reported marijuana use in the same range for risk of a cannabis use disorder. For illicit drugs, 9% reported past 6 month stimulant use, 6.5% reported club drug use, and 11.6% reported use of any other illicit drug. Compared to TGNC youth assigned female at birth, youth assigned male at birth reported more alcohol-related problems ($\beta = 3.17$, $p < .01$), more stimulant use ($OR = 4.54$, $p < .05$), higher levels of victimization ($\beta = 2.07$, $p < .001$), and lower levels of perceived social support ($\beta = -0.59$, $p < .01$). TGNC youth assigned female at birth reported higher levels of depressive symptoms ($\beta = -2.90$, $p < .05$), but those assigned male at birth were more likely to report a previous suicide attempt ($OR = 7.15$, $p < .05$).

Discussion: These analyses provide compelling evidence that TGNC youth are at high risk for various negative health outcomes. TGNC youth assigned male at birth are particularly high risk for substance use problems, violence, and suicide. More work is needed to understand how to mitigate these disparities and promote resilience.

8:00 AM-9:15 AM

CULTURE AND PSYCHOSOCIAL RISK FACTORS FOR DIABETES IN LATINOS: FINDINGS OF THE HISPANIC COMMUNITY HEALTH STUDY/STUDY OF LATINOS

Jeffrey S. Gonzalez, PhD¹, Neil Schneiderman, PhD², Maria Llabre, PhD², Jessica McCurley, M.S., M.P.H.³, Gregory A. Talavera, MD, MPH⁴

¹Yeshiva University and Albert Einstein College of Medicine, Bronx, NY; ²University of Miami, Coral Gables, FL; ³Massachusetts General Hospital/Harvard Medical School, Boston, MA; ⁴San Diego State University, Chula Vista, CA

Type 2 Diabetes is a major public health concern for the United States and disproportionately affects Hispanics/Latinos. Yet, little research is available on the cultural, psychological and social factors that are involved in explaining risk for diabetes in this population. Even less research has examined the considerable heterogeneity in risk among the various groups of origin that are included in the diverse ethnic category of Hispanic/Latino. The Hispanic Community Health Study/Study of Latinos (HCHS/SOL) is a landmark longitudinal multicenter community-based cohort study that represents the largest and most comprehensive study of Latino health ever undertaken in the United States. Beginning in 2008, 16,415 U.S. Hispanic/Latino adults who self-identified as Cuban, Dominican, Puerto Rican, Mexican, Central American, or South American were recruited from a random sample of households in four communities located in the Bronx, Chicago, Miami, and San Diego. Participants underwent an extensive clinic examination at baseline to determine disease prevalence and to identify potential risk and protective factors. Comprehensive questionnaires on personal and family health, acculturation, health behaviors and other personal characteristics were also collected. Participants were followed regularly by telephone to track important health outcomes and were re-evaluated with a second clinic examination beginning in 2013. This rich dataset provides an opportunity to significantly improve our understanding of diabetes risk in this population. The first presentation in this symposium will focus on the prevalence and incidence of Type 2 diabetes over 6 years in HCHS/SOL, highlighting origin group differences and associations with cardiovascular disease (CVD). The second presentation will examine adverse childhood experiences and their associations with risk for diabetes and CVD and will highlight acculturation factors that moderate these relationships. The third presentation will examine social adversity factors as predictors of risk for comorbid depression and diabetes in HCHS/SOL participants. The discussant will address the implications of these findings and will highlight the role of the Latino Network for Diabetes Translational Research, a National Resource Core based in the NIDDK-funded New York Regional Center for Diabetes Translation Research, in supporting collaborative translational research for diabetes prevention and control in the U.S. Latino population.

Symposium 8A

PREVALENCE AND INCIDENCE OF DIABETES IN THE HISPANIC COMMUNITY HEALTH STUDY/STUDY OF LATINOS (HCHS/SOL)

Neil Schneiderman, PhD

Diabetes mellitus (DM) has been associated with elevated risk of cardiovascular disease (CVD). The nature of this relationship as a function of Hispanic/Latino (H/L) background was examined over 6 years in HCHS/SOL. Prevalence estimates were weighted to the known population distribution, adjusted for sampling probability and nonresponse, and trimmed to handle extreme values of weights. Age-adjusted incidence rates/100 person years were estimated across visits based upon Poisson regression with robust variance taking into account the complex survey design. Both prevalence and incidence values are presented as % (95% CI). Based upon 16386 participants at V1 and about 93% of the expected 11706 participants at V2, DM prevalence was 17.8 (17.0, 18.6) at V1 and 19.8 (18.84, 20.88) at V2. Prevalence of DM at V2 was lowest, 10.6 (8.49, 13.21) for those of South American and highest for those of Puerto Rican, 22.6 (19.87, 25.59) background. The overall prevalence of CVD was significantly higher for DM than for non-DM participants at V2: 10.7 (8.50, 13.49) vs 5.2 (4.52, 6.05). The incidence rate, 0.69 (0.54, 0.87) vs. 0.19 (0.15, 0.25) was also higher for DM. The relationship of CVD prevalence to DM status revealed different patterns among H/L background groups. At V2 South Americans showed relatively low CVD prevalence, 6.3 (3.35, 11.36) with DM vs. 4.0 (2.33, 6.62) without DM. In contrast Puerto Ricans showed CVD prevalence of 20.3 (11.89, 32.38) with DM, but only 6.6 (5.86, 8.95) without DM. Our results confirm that the overall prevalence of CVD is higher for DM than for non-DM participants and that the DM-CVD relationship varies markedly as a function of H/L background.

Symposium 8B

ADVERSE CHILDHOOD EXPERIENCES AND THEIR ASSOCIATION WITH DIABETES AND CORONARY HEART DISEASE IN HCHS/SOL

Dr. Maria Llabre, PhD

Much of what we know about associations between adverse childhood experiences (ACE) and adult disease comes from the ACE study (Felitti et al., 1998) of over 17,000 middle class US adults. The ACEs include physical, emotional, and sexual abuse, physical and emotional neglect, having a family member go to prison, physical abuse of the mother, having a family member with mental illness or abusing drugs, and parental divorce. Results from the original study showed over 2/3 of adults report at least one and about 10% of men and 15% of women report 4 or more ACEs. ACEs have been linked to heart disease and diabetes, among other chronic diseases and risk behaviors. Only a small percent of participants in the original study were Hispanic. Within the HCHS/SOL we assessed ACEs in 5,117 adult participants and found 77% reported at least one ACE and over 28% reported 4 or more. However, the associations with disease were weaker in HCHS/SOL compared to the original study. With respect to diabetes, the association between ACEs and disease was not significant, once risk factors (including BMI) were controlled. There was an 8% increase in the odds of having CHD for each additional ACE. We examined several potential moderators of these associations, including social support, language use and years in the US. While social support did not moderate the associations, the two measures of acculturation moderated the association of ACEs with CHD. Stronger associations were observed with participants who reported in English or those living longer in the US. In interpreting results, we discuss the role of language and culture in the appraisal of stress in CHD and the major role of obesity as a primary risk factor for diabetes.

Symposium 8C

ASSOCIATION OF SOCIAL ADVERSITY WITH COMORBID DIABETES AND DEPRESSION SYMPTOMS IN THE HCHS/SOL: A SYNDOMIC APPROACH.

Ms. Jessica McCurley, M.S., M.PH

U.S. Hispanics/Latinos experience high lifetime risk for type 2 diabetes and concurrent psychological depression. This comorbidity is associated with poorer diabetes management, worse outcomes in both conditions, and higher mortality. Informed by syndemic theory, this study explored associations of socioeconomic and psychosocial adversity [low income/education, trauma history, adverse childhood experiences (ACEs), perceived ethnic discrimination, and neighborhood problems (e.g., lack of healthy foods, violence)] with comorbid diabetes and depression symptoms in the Hispanic Community Health Study/Study of Latinos Sociocultural Ancillary Study. Participants were 5247 Hispanic/Latino adults aged 18–74 who completed a self-report measures and objective assessment of diabetes. Multinomial logistic regression analyses examined associations of adversity variables with comorbid diabetes and clinically significant depression. Household income <\$30,000/year was associated with higher odds of diabetes/depression comorbidity (OR = 4.61, 95% CI: 2.89, 7.33), as was each standard deviation increase in ACEs (OR = 1.41, 95% CI: 1.16, 1.71), discrimination (OR = 1.23, 95% CI: 1.01, 1.50), and neighborhood problems (OR = 1.53, 95% CI: 1.30, 1.80), compared to individuals with no diabetes/low depression symptoms. Low income, ACEs, ethnic discrimination, and neighborhood problems are related to higher odds of diabetes/depression comorbidity in U.S. Hispanics/Latinos. Future studies should explore these relationships longitudinally.

Symposium 9

8:00 AM-9:15 AM

HEALTH NEUROSCIENCE: FUTURE DIRECTIONS IN MIND AND BRAIN RESEARCH.

Elliott A. Beaton, Ph.D.¹, Peter Hall, Ph.D.², Warren K. Bickel, Ph.D.³¹University of New Orleans, New Orleans, LA; ²University of Waterloo, Waterloo, ON, Canada; ³Virginia Tech Carilion Research Institute, Roanoke, VA

Health Neuroscience is a relatively new field that is dedicated to bringing neuroscience concepts and methods to bear on topics in disease prevention and health promotion. Within this framework, the brain can be a predictor, a mediator, a moderator, or an outcome. In the current symposium, we explore several of these possibilities. The first talk provides an example of the brain-as-outcome approach, with reference to the behavioral and structural brain consequences of a high-risk genetic disorder. The second talk describes a brain-as-mediator and brain-as-moderator approach involving attitudes toward high calorie snack foods in the context of a neuromodulation paradigm targeting self-control networks. Finally, the third speaker describes a novel method for balancing executive and controlled processing via the use of narrative interventions in two studies involving current smokers. The discussion will focus on cross-cutting themes--brain health, cognitive control, and delay discounting--that might push forward the boundaries of what methods are used in behavioral medicine research, what concepts are brought to bear on important questions, and what new approaches can be derived for intervention.

All three studies in this symposium make use of methods that are currently used only occasionally in behavioral medicine: functional magnetic resonance imaging/structural MRI, neuromodulation (specifically repetitive transcranial magnetic stimulation; rTMS), and delay discounting paradigms coupled with narrative methods. There is considerable potential for such methods to benefit behavioral medicine research, particularly when used to explore research questions that are rarely addressed in basic neuroscience or psychiatric research contexts. For instance, learning about the role of the brain in modulation of emotion/stress responses, social cognitive decision-making processes, and behavior implementation is of central interest to most in the field. Beyond the specific studies described, we will attempt to provide an accessible overview of the techniques themselves and describe some additional examples of questions that could be addressed using them in the field of behavioral medicine.

Symposium 9A

BRAIN AND HORMONAL CORRELATES OF STRESS REACTIVITY AND VULNERABILITY IN CHILDREN AT ULTRA-HIGH RISK FOR SCHIZOPHRENIA.

Dr. Elliott A. Beaton, Ph.D.

Background: Children with 22q11.2 deletion syndrome (22q11.2DS) face complex and serious medical, behavioral, and socioemotional challenges. 25 to 30 percent will develop schizophrenia (SCZ). Stress and related physiological sequelae may contribute to the development of psychosis in this population via damage to components of the salience network including the hippocampus. We are searching for early behavioral- and biomarkers of risk that also provide insight into the etiopathology of SCZ in this population.

Methods: Participants were 8–16 year-olds with 22q11.2DS ($n=21$) and healthy-controls (HC; $n=31$). Parents completed the Behavior Assessment System for Children 2nd ed (BASC-2). We measured hypothalamic-pituitary-adrenal (HPA) and sympathetic-adrenomedullary (SAM) activity to a mild stressor via salivary cortisol (CORT), dehydroepiandrosterone (DHEA), and alpha-amylase (AA) before, during, and after a math stressor task. High-resolution brain images were acquired using magnetic resonance imaging. Hippocampi volumes were measured using a semi-automated reconstruction method.

Results: BASC-2 parent reports revealed significant between-group differences including higher atypicality, anxiety, depression, externalizing, and attention problems with lower adaptive function and communication in children with 22q11.2DS. Children with 22q11.2DS had higher levels of CORT and AA with lower levels of DHEA, and a higher CORT/DHEA ratio. Higher levels of AA were associated with anxiety, depression, and internalizing problems. Higher CORT/DHEA ratios were associated with attention difficulties, externalizing, hyperactivity, and poorer adaptive function and communication. Hippocampal volumes were smaller in children with 22q11.2DS (ps

Conclusions: These findings indicate a role for stress-mediated activation of the HPA and SAM systems that could contribute to the etiopathology of schizophrenia in people with 22q11.2DS. Chronically elevated stress likely magnifies congenital brain diatheses and could damage components of the salience network such as the hippocampus. HPA activation may be predictive of externalizing behaviors and SAM activation predictive of internalizing behaviors. Longitudinal study is required to truly test the hypothesis that stress contributes to etiopathology of SCZ in those with 22q11.2DS. Nevertheless, interventions to reduce stress in childhood would improve quality of life and potentially reduce the risk of psychosis in adulthood.

Symposium 9B

CAUSAL EFFECTS OF THE DLPFC ON THE GENERATION OF EXPLICIT ATTITUDES TOWARDS HIGH CALORIE FOODS: AN RTMS INVESTIGATION.

Dr. Peter Hall, Ph.D.

Background: Attitudes towards high-calorie foods are theorized to be important determinants of actual food consumption, but are potentially subject to impression management. One brain structure whose function is known to enable impression management is the dorsolateral prefrontal cortex (dlPFC). Because impression management might require the suspension of a default tendency to report authentic positive attitudes toward high calorie foods, temporary attenuation of this cortical structure might reveal attitudes that are less contaminated by impression management. Alternatively, it is possible that attenuating dlPFC function might enable visceral drives to override social cognitive evaluation processes altogether, thereby reducing the predictive validity of attitude measures. If the former hypothesis is correct, attitudes should be *more* predictively valid following down-regulation of dlPFC function; if the latter is correct, attitudes should be *less* predictively valid following dlPFC attenuation. In this study we evaluate these two alternative possibilities.

Methods: Young adult female participants ($N=21$; $M_{age}=19.1$) were randomly assigned to active or sham continuous theta-burst stimulation (cTBS; a down-regulating variant of rTMS) targeting the left dlPFC. Participants subsequently completed measures of explicit attitudes toward high calorie foods, and were offered an opportunity to consume high calorie foods (and control foods) in a taste test.

Results: Findings revealed a reliable effect of cTBS (active vs. sham) on attitudes towards high calorie snack foods ($t(1,19)=3.055, p=.007; d=1.34$), such that attitudes toward high calorie foods were significantly more positive following active stimulation ($M=3.40, SD=1.01$) than following sham stimulation ($M=1.97, SD=1.08$). Correlational analyses revealed that attitudes articulated following sham cTBS were moderately strong predictors of consumption of high calorie foods during the taste test ($r=.582, p=.030$); attitudes were not predictive of consumption following active cTBS ($r=.086, p=.406$). Attitudes toward high calorie foods were not predictive of control food consumption in either experimental condition.

Conclusions: Downregulation of the left dlPFC results in reliable increases in positively valenced attitudes towards high-calorie foods. However, such attitudes are less predictive of consumption than when following sham stimulation, suggesting that they may reflect an increased visceral drive for eating rather than a reflection of true social cognitive evaluation processes.

Symposium 9C

NARRATIVE THEORY: REBALANCING DUAL PROCESSES TO CHANGE CIGARETTE VALUATION

Dr. Warren K. Bickel, Ph.D.

Dysregulation of the impulsive and executive decision systems are common in cigarette smoking and other addictive disorders. Excessive delay discounting (DD) is a trans-disease process contributing to addiction and may be the product of a hyperactive impulsive system, hypoactive executive system, or both. Previous research demonstrates that listening to narratives engages neural structures from both systems. Thus, narratives may be used to rebalance these systems. In two separate studies, we examined the effects of narratives on DD and various measures of cigarette valuation in cigarette smokers.

Study 1 examines the effects of mating narratives on DD and cigarette craving and valuation. Smokers ($N=275$) were randomly assigned to one of three motivational narratives (control, romance, and sex). Participants were more inclined to choose the larger later rewards after reading the romance scenario ($p=0.044$) compared to control. However, the sex scenarios increased their preference for smaller sooner rewards ($p=0.040$). Moreover, reading the romance scenario significantly decreased cigarette craving, while reading the sex scenario increased cigarette's valuation.

Study 2 examines the effect of narratives on cigarette preference and willingness to switch to e-cigarettes. Smokers ($N=162$) were randomly assigned to one of four narratives in which a close friend becomes ill and thinks it is smoking-related. The 4 narratives have different endings. The friend 1) finds out it was just the flu (control), 2) finds out it is because of smoking, 3) expresses remorse for ever starting to smoke and 4) switches to e-cigarettes and feels much better. Compared to controls, lower demand for cigarettes ($p=0.008$) and greater preference for switching to e-cigarettes ($p=0.035$) were reported in the narrative 4. Moreover, changes in DD were differentially observed depending on which narrative the participant experienced.

Conclusions: Narratives interventions can influence DD, alter smoking valuation, and change preference among tobacco products. Hence, narratives have a potential as a component of future addiction interventions.

Symposium 10

8:00 AM-9:15 AM

GEOFLASHE: EXPLORING THE ROLE OF SPACE AND PLACE ON HEALTH BEHAVIORS

April Oh, PhD, MPH¹, Laura A. Dwyer, PhD², Erin Hennessy, PhD, MPH³, Lilian Perez, PhD, MPH¹, Minal Patel, PhD, MPH⁴¹National Cancer Institute, Rockville, MD; ²Cape Fox Facilities Services, Fountain, CO; ³Tufts University Friedman School of Nutrition Science and Policy, Boston, MA; ⁴NCI, Rockville, MD

Spatial data are increasingly being used in behavioral studies as more research focuses on ecologic approaches to understanding the multilevel influences on health behaviors and behavior change. These studies include examination of the role of neighborhood and environmental exposures on health, and are enabled via GIS tools, greater availability of spatial data, and evolving behavioral theory. To this end, the National Cancer Institute's Family Life, Activity, Sun and Healthy Eating (FLASHE) study geocoded survey participant school and home addresses and calculated 'neighborhood' geospatial variables in these settings for public use. This study involved 1,479 parent-adolescent dyads from across the nation who completed online surveys on cancer-preventive behaviors. The purpose of this panel is two-fold: 1) To describe the availability of the National Cancer Institute's geoFLASHE spatial data for examining contextual correlates of survey participant health behaviors and; 2) Provide examples of how these spatial data can be used to examine the role of neighborhood on cancer preventive health behaviors. The first speaker will provide an overview of the methodology used in geoFLASHE to calculate geospatial variables, with a focus on challenges in operationalizing 'neighborhood' in behavioral studies, and explores the association between neighborhood-level SES and individual-level F/V intake by different neighborhood spatial definitions. Following the methodologic overview, three examples of how spatial data can be integrated with survey data to explore the influence of neighborhood context on behavior will be presented. The first study will describe the relationship between neighborhood SES and parenting (e.g. parenting styles and physical-activity related parenting practices). The second speaker will explore the relationship between school physical activity policies and the school neighborhood environment on adolescent physical activity. The final speaker will describe the association between UV environmental exposure and sun-protective behaviors among parents and their adolescent children. The symposium will end with a discussion of how geospatial data can enhance our understanding of the environmental correlates of health behaviors, and some opportunities and challenges when working with these data in behavioral studies.

Symposium 10A

ASSOCIATIONS BETWEEN NEIGHBORHOOD UV EXPOSURE AND SUN PROTECTION BEHAVIORS AMONG PARENTS AND THEIR ADOLESCENT CHILDREN

Laura A. Dwyer, PhD

Introduction: Associations between geocoded UV exposure and risk of melanoma have been demonstrated in some studies (Richards et al., 2011; Tatalovich et al., 2006). Environmental UV exposure has been infrequently examined in relation to skin cancer prevention behaviors and adolescent outcomes, although research suggests that related aspects of the environment (e.g., temperature or latitude) correlate with sun protection behaviors (Andersen et al., 2016). Examining these relationships may provide insights for educational and targeted skin cancer prevention interventions.

Method: Survey data on sun protection and exposure behaviors were collected in 2014 from parent-adolescent dyads in the National Cancer Institute's Family Life, Activity, Sun, Health, and Eating Study. UV exposure was computed for each dyads' home and adolescents' school locations at multiple neighborhood sizes (400–1200 meters). UV exposure did not significantly vary by neighborhood size (Westat, 2017), so we examined the mean UV exposure for each location as related to behavior. Weighted regressions controlled for age, sex, race/ethnicity, and parent education.

Results: In the full sample of 1,306 dyads, neighborhood UV exposures were not significantly associated with parent or adolescent sunscreen or hat use ($ps \geq .54$) or adolescent use of protective clothing or shade seeking ($ps \geq .07$). However, higher neighborhood UV exposure was positively associated with parent use of protective clothing ($\beta = 0.10, ps < .01$) and shade-seeking ($\beta \geq 0.07, ps < .05$) and negatively associated with time spent in the sun to get a tan among both parents and adolescents ($\beta \leq -0.09, ps < .001$). UV exposure did not predict the number of sunburns reported from the past year. Additional models revealed that some of these associations differed by race/ethnicity. For example, neighborhood UV exposure predicted greater shade seeking among non-Hispanic White parents only ($\beta = 0.12, p = .001$) and lower sunscreen use among Hispanic adolescents only ($\beta \leq -0.27, ps < .01$).

Conclusion: Relationships between neighborhood UV exposures and behavior varied by behavior, by age (adult versus adolescent), and, in some cases, by ethnicity and race. The most salient sun protection behaviors that people engage in may vary by UV exposure, and efforts to promote sun protection may consider including education about UV exposure at one's residential location.

Symposium 10B

PARENTING IN CONTEXT: UNDERSTANDING NEIGHBORHOOD INFLUENCE

Dr. Erin Hennessy, PhD, MPH

Introduction: Parenting is one of the most important influences on child behavior and health; yet, relatively little is known in about the contextual factors that influence parenting. Moreover, research on the influence of macro-level factors such as neighborhood context on child outcomes has grown but with less attention on potential mechanisms. The purpose of this study is to evaluate one possible mechanism: parenting.

Method: Data were drawn from the 2014 National Cancer Institute's Family Life, Activity, Sun, Health, and Eating (FLASHE) Study, a U.S. survey of parent-adolescent dyads. Six items measuring three parenting style dimensions: demandingness, responsiveness, and autonomy-granting, and were adapted from the valid Parenting Style Inventory-II instrument. Neighborhood socioeconomic status (nSES), a marker of larger institutional and economic need of the community that is not necessarily reflective of individual SES, was defined according to Yost et al. using circular buffers of varying distances (400 meters -1200 meters) from the dyad's home location.

Results: A total of 1,533 parent-adolescent dyads had complete data on: nSES, parenting style, parent sex, and residential tenure. In linear regressions controlling for sex and residential tenure, models showed that nSES was positively associated with autonomy-granting ($B_s = 0.11$, $p < .001$) but not demandingness or responsiveness. At the smallest neighborhood sizes (400-500m), there were significant interactions between nSES and parent sex on autonomy granting: nSES was positively associated with autonomy-granting among mothers ($B = 0.13$, $p < .001$) but not among fathers ($p > 0.19$). Autonomy-granting was also higher among parents reporting more than 15 years at the same address ($B_s = 0.22$, $p < .001$).

Conclusion: This study suggests that one marker of neighborhood context, nSES, is positively associated with some but not all aspects of parenting and that this relationship may vary by factors such as parent sex and residential tenure. FLASHE provides the breadth and depth of data needed to significantly expand research on the multilevel influences of health. Future analyses will evaluate other potential moderators (e.g. family income), and test mediation models with child outcomes. Increased understanding of neighborhood context may inform more tailored and specific parenting interventions to improve child health.

Symposium 10C

DO SCHOOL POLICIES AND ENVIRONMENT EXPLAIN ADOLESCENT SCHOOL-RELATED PHYSICAL ACTIVITY?

Dr. Lilian Perez, PhD, MPH

Introduction: Few U.S. adolescents report meeting federal aerobic physical activity (PA) guidelines, with a lower prevalence reported by high school versus middle school students. School policies and environments around schools may influence adolescent time use, including physical activity and transportation behavior. However, evidence supporting the effects of such contextual factors on PA is limited. This study examined associations of school policy and environments with adolescent physical activity.

Methods: Cross-sectional data came from the adolescent sample of the Family Life, Activity, Sun, Health, and Eating study ($N=963$; age range: 12–17 years). Minutes/week of school-related moderate-to-vigorous physical activity (MVPA) were estimated based on self-reported PA during school time and walking or bicycling to/from school, calibrated with an accelerometer substudy. Presence/absence of state policies concerning PA or MVPA were obtained from the Classification of Laws Associated with School Students (CLASS) data resource. Census data were used to estimate neighborhood variables within a 1200-m street-network buffer around each respondent's school: walkability via population density, age of neighborhood homes, and length of commuting time as well as neighborhood socio-economic status. Generalized linear regression models tested associations of policy and environment factors, and their interactions, with school-related MVPA, controlling for socio-demographics, urbanicity, and distance from home to school. Analyses were also stratified by school level (middle/high).

Results: Greater school-related MVPA was associated with presence of a state school PA policy (β (SE)=4.3 (2.1), $p=.04$) and attending a school in a higher density (β (SE)=4.8 (1.8), $p=.01$) and older neighborhood (β (SE)=2.6 (1.2), $p=.03$). Stratified models showed the positive associations of PA policy ($p=.03$) and older neighborhood ($p=.05$) were significant only among those in high school. The positive association of higher density was significant only among those in middle school ($p=.01$). No significant policy by environment interactions were found.

Discussion: Few past studies have examined associations of school PA policies and school environments with high-quality measurement of school-related PA. Our findings are consistent with ecologic approaches that posit policy and environmental factors are related to physical activity behaviors.

Symposium 10D

EXPLORING VARIOUS GEOSPATIAL DEFINITIONS OF NEIGHBORHOOD SES IN THE CONTEXT OF ADULT FRUIT AND VEGETABLE CONSUMPTION

Dr. Minal Patel, PhD, MPH

Background: Neighborhood level contextual factors, such as neighborhood socioeconomic status (NSES), are important for understanding the determinants of health behaviors beyond individual factors. However, understanding the role of the neighborhood requires defining spatial boundaries since different spatial definitions of neighborhoods can lead to inconsistent associations between neighborhood factors and health behaviors and outcomes. In addition, how to define and measure neighborhood characteristics is important for behavioral studies with the growing adoption of social ecologic models. Using varying neighborhood size and shape to measure NSES, we examined 1) the associations between NSES using different neighborhood definitions, and 2) what neighborhood size and shape is associated with fruit and vegetable (*f/v*) consumption in a sample of U.S. adults. Additional secondary analyses examine the potential moderating role of self-efficacy on the relationship of NSES and fruit and vegetable consumption.

Methods: Data were from GeoFLASHE, a geospatial extension of the Family Life, Activity, Sun, Health and Eating Study (FLASHE) ($n=1736$). Weighted census demographic NSES percentages were calculated using a composite measure of seven census indicator measures at buffer sizes of: 400, 500, 750, 800, 1000 and 1200 meters(m). Pearson's correlations examined the NSES Index at various buffer sizes and shapes. Weighted bivariate and multivariate analyses tested NSES and *f/v* consumption, adjusting for age, sex, education, urbanicity, race/ethnicity, and self-efficacy. Adjusted models were further stratified by sex.

Results: NSES are highly correlated between various buffers ($r \geq .99$, $p < .01$). Circular buffers of all sizes and street NSES buffers 750m and larger remain significant in adjusted models for women only ($\beta: 0.13-0.18$; $p < 0.05$). Individuals with higher self-efficacy to eat fruits and vegetables had higher *f/v* consumption regardless of the NSES buffer size and shape or when stratified by sex ($\beta: 1.02-1.10$; $p < 0.05$).

Conclusion: For behavioral studies that include the neighborhood environment, definitions of space can vary, impacting results. This methods analysis, found that although different NSES buffers are highly correlated, researchers should conceptually determine spatial areas a priori, depending on the research question and behavior examined. Further applications to other health behaviors include physical activity, sedentary behaviors, and tobacco use.

8:00 AM-9:15 AM

UNDERSTANDING THE CONTRIBUTION OF BINGE EATING TO OVERWEIGHT AND OBESITY AMONG DIVERSE POPULATIONS

Alyssa Vela, M.A.¹, Brooke Palmer, M.A.², Alyssa Minnick, M.S.³, Emily Panza, M.S.⁴, Virginia Gil-Rivas, Ph.D.⁵

¹The University of North Carolina at Charlotte, Cleveland Heights, OH; ²University of North Carolina Charlotte, Charlotte, NC; ³UNC at Charlotte, Charlotte, NC; ⁴Alpert Medical School of Brown University, Providence, RI; ⁵UNC Charlotte, Charlotte, NC

The majority of U.S. adults are overweight or obese (Ogden, Carroll, Fryar, & Flegal, 2016). Obesity is disproportionately prevalent among minority group members and is associated with increased risk for cardiovascular disease, type 2 diabetes, cancer, and poor quality of life (DHSS, 2010; Ogden et al., 2016). The incidence of binge eating behaviors is elevated among obese adults, and confers independent risks for metabolic and cardiovascular diseases (Kenardy et al., 2001). Despite the health implications of binge eating, the majority of studies have investigated binge eating behaviors among White women, and research is needed to elucidate the sociocultural and individual factors that may contribute to binge eating and obesity in these groups. The current symposium aims to fill this gap in the literature by identifying the correlates of binge eating and overweight and obesity, implications for binge eating treatments among minority group members, and importance of considering binge eating for health maintenance including weight and chronic illness management. Specifically, the first presentation will discuss the role of sociocultural factors (i.e., discrimination, ethnic identity, and psychological distress) in contributing to binge eating symptoms among a racial and ethnically diverse group of college men. Our next presentation will build on this by exploring how minority stress related to sexual orientation, weight, and gender contributes to binge eating behaviors among sexual minority women. Our third presentation will explore individual and social factors associated with treatment-seeking among Latina women who binge eat. Our final presentation will present the preliminary findings of the efficacy and acceptability of a guided self-help lifestyle intervention for reducing disordered eating behaviors among women with Type 2 diabetes. The symposium discussant, will tie together these diverse presentations to highlight the relevance of the unique experiences and needs of diverse populations who commonly engage in binge eating. Implications for future research, prevention, and treatment efforts will also be explored.

Symposium 11A

AN INTERVENTION FOR WOMEN WITH COMORBID TYPE 2 DIABETES MELLITUS & DISORDERED EATING

Alyssa Vela, M.A.

Rates of type 2 (T2) diabetes mellitus continue to rise in the United States and around the world, with growth to epidemic proportions largely attributed to health behaviors such as poor diet, overeating, and lack of physical activity. For those with T2 diabetes, management is demanding, requiring daily effort with responsibilities pertaining to eating behaviors, physical activity, and blood glucose monitoring. Eating is often the most challenging aspect of diabetes management, and when disordered, has been associated with increased risk for diabetes-related complications. Disordered eating (i.e., binge, emotional, external, and restrictive types of eating behaviors), appears to occur more often in populations diagnosed with T2 diabetes than in the general population. Disordered eating for individuals with T2 diabetes has been associated with increased risk for severe diabetes-related complications, as well as higher HbA1c and poor diabetes management. Thus, there is a need for further development of low-cost and accessible treatment modalities for T2 diabetes and related health problems, including disordered eating.

The current project sought to assess the efficacy and acceptability of an eating-focused CBT guided-self help (CBTgsh) lifestyle intervention for women with T2 diabetes who engage in disordered eating and wish to improve their eating behaviors, health and well-being. Ten women completed the 12-week intervention that sought to support them in establishing a regular pattern of eating, food monitoring, adjusting thought patterns about eating and health, and increasing physical activity. Paired *t*-tests indicated that the intervention was effective in reducing disordered eating behaviors, HbA1c, and diabetes distress. Constant-comparative analysis of qualitative data regarding the intervention revealed several themes. Specifically, participants liked the connection and accountability, the inclusion of clear and useful information, the thought provoking material, and the encouragement of positive change in perspective. Participants also suggested modifications such as developing an easier way of monitoring, and the addition of group support. Notably, participants spoke highly of the program, with some stating that it was life changing, and that they would recommend the intervention to others. Recommendations for the further development and dissemination of the intervention will be discussed.

Symposium 11B

UNDERSTANDING TREATMENT-SEEKING BEHAVIOR IN LATINAS WITH BINGE-EATING

Brooke Palmer, M.A.

Binge eating disorders are related to numerous physical and mental health consequences, yet treatment rates are low, especially in minority populations. Low treatment rates may be due to stigma (in both patient and providers) and lack of treatment services. Latinas in particular have high rates of binge eating (BE) behavior with very low rates of treatment utilization. This study investigated Latinas' beliefs and behaviors about BE in order to better understand the factors associated with treatment-seeking. Data from a community sample of Latinas ($N = 167$) from Charlotte, NC and Los Angeles, CA were analyzed. Participants self-identified as having a problem with overeating participated in an interview assessing BE and comorbid symptoms. Qualitative data were also analyzed from a subsample ($n = 17$) of participants who were recruited into a CBT-based guided self-help intervention to reduce BE. Results indicated that participants were engaging in BE frequently ($M = 6.2$, $SD = 7.31$ objective binge episodes in the prior 28 days), and that the majority of participants (54%) met DSM-5 criteria for an eating disorder. Many (69%) participants reported that they felt they had an eating problem, and 56% wanted help for an eating problem, while only 9% of the participants had received treatment for an eating problem despite the fact that the majority (77%) had insurance in the previous 5 years. Logistic regression revealed that severity of BE was not associated with participants identifying their eating behavior as problematic or wanting treatment. Overvaluing their weight and shape, however, did predict wanting treatment and identifying disordered eating while BMI only predicted wanting treatment. In order to understand the heterogeneous picture of Latinas with BE, qualitative data from participants highlighted additional themes that further exposed the decision-making process for treatment-seeking in Latinas with BE. In particular, Latinas who desired help with their BE did not have family support, whereas family support was reported by those who did not want help. In addition, multiple participants reported that they were not aware that their BE was problematic until completing the interview. These findings help explain discrepancies in participants desire to seek treatment. Implications for prevention and treatment efforts will be discussed.

Symposium 11C

BINGE EATING AMONG COLLEGE MEN: EXPLORING THE ROLE OF RACE AND ETHNICITY

Alyssa Minnick, M.S.

Extant literature is currently limited in the examination of binge eating among college age men, particularly those from racial and ethnically diverse backgrounds. Therefore, the present study explored predictors of the frequency of binge eating episodes in a sample of racial/ethnically diverse college men. A total of 486 young college men (aged 18–24 years old) completed an online survey that included questionnaires about frequency of perceived racial-based discrimination experiences, perceived stress, psychological distress, and eating disorder symptomatology (e.g., binge eating episodes). Path analyses were conducted with the overall sample and the subsample of men from minority backgrounds ($n = 170$). The results indicated that, among the overall sample, race/ethnicity had an indirect effect on frequency of binge eating episodes through perceived discrimination, perceived stress, and psychological distress; however, psychological distress did not predict binge eating among men from minority backgrounds. These findings indicate racial/ethnic differences in eating pathology among men, suggesting the need for culturally-appropriate behavioral health interventions. Additional research is needed to clarify predictors of binge eating in both groups, with specific emphasis on identifying possible factors associated with disordered eating among men from ethnic/racial minority backgrounds.

Symposium 11D

OVEREATING AND BINGE EATING AMONG OVERWEIGHT AND OBESE SEXUAL MINORITY WOMEN

Emily Panza, M.S.

Sexual minority women display disproportionately higher rates of disordered eating behaviors, such as binge eating, fasting, and vomiting, than their heterosexual counterparts (Bankoff & Pantalone, 2014). However, little research has examined *why* this disparity exists. The current study examined whether minority stress, including repeated experiences of external stigmatization, may be one contributing factor (Meyer, 2003). Sexual minority women belong to multiple socially stigmatized groups: being non-heterosexual, being female, and for 60%, being overweight. Exposure to unique and chronic minority stressors may cause chronic elevations in stress and negative emotion that some sexual minority women may try to regulate by overeating and/or binge eating.

To test this proposed model, the current study used Ecological Momentary Assessment (EMA) to examine whether lifetime and acute minority stress increased risk for overeating and binge eating in sexual minority women. 55 overweight or obese ($BMI > 25$) sexual minority (e.g., lesbian, bisexual) women were recruited from the community to complete baseline assessments of eating behavior and minority stress due to sexual orientation, weight, and gender. For the following five days, participants used a smartphone application to report experiences of stigmatization, overeating and binge eating five times daily.

Findings revealed that women who reported greater lifetime heterosexual, gender, and weight-based stigma reported higher baseline levels of disordered eating and binge eating. As expected, greater daily negative emotion and daily stress interacted with daily stigma to predict greater daily binge eating, and stigma events during the EMA period were associated with greater concurrent overeating at the same time point. Finally, being stigmatized on any given day was associated with more overeating and binge eating on that day.

The current study provides preliminary support for minority stress as a factor contributing to disproportionate rates of overeating and binge eating among sexual minority women. Given the paucity of research in this area, findings justify future research to unpack the relevance and significance of minority stress as a risk factor for disordered eating behaviors in this group. This will be essential for developing effective interventions to reduce disordered eating behaviors and to improve health among sexual minority women.

Symposium 12

8:00 AM-9:15 AM

BEYOND KNOWLEDGE: ADDRESSING GENOMIC LITERACY IN THE TRANSLATION OF GENOMIC TECHNOLOGIES

Kimberly Kaphingst, ScD¹, Catharine Wang, PhD, MSc², Galen Joseph, PhD³, Deborah Bowen, PhD⁴¹University of Utah, Salt Lake City, UT; ²Boston University School of Public Health, Boston, MA; ³University of California, San Francisco, San Francisco, CA; ⁴University of Washington, Seattle, WA

In the era of precision medicine, genetic and genomic technologies are increasingly becoming part of mainstream medicine. Effective translation of this information is critical to its clinical utility and impact on population health outcomes. This translation will depend, in part, on effective communication and the genomic literacy of those delivering the information (e.g., clinicians, interactive electronic tools) as well as the recipients (e.g., patients, general public). The National Human Genome Research Institute's 2013 report on genomic literacy in the US defined *genomic health literacy* as the capacity to obtain, process, understand, and use genomic information for health-related decision-making. Yet, the conceptualization and operationalization of genomic literacy in applied behavioral research has been limited to date. Moreover, intervention studies to address genomic literacy are lacking. This symposium will highlight ongoing research that examines genomic literacy from the conceptual to the practical, and presents examples of how genomic literacy has been addressed in communication interventions. The first presenter will report on the findings of a scoping literature review, which examined how genomic literacy has been conceptualized across studies, and will discuss the limitations in current definitions and intervention applications. The second presenter will describe a web-based family health history tool designed for diverse underserved patients and discuss the implications of design considerations for patients with limited genomic and computer literacy. The third presenter will describe an intervention designed to improve oral communication between genetic counselors and their linguistically diverse, limited health literacy patients, and discuss how the intervention addressed both the information needs of patients and the communication skills of counselors. Finally, the discussant will summarize the implications of the findings presented and consider next steps for advancing research in genomic literacy. This symposium will highlight the need to move beyond knowledge in considering genomic literacy and identify strategies for better integration of genomic literacy into genomic translation efforts.

Symposium 12A

CONCEPTUAL AND MEASUREMENT ISSUES IN DEFINING GENOMIC LITERACY

Kimberly Kaphingst, ScD

In the context of cancer, genetic and genomic information have become increasingly important in research and clinical care. The successful translation of this information into patient-centered care and improved outcomes is thought to be dependent upon providers' and patients' genomic literacy, which can be conceptualized as genetics- and genomics-related knowledge and skills. However, the domains of knowledge and skills most critical to individuals' use of this information need to be defined. We therefore examined how genomic literacy was addressed in the recent literature. We conducted a scoping review to synthesize the recent published research on communication of genetic and genomic information related to cancer. For the present analysis, we examined data regarding whether and how the communication studies assessed or described genomic literacy, health literacy, numeracy, or genomics-related knowledge. A comprehensive search for papers published between 2010 and 2017 was conducted in six databases. The search resulted in 9,251 unique records, and 537 papers were included in the review. Few papers assessed genomic literacy (1.2%), health literacy (3.0%) or numeracy (4.2%). Only one paper included a validated measure of genomic literacy; a second created a measure that assessed interpretation of genetic risk information. In these studies, genomic literacy was found to be related to learning from a videotaped genetic counseling session and forming opinions about mastectomies. In other studies, genomic literacy was not directly assessed but inadequate genomic literacy was assumed to underlie misunderstandings of information or to mean limited genetic knowledge. More papers included assessments of genetic or genomic knowledge (17.7%). Items used to assess knowledge varied widely and often focused on specific knowledge about mechanisms of inheritance. Few papers provided a conceptual or theoretical rationale for the selection of knowledge items. Based on this synthesis of recent research, we will summarize major findings in how genomic literacy and related constructs are being used in the literature on the communication of genetic and genomic information. We will also describe major domains of genetic and genomics-related knowledge that have been assessed. Emerging conceptual and methodological issues will be highlighted. Further development in this area is critical to translating genetic and genomic discoveries into improvements in population health.

Symposium 12B

CHALLENGES TO USING WEB-BASED FAMILY HISTORY TOOLS AMONG VULNERABLE PATIENT POPULATIONS

Dr. Catharine Wang, PhD, MSc

Family health history is an important risk factor for chronic disease and its assessment is essential for accurate interpretation of genetic and genomic data. Online tools are currently available to facilitate in the collection of family history, but may be too complex and challenging for many patients to use, particularly those with limited or low health literacy. We developed a computer animated "virtual counselor" (VICKY) to interview patients and collect family history information. VICKY is being evaluated in a randomized controlled trial to evaluate its accuracy compared to My Family Health Portrait (MFHP), a publically available tool developed by the Department of Health and Human Services. As part of the ongoing trial, the usability of both tools is being tracked to identify usability challenges among patients. To date, a total of 95 participants have been enrolled in the trial. Only 38% were able to successfully use MFHP to generate a pedigree, while 90% were able to do this with VICKY. Challenges to MFHP use stemmed from patient frustrations while navigating the tool to enter information. These navigation issues included the inability to enter the tool from the home screen, enter date of birth for self, and adding and saving conditions for self and relatives. Ongoing efforts will monitor the extent to which usability varies as function of demographics (i.e., age, education) and family structure (i.e., size, complexity), particularly among racial/ethnic subgroups. Accuracy of family health history data collected will also be evaluated in comparison to a genetic counselor. Future efforts to develop patient-facing family health history tools will need to consider usability issues to ensure their effective use, particularly among populations with more limited genomic and computer literacy skills.

Symposium 12C

A PILOT INTERVENTION TO IMPROVE PATIENT-PROVIDER COMMUNICATION IN CANCER GENETIC COUNSELING

Galen Joseph, PhD

Genomic literacy is necessary to realize the promise of Genomic Medicine, particularly in the context of efforts to increase participation of diverse populations in genomics research and clinical practice. Here we present a pilot intervention to improve oral communication between genetic counselors (GCs) and their limited health literacy (LHL) patients. GCs are genetics clinicians who assess risk of hereditary conditions and provide psychosocial counseling and genetics education to patients and their families. This pilot intervention consisted of: communication workshop curriculum development and evaluation; 2-month post-workshop interviews with participating GCs (n=9) about their efforts to apply LHL communication strategies in practice; observations of counseling sessions with 2 trained GCs (n=24) and patient interviews (n=9). The 4.5-hour workshop presented evidenced-based principles and strategies for effective communication with LHL patients (e.g. Plain Language, Teach-back), and exercises to practice adapting them to the counseling context. GCs reported appreciating the opportunity to refine their communication skills; however, they found communication techniques like plain talk and teach back challenging to adopt given their training and communication habits. GCs also raised concerns about achieving informed consent and providing scientifically accurate information when using plain language techniques. Observations and patient interviews showed that GCs were sometimes able to employ the LHL communication strategies to positive effect. Patients left their appointments understanding the implications of the test, in contrast to our prior study which found that many patients were confused about the purpose of genetic testing. These findings are the starting point for a RCT that will compare traditional genetic counseling with a modified protocol incorporating LHL principles and strategies for the return of exome sequencing results to diverse patients as part of the CSER2 (Clinical Sequencing Evidence-Generating Research) consortium. If proven beneficial, we will work with GC training programs and practicing counselors to adopt these modified practices to ensure that the benefits of genomic science reach all populations and do not exacerbate existing health disparities.

Symposium 13

8:00 AM-9:15 AM

CUSTOMIZED ADHERENCE INTERVENTIONS FOR COMPLEX AND CHALLENGING CLINICAL POPULATIONS

Jennifer B. Levin, PhD¹, Martha Sajatovic, MD², Jessica Montoya, PhD³, David J. Moore, Ph.D.⁴

¹Case Western Reserve University School of Medicine, Cleveland, OH; ²Case Western Reserve University School of Medicine, Gates Mills, OH; ³University of California, San Diego (UCSD), San Diego, CA; ⁴University of California, San Diego, San Diego, CA

Despite considerable progress in the development and efficacy of pharmacological treatments for serious mental health and chronic medical conditions, suboptimal medication adherence remains a major obstacle to the success of such medication treatments on health outcomes. The adherence problem becomes even more challenging with the complexity of multi-morbidity. In this symposium, we will introduce various models of adherence behaviors, leading to the development and testing of adherence enhancing interventions applied to individuals with various complex medical and/or serious mental health conditions with notable barriers to treatment adherence. All interventions described have an element of customization. First, Dr. A. will describe a recent randomized control trial of Customized Adherence Enhancement (CAE) compared to an educational control in poorly adherent adults with bipolar disorder. CAE targets patient endorsed barriers to treatment adherence through the administration of 4 potential modules: Psychoeducation, Communication with Providers, Medication Routines, and Substance Abuse using Modified Motivational Interviewing. Next, Dr. B. will describe the results of a study examined whether methamphetamine (MA) users with continuous virologic suppression demonstrate better adherence behaviors (e.g., superior dose timing) than MA users with continuous detectable viral load in response to the Individualized Texting for Adherence Building (iTAB) intervention, whose aim is to promote antiretroviral therapy adherence among persons living with HIV/AIDS who use MA. Finally, Dr. C. will describe the development of an adherence intervention utilizing the iTAB platform, iTAB-CV, informed by feedback from focus groups and will report preliminary data on feasibility and acceptability of the intervention in poorly adherent individuals with hypertension and bipolar disorder. Following completion of the 3 presentations, Dr. D., an expert in adherence interventions and the creator of the iTAB platform, will pull together the presentations by pointing out the shared and differing elements of the various interventions, which depend on both the platforms, patient characteristics, and target outcomes. The session will conclude with panel comments on how the symposium findings can inform future efforts by other researchers and clinicians to optimize medication adherence among individuals with chronic medical and/or mental health conditions with complicating barriers.

Symposium 13A

DEVELOPMENT AND FEASIBILITY OF ITAB-CV FOR POORLY ADHERENT INDIVIDUALS WITH HYPERTENSION AND BIPOLAR DISORDER

Dr. Jennifer B. Levin, PhD

Individuals with Bipolar Disorder (BD) have high rates of chronic medical conditions such as hypertension (HTN) and poor treatment adherence, with increased hospital visits, a mortality rate of approximately twice that of the general population and a shortened life expectancy. Poor antihypertensive adherence occurs in 50–80% of those with BD. No single intervention has strong evidence for improving adherence to antihypertensives, there are few effective interventions to enhance adherence and improve outcomes in BD, and those that exist do not simultaneously target non-psychotropic adherence. A bidirectional text-messaging system (Individualized Texting for Adherence Building; iTAB) has been used in other complex populations where medication adherence is critical for health outcomes. We describe the development phase of a two-phase 24-month project to adapt iTAB for poorly adherent individuals with comorbid HTN and BD.

We used an exploratory sequential mixed methods design to inform Phase II and are evaluating the feasibility and acceptance of the resulting m-Health intervention (iTAB-CV) in the first 7 participants. Focus group inclusion criteria were ≥ 21 years old, self-reported clinical diagnoses of BD and HTN, and current or past difficulties with adherence to antihypertensives. iTAB-CV trial inclusion were ≥ 21 years old, HTN for ≥ 6 months and ≥ 3 months of antihypertensive treatment, BD for ≥ 2 years, ≥ 20% of days with missed antihypertensive doses, and systolic BP of ≥ 130mmHg. Feasibility was measured by response rate to texts for months 1 and 2 of iTAB-CV and exit interview responses.

A total of 13 participants comprised three focus groups. Mean age was 52.8 years (SD=9.46), with 80% female and 92% African American. The original feasibility sample had a mean age of 53.57 (SD=9.66), 57% male, 57% African American. At screen, average % of days with missed doses measured by self-reported Tablets Routine Questionnaire was 44% for HTN and 51% for BD medications and average systolic blood pressure (BP) was 135.8 (SD=8.96) mmHg.

Transcript-based analysis generated data on four patient-centered issues: Barriers to Anti-Hypertensive Medication Adherence, Facilitators to Antihypertensive Medication Adherence, Use and Comfort with Technologies/Texting, and Demonstration/Feedback of iTAB. Mean % response was 68.7 (SD=33.7) for educational/motivational texts and 58.9 (SD=36.1) to mood messages in month 1 and 64.1 (SD=23.4) for educational/motivational texts and 53.5 (SD=29.6) for mood messages in month 2. Exit interviews indicate 85.8% found iTAB-CV messages useful and benefits outweighed the potential downside of receiving texts. 100% would recommend the program to others.

Based on preliminary data, iTAB-CV appears to be feasible and well-received with a high degree of engagement. In the next stage, change in adherence, BP and BD symptoms will be evaluated.

Symposium 13B

CUSTOMIZED ADHERENCE ENHANCEMENT TO ADDRESS ADHERENCE VULNERABILITIES IN PEOPLE WITH BIPOLAR DISORDER

Dr. Martha Sajatovic, MD

This presentation will present results from a recently completed 6 month, prospective randomized, controlled trial (RCT) of customized adherence enhancement (CAE) vs. broadly-directed, non-individualized education (EDU) in poorly adherent individuals with bipolar disorder (BD). There were 184 participants randomized to receive either CAE (N=92) or EDU (N=92). CAE is a brief behavioral adjunct to standard mental health treatment. Research assessments were conducted at screening, baseline, 10, 14 and 26 weeks follow-up. Mean age of the sample was 47.4 years (SD 10.46), 126 women (68.5%), 123 African-Americans (66.8%). The majority had Type 1 BD (N=136, 73.9%) with an average age of onset of 24 years (SD 12.3). Consistent with the negative effects of BD on both occupational and personal role achievement, only a minority were employed full time (N=7, 3.8%), with 53 (29.1%) living in a private home and 11 (6%) married. Psychiatric comorbidity was common including alcohol disorder (10.5%), post-traumatic stress disorder (40.5%) and generalized anxiety (23.9%). At study screening patients averaged missing 55.2% (SD= 28.21) of BD drugs within the past week and 48.0% (SD= 28.46) within the past month. Comparing change in key outcomes over 26 weeks, CAE was associated with improved medication adherence ($p=.03$) and functional status ($p=.04$) but not with global BD symptoms compared to EDU. CAE appears acceptable to individuals that are often not included in typical research studies (minorities, individuals with known poor adherence). The presentation will discuss additional study findings and opportunities for broader scale-up.

Symposium 13C

SUPERIOR DOSE TIMING IS RELATED TO HIV UNDETECTABILITY AMONG PLWHA WHO USE METHAMPHETAMINE

Dr. Jessica Montoya, PhD

Background: The effectiveness of antiretroviral (ARV) therapy for HIV suppression depends on adherence. Methamphetamine (MA) use poses a barrier to ARV adherence. The individualized texting for adherence building (iTAB) intervention aimed to promote ARV adherence among persons living with HIV/AIDS (PLWHA) who use MA. The present study examines whether MA users with continuous virologic suppression (CS) demonstrate better adherence behaviors (e.g., superior dose timing) than MA users with continuous detectable (CD) viral load.

Methods: Participants were randomized 2:1 to iTAB and to an active comparison condition (CTRL); all participants received daily text messages evaluating MA use and depressed mood for six weeks. Participants randomized to iTAB received personalized ARV reminder texts at a self-identified dose time. CS was defined as achieving a viral load ≤ 50 copies/mL at baseline and final study visits; CD was defined as having a viral load > 50 copies/mL at both visits. ARV adherence was tracked with an electronic monitoring system and calculated as the proportion of doses taken. Dose timing was calculated as the difference between actual and intended dose time. Perceived medication management efficacy was assessed with the Beliefs Related to Medications Survey. Mann-Whitney tests were conducted to examine group differences on overall ARV adherence and dose timing.

Results: Among study participants, 45 achieved CS (iTAB: $n=31$, CTRL: $n=14$) and 17 had CD (iTAB: $n=10$, CTRL: $n=7$). The proportion of CS participants did not differ by intervention arm ($p>0.05$). While there were no significant differences in adherence rates between iTAB and CTRL ($p>0.05$), CS participants had a greater adherence rate (74.8%) than CD participants (51.2%; $p=0.001$). Concordantly, CS participants had superior dose timing (median of 117 mins from target dose time) compared to CD participants (median of 185 mins from target dose time; $p=0.02$). Compared to CS participants, CD participants reported lower perceived efficacy of medication management ($p=0.02$). Differences in overall adherence rates between CS and CD groups remained statistically significant when controlling for covariates (i.e., education, ethnicity, and medication management efficacy).

Conclusion: A subset of PLWHA who use MA demonstrate adherence behaviors (e.g., superior dose timing) that are associated with CS. Dose timing may be a specific behavior to target in interventions promoting adherence among substance-using populations.

Symposium 14

8:00 AM-9:15 AM

INTIMATE PARTNER VIOLENCE PREDICTS POOR HEALTH, BUT MAYBE HELP IS ON THE WAY?

Andrea D. Clements, PhD¹, Matthew W. Henninger, BA², Emily Rothman, ScD³, Tamara Newton, PhD⁴¹Department of Psychology, East Tennessee State University, Johnson City, TN, TN; ²The Miriam Hospital, Brookfield, CT; ³Boston University, Boston, MA; ⁴University of Louisville, Louisville, KY

Intimate Partner Violence (IPV) is an important public health concern. IPV is both a risk factor for other health conditions such as substance abuse, and is also predicted by lifestyle factors such as divorce. The papers included in this symposium confirm some of these relationships. Henninger, McAdams, Clements, Rothman, and Bailey confirm a suspected relationship between IPV and substance abuse in pregnant women in Southern Appalachia, with opioid use being significantly related to physical IPV. Newton and Patton also confirmed that among women who have experienced multiple marital dissolutions IPV predicted poor physical health. Although not surprising, the studies confirm that IPV is related to health risk behaviors and poor health. The third paper, however, by Clements, Haas, Bastian, and Cyphers, offers hope for beginning to address IPV. They have been developing a trauma informed workforce over the past two years, and have seen a rapid increase in familiarity in trauma informed care (TIC), and agencies have begun to report implementation of TIC practices. Hopefully this increase in the use of TIC will be helpful in alleviating some of the risk factors for IPV as well as IPV itself.

Symposium 14A

ADDRESSING INTIMATE PARTNER VIOLENCE: DEVELOPMENT OF A TRAUMA INFORMED WORKFORCE

Dr. Andrea D. Clements, PhD

Introduction: A trauma informed system of care has been under development in Johnson City, Tennessee since fall 2015, with the goal of developing a trauma informed workforce, which is vital for addressing intimate partner violence. Over 30 separate Trauma Informed Care (TIC) training events, community talks, film showings, and two train-the-trainer sessions have been held in Northeast Tennessee, attended by more than 2000 participants, since in October 2015.

Methods: Online surveys using snowball sampling have been conducted at six month intervals beginning prior to initial training in order to document change over time in familiarity with TIC. Each survey also captured detailed information about trauma-informed care implementation within area organizations, including TIC understanding; client trauma screening; use of trauma assessment data in client interaction; consideration of cultural appropriateness of assessment and treatment; promotion of resilience and protective factors; consideration of trauma and its effects in extended family of clients and in staff; administrative support of trauma-informed approaches in areas of staffing, staff training, assessment, agency self-monitoring, and budgeting; TIC alignment of physical environment; offering opportunities for survivor feedback; and investigation of TIC alignment of referral agencies.

Results: The initial survey (October 2015) yielded 105 responses from multiple occupational areas (law enforcement, education, social work, psychology, higher education, nursing, counseling, probation/parole, faith-based organizations). At that time 42.1% were familiar with TIC. The online survey was repeated using the same email solicitation methodology, with increases in familiarity at each time point (April 2016, 80.4% familiar; October 2016, 84% familiar; April 2017, 86.2% familiar). By the time of the most recent survey in April 2017, only 5.2% indicated they were unfamiliar with TIC, down from 23.6% at the time of the baseline survey. Areas of increased TIC use included: trauma screening and use of findings with clients and monitoring progress toward becoming more trauma-informed. Little or no change has been seen in soliciting survivor feedback, formal measurement of TIC procedures or TIC-focused staffing and budgeting.

Conclusions: This study confirms that TIC understanding and implementation can be increased through community training events.

Symposium 14B

INTIMATE PARTNER VIOLENCE VICTIMIZATION AND OPIOID USE BY PREGNANT WOMEN IN RURAL APPALACHIA: A CROSS-SECTIONAL ANALYSIS

Matthew W. Henninger, BA

Introduction. Intimate partner violence (IPV) and comorbid substance use are substantial and consequential public health problems. The specific subtopic of opioid use by pregnant women and its relationship to IPV victimization and adverse fetal and maternal health outcomes is understudied but critically important. Recent research suggests that 75% of a sample of pregnant women in rural southeastern counties of Appalachia experienced IPV in the past year, and that 98% of the women also engaged in both past year and lifetime illegal opioid use. Cross-sectional studies indicate that pregnant women in rural communities are at increased risk of experiencing IPV and also at increased risk for illicit opioid use compared to urban-residing pregnant women not exposed to violence. Using a bioecological framework for health promotion, the current study examined the bi-directional relationship between IPV and opioid use in a sample of rural Appalachian pregnant women.

Methods. A convenience sample of pregnant women who were enrolled in a smoking cessation research study was used for this analysis. Participants included 530 pregnant smokers and nonsmokers from six prenatal clinics in the Southern Appalachia who were enrolled in the Tennessee Intervention for Pregnant Smokers (TIPS) study. Data were from self-reported assessments and semi-structured interviews on substance use and IPV conducted from the first trimester of pregnancy until 15 months postpartum.

Results. 426 participants (80.4%) reported experiencing IPV in the past year. Using Pearson Chi-Square, we found that IPV victimization was associated with using at least one of five substances (i.e., opioids, marijuana, sedatives, cocaine, amphetamines; $p < .01$). Of those who reported IPV and any drug use, 14% were using opioids illicitly. When IPV was stratified by subtype—physical, sexual, and psychological—we found that physical IPV was associated with opioid use (87.5% of total opioid users experienced physical IPV; $p < .01$), but that sexual and psychological IPV were not.

Conclusions. This study suggests that there is a need for comprehensive and integrative interventions as well as trauma-informed care practices within prenatal and primary care facilities. This research further identifies the feasibility and preliminary efficacy of evidence-based screening mechanisms and behavioral health programs to support rural pregnant women who use substances.

Symposium 14C

DIVORCE AND HEALTH: A ROLE FOR PARTNER VIOLENCE?

Dr. Tamara Newton, PhD

A marital status of divorced versus married is a key social determinant of health. It is associated with elevated risk for poorer health, and this risk increases with multiple marital dissolutions. Health does not suffer for all divorced persons, however, and explaining this heterogeneity is a priority. Intimate partner violence (IPV) history is an overlooked, yet potentially critical, factor in the link between divorce and health: IPV histories are up to five times more common among divorced versus married persons, and IPV exposure has been associated with poorer health. The aim of this cross-sectional study was to begin to address this research gap. Aim 1 was to replicate a newly validated approach to IPV classification that is theoretically grounded, and draws on psychological and physical aspects of IPV to identify four groups: No IPV, coercive controlling violence, situational couple violence, coercive control/no violence. Aim 2 was to determine whether IPV, so classified, explains variation in self-reported health in women with divorce histories. Midlife women ($N = 192$; median of 8.58 years post-divorce) completed validated self-report measures of direct violence and coercive control in prior marriages, and current mental and physical health. Analyses were conducted separately for women with one ($n = 73$) or multiple ($n = 119$) divorces. In both subsamples, IPV classification was related to theoretically associated features (i.e., frequency of violence and IPA-related injury, number of severe acts of violence) as predicted, replicating the original validation study ($ps < .01$). In women with one divorce, there were no statistically significant associations between the IPV classification and self-reported mental ($p = 0.33$) or physical health ($p = 0.08$). In women with multiple divorces, there were statistically significant associations between the IPV classification and physical health ($p = 0.007$), but not mental health ($p = 0.20$). Specifically, women with histories of situational couple violence or coercive controlling violence reported poorer physical health than women without IPV histories ($ps < .008$), with medium effects. Among midlife women with divorce histories, attention to IPV helps identify those with poorer physical health. This lays the groundwork for testing the role of IPV in connections between marital status and health more broadly.

Symposium 15

8:00 AM-9:15 AM

HEARING HEALTH: OVERCOMING UBIQUITOUS NOISE & STIGMA, OPTIMIZING CARE, AND IMPROVING QUALITY OF LIFE

Amy Boudin-George, Au.D.¹, Tanisha L. Hammill, PhD, MPH², M. Patrick Feeney, Ph.D.³, William J. Murphy, Ph.D.⁴

¹DOD Hearing Center of Excellence, JBSA Lackland, TX; ²DoD Hearing Center of Excellence, New Braunfels, TX; ³VA Portland Health Care System, West Linn, OR; ⁴National Institute for Occupational Safety and Health (NIOSH)/Centers for Disease Control (CDC), Cincinnati, OH

Hearing loss and tinnitus were the most prevalent service connected disabilities for Veterans, according to the Fiscal Year 2016 Veterans Benefits Administration Report. While these disorders are largely preventable, we continue to see the cases rise, rather than decline in Veterans. Further, sensorineural hearing loss tends to be progressive and compounded by external factors, including the presence of diabetes, administration of ototoxic medications (including anti-neoplastic agents), and, most frequently, exposure to excessive occupational and/or recreational noise. The effects of hearing loss and tinnitus on quality of life are substantial when in isolation, having social and cognitive effects that can create significant detriments in the work-place and in relationships. When present as a co-morbidity, such as with diabetes, depression, or secondary to aggressive treatment for cancer, the effects of hearing loss and tinnitus are farther-reaching. Patients can have difficulty following conversations with providers, which can create issues understanding and adhering to treatment care plans. The aim of this symposium is to introduce Hearing Health to the SBM, posed as a new focal topic for adoption by the community at large. This symposium will provide a framework for discussion of the effects of auditory/vestibular disorders on patient quality of life and, potentially, on research outcomes by characterizing the populations affected, the associated social/emotional issues, and the work being done to mitigate and rehabilitate these disorders. Representatives from the Department of Defense Hearing Center of Excellence, the VA National Center for Rehabilitative Auditory Research, the National Institutes of Health - National Institute on Deafness and Communication Disorders, and the National Institute for Occupational Safety and Health will be presenting. Each presenter will discuss the research being conducted within their respective purview that drives policy changes and best practice development and, when applicable, their accompanying implementation processes. All talks will explore and highlight ways in which current Hearing Health approaches overlap with existing primary Society of Behavioral Medicine (SBM) topic lanes and expertise.

Symposium 15A

HEARING HEALTH DISORDERS AS A GLOBAL HEALTH ISSUE

Dr. Amy Boudin-George, Au.D.

This presentation will serve as an introduction to hearing health as a global health issue. It will bring to light the need for collaborative efforts to drive behavioral change for the prevention and early identification of hearing health disorders and successful utilization of rehabilitative services, especially for those who experience the effects of a hearing loss that has not yet been diagnosed. This presentation will cover the scope, incidence and prevalence of hearing health disorders, with a view of the epidemiological challenges presented by incomplete data, and the approaches that have been used to overcome these challenges. It will present data from the World Health Organization, Department of Defense (DOD), Department of Veterans Affairs (VA), and the National Health and Nutrition Examination Surveys.

This presentation will provide an overview of the common causes, types, and degrees of hearing loss, with information on the implications of hearing loss severity on child development, social/emotional function, and career development. It will cover conditions that commonly occur as comorbidities with hearing loss and the synergistic effects of these conditions. Mental health diagnoses such as depression, anxiety, and dementia can be confounded by hearing loss, as it may impede a patient's ability to communicate effectively with others when it is left untreated. Aggressive treatments for cancer or infectious diseases can include medications that are potentially ototoxic; the identification, mitigation, and/or rehabilitation of any resulting hearing loss is important for the preservation of the patient's ability to communicate with treatment care providers, as well as post-treatment quality of life. Similar statements can be made regarding diabetes, as sensorineural hearing loss is a subset of the associated neuropathy; adherence to treatment care plans and preservation of quality of life relies on successful communication. Tinnitus, the perception of sound when no actual external noise is present, commonly described as ringing in the ears, is a common symptom associated with other health issues. Tinnitus associated with noise-induced hearing loss is largely preventable and can affect a person's quality of life. This presentation will cover types of tinnitus and their social/emotional effects. Cross-organizational efforts to address the prevention and rehabilitation of hearing loss and tinnitus are ongoing; this will introduce these collaborations to set the tone for presentations that follow.

Symposium 15B

HOW THE DEFENSE HEARING CENTER OF EXCELLENCE (HCE) IS RISING TO MEET THE HEARING HEALTH CHALLENGE

Dr. Tanisha L. Hammill, PhD, MPH

Noise-induced hearing loss is frequently associated with military service, primarily due to Service member exposure to hazardous noise levels in operational and training settings common to military life. In light of this inherent risk and common injury, the DOD has implemented many programs aimed at the prevention, mitigation, diagnosis, treatment, and rehabilitation of hearing loss among its Service members. These efforts are varied and require a multitude of approaches and disciplines to develop, disseminate, implement, and evaluate.

This talk will provide the overview of hearing health within the context of the U.S. military environment, specifically highlighting the perspective and initiatives of the DOD Hearing Center of Excellence (HCE). We will discuss areas of interest to the SBM community, including translational planning and execution in the DOD. Specific projects currently underway in the HCE include a Comprehensive Hearing Health Program (CHHP) which aims to positively change knowledge, attitudes, beliefs, and behaviors regarding hearing and hearing health among Service members and their family members Veterans,, and healthcare providers. Additionally, the HCE is focused on identifying gaps in and developing solutions for clinical best practices, as well as creating and executing well-designed dissemination, implementation, and evaluation plans to bring best practices into the clinic or the operational environment as appropriate. Challenges in translational work unique to the DOD, and approaches to mitigate those challenges, will be discussed.

New directions for hearing health relevant to current SBM domains, including policy development, will conclude the talk, including descriptions of DOD Instruction (policy) development, coordination, approval, and impact, as well as HCE's plethora of inter-agency, inter-departmental, and international collaborations, alliances, and partnerships within and external to the DOD including the VA, NIH and NATO partner nations.

Symposium 15C

RESEARCH AT THE VA RR&D NATIONAL CENTER FOR REHABILITATIVE AUDITORY RESEARCH (NCRAR)

Dr. M. Patrick Feeney, Ph.D.

This presentation will discuss several ongoing research programs at the VA Rehabilitation Research and Development, National Center for Rehabilitative Auditory Research (NCRAR) in Portland, OR. Over a long career at the NCRAR, James Henry, Ph.D. developed Progressive Tinnitus Management, which has been adopted for use in tinnitus treatment in VA audiology clinics. This management scheme will be discussed along with several recent clinical trials using this method. We will also review Dr. Henry's collaborative study with the DoD Hearing Center of Excellence on the effects of noise exposure on hearing and tinnitus in Veterans. Studies of auditory processing in Veterans have shown that those exposed to high-intensity blasts are more likely to experience problems with central auditory processing. Studies by Erick Gallun, Ph.D. and colleagues have examined short and long-term effects of blast exposure on central auditory processing, and new strategies are under way for bringing assessment for these disorders into the clinic using tablet computing. Finally, a phenomenon called "hidden hearing loss" is being explored by Naomi Bramhall, Ph.D. Individuals who have been exposed to high noise levels may have normal thresholds, but exhibit difficulty hearing speech in noisy backgrounds, which is thought, based on animal studies, to be the result of damage to auditory nerve synapses. Dr. Bramhall has found a relationship between noise exposure and speech-in-noise deficits in Veterans with normal hearing thresholds and exposure to high noise levels who also exhibit deficits in brainstem auditory evoked potentials.

Symposium 15D

OVERVIEW OF THE NATIONAL INSTITUTE FOR OCCUPATIONAL SAFETY AND HEALTH HEARING LOSS PREVENTION RESEARCH PROGRAM

Dr. William J. Murphy, Ph.D.

The National Institute for Occupational Safety and Health (NIOSH) Hearing Loss Prevention Research program conducts research in surveillance, engineering noise controls, personal protective equipment and best practices and other risk factors for hearing loss prevention. Our efforts in hearing loss surveillance have led to the development of partnership with hearing conservation providers to provide hearing screening data from a wide range of industries to better inform NIOSH about the risks associated with different occupations. Engineering noise control research is largely concentrated on the mining, manufacturing and constructions sectors. The development of new controls leads to partnerships with industrial equipment manufacturers and reduces noise exposures for workers. Personal protective equipment presents many challenges with respect to assessing the performance of new products and technologies (e.g. active noise cancellation or level dependent protectors). As well, our research in hearing protection fit-testing systems informs users about how best to assure their workers are adequately protected. NIOSH provides authoritative recommendations to regulatory agencies (e.g. OSHA, MSHA and EPA) as well as providing best practices to implement hearing loss prevention strategies to safety and health professionals. Finally NIOSH hearing loss prevention research investigates other risk factors such as impulse noise or mixed exposures to noise and ototoxic substances. Our mission is to deliver on the promise of occupational safety and health

Symposium 16

8:00 AM-9:15 AM

EXTENDING OUR REACH: INTEGRATING PSYCHOSOCIAL FACTORS INTO ORTHOPEDIC SURGICAL PRACTICES

Emily Zale, Ph.D.¹, Ana-Maria Vranceanu, Ph.D.¹, Jessica Magidson, Ph.D.², David Ring, M.D., Ph.D.³

¹Massachusetts General Hospital/Harvard Medical School, Boston, MA; ²Massachusetts General Hospital/ Harvard Medical School; University of Maryland, College Park, Boston, MA; ³Dell Medical School—The University of Texas at Austin, Austin, TX

Recently, there has been an emerging emphasis on integrated healthcare that focuses on comprehensively assessing and addressing the biological, psychological and social needs of a patient. In parallel, medical care is undergoing a shift in priorities towards selective hypothesis driven diagnostic tests, caution around medical procedures, and multidisciplinary treatment to optimize resiliency and quality of life. Integrated care models improve patient outcomes, are cost effective, and decrease healthcare utilization over time. Orthopedic surgical practices treat patients across the continuum of health (e.g., acute injury, self-limiting problems, persistent illness, or aspects of normal human aging), and are in an optimal position to evolve healthcare by spearheading the integration of techniques to address psychosocial factors. This symposium presents findings from research that seeks to understand and address psychosocial factors in orthopedic surgical setting. Taken together, the studies presented in this symposium indicate that patients are amenable to psychosocial interventions in orthopedic practices and that such interventions can improve patient outcomes. In the first presentation, Dr. Magidson will present work that identifies patient beliefs (N = 118) about prescription opioid medications and opioid prescribing policies in orthopedic surgery. In the second presentation, Dr. Zale will present results of a randomized controlled trial of a brief mindfulness intervention (N = 125) that can easily be implemented within busy orthopedic settings. In the third presentation, Dr. Vranceanu will present results of a pilot randomized controlled trial (N = 50) of a psychosocial skills-based intervention to optimize recovery after orthopedic injury that is delivered via live videoconferencing. Dr. Ring will discuss common barriers to addressing psychosocial factors in orthopedic practices, such as the traditional mind-body dichotomy, stigma, and patient-provider communication. His discussion will note the clinical implications of the three presented studies, including the ways in which they address current barriers to integrated care, and provide insights for future research directions and policy recommendations.

Symposium 16A

A BRIEF MINDFULNESS EXERCISE IMPROVES ORTHOPEDIC SURGERY PATIENTS' PAIN AND DISTRESS: RESULTS OF A RANDOMIZED CONTROLLED TRIAL

Dr. Emily Zale, Ph.D.

Mindfulness-based interventions teach patients to change their relationship with unpleasant thoughts, feelings, and bodily sensations by allowing those experiences to be held in nonjudgemental awareness rather than dictate behaviors. Mindfulness-based interventions are a promising pain treatment, and have been shown to reduce pain intensity and psychological distress in patients with chronic pain. However, most mindfulness-based interventions cannot be feasibly integrated into busy orthopaedic surgical practices because they are resource-intensive, lengthy, and costly. It is not known whether very brief mindfulness interventions affect pain or distress among orthopedic patients. Patients (N = 125, 50% Female, M age = 55 ± 15) presenting to an orthopedic surgery practice were randomized to receive a 60-second mindfulness-based video exercise or an attention placebo control (educational pamphlet about stress). The study was completed in a private exam room during the normal wait time to see the surgeon, and patients completed measures of pain intensity, state anxiety symptoms, and psychological distress (emotion thermometers measuring anxiety, anger, and depression) pre- and post-intervention. The mindfulness intervention consisted of guided imagery of a distressing thought, generated by the patient, floating away on a star. After controlling for baseline scores, ANCOVA revealed that the mindfulness-based video exercise improved pain intensity, relative to attention placebo control (p = 0.008). Participants who received the mindfulness-based intervention also demonstrated greater improvement all measures of psychosocial distress, as measured by state anxiety symptoms and emotional thermometers (anger, depression, anxiety), relative to participants who received the control intervention (all ps < 0.024). Taken together, results indicate that a very brief, 60-second mindfulness-based video exercise, which addresses multiple barriers to providing mindfulness-based interventions in busy orthopedic practices (e.g., time, cost, the need for trained providers), can be useful in improving momentary pain and distress among patients.

Symposium 16B

THE TOOLKIT FOR OPTIMAL RECOVERY AFTER INJURY; A PILOT RANDOMIZED CONTROLLED TRIAL VIA SECURE LIVE VIDEO

Dr. Ana-Maria Vranceanu, Ph.D.

Musculoskeletal injuries are the leading cause of hospital admissions for adults, and often lead to long term disability and chronic pain. Our prior work has identified that catastrophic thinking about pain and pain anxiety at 1–2 months after injury (e.g., acute phase) predict pain intensity and disability 5–8 months later (e.g., chronic phase), after controlling for injury severity. We developed the “Toolkit for optimal recovery,” a 4-session program delivered via live video to patients with orthopedic injuries at risk for poor recovery and chronic pain. The Toolkit teaches coping skills (e.g., activity pacing, deep breathing, acceptance and adaptive thinking) using simple nonstigmatizing language.

We conducted a pilot RCT of the Toolkit against usual care. The primary aim was to determine the feasibility and acceptability of the Toolkit. The secondary aim was to determine the preliminary effect of the Toolkit in improving physical function and pain (primary quantitative outcomes) as well as catastrophic thinking about pain, pain anxiety, depressive symptoms and post traumatic stress symptoms (secondary quantitative outcomes) compared to usual care.

Patients were recruited from the Orthopedic Trauma Unit of a major medical center. Out of 101 participants screened, 50 (50%) were depicted as at risk (e.g., scores above median split on catastrophic thinking about pain or pain anxiety), met inclusionary/exclusionary criteria and were randomized (25/arm). Patients had a mean age of 51 and were women in majority (62%), white (80%), employed (82%), without a work related injury (91%) and married (52%). Of these 42 completed the intervention and post test (84%). Satisfaction with the intervention was high ($M=5$, $SD=0$, 1–5 scale). Analyses of covariance showed that patients in the Toolkit improved significantly more from baseline to post intervention on pain ($p=.08$; partial eta squared $.20$), and physical function ($p=.004$; partial eta squared $.31$) as well as all secondary outcome variables ($p=.001-.02$; partial eta squared $.20-.50$).

Results suggest that patients are receptive to skills building when delivered via secure live video. Results of ANCOVA analyses support a fully powered efficacy RCT.

Symposium 16C

PATIENT BELIEFS ABOUT PRESCRIPTION OPIOIDS AND OPIOID PRESCRIBING POLICIES IN ORTHOPAEDIC SURGERY

Dr. Jessica Magidson, Ph.D.

The United States consumes 80% of the global opioid supply, misuse of prescription opioid medications accounts for more than half (61%) of drug overdose deaths, and opioid-related emergency room visits have increased 99% in the past decade. Orthopaedic surgeons are ranked first in opioid prescribing among all surgical specialties, but represent only 31% of practicing surgeons. Prescription opioid use after orthopaedic surgery is associated with greater pain, poorer physical functioning, and poorer satisfaction with pain relief. The development and implementation of prescribing regulations designed to reduce the number and quantity of opioid pills that are available for misuse and diversion has been identified as a necessary step in confronting the opioid epidemic. Therefore, we sought to assess beliefs of opioid medications and prescribing policies among patients ($N = 118$, Median age = 49, 50% Female) presenting to an orthopaedic surgery practice. The majority of patients (64%) had at least one opioid prescription documented in their medical record and 72% self-reported lifetime prescription opioid use. Results suggest that most patients hold accurate beliefs about opioids (e.g., 80% are aware of addictive properties) and would support opioid prescribing policies that aim to decrease opioid misuse and diversion. However, a small but important number of patients have erroneous beliefs about prescription opioids (e.g., 28% believe opioids work well for long term pain) or believe that doctors should prescribe “as much medication as the patient needs” (7%). The vast majority (98%) of patients want to receive more education about opioids and believe that information about prescription opioids should be provided to all patients in orthopaedic practices. Taken together, results suggest that patients are amenable to opioid prescribing policies that seek to limit opioid use and promote alternative pain relief strategies. Future research should test the effects of opioid prescribing policies and non-opioid pain relief strategies on trends in opioid prescribing and opioid use.

Symposium 17

8:00 AM-9:15 AM

PASSIVE SENSING OF EATING BEHAVIORS IN THE WILD: CURRENT STATE OF THE ART AND IMPLICATIONS FOR OBESITY RESEARCH

Nabil Alshurafa, PhD¹, Angela F. Pfammatter, PhD², Edward Sazonov, PhD³, Bonnie Spring, PhD¹

¹Northwestern University, Chicago, IL; ²Northwestern University Feinberg School of Medicine, Chicago, IL; ³The University of Alabama, Tuscaloosa, AL

Eating behaviors contribute to a variety of health outcomes such as cardiovascular disease, diabetes, cancer, and obesity. To date, the vast majority of behavioral medicine research has relied on measurements of eating that are inherently flawed. Daily self-monitoring is often burdensome, incomplete, and inaccurate. 24 hour recalls, considered the gold standard in dietary intake assessment, is burdensome, often limited in accuracy, and only captures a snapshot in time of what was consumed. Further, using today’s technology, behavioral scientists are increasingly able to intervene on individuals just-in-time, when the person most needs or would most benefit from support. However, with both popular methods of dietary intake, the measures are retrospective and not assessed while eating is occurring, limiting the potential of using just in time interventions. Other behaviors such as physical activity have benefitted from passive sensing technologies to overcome this barrier. Passive sensing, detection, and prediction of eating has the potential to decrease biased reports of eating, gather real time information about eating, and predict problematic eating behaviors. In this symposium, we seek to review the state of the science of passive sensing of eating in the first presentation. We will then move on to discuss how to build effective machine learning models to detect eating behavior in the wild. In our third presentation, we will discuss the challenges of capturing naturally occurring behavior in the wild through passive sensing and ways to address these challenges. Finally, we will review the implications of moving this aspect of science forward as it pertains to prevention and treatment of problematic eating, particularly among populations with obesity.

Symposium 17A

ANALYTICS OF EATING: HOW TO BUILD MACHINE LEARNING MODELS OF EATING IN THE WILD

Prof. Nabil Alshurafa, PhD

Wearable sensors combined with computer science machine learning methods have given rise to passive sensing, making it feasible to validly infer in real time physical features of psychological states, such as stress, and appetitive behaviors, such as overeating. The advantage of these real time passive sensing capabilities is their ability to use machine learning models to measure objectively (minimizing self-report bias), precisely (with high sensitivity and specificity), passively (without burden or disruption), and dynamically (detecting rapidly changing states). However, to succeed in passively sensing, people must be willing to wear them, and sensing algorithms must be able to sense eating in the real world. Despite the continuous growth in the wearable market, adherence continues to be impacted by concerns of user privacy, social stigma associated with wearing eating-detection based sensors, and user-comfort. Understanding these concerns will help the wearable community and researchers ultimately improve our ability to design wearables that mitigate these effects, increasing adherence to passive sensing and ultimately paving the way towards personalized behavioral medicine. This talk will present the process of building machine learning models to detect eating in the wild. A study will also be presented aimed at understanding the factors that influence adherence to wearing sensors used to detect eating-habits including a wrist-worn, neck-worn sensor and a camera to validate ground truth in different environments and situations.

Symposium 17B

FROM SENSING TO THEORY: IMPLICATIONS OF CAPTURING NATURALLY OCCURRING BEHAVIORS IN THE WILD

Dr. Angela F. Pfammatter, PhD

Passive sensing technologies have advanced, making possible objective measurement of behaviors once left to be measured solely by self-report. The objective, in the field measurement may lead to deeper insights into human behavior, allowing for progress to be made in our ever evolving behavioral theories. Though passive sensing of behavior has garnered much attention in behavioral medicine, challenges are still pervasive and researchers must heed caution. First, our research has demonstrated significant changes in participant behavior while wearing devices that may not dissipate over time, casting doubt on the hypothesis that participants habituate or forget that they are being watched. Second, we put forth a hybrid theoretical approach to explaining participant behavior in the field while wearing devices that has the potential to guide sensor design to mitigate unintended behavioral changes. Third, findings from traditional behavioral interventions do not always replicate in the digital space, but with more intensive data availability, researchers can now innovate to improve behavioral theories for application in mHealth interventions. Specifically, we have found that while self-monitoring continues to predict behavior change outcomes during mHealth interventions, machine learning approaches have revealed that there might be several mediators to that relationship. Time spent entering data, time spent reviewing progress, and the pattern of use over a week might better predict health behavior changes. Put together, findings from acceptability of sensor wearing, explanatory constructs for unintended changes in user behavior, and insights into effective patterns of mHealth intervention engagement can better inform sensor enabled research to improve accuracy of measurement and improve the effects of our behavioral interventions in the field.

Symposium 17C

WEARABLE SENSORS FOR DETECTION AND CHARACTERIZATION OF FOOD INTAKE IN THE WILD

Dr. Edward Sazonov, PhD

Food intake provides energy and nutrients to sustain human life. Studying the ingestive behavior of individuals is of particular interest for understanding and treatment of medical conditions strongly associated with food intake, such as obesity and eating disorders. Traditionally, ingestive behavior in humans has been assessed through self-monitoring of food intake. However, this approach is time-consuming and suffers from the observation and misreporting effects. Wearable sensors present a compelling alternative to overcome the limitations of self-reporting methods. These sensors can potentially provide more objective measurements of food intake by monitoring behavioral and physiological phenomena related to one or more stages of the food consumption process: hand-to-mouth gestures, bites, chewing or swallowing. Specialized signal processing and pattern recognition methodologies applied to the sensor signals are used to automatically detect and characterize each intake episodes. Timing, duration of the meals, the mass and volume, caloric and nutritional content of ingested food, and the rate of ingestion could potentially be estimated from sensor data. Furthermore, the sensor-derived measurements of ingestive behavior may inform tailored, real-time interventions aimed at modification of food intake. This talk presents an overview of the wearable sensors and accompanying methodologies that have been proposed for monitoring and modifying ingestive behavior in humans.

Paper Session 1: Advances in Cancer Interventions Across the Cancer Continuum

10:45 AM-11:00 AM

RESULTS FROM THE MOVING FORWARD WEIGHT LOSS INTERVENTION TRIAL WITH AFRICAN-AMERICAN BREAST CANCER SURVIVORS

Melinda Stolley, PhD¹, Patricia Sheean, PhD, RD², Lisa Sharp, PhD³, Alexis Visotcky, MS¹

¹Medical College of Wisconsin, Milwaukee, WI; ²Loyola University Chicago, Maywood, IL; ³University of Illinois at Chicago, Chicago, IL

Purpose. Cancer specific and overall mortality rates are higher among African-American women with breast cancer. Many factors drive these disparities among which obesity and health behaviors may be important, yet modifiable contributors. Obesity is common among African-American women, yet until recently, few weight loss intervention studies targeted African American breast cancer survivors. Weight loss trials with non-Hispanic white women positively impact weight, behavior, biomarkers and psychosocial outcomes. This study examined the effects of Moving Forward, a weight loss intervention for African-American breast cancer survivors (AABCS) on weight, behavior and quality of life.

Methods. Early stage (I-III) AABCS were randomized to a 6-month community-based interventionist guided (n=125) or self-guided (n=121) weight loss program supporting behavioral changes to promote weight loss. Weight, behavioral and PROMIS-10 data were collected at baseline, post-intervention (6 months) and follow-up (12-months). Descriptive statistics and mixed models analyses assessed differences between groups over time.

Results. Mean \pm SD age and BMI were 57.5 ± 10.1 years and 36.1 ± 6.2 kg/m² respectively and 82% had Stage II or III breast cancer. Both groups lost weight. Mean and % weight loss were greater in the guided versus self-guided group (-3.49 (0.39) vs -1.27 (0.40) P<.0001; 3.6% (5.1) vs 1.4% (3.6). Significant post-intervention between group differences were also noted for vigorous physical activity, fiber and added sugar. In addition, the interventionist guided group showed significant improvements in mental and physical functioning compared to the self-guided group (3.0 (6.4) vs 0.6 (6.1)).

Conclusion. The study supports the efficacy of a community-based interventionist guided weight loss program targeting AABCS. Although mean weight loss did not reach the targeted 5%, the mean loss of >3% at 6 months is associated with improved health outcomes. Affordable, accessible health promotion programs represent a critical resource for AABCS.

SURVEILLANCE MAMMOGRAPHY ADHERENCE AMONG AFRICAN AMERICAN WOMEN WITH BREAST CANCER: A RANDOMIZED CONTROLLED TRIAL

Caitlin Laughney, MSW¹, Maria Pérez, MA², Matthew Kreuter, PhD, MPH³, Julie Margenthaler, MD², Graham Colditz, MD, DrPH², Donna B. Jeffe, PhD²

¹Washington University in St. Louis, Mercer Island, WA; ²Washington University School of Medicine, St. Louis, MO; ³Washington University in St. Louis, St. Louis, MO

Surveillance mammography has important breast cancer survival benefits, yet African American survivors have lower rates of use compared with white survivors. A novel, interactive, computer-based cancer-communication intervention using African American survivor story videos was created for a randomized control trial. African American women diagnosed with first primary breast cancer (stages 0–3) were randomized to either intervention (n=107) or standard care arms (n=120). Patients completed interviews a mean 6 days from surgical post-op visit or start of neoadjuvant therapy (before intervention) and again one month later (after intervention). Two more 2-week video exposures followed at 6 and 12 months after definitive surgical treatment, with follow-up interviews a mean 6.5, 12.7 and 24.5 months later. Demographic, psychosocial, and clinical data were collected by interview and from medical records, and surveillance mammography data were obtained from imaging facilities; adherence was defined as receipt of a mammogram 1 year and 2 years after definitive surgical treatment in eligible patients (i.e., no bilateral mastectomy). Two logistic regression models tested the independent effects of several variables on 1- and 2-year surveillance-mammography adherence. Most eligible patients in both arms received surveillance mammograms at year 1 (99/114 standard care, 89/95 intervention) and year 2 (96/112 standard care, 84/94 intervention). Patients in the intervention arm (vs. standard care) were more likely to receive a 1-year mammogram (odds ratio [OR] 5.77, 95% confidence interval [CI] 1.04–31.97); patients who received single mastectomy (vs. lumpectomy) were less likely to be adherent (OR 0.05, 95% CI 0.003–0.74). The only predictor of adherence to surveillance mammography at 2 years was adherence at 1 year (OR 104.56, CI 14.74–741.83). High rates of adherence to surveillance mammography were observed. Our intervention, which included videos of African American breast cancer survivors describing benefits of mammography, was associated with adherence to the 1-year surveillance mammogram. We interpret our results cautiously as the CIs were wide, likely due to small numbers of non-adherent patients. Other unmeasured variables may be associated with adherence to surveillance mammography in African American breast cancer patients. Further investigation of the reasons for the lower likelihood of surveillance among patients who received a mastectomy is warranted.

DIFFUSION OF INNOVATION? UPTAKE OF THE ENGLISH BOWEL CANCER SCREENING PROGRAMME: AN UPDATE AFTER 5 YEARS OF FULL-ROLL OUT

Yasemin Hirst, PhD¹, Sandro Tiziano Stoffel, N/A², Gianluca Baio, PhD³, Christian von Wagner, PhD²

¹University College London, London, England, United Kingdom; ²UCL, London, England, United Kingdom; ³University College London, London, N/A, United Kingdom

Background: *Diffusion of innovation (DOI)* theory suggests that the rate with which new technologies are adopted depends on the characteristics of cohorts and will happen over time through social interactions. A previous analysis of the initial roll-out of the English Bowel (Colorectal) Cancer Screening programme (which invites all adults 60–74 to complete a guaiac-based fecal occult blood test every two years), during 2006 and 2009, found uptake to be low (54%) and socially graded by area-level deprivation, ethnic diversity and gender. The current analysis uses data from 2010 (the first year the programme was fully rolled out) to 2015 to test whether uptake is increasing and becoming less socially graded over time.

Methods: Area-level uptake of 4.4 million first-time invitees stratified by gender and year of first invitation (2010–2015) at the postcode district level was generated using the National Bowel Cancer Screening System. Data were limited to first-time invitees aged 60–64. Binomial regression tested for variations in uptake by year of invitation, gender, region, area-based socioeconomic deprivation and area-based ethnic diversity.

Results: Overall, the first-time colorectal cancer screening uptake across six years was 52% (n=2,285,996/4,423,734) with a decline between 2010 and 2015 (53%, 54%, 52%, 50%, 49%, 49% respectively). Uptake continued to be socially graded by area-level socioeconomic deprivation quintiles (41% vs 57%), area-based ethnic diversity (39% vs 57%) and between men and women (47% vs 56%). Multivariate analysis demonstrated effects of year, deprivation, ethnicity and gender on uptake where the effect of deprivation was more pronounced in women in most deprived area quintile (47% vs 40% uptake in the same quintile by men) than least deprived area quintile (62% vs 52% uptake in the same quintile by men). The small temporal decline was observed across all sociodemographic predictors; however, the difference was larger among men, most affluent and least ethnically diverse areas while uptake of the most deprived and ethnically diverse areas remained stable.

Discussion: We did not find evidence of any ‘diffusion’ of CRC screening since its initial launch 10 years ago. Data from the previous 5 years implies that there are structural, and motivational barriers, which are unlikely to be resolved by ‘word of mouth’. There is also a worrying negative trend in uptake particularly among more affluent groups. As it stands, the programme is unlikely to realise its full public health benefits and will ultimately widen inequalities in CRC outcomes.

TRUENTH LIFESTYLE MANAGEMENT: FEASIBILITY OF COMMUNITY PHYSICAL ACTIVITY PROGRAMS FOR PROSTATE CANCER SURVIVORS IN CANADA

Nicole Culos-Reed, PhD¹, Michael Dew, MSC, CSEP-CEP², Ashley Zahavich, RN, MSc, CSEP-CPT³, Margaret McNeely, PhD⁴, Kristin Campbell, P.T., MSc, Ph.D⁵, Liam Kronlund, MSc(c)², Natalia Albinati, MSc(c)², David Michael Langelier, MD, BSc.⁶, Daniel Santa Mina, PhD⁷

¹Faculty of Kinesiology, University of Calgary, Calgary, AB, Canada; ²University of Calgary Faculty of Kinesiology, Calgary, AB, Canada; ³Kinesic Sport Lab Halifax, NS, Halifax, NS, Canada; ⁴University of Alberta, Edmonton, AB, Canada; ⁵Faculty of Medicine, Vancouver, BC, Canada; ⁶Department of Physiatry/Division of Clinical Neurosciences/University of Calgary, Calgary, AB, Canada; ⁷University of Toronto, Toronto, ON, Canada

Introduction: TrueNTH Lifestyle Management (LM) delivers community-based physical activity (PA) programs to improve the quality of life (QOL) for prostate cancer survivors. Programs were implemented at wellness centres and in academic/clinical institutions in 10 cities across Canada. The current project assessed the feasibility and participant benefits from the 12-week group-based fitness and/or yoga classes designed specifically to address prostate cancer treatment-related side effects.

Methods: Flexible protocols allowed each site to implement a sustainable program that could be adapted according to the setting and available expertise. Instructors were trained in prostate cancer and exercise and provided with structured class plans. Assessments occurred pre and post-intervention, including fitness (i.e. CSEP-PATH, Senior Fitness Test), PA levels (Godin Leisure Time Exercise Questionnaire (GLTEQ)), and patient-reported outcomes (PROs) for QOL and well-being (FACT-P, EQ-5D). Assessments were facilitated by local exercise physiologists.

Results: The mean age was 67 years with 11% on active surveillance, 23% on active treatment, and 66% completed treatment. Treatments included surgery (66%), radiation (32%), hormone (27%), and chemotherapy (5%). Among $n=185$ participants, 69% completed fitness assessments at both time points. Survey measures collected via online methods had only a 12% completion rate while those collected in-person had a 57% completion rate. RM ANOVA's to examine pre to post-program changes showed significant improvements in fitness measures (body composition (BMI, $p=.01$; waist circumference, $p=.02$)), functional aerobic capacity (6-minute walk test, $p=.00$), flexibility (sit and reach, $p=.00$), dynamic balance (8-foot timed-up-and-go, $p=.00$), muscular endurance (push-ups, $p=.00$; 30-second sit-to-stand, $p=.00$); and overall moderate/strenuous PA levels (GLTEQ, $p=.00$). Initially sedentary men reached ACSM guidelines for PA at 12-weeks (GLTEQ, $p=.00$). Trends were seen towards improvements in PROs of well-being and QOL but were non-significant.

Conclusions: The findings from this initial implementation of a national scale initiative indicate that community-based programs are feasible and can be effective on physical fitness outcomes. Future work will examine the host of patient-reported outcomes, as well as longer-term follow up. The goal is to implement sustainable clinic-to-community models for PA programming in prostate cancer care in Canada.

CAN AN EHEALTH GAMIFIED INTERVENTION MOVE UNDERGRADS FROM “ICK” TO “CLICK” SO THEY DECIDE TO BE AN ORGAN DONOR ON DRIVER’S LICENSE?

Cheryl Lynn Albright, PhD, MPH¹, Kara Saiki, BS, MPH¹, Lynne R. Wilkens, DrPH², Ashley M. Biddle, BA, MA, PhD³, Kami White, MPH¹, Misty Pacheco, MHA, DrPH⁴, Pamela Smith, APRN, RNFA, FNP-BC⁵

¹University of Hawaii, Honolulu, HI; ²University of Hawaii Cancer Center, Honolulu, HI; ³University of Hawaii, Leeward Community College, Pearl City, HI; ⁴University of Hawaii at Hilo, Hilo, HI; ⁵Hawaii Pacific University, Honolulu, HI

The iDecide Hawaii Project was a multiple baseline, group randomized trial designed to educate, engage, and normalize the choice to be a Designated Organ Donor (DOD) on Department of Motor Vehicles issued drivers' licenses of undergraduates (in most cases the “adult” formatted license for those 21+ years of age). The eHealth intervention included online contests for individual students (e.g., Instagram pictures, YouTube videos) and pledge contests for student organizations with cash prizes for all contests. The website's home page had links based on a visitors' stage of change for deceased organ donation (i.e., “I'm uncomfortable”, “I'm interested”, and an Action stage: “I want to win”). From 2014–2016, across 3 university sites, 20 online surveys were conducted consisting of 9 baselines ($N=2,138$ surveys) and 11 post-tests ($N=2,689$ surveys; Mean age = 22yrs, 75% F, 63% Asian, Native Hawaiian, or Pacific Islander, 31% not religious). There were a total of 63 online contests resulting in 3,742 entrants with 237 winners. Contest entrants were not required to complete a survey and survey respondents were not specifically encouraged to enter contests. Overall, there was no evidence of a pre-post cross-sectional increase in the percentage of students who reported being a DOD after adjusting for age, sex, ethnicity, religion, site, and semester (e.g., Fall, 2016). However, in the longitudinal sample of those who provided a survey pre and post intervention, the percent of students who were a DOD increased from 50.8% at pretest to 52.4% at post ($p = 0.02$). A greater pre-post increase in the percentage of students who were DODs was found (pretest = 37.6% to post = 42.6%, $p < 0.0001$) among respondents who had a probability of being a DOD of less than 50% based on significant host factors (predicted from regression of pretest DOD status on age, sex, ethnicity, college year, religion, and tuition source, to identify those possibly-less likely to be a donor at pretest). Engagement in the gamified eHealth intervention varied by site and type of contest; but, thousands of undergraduates entered contests, each having an organ donation-related theme (e.g., go green and recycle yourself for the “human” environment). Thus, our eHealth intervention engaged undergraduates in a topic that can be unappealing (e.g., “ick” factor) and significantly increased the proportion of DODs following a campus-wide gamified intervention. Examples of contest winners in Instagram and YouTube contests will be presented.

IDENTIFYING DYNAMIC DAILY USER ENGAGEMENT WITH
A MOBILE CESSATION APP USING MULTILEVEL LATENT CLASS
ANALYSIS

Christian J. Cerrada, BS, Jimi Huh, PhD
 University of Southern California, Los Angeles, CA

Introduction: Research on user engagement (UE) has primarily focused on cross-sectional, composite scores of UE that sum across each type of app interaction across time, such as total log-ins. An alternative approach is to examine app interactions longitudinally, which allows researchers to investigate UE in a dynamic fashion. Multidimensional approaches might also help to reveal underlying patterns of UE by examining multiple interaction types concurrently. The present study applies one such approach, multilevel latent class analysis (MLCA), to explore subgroups of daily UE patterns within individuals over the course of a quit attempt.

Methods: A series of MLCA models were conducted to identify distinct subgroups of daily UE patterns (i.e., latent classes), accounting for the repeated data structure. MLCA indicators for this analysis were five unique interactions with a quit app, MyQuit USC (MQU), logged automatically over 28 days. Young adult smokers (n=35) from an ongoing investigation (target N=60) provided a maximum of 980 UE observation days (n=35*28=980). Random means were tested to allow for the probability of belonging to a daily UE class to vary across participants. All analyses were conducted using Mplus v6.

Results: 972 UE observation days were non-missing and used for analysis. The best fitting model yielded a three-class solution for daily UE class membership. Latent classes were distributed as follows: not engaged (45% of the sample), engagement with multiple features (20%), and engagement only with study assessments (35%). All models controlled for individual-level variables, i.e., gender and nicotine dependence. Week in quit attempt was a significant day-level predictor of UE class. Specifically, the probability of belonging to the “engaged with multiple features” class relative to the “not engaged” daily UE class decreased as a function of week in quit attempt (OR=.48, p=.015).

Conclusion: To our knowledge, no studies have applied MLCA to investigate patterns of daily UE nor evaluated day-level predictors of UE in the context of quit attempts. Information regarding the variety of possible daily UE patterns will be useful for devising strategies to optimize and maintain engagement over time with MQU based on individual characteristics and time in quit attempt.

PEOPLE WITH TYPE 2 DIABETES PAYING FOR A ONE DROP | EXPERT
COACH IMPROVE AND MAINTAIN ‘AT GOAL’ BLOOD GLUCOSE

Chandra Osborn, PhD, MPH¹, Lindsay Sears, PhD¹, Mark Heyman, PhD, CDE², David Rodbard, MD³, Rachel Head, RD, CDE¹, Brian Huddleston, JD², Jeff Dachis, MA²

¹Informed Data Systems Inc., New York, NY; ²Informed Data Systems, Inc, New York, NY; ³Biomedical Informatics Consultants LLC, Potomac, MD

Objective: People using the One Drop | Mobile app can log and track self-care and health data, get data-driven insights, set goals and monitor progress, give and receive support to/from other users, view tips/recipes, and more. With a paid subscription, a Certified Diabetes Educator (‘Expert’) sends personalized in-app messages to educate, strategize, answer questions, and provide accountability with managing diabetes. An independent company previously tested ‘Mobile’ with ‘Experts’ at no cost to users, and found people with type 2 diabetes (T2D) and A1c $\geq 7.5\%$ had a -0.90% lab A1c improvement at 3 months. Using self-reported, app-collected data, we found an average -29 mg/dL blood glucose (BG) improvement (estimated -1.0% eA1c) among that sample. The present study was designed to test the outcomes of people paying for an ‘Expert’ and the Bluetooth-connected One Drop | Chrome meter with strips. Specifically, we tested changes in objective, app-collected BG among people with a 1st-week average BG ≥ 169 mg/dL (eA1c $\geq 7.5\%$). We also tested the likelihood of having an average BG < 155 mg/dL (eA1c $\leq 7\%$) in week 12 if starting with a 1st-week average BG < 155 mg/dL.

Method: We queried One Drop’s database for people with T2D and an ‘Expert’ for 3 months. Three mixed repeated measures models assessed 1st- to 12th-week change in average BG, percentage of high BGs, and percentage of in-range BGs by coach program (‘On Call’ vs. ‘On Track’). Unadjusted and adjusted logistic regression models tested the likelihood of a 12th-week average BG < 155 mg/dL if the 1st-week average BG was < 155 mg/dL.

Results: The sample (N=290) was 63% male with diagnosed diabetes for 7.1 ± 7.5 years. People (n=107) with a 1st-week average BG ≥ 169 mg/dL (eA1c $\geq 7.5\%$) had a -53.1 mg/dL lower average BG in week 12, $p < .001$, equivalent to a -1.9 lower eA1c. Average percentage of high BGs was -26% lower and in-range BGs $+27\%$ higher, $p < .001$. There was no interaction by coaching program. People with a 1st-week average BG < 155 mg/dL (eA1c $\leq 7\%$) had a higher likelihood (4.1 OR, 4.3 AOR) of maintaining an average BG < 155 mg/dL in week 12.

Conclusion: Among people with T2D paying for an ‘Expert’ and ‘Chrome’ meter with strips, average, objective BG improved among people with an initially elevated average BG, and was maintained for people with a low average BG at baseline. People paying for an in-app coach and meter with strips may be more motivated than someone not paying for these services. More studies employing different methods should evaluate the impact of apps with coaching for people with diabetes.

TEXT MESSAGE-BASED DIABETES SELF-MANAGEMENT SUPPORT: RESULTS FROM THE SMS4BG RANDOMISED CONTROLLED TRIAL

Rosie Dobson, MSc¹, Robyn Whittaker, PhD¹, Yannan Jiang, PhD¹, Ralph Mad-dison, PhD², Matthew Shepherd, DClinPsy¹, Richard Cutfield, MBChB FRAC³, Catherine McNamara, MD³, Manish Khanolkar, MD⁴, Rinki Murphy, MBChB, PhD¹

¹University of Auckland, Auckland, Auckland, New Zealand; ²Deakin University, Melbourne, Victoria, Australia; ³Waitemata District Health Board, Auckland, Auckland, New Zealand; ⁴Auckland District Health Board, Auckland, Auckland, New Zealand

Introduction: Effective diabetes self-management support is key to address the increase in costly and debilitating long-term complications associated with poor diabetes control. Text messages (SMS) are an ideal tool for the delivery of self-management interventions to patients with poorly controlled diabetes given the ubiquity of mobile phones, and the ability of SMS to reach people in their everyday lives when self-management of the condition is crucial. We developed a novel, theoretically based, SMS-based self-management support programme (SMS4BG) for adults with poorly controlled diabetes in New Zealand. The programme addresses the behaviours required for successful diabetes self-management and is made up of modules to allow tailoring of the content. The programme is also tailored to individual patient preferences, demographics, clinical characteristics, and culture. This study investigated the effectiveness of SMS4BG to improve glycaemic control in adults with poorly controlled diabetes.

Methods: A 2-arm, parallel, randomized controlled trial was conducted in adults (16 years and over) with poorly controlled type 1 or type 2 diabetes (HbA1c \geq 65mmol/mol). Participants were recruited across New Zealand and randomised at a 1:1 ratio to receive SMS4BG (intervention) in addition to usual care, or usual care alone (control). The primary outcome was change in glycaemic control (HbA1c) at 9 months. Secondary outcomes include HbA1c at 3 and 6 months, self-efficacy, self-care behaviours, diabetes distress, and health-related quality of life.

Results: Eligible patients (N=366) were randomized to the intervention (n=183) or the control (n=183) group. At 9 months HbA1c was significantly lower in the intervention group compared with the control group (adjusted mean difference, -4.23 [95%CI, -7.30, -1.15], $p=0.01$). Significant improvements in foot care behaviour was seen in the intervention group compared to the control group (adjusted mean difference, 0.85 [95% CI 0.40, 1.29], $p<0.01$), and diabetes related support (adjusted mean difference, 0.26 [95% CI 0.03, 0.50], $p=0.03$). High levels of satisfaction with SMS4BG were found with 95% of participants reporting it to be useful, 97% reporting it to be culturally appropriate, and 97% would recommend SMS4BG to other people with diabetes.

Discussion: This study found that a tailored SMS based self-management support programme is effective at improving glycaemic control in adults with poorly controlled diabetes.

CAN SELF-AFFIRMATION IMPROVE ACCEPTANCE OF HEALTH MESSAGES? - THE ROLE OF INTERNAL VERSUS EXTERNAL THREAT TO THE SELF

Xuan Zhu, PhD

Mayo Clinic, Rochester, MN

Self-affirmation research suggests that allowing people to affirm important values can increase acceptance of health messages and improve health behaviors. Largely unstudied, however, is how variations in message features induce different perceptions of threat to the self, which influences when self-affirmation produces positive effects on message processing. A health message delivering behavioral recommendations through the use of controlling language (e.g., “You must quit smoking”) challenges one’s belief that his/her decision making should be free from outside control. This represents a threat to the self induced by an external force (i.e., external self-threat). In contrast, a message emphasizing the negative outcomes of one’s unhealthy behavior (e.g., “Smoking increases your cancer risk”) contradicts one’s belief that he/she is capable of making wise decisions. This represents a threat to the self induced by one’s own actions (i.e., internal self-threat).

After perceiving an external self-threat from a health message, self-affirmed people will be less receptive of the message than unaffirmed people, because self-affirmation boosts confidence in oneself thus highlighting the intrusiveness of the message. In contrast, after perceiving an internal self-threat from a health message, self-affirmed people will be more receptive of the message than unaffirmed people, because self-affirmation secures self-worth thus easing the discomfort caused by reflecting on one’s unwise decisions.

A 2(Threat type in message: internal, external) by 3(Self-affirmation: value affirmation, control task, message only) between-subjects experiment on fruit and vegetable intake was conducted. Participants were 333 US adults who self-reported not meeting USDA fruit and vegetable intake guidelines.

Among those who read the internal (but not external) self-threat health message, self-affirmation increased intention to meet fruit and vegetable intake guidelines ($F[2, 324] = 3.4, p = .035, \eta^2 = .02$; Affirm: $M = 4.82, SE = .21$; Ctrl: $M = 4.23, SE = .21$; Msg only: $M = 4.44, SE = .19$). Among those who read the external (but not internal) self-threat health message, self-affirmation reduced positive mood ($F[2, 321] = 4.56, p = .011, \eta^2 = .03$; Affirm: $M = 4.61, SE = .19$; Ctrl: $M = 5.23, SE = .18$; Msg only: $M = 5.39, SE = .19$) and increased anger ($F[2, 324] = 3.45, p = .033, \eta^2 = .02$; Affirm: $M = 1.64, SE = .17$; Ctrl: $M = 1.19, SE = .17$; Msg only: $M = .97, SE = .17$).

This study suggests that message features can shape the outcomes of self-affirmation based health interventions. Self-affirmation coupled with a health message signaling external self-threat may lead to undesirable outcomes. Future self-affirmation studies should continue researching the psychological constructs that underlie various message features to further explain when self-affirmation produces positive effects.

FROM MESSAGE TO MOJITO: REACTANCE PATHWAYS AND BINGE DRINKING IN COLLEGE AND NON-COLLEGE EMERGING ADULTS

Bethany Shorey Fennell, M.S., Renee Magnan, PhD

Washington State University Vancouver, Vancouver, WA

One drawback to health communications is greater reactance to the information among those who need it most. Strong messages are rated as more important and expert; however, the clear, controlling language often employed by strong messages is also perceived as more of a threat and elicits more reactance. Much of the work on binge drinking messages has focused on young adult college student populations, with relatively little given to young adults who have never attended college. There is evidence these groups may engage with alcohol use differently. The current examination investigated potential reactance mechanisms through which message strength influences binge drinking intention and behavior among college and non-college emerging adults. As a part of a larger study, participants rated either high or low threat messages about the consequences of binge drinking on three reactance experiences: anger, negative cognitions, and freedom threat. Regression analyses tested the direct and indirect effects using bootstrapping procedures. For college students ($n=348$), anger, negative cognitions, and freedom threat were higher in response to high threat than low threat messages (p s p s) while message threat had no effect on freedom threat ($p=.14$). For college students, there was an indirect effect on binge drinking through cognitive evaluations of the messages ($b=.28, p=.011$). For non-college emerging adults, there was an indirect effect of message threat on binge intentions via cognitive evaluations ($b=.30, p=.009$) and an indirect effect of message threat on binge behavior via anger ($b=.15, p=.012$). These results extend the reach of the current literature on binge drinking communications by demonstrating that age-equivalent college students and emerging adults who have never attended college may respond to anti-binge drinking health messages differently via distinctive reactance pathways. These differences should be taken into account in order to maximize efficacy of future messaging campaigns.

Paper Session 3: Health Messaging for Chronic Disease Prevention 11:15 AM-11:30 AM

IMPACT OF LOWER ALCOHOL STRENGTH LABELS ON CONSUMPTION OF WINE AND BEER: A BAR LAB RANDOMISED CONTROLLED TRIAL

Milica Vasiljevic, PhD¹, Dominique-Laurent Couturier, PhD¹, Daniel Frings, PhD², Antony C. Moss, PhD², Ian P. Albery, PhD², Theresa M. Marteau, PhD¹

¹University of Cambridge, Cambridge, England, United Kingdom; ²London South Bank University, London, England, United Kingdom

Background: Labels indicating low/light versions of tobacco and foods are perceived as less harmful which may increase consumption. The current study tests the hypothesis that labelling wine and beer as lower in alcohol increases their consumption.

Methods: Weekly wine and beer drinkers ($n=264$) sampled from a representative panel of the general population of England were randomised to one of three groups to taste test drinks in a bar laboratory varying only in the label displayed: *Group 1*: No verbal descriptors of strength; *Group 2*: verbal descriptor *Low* combined with 8%ABV for wine/3%ABV for beer; *Group 3*: verbal descriptor *Super Low* combined with 4%ABV for wine/1%ABV for beer. Primary outcome was total volume of drink consumed (in ml).

Results: The results supported the study hypothesis: the total amount of drink consumed increased as the label on the drink denoted successively lower alcohol strength, $B=.71, p=.019, [95\%CI 0.11, 1.29]$. Group contrasts showed significant differences between those offered drinks labelled as *Super Low* ($M=213.77$) compared to the drinks labelled as *Regular* ($M=176.85$), $B=1.43, p=.019, [95\%CI 0.24, 2.61]$. There was no significant difference in amount consumed between those offered drinks labelled as *Low* ($M=194.60$) compared to *Regular*, $p=.340$.

Conclusions: These results suggest that labelling drinks as lower in strength increases the amount consumed. Further studies are warranted to test for replication in non-laboratory settings and to estimate the potential for any effects to be at a level with the potential to harm health.

AGE OF FIRST SEXUALLY EXPLICIT MEDIA EXPOSURE IS ASSOCIATED WITH RECENT CONDOMLESS SEX AMONG ADULT SEXUAL MINORITY MEN

Nicholas Perry, M.S.¹, Kimberly Nelson, PhD, MPH¹, Jane Simoni, Ph.D.²

¹Brown University, Providence, RI; ²University of Washington, Seattle, WA

Sexual minority men remain at high risk of HIV infection via condomless anal sex (CAS). Sexual script theory suggests that social messages influence sexual behavior by shaping sexual expectations. However, sexual minority men have few conventional role models of sexual behavior (e.g., peers, popular media). Sexually explicit media (SEM; i.e., pornography) is a possible social influence on sexual minority men's sexual behavior and consumption of SEM has been associated with CAS. SEM messages are especially potent when received at a formative developmental period. However, the impact of early SEM exposure on adult sexuality might be confounded by the well-known effect of early sexual debut on later sexual behavior.

Using data from a cross-sectional online study of SEM use and sexual behavior, we examined the association of age of first SEM exposure with recent CAS among a sample of adult sexual minority men ($N = 1,112$). We hypothesized that earlier SEM debut would be associated with recent CAS, independent of age of anal sex debut. Exploratory analyses tested differences in this association by race/ethnicity and HIV-status to characterize findings within the current HIV epidemic. Men reported demographics, age at first exposure to SEM ($M = 15.1, SD = 6.3$), age of anal sex debut ($M=20.4, SD=7.2$), and CAS over the past three months. Recent CAS was dichotomized due to non-normality. Bivariate and multivariable logistic regression models were run.

Over half the sample (56%) reported recent CAS. Age of SEM exposure was negatively associated with recent CAS. Specifically, every one-year increase in age of first SEM exposure was associated with decreased odds of recent engagement in CAS ($OR=.97, [95, .99], p=.01$). This association remained when controlling for age of anal sex debut ($AOR = .98, [96, 1.00], p=0.03$). We did not find significant differences in the strength of this association by race/ethnicity or HIV status ($p=.55; p=.70$).

Men who are exposed to SEM later in life were less likely to engage in sexual risk behaviors. These findings did not vary by racial identity or HIV-status in our sample, and remained significant controlling for age of anal sex debut. For many sexual minority men, early exposure to SEM may have a durable effect on adult sexual behavior. Future research should examine processes linking early SEM exposure to sexual development and later engagement in riskier sex for sexual minority men.

RACE DIFFERENCES IN WEIGHT GAIN AMONG A COMMUNITY SAMPLE OF SMOKERS RECEIVING A MULTIPLE BEHAVIOR CHANGE INTERVENTION

Marcia M. Tan, PhD, MPH¹, Terry Bush, PhD², Jennifer Lovejoy, PhD³, Alula Jimenez Torres, MPH, MSW⁴, Bonnie Spring, PhD⁵, Harold Javitz, PhD⁶

¹Northwestern University Feinberg School of Medicine, Chicago, IL; ²Optum (formerly Alere Wellbeing), Seattle, WA; ³Arivale, Inc, Seattle, WA; ⁴Optum, Seattle, WA; ⁵Northwestern University, Chicago, IL; ⁶SRI International, Menlo Park, CA

Introduction: Racial disparities have been reported in post-cessation weight gain, with African American smokers gaining excessive weight. These findings have been seen primarily in observational research; few studies have compared weight in multiethnic smokers receiving evidence-based treatment in a community setting. We examined race differences in short-term weight gain during an intervention to foster smoking cessation plus weight management.

Methods: Data were drawn from a randomized controlled trial testing the effect on cessation and weight gain prevention of adding weight control intervention either simultaneously with or sequentially after smoking cessation treatment delivered via telephone quitlines. African Americans (n=667) and whites (n=1721) self-reported smoking status and weight during each of 10 intervention calls focused on either cessation (all groups), weight management (sequential), both cessation and weight (simultaneous), or healthy living (control, simultaneous). Random effects longitudinal modeling was used to test the association of race and smoking on weight change over the intervention period (an average of 16 weeks).

Results: Abstinence predicted weight gain over the intervention period ($\beta=0.199$, $SE=0.089$, $p=0.03$); there was no effect of intervention over time. Race was not associated with weight gain or the association between smoking and weight. There was a significant race x treatment x time effect, such that, in the simultaneous group, weight increased for African Americans at a faster rate compared to whites ($\beta=0.295$, $SE=0.127$, $p=0.02$), independent of smoking status, age, baseline obesity, and education.

Discussion: No race differences in overall weight gain were observed. However, African Americans receiving smoking and weight content simultaneously demonstrated an increase in weight compared to whites in the same group. As previous research has shown lower engagement and abstinence rates in simultaneous interventions, future studies are needed to understand factors associated with treatment receptivity that may influence weight among multiethnic smokers.

PHYSICAL ACTIVITY AND PSYCHOSOCIAL OUTCOMES FROM A PILOT RANDOMIZED TRIAL OF AN IVR-SUPPORTED INTERVENTION IN THE DEEP SOUTH

Dori Pekmezi, PhD¹, Matthew C. Ainsworth, MPH¹, Taylor Holly, BSPH¹, Victoria Williams, MPH, MEd, MCHES², Rodney P. Joseph, PhD³, Kaiying Wang, BS⁴, Laura Q. Rogers, MD, MPH¹, Bess H. Marcus, Ph.D.⁵, Wendy Demark-Wahnefried, PhD¹

¹University of Alabama at Birmingham, Birmingham, AL; ²University of Alabama at Birmingham, Atlanta, GA; ³Arizona State University, Phoenix, AZ; ⁴University of Alabama at Birmingham, Irondale, AL; ⁵Brown University, Providence, RI

Background: The American Cancer Society recommends ≥ 150 minutes of moderate-intensity aerobic physical activity per week to reduce cancer risk. Most Americans are sedentary, especially in the South, where cancer incidence and mortality rates are generally higher. Telephone-based physical activity interventions can help reduce intervention barriers in this region (literacy, costs, lack of transportation/expensive technology, distance from facilities) and can be automated via Interactive Voice Response (IVR) systems for improved reach and cost-effectiveness. The purpose of the current study is to report the outcomes (feasibility, acceptability, preliminary efficacy) of the 12-week Deep south IVR-supported Active Lifestyle (DIAL) intervention.

Methods: A randomized controlled trial was used to test the 12-week, Social Cognitive Theory-based DIAL intervention (N=32) vs. a Waitlist Control arm (N=31). Physical activity (7-Day Physical Activity Recalls) and psychosocial measures were administered at baseline and 12 weeks.

Results: The sample included underactive adults from Birmingham, AL. The mean BMI was 31.1 kg/m² and mean age was 43 years old. A majority of the participants were male (55.6%) and African American (58.7%). Retention was high at 12 weeks (88.89%). Adherence to intervention protocol was adequate, with 62% calling the IVR system on at least 63 of the 84 required days ($\geq 75\%$ adherence) and 86.2% completing at least 2 of the 3 required monthly counseling calls. Intervention participants reported being satisfied or very satisfied with the DIAL program (71.43%) and would recommend it a friend (92.86%). Moreover, participants found the DIAL automated telephone system easy to use (85.71%). As for preliminary efficacy, self report moderate-vigorous intensity physical activity increases at 12 weeks were significantly greater for the DIAL intervention arm (M= +74.4 minutes/week, SD=80.8) vs. the waitlist control arm (M=+47.9 minutes/week, SD=109.6), $p < .001$. Moreover, the intervention produced significantly greater increases in physical activity self-regulation ($p < .001$) and social support from family ($p = .001$) and friends ($p = .009$) from baseline to 12 weeks, compared to a waitlist control. Significant decreases in sleep disturbance from baseline to 12 weeks were also found in the intervention arm and not the control arm, $p < 0.05$.

Discussion: Findings support the feasibility, acceptability, and preliminary efficacy of the DIAL intervention. Next steps include intervention refinement in preparation for a fully-powered efficacy trial and eventual dissemination in rural counties.

FAMILY FUNCTIONING, SOCIAL SUPPORT, SELF REGULATION & SELF EFFICACY IN A SPOUSAL SUPPORT WEIGHT LOSS INTERVENTION FOR BLACK MEN

Candice Alick, PhD¹, Carmen Samuel-Hodge, PhD², Dianne S. Ward, EdD³, Alice Ammerman, DrPH⁴, Christine Rini, PhD⁵, Deborah F. Tate, Ph.D.⁶

¹University of NC-Chapel Hill, Durham, NC; ²University of North Carolina at Chapel Hill Gillings School of Global Public Health and School of Medicine, Chapel Hill, NC; ³Gillings School of Global Public Health, Chapel Hill, NC; ⁴Gillings School of Global Public Health and School of Medicine University of North Carolina at Chapel Hill, Chapel Hill, NC; ⁵John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, NJ; ⁶University of North Carolina at Chapel Hill, Chapel Hill, NC

Black men demonstrate significant disparities in morbidity and mortality caused by top chronic diseases related to weight. Yet, few management studies include sufficient data on Black men to enable evaluation of their behaviors and weight outcomes. Together Eating & Activity Matters (TEAM) was a 12-week randomized controlled pilot study for weight loss among Black men testing whether enhancing a standard behavioral intervention by adding a spousal support component produced greater weight loss than the standard behavioral weight loss treatment alone. Mean (SD) weight changes over 3 months among men were -3.4[.04] and -4.7[5.9] kg and among female partners -0.23[4.46] and -2.47[3.62], in the standard and enhanced groups, respectively. This secondary analysis of data from this pilot study focused on whether including spousal support (Enhanced) within the intervention changed the theory-based constructs of family functioning (i.e., communication, family cohesion, emotional involvement), social support, self-regulation, and self-efficacy. We collected self-report data from 40 Black men randomized to the standard (n=19) or the enhanced (n=21) behavioral weight loss treatment. Exploring moderate effect sizes to represent differences between groups, the enhanced group showed increased communication (standard: -0.17 ± 0.60 ; enhanced: 0.23 ± 0.65 , $d=0.64$, $p=0.06$) and incendiary communication (standard: -0.55 ± 2.43 ; enhanced: 0.52 ± 2.43 , $d=0.44$, $p=0.19$) and decreased family cohesion (standard: 1.77 ± 5.38 ; enhanced: -2.33 ± 5.38 , $d=0.76$, $p=0.06$) and emotional involvement (standard: 1.12 ± 3.68 ; enhanced: -1.70 ± 3.59 , $d=0.77$, $p=0.04$) compared to the standard group. There were no differences between groups on other measures. Thus, although the pilot study showed that participating with a partner produced an additional 1 kilogram of weight loss in the men ($d=0.18$) and 2 kgs in their partners compared to the standard weight loss treatment, the spousal support-enhanced intervention, which focused on spousal communication, caused unexpected negative changes in couple functioning on some measures. Changes in these communication variables should be replicated in a larger sample and studied over a longer period of time to determine if the effects are transient or sustained.

DESIGNING FIT WITH FAITH: AN EHEALTH INTERVENTION FOR CLERGY AND THEIR SPOUSES

Brook E. Harmon, PhD, RD, FAND¹, Shaila Strayhorn, MPH¹, Lindsey Grant, MPH¹, Benjamin Webb, PhD², Stacy Smith, M.Div., Ed.D³

¹University of Memphis, Memphis, TN; ²Southern Illinois University - Edwardsville, Edwardsville, IL; ³Methodist Le Bonheur Healthcare, Memphis, TN

Introduction: Clergy and their spouses are influential leaders in their communities. They are often asked to promote and model healthy behaviors. Unfortunately, clergy experience higher rates of obesity and other chronic diseases compared to non-clergy. Clergy also report lifestyles that make it difficult for them to participate in traditional health promotion programs. An eHealth program may be an effective strategy for providing clergy and their spouses with resources needed to improve lifestyle behaviors.

Objective: To identify factors necessary for an effective clergy/spouse health promotion program. To examine the potentially unique health needs of male clergy within the greater Memphis, TN area.

Methods: Three focus groups were conducted with 18 male clergy and an additional three groups with 14 spouses. Focus group data were analyzed in NVivo using a grounded theory approach.

Results: Clergy and spouses expressed the need for clergy specific interventions with sex-specific components in order to feel safe and understood when sharing health struggles. Additional themes included: 1) A need for diet, physical activity, and role-related stress management tools; 2) A desire for structure in the form of meal plans, goal setting, and accountability; 3) Technology was viewed as a way to overcome the barrier of time, assist with tracking behaviors, provide accountability, and opportunities for competition; 4) Various technologies were deemed appropriate, but opportunities for face-to-face support were also requested.

Conclusion: Based on these findings, the Fit with Faith intervention will use a diet and physical activity tracking app, educational and skill building website materials, individual and family challenges, and opportunities for group and individual counseling to aid participants in improving their diet, physical activity, and stress reduction behaviors. Research is still needed to understand the health needs of female clergy and their spouses.

ASSOCIATIONS BETWEEN PARENTING BEHAVIORS AND CHILDREN'S SOCIAL-EMOTIONAL, BEHAVIORAL, AND COGNITIVE WELL-BEING IN LIBERIA

Eve Puffer, PhD¹, Eric Green, PhD¹, Rhea M. Chase, PhD², Amanda L. Sim, MA³

¹Duke University, Durham, NC; ²Judge Baker Children's Center, Boston, MA; ³University of Oxford, Oxford, England, United Kingdom

Purpose. Research has identified parenting behaviors associated with children's well-being in high-income countries, but the literature is weak in low- and middle-income countries. We examine associations between harsh discipline and parent-child relationship quality with children's social-emotional, behavioral, and language development in Liberia.

Methods. Participants were 204 caregivers and their children aged 3 to 4 years. Harsh discipline was assessed with the Discipline Interview. Relationship quality was measured with the Parental Acceptance-Rejection Questionnaire (PARQ) and a locally-derived positive interactions scale. Child outcome measures included: the Ages and Stages Questionnaire: Social-Emotional (ASQ:SE); the Strengths and Difficulties Questionnaire (SDQ); and a locally-derived measure of disruptive behavior. Receptive language was assessed with locally-derived story comprehension and instruction-following tasks. Linear regression was used to test associations, controlling for gender and age of caregivers and children, as well as caregiver education level.

Results. Harsh discipline was associated with worse child outcomes on all measures: poorer scores on the ASQ:SE ($F(6,196) = 2.6, p < 0.01$), more problems in social, emotional, and behavioral domains on the SDQ ($F(6,196) = 8.9, p < 0.001$), and more problem behaviors ($F(6,196) = 8.0, p < 0.001$). Harsh discipline also was negatively associated with scores on story comprehension ($F(6,196) = 8.4, p < 0.10$) but not on the instructions task.

Associations between relationship quality and child well-being varied. On the locally-derived positive interactions scale, quality was related to better functioning on the ASQ:SE ($F(6,196) = 5.2, p < 0.001$) but not on the SDQ or problem behavior scale. Surprisingly, positive interactions were associated with worse performance on story comprehension ($F(6,196) = 8.8, p < 0.05$) and the instructions task ($F(6,196) = 5.8, p < 0.01$). On the PARQ, rejection was associated with worse scores on the ASQ:SE ($F(6,196) = 7.6, p < 0.001$), SDQ ($F(6,196) = 13.3, p < 0.001$) and problem behavior scale ($F(6,196) = 10.4, p < 0.001$). Associations with verbal abilities were in the expected direction, but not statistically significant.

Conclusions. Harsh discipline and rejection emerged as risk factors for poorer child well-being. Results were mixed on associations between parenting and verbal ability and between positive interactions and child wellbeing. Results suggest the need to target harsh discipline in interventions and highlight the importance of more diffuse negative relationship characteristics that may deserve more attention in intervention research.

CLUSTERING OF MULTIPLE HEALTH RISK BEHAVIORS AMONG YOUNG ADULTS IN AUSTRALIA: A LATENT CLASS ANALYSIS

Katrina E. Champion, BA Psych(Hons), PhD¹, Nicola C. Newton, PhD², Marius Mather, BA Psych(Hons)², Bonnie Spring, PhD¹, Maree Teesson, BSc Psych(Hons), PhD²

¹Northwestern University, Chicago, IL; ²UNSW Sydney, Sydney, New South Wales, Australia

Six key risk behaviors (physical inactivity, diet, smoking, alcohol use, sedentary behavior and sleep) have been associated with risk of chronic disease, such as cardiovascular disease and cancers. These risk behaviors ("Big 6") commonly co-occur and typically emerge in adolescence and early adulthood, a critical transitional period characterized by greater autonomy over lifestyle choices. An examination of the clustering of these behaviors is important for guiding the development of multiple health behavior interventions to prevent chronic disease. This study aimed to investigate the clustering of the "Big 6" among young adults in Australia, and examine how the clusters relate to mental health and socio-demographic factors. A total of 350 participants ($M_{age} = 18.8$ yrs, 68% male) completed an online self-report survey assessing the six behaviors (binge drinking and smoking in the past 6 months, moderate-to-vigorous physical activity/week, sitting time/day, fruit and vegetable intake/day and sleep duration/night). Engagement in each behavior was represented by a dichotomous variable reflecting adherence to national guidelines. Clusters were identified using latent class analysis and associations with psychological distress, anxiety, depression, gender, employment, and tertiary education were examined via chi-square analysis and ANOVAs. Three distinct classes emerged: 'Poor diet, nonsmokers' [nonsmokers, highly likely to meet sleep, physical activity and sedentary behavior guidelines, moderately likely to binge drink and not eat enough fruit and majority have poor vegetable intake; Class 1, 64%]; 'Binge drinkers and smokers' (majority binge drink, smoke and have poor vegetable intake, but highly likely to meet fruit, sleep, physical activity and sedentary behavior guidelines; Class 2, 24%) and 'High risk' (high rates of smoking and binge drinking, poor fruit and vegetable intake and comparatively high rates of sedentary behavior; Class 3, 12%). There were no significant socio-demographic differences between the classes, however there were significant differences in terms of psychological distress [$F(2,347) = 10.29, p < .001$], anxiety [$F(2,347) = 4.99, p = .01$], and depression [$F(2,347) = 7.95, p < .001$]. Specifically, the 'high risk' class had significantly greater psychological distress ($p < .000$) and depression ($p = .01$) than the other classes, and higher anxiety ($p = .01$) than 'poor diet, nonsmokers'. These results indicate that health risk behaviors cluster in young Australian adults and covary with mental ill health. Findings reinforce the importance of delivering multiple health interventions to reduce later chronic disease risk and to improve current mental wellbeing.

TRAINING MH PROFESSIONALS IN LMICS TO DELIVER LIFESTYLE INTERVENTIONS FOR PEOPLE WITH MENTAL ILLNESS: A PILOT PROJECT IN UGANDA

Philip B. Ward, BMedSc, PhD¹, Simon Rosenbaum, PhD², Justin Richards, PhD³

¹UNSW Sydney, Liverpool BC, New South Wales, Australia; ²UNSW Sydney, Sydney, New South Wales, Australia; ³University of Sydney, Sydney, New South Wales, Australia

Background: The prevalence of non-communicable diseases (NCDs) is rapidly rising in low income countries. People with mental illness living in low-income countries represent a particularly vulnerable population at risk of developing non-communicable diseases secondary to mental illness. Physical inactivity, poor diet quality and smoking are key modifiable risk factors. Robust evidence demonstrates that targeting these modifiable risk factors can reduce symptoms of mental illness. Implementation of targeted lifestyle interventions within mental health services in high-income settings remains ad-hoc, with a dearth of literature guiding adaptation of programs to low-income settings. We aimed to train mental health professionals from a psychiatric hospital in Uganda, in the principles of lifestyle interventions.

Methods: A one-day workshop for mental health staff (primarily clinical psychologists) was conducted in July 2017. The workshop covered topics including the rising prevalence of NCDs, cardiometabolic health of people with mental illness, staff culture, assessing and reporting on physical health outcomes, principles of exercise and dietary prescription and medical management of mental disorders. Outcomes assessed included the Metabolic Barriers, Attitudes, Knowledge and Confidence questionnaire (M-BACK).

Results: In total, n=39 clinical psychologists attended the workshop. N=29 completed pre- and post questionnaires. Total mean M-BACK scores increased from 56.1 (SD=5.6) to 65.1 (SD=7.3), $p=0.064$. 100% of respondents reported that the workshop was effective in increasing understanding of the importance of addressing physical health of people with mental illness.

Conclusion: A one-day training workshop was feasible, acceptable and effective in improving the knowledge and confidence of mental health professionals regarding the physical health and delivery of lifestyle interventions for people with a mental illness in a low-resource setting.

INCREASING UPTAKE OF VOLUNTARY MEDICAL MALE CIRCUMCISION IN ZAMBIA: PRELIMINARY REGIONAL RESULTS

Stephen M. Weiss, PhD, MPH¹, Tae Kyoung Lee, Ph.D¹, Suat Babayigit, MSEd¹, Deborah L. Jones, PhD, MEd¹, Robert Zulu, MD²

¹University of Miami Miller School of Medicine, Miami, FL; ²University Teaching Hospital, Lusaka, Lusaka, Zambia

Background. Voluntary medical male circumcision (VMMC) uptake in Africa could prevent 3.4 million HIV infections across a 10-year span and is an effective strategy for HIV prevention in high-prevalence populations. Despite high levels of HIV protection, ~80% of uncircumcised men in Zambia express *no* interest in undergoing VMMC. The Spear & Shield (S&S) intervention has been shown to be 2.4 times more effective than control and 8.5 times more effective than observation-only conditions at increasing the number of VMMCs among Zambian men with no prior interest in undergoing the procedure. This paper examines the initial impact of scale up of the S&S VMMC dissemination and implementation science program.

Methods. Three Community Health Center (CHC) medical staff (n = 72) from each of 24 CHCs in Lusaka Province were trained to perform VMMC, and four CHC counselors from each CHC were trained to conduct the S&S intervention for CHC attendees. The 24 CHCs were divided into two groups of 12 CHCs to 1) provide VMMC *and* four weekly S&S intervention sessions on HIV prevention highlighting VMMC (“immediate”), or 2) provide VMMC only for the first 6 months, i.e., “*delayed*” S&S intervention onset for 6 months to determine the impact of providing VMMC services alone. The percentage of men testing HIV- *and* electing to undergo VMMC at each clinic was compared with VMMC percentages over 12 months prior to study onset (i.e., historical control).

Results. At 15 months post-intervention onset, there were no differences between immediate S&S intervention and the delayed intervention onset arm ($b = -0.003$, 95% CI = $-0.047, .030$) during the post-intervention period. In contrast, average rates of changes (slope) in VMMC uptake in the intervention arm significantly increased ($b = .021$, 95% CI = $0.001, 0.044$) compared to historical data (0.014 and 0.035 for historic and intervention periods, respectively).

Discussion. Preliminary results of this ongoing study suggest that the intervention arm positively impacts rates of VMMC uptake. However, the comparison of “*delayed*” CHCs (VMMC only) vs. 12 “*immediate*” CHCs (VMMC plus S&S intervention) to assess the impact of offering VMMC only for the initial 6 months was premature; additional data from the remaining 3 Provinces will provide a more definitive comparison of these two conditions. Program adjustments based upon these initial implementation and dissemination findings will be discussed.

DOES GENDER MODERATE THE ASSOCIATION BETWEEN PARTNER SUPPORT AND PHYSICAL ACTIVITY AMONG INDIVIDUALS WITH OSTEOARTHRITIS?

Sandra H. Soto, PhD, MPH, BSN¹, Leigh Callahan, PhD¹, Stephanie G. Bahorski, MPH², Mary Altpeter, PhD¹, Ashley Phillips, MPH¹, Christine Rini, PhD³

¹UNC, Chapel Hill, Chapel Hill, NC; ²University of North Carolina at Chapel Hill, Chapel Hill, NC; ³John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, NJ

Purpose. Most individuals with knee or hip osteoarthritis (OA) are not meeting recommendations for physical activity (PA). Of the potential sources of influence on PA, cohabitating partners likely play an important role given that PA often occurs in the presence of or with the support of others. Research shows that women tend to provide higher quality social support than men and individuals tend to prefer the support provided by women versus men. The purpose of this study was to examine the moderating role of gender on the association between partner support for PA and light, moderate, and vigorous PA (LMVPA) among individuals with OA.

Methods. Baseline data were collected from 170 insufficiently active (<150 minutes of moderate-vigorous PA) adults with OA of the knee(s) and/or hip(s) and their partner. All couples were heterosexual. Objective LMVPA was assessed using accelerometers. Positive and negative partner support for PA was examined in the following categories: a) partner joins in activity, b) partner communicates support for activity, c) partner is critical of activity, and d) partner expresses concern over activity. Linear regression models were evaluated for each type of partner support, adjusting for gender and socio-demographic covariates including age, race, education, employment, and income. Interactions between gender and each category of partner support were tested, and if statistically significant ($p < 0.05$), simple slopes for men and women were probed.

Results. Participants were on average 66 years old ($SD=9$), 65% female, and 86% Caucasian. Across adjusted models, women engaged in more weekly minutes of LMVPA than men and having a partner who was critical of PA was associated with fewer minutes of LMVPA ($\beta = -0.19$, $p = 0.02$). Gender moderated the relation between partner communicating support for activity and LMVPA ($\beta = -0.53$, $p = 0.01$). More partner support was associated with more minutes of LMVPA among men ($\beta = 0.24$, $p = 0.07$) but fewer minutes of LMVPA among women ($\beta = -0.20$, $p = 0.04$).

Discussion. Findings support theoretical and empirical evidence that interpersonal factors play an integral role in PA. Further investigation is needed to understand how women differ from men in their provision of positive communication support for PA to explain why men benefited from this type of support but women did not. Future interventions should test strategies for improving communication support from men to promote PA in women with OA.

INSTRUMENTED TRAIL-MAKING TASK (iTMT) TO IDENTIFY PHYSICAL FRAILTY - PROOF OF CONCEPT STUDY

He Zhou, PhD¹, Javad Razjouyan, PhD², Aanand D. Naik, MD¹, Mark E. Kunik, MD¹, Bijan Najafi, PhD¹

¹Baylor College of Medicine, Houston, TX; ²Baylor College of Medicine, Houston, TX

Background: While timed gait speed tests are strong predictors of physical frailty, they are often impractical for busy settings. A non-walking based tool sensitive to physical frailty, may facilitate such assessments irrespective of setting.

Objective: We proposed a wearable platform, the instrumented trail-making task (iTMT), to quantify both cognition (working memory) and motor (ankle motion) function consisting of an ankle reaching test. We examined the accuracy of the iTMT to determine presence of major frailty phenotypes including slowness, weakness, exhaustion, and low activity.

Methods: The iTMT uses an ankle-worn sensor, which transmits the ankle motion as movement on a computer cursor. The iTMT mirrors the trail-making test by navigating the cursor to five targets indexed with numbers or letters in the correct order. Thirty-five older subjects (age=76.7 ± 9.5 years, body mass index=26.6 ± 5.7 kg/m², male=51.4%) were recruited to validate this platform. According to the Frailty Phenotype by Fried et al., 15 subjects were determined as non-frail, 15 as pre-frail, and 5 as frail. In addition, 17 young-healthy subjects (age=29.7 ± 8.2 years, body mass index=26.1 ± 4.7 kg/m², male=58.8%) were recruited to establish a healthy benchmark. The ankle-sensor allows quantifying ankle-velocity (surrogate for slowness) and its decline during the test (surrogate for exhaustion), ankle jerkiness (surrogate for activity inefficiency), and the time consumed to reach all targets in the correct sequence (surrogate for poor cognition and/or weakness).

Results: The iTMT parameters were able to identify presence of slowness (*Cohen's* $d=1.15$, $p=0.015$), weakness ($d=0.81$, $p=0.041$), exhaustion ($d=1.56$, $p=0.025$), and low activity ($d=0.99$, $p=0.008$). Among these iTMT parameters, the average iTMT ankle-velocity in young-healthy, elderly non-frail, pre-frail, and frail groups were 5.9 ± 0.9 unit/s, 4.7 ± 0.7 unit/s, 4.0 ± 0.7 unit/s, and 3.2 ± 0.8 unit/s ($pd=1.04-3.14$ to discriminate between groups. High correlations were observed between the iTMT ankle-velocity and measures of gait velocity, grip force, and dual-task cost ($r=0.627-0.738$, $p<0.001$).

Conclusions: This study demonstrated that the iTMT platform is able to identify frailty phenotypes using a quick non-walking based test. This may facilitate routine assessment of physical frailty irrespective of setting. Results need to be confirmed in larger samples.

DO INFORMAL CAREGIVERS KNOW WHEN A PATIENT IS DEPRESSED? A STUDY OF PATIENTS WITH HEART FAILURE AND THEIR CARE PARTNERS

Aaron A. Lee, Ph.D.¹, James E. Aikens, Ph.D.², Ann-Marie Rosland, MD MS³, John Piette, PhD⁴

¹VA Center for Chronic Disease Management, Ann Arbor, MI; ²University of Michigan, Ann Arbor, MI; ³University of Pittsburgh, Pittsburgh, PA; ⁴University of Michigan School of Public Health, Ann Arbor, MI

Background: More than 1 in 5 patients with chronic heart failure (CHF) experiences co-occurring depression. Among adults with CHF, depressive symptoms are associated with poorer quality of life and higher rates of mortality, morbidity, and re-hospitalization. Yet, depression is under-diagnosed and under-treated among patients with CHF. Social network members such as spouses, adult children, or friends have regular contact with patients and frequently accompany patients to their medical appointments. Consequently, these Care Partners (CPs) may be well-positioned to help CHF patients and their healthcare providers identify depressive symptoms. To understand the extent to which CPs could serve as a source of information about patients' mood, we examined concordance between patients' self-reported depressive symptoms and their CPs' impressions perceptions of the same symptoms.

Methods: The study used baseline data from 201 non-cohabitating patient-CP dyads participating in a randomized trial of CP support. Depressive symptoms were measured using the Center for Epidemiological Studies-10 (CESD). Correspondence correlations (CCs) and difference scores (CP estimate of patient CESD score – patient CESD score) were used to assess patient-CP agreement on depressive symptoms. ANCOVA was used to examine variation in CESD differences scores across CP characteristics, adjusting for CP depressive symptoms and patients' total cardiovascular comorbidities.

Results: The median difference in patient reported CESD score and CP estimated CESD scores was 0 (interquartile range: -5 to +5 points). Patient-CP dyads demonstrated fair concordance on ratings of patient depression ($CC = .32$, 95%CI: 0.22, .44). Female CPs estimated patients' CESD scores ($p = .004$) more accurately than male CPs, who significantly overestimated patients' CESD scores ($M_{diff} = 2.50$, 95%CI: 0.60, 4.41). CPs living less than five miles from the patient significantly overestimated the patient's CESD score compared to CPs living farther away ($p = .004$). CPs' education, frequency of contact, and relationship with the patient did not predict accuracy, $p > .05$.

Conclusion: CPs living outside patients' homes are relatively accurate in their assessment of patients' depressive symptoms, and could serve as an additional source of information for providers when assessing depression among patients with CHF. Male CPs and CPs living within five miles of patients may tend to overestimate patients' depressive symptoms.

Paper Session 6: Supporting the Health of Aging Adults 11:30 AM-11:45 AM

USE OF THE PROMIS DEPRESSION MEASURE IN PATIENTS WITH HEART FAILURE

Kenneth E. Freedland, PhD¹, Robert M. Carney, PhD¹, Michael W. Rich, MD¹, Eugene H. Rubin, MD²

¹Washington University School of Medicine, St Louis, MO; ²Washington University School of Medicine, ST Louis, MO

Background: The Patient-Reported Outcomes Measurement System (PROMIS) is the product of an NIH Roadmap initiative. It used state-of-the-art psychometric methods to improve the assessment of patient-reported outcomes. Research is needed on the use of PROMIS measures in specific clinical populations. This study evaluated the agreement between the PROMIS Depression measure and the Beck Depression Inventory (BDI-II) in patients with heart failure.

Methods: Outpatients (n=158) with New York Heart Association Class I-III heart failure and comorbid major depression were enrolled in a randomized controlled trial of a cognitive-behavioral intervention. The BDI-II was the primary outcome measure; the PROMIS Depression scale was a secondary outcome. In addition, the PROMIS crosswalk was used to estimate BDI-II scores from PROMIS Depression scores. Bland-Altman analysis was used to evaluate the agreement between the measures at baseline.

Results: The PROMIS Depression scale correlated $r=0.55$ ($p<.05$) with the BDI-II. However, the interval of agreement on the Bland Altman raw score plot was +/-14 points (42%). The predicted BDI-II score (i.e., predicted by the PROMIS crosswalk) correlated with the observed BDI-II score $r=0.57$ ($p<.05$). With respect to the estimated bias, the observed BDI-II score was 3.2 points higher than the PROMIS-predicted (crosswalk) score. The upper and lower limits of agreement were 37 points apart.

Conclusions: BDI-II scores cannot be accurately estimated from the PROMIS Depression crosswalk in patients with heart failure and comorbid major depression. Further research will be needed to evaluate the utility of the PROMIS measures in patients with heart failure.

CHALLENGES AND OPPORTUNITIES IN OPIOID RISK MITIGATION ACROSS MILITARY, VETERAN, AND CIVILIAN HEALTH SYSTEMS

Erin Finley, PhD, MPH¹, Suyen Schneegans, MA², Lauren Penney, PhD³, Mary Jo Pugh, PhD, RN³, Joseph Maddry, MD⁴, Megan Curtis, MA⁵

¹UT Health San Antonio/South Texas Veterans Health Care System, Boerne, TX; ²UT Health San Antonio, San Antonio, TX; ³UT Health San Antonio/South Texas Veterans Health Care System, San Antonio, TX; ⁴US Air Force, San Antonio, TX; ⁵University of Texas at San Antonio, San Antonio, TX

Background: Amid the ongoing U.S. opioid crisis, achieving significant change in opioid-related morbidity and mortality is likely to require multi-level efforts across health systems, including the Department of Defense (DoD), Department of Veterans Affairs (VA), and civilian sectors. We conducted a series of focus groups with national experts to identify core challenges and elicit recommendations toward increasing the safety of opioid prescribing in the U.S., including through use of clinical decision support (CDS).

Methods: We invited a panel of national experts to participate in a series of focus groups to discuss (a) challenges in opioid risk mitigation, (b) how best to support providers in safe and appropriate opioid prescribing across DoD, VA, and civilian healthcare systems, and (c) the role of CDS. Six focus groups were conducted via teleconference with 18 experts, 13 of whom participated in two groups occurring on separate days, allowing for in-depth, extended discussion. Transcripts were coded using grounded theory, resulting in generation of a summative framework describing the current climate of opioid prescribing and suggestions for targeted solutions.

Results: Eighteen experts representing primary care, emergency medicine, psychology, pharmacy, and public health/policy participated. Participants described a wide variety of challenges related to reducing opioid risk, including aspects of the current national climate, as well as challenges and opportunities specific to DoD, VA, and civilian healthcare sectors (e.g., high mobility among patients and providers in the military), and common barriers to safe opioid prescribing and use at the provider and patient levels. Participating experts identified recommendations for national-, system-, clinic-, provider- and patient-level change efforts spanning policy, research, education, and organization of health care delivery. CDS was identified as an important component of a comprehensive opioid risk mitigation strategy via (1) increasing integration of information across often-fragmented systems and (2) supporting providers in identifying and treating patients at increased risk for opioid misuse.

Discussion: Reducing opioid risk while ensuring safe and effective pain care, according to participating experts, is likely to require multi-level efforts spanning military, veteran, and civilian healthcare systems. CDS should be considered a core tool in this effort, accompanied by efforts to increase education for patients and providers, increase access to non-pharmacologic pain care, and support use of existing CDS, including state-level prescription drug monitoring programs.

CHANGES IN PAIN INTENSITY FOLLOWING DISCONTINUATION OF LONG-TERM OPIOID THERAPY

Travis Lovejoy, PhD, MPH¹, Crystal L. Smith, M.S.², Steven K. Dobscha, M.D.¹, Benjamin Morasco, PhD¹, Thomas Meath, MPH³, Michael Demidenko, BS⁴, Sterling McPherson, M.S.; Ph.D.⁵

¹VA Portland Health Care System, Portland, OR; ²Washington State University, Athol, ID; ³Oregon Health & Science University, Portland, OR; ⁴VA Portland Health Care System, Ypsilanti, MI; ⁵Elson S. Floyd College of Medicine, Spokane, WA

Background: Recent trends in opioid prescribing suggest fewer new opioid prescriptions and increased discontinuation of opioids for patients prescribed long-term opioid therapy (LTOT). However, consequences of opioid discontinuation, including its impact on patient-reported outcomes of pain intensity, are unknown.

Objective: To characterize changes in pain intensity in the year following LTOT discontinuation.

Methods: Retrospective electronic health record data were obtained from a national sample of N=600 U.S. Department of Veterans Affairs (VA) patients who discontinued LTOT in 2012. Data included demographic and clinical characteristics of the sample, as well as patient-reported pain intensity ratings obtained during routine outpatient clinical encounters in the year prior to and following opioid discontinuation.

Analysis: Latent growth models characterized the average pain trajectory across the entire sample, while growth mixture models delineated distinct pain trajectory sub-classes.

Results: Average pain at the time of opioid discontinuation was 4.9 on a scale of 0 (“no pain”) to 10 (“worst pain imaginable”). Several different growth curves were fit to the data to account for the possibility of curvilinear pain score trajectories. However, the best fitting model was linear, characterized by slight but statistically non-significant declines in pain over the 12-month post-discontinuation period ($B=-0.179$, $SE=0.142$, $p=0.208$). Pain at the time of LTOT discontinuation varied widely between patients suggesting the possibility of distinct pain trajectory sub-classes. Follow-up growth mixture models identified four sub-classes: sub-clinical pain (30% of the sample; average pain at discontinuation=0.054), mild clinically-significant pain (17%; average pain=3.590), moderate clinically-significant pain (27%; average pain=5.972), and severe clinically-significant pain (26%; average pain=7.827). Similar to the overall sample, pain trajectories in each of the four sub-classes were characterized by slight reductions in pain over time, with patients in the mild and moderate pain trajectory categories experiencing the greatest pain reductions post-discontinuation ($B=-0.106$, $SE=0.053$, $p=0.046$ and $B=-0.113$, $SE=0.055$, $p=0.041$, respectively).

Conclusions: Pain intensity following discontinuation of LTOT does not, on average, worsen for patients and may slightly improve, particularly for patients with low-to-moderate pain at the time of discontinuation.

ARE PAIN-RELATED OUTCOME EXPECTANCIES ASSOCIATED WITH SMOKING CESSATION OUTCOMES AMONG PEOPLE WITH MOBILITY IMPAIRMENTS?

Romano Endrighi, PhD¹, Elizabeth M. Glowacki, PhD², Nicolle Rueras, MPH¹, Shira Dunsiger, PhD³, Belinda Borrelli, PhD²

¹Boston University, Boston, MA; ²Boston University, Henry M. Goldman School of Dental Medicine, Boston, MA; ³The Miriam Hospital/Brown University, Portsmouth, RI

Research indicates that smokers with chronic pain (CP) are less likely to quit smoking. People with Mobility Impairments (MI; use equipment to ambulate) have a high prevalence of both smoking (35%) and CP. The effect of CP on smoking cessation in this population is unknown. Moreover, no studies have examined the role of smokers' perceptions and outcome expectations (OEs) regarding the effect of smoking on pain in the context of smoking cessation among people with MIs. The aim of this study is to examine whether OEs are prospectively associated with smoking cessation and motivation to quit after controlling for CP. Hypotheses were 1) OEs regarding the effect of smoking on pain would be prospectively associated with smoking cessation over and above the effect of self-reported CP, and 2) among non-quiters, OEs would predict motivation to quit over and above the effect of CP. This study is a secondary analysis of a smoking cessation induction trial among smokers with MIs ($n=263$, $M=54$ yrs, 55% female). Smokers did not have to be motivated to quit to enroll. Baseline measures were: Self-reported CP (constant & frequent pain, not fleeting or minor) and the Pain and Smoking Inventory (PSI), which has 3 subscales assessing OEs: smoking as a strategy for coping with pain (PSI-Cope), pain as motivator of smoking (PSI-Motiv) and pain as a barrier to smoking cessation (PSI-Barrier). Outcomes were 7 and 30-day point prevalence abstinence (ppa) 4 and 6-months post-baseline. Motivation to quit was assessed at baseline and 6-months (are you planning to quit smoking within 30-days? Yes vs no). Data were analyzed on an intention to treat approach (missing=smoking) with logistic regression models adjusted for age, treatment group, past year quit attempts and CP. Baseline motivation was also controlled for in models with motivation as the outcome. At baseline, 86% self-reported CP. PSI scores on all subscales were significantly higher in those with, vs. those without CP ($p<.01$). Only the PSI-Cope scale was significantly associated with 7-day ppa ($OR=.76$, 95%CI=.58, 1.0) and 30-day ppa ($OR=.68$, 95%CI=.50, .93), such that greater use of smoking to cope with pain predicted lower odds of smoking cessation; self-reported CP was not significant associated with either outcome. Among smokers who never quit during the study ($n=137$), the PSI-Motiv ($OR=1.44$, 95%CI=1.03, 2.0) and PSI-Barrier ($OR=1.5$, 95%CI=1.03, 2.1) scales were significant predictors (not the PSI-Cope scale), such that those who perceived pain as a motivator to smoke and those who perceived it as a barrier to quitting were more likely to be planning to quit within 30 days. Smoking to cope with CP appears to be a more important predictor of smoking cessation vs. self-report of CP, which has implications for identifying smokers who may need more support with cessation.

INJURY STATUS AS A MODERATOR OF BIDIRECTIONALITY BETWEEN PAIN AND PTSD SYMPTOMS IN VETERANS

Sharon Y. Lee, M.A., M.S.¹, Lucy Finkelstein-Fox, M.S.¹, Crystal Park, Ph.D.²

¹University of Connecticut, Storrs, CT; ²University of Connecticut, 06269-1020, CT

The Department of Veterans Affairs estimates that 17% percent of recent veterans have comorbid pain and PTSD, which is higher than rates found in nationally representative samples. According to the Mutual Maintenance Model of pain and PTSD, properties of one condition feed into the escalation of symptoms for the other condition (Sharp & Harvey, 2001). However, few studies have empirically tested this model by examining the bidirectional relationship between pain and PTSD symptoms over time, and none have examined deployment injury status as a moderator of these bidirectional effects. To address these gaps in the literature, the present longitudinal study examined the bidirectional relationship between self-reported pain interference and PTSD symptoms in a sample of male and female OEF/OIF/OND veterans, and tested deployment injury status as a moderator of these links. The following hypotheses were tested: The relationship between pain and PTSD symptoms is bidirectional for both injured and non-injured veterans (H1); reciprocal relationships between pain and PTSD symptoms are stronger for injured veterans than for non-injured veterans (H2); and PTSD symptoms, rather than pain, are a stronger determinant of the reciprocal relationship between pain and PTSD symptoms for both injured and non-injured veterans (H3). Participants completed phone interviews about pain interference and PTSD symptoms at three time points, each three months apart. We conducted two separate cross-lagged panel analyses using structural equation modeling for injured veterans ($n=381$) and non-injured veterans ($n=338$), with the end of active service date as a covariate. Results partially supported H1 and fully supported H2, demonstrating bidirectionality between pain and PTSD for the subset of veterans who sustained injuries during deployment, but not for veterans with pain symptoms unrelated to deployment injuries. For injured veterans, elevated PTSD symptomology over time was mediated by pain (Time 1 PTSD to Time 2 Pain: $\beta=-.15(.05)$, $p<.01$; Time 2 Pain to Time 3 PTSD: $\beta=.10(.04)$, $p<.05$), whereas elevated pain over time was not mediated by PTSD symptoms; therefore, H3 was not supported. These results suggest that pain management may be a crucial target for the comprehensive care of returning veterans with PTSD symptoms and deployment-related injuries.

UNDERSTANDING FACTORS LINKED TO WEIGHT GAIN EARLY
IN PREGNANCY AMONG WOMEN WHO BEGIN PREGNANCY
WITH OVERWEIGHT OR OBESITY

Michele D. Levine, PhD¹, Maria Tina Benno, BS², Rachel P. Kolko, PhD³, Rachel H. Salk, PhD⁴, Marsha D. Marcus, PhD¹, Elizabeth M. Venditti, PhD⁵

¹University Of Pittsburgh, Pittsburgh, PA; ²University Of Pittsburgh School of Medicine, Pittsburgh, PA; ³University Of Pittsburgh, School of Medicine, Pittsburgh, PA; ⁴University Of Pittsburgh, Pittsburgh, PA; ⁵University of Pittsburgh, Pittsburgh, PA

Women who begin pregnancy overweight or obesity (OV/OB) are at risk for gaining more weight during gestation than is recommended. Gaining excessive gestational weight is associated with negative obstetric outcomes and weight-related health complications. To address pregnancy-associated weight gain, it is important to examine the timing of gestational weight gain (GWG) and to identify modifiable factors associated with excessive gestational weight gain. Accordingly, we sought to examine prenatal characteristics among pregnant women with OV/OB.

Pregnant women ($N = 200$) with a body mass index ≥ 25.0 kg/m² ($M = 32.7 \pm 6.45$) and gestational age < 20 ($M = 15.6 \pm 2.4$) were enrolled in a longitudinal study of the psychosocial predictors of GWG. Women were 28.2 ± 5.5 years old and 55% ($n=109$) reported the current pregnancy to be unintentional. All women self-reported their weight prior to pregnancy and height and weight were measured at study enrollment. Early GWG was calculated as the difference between current weight and self-reported pre-pregnancy weight. Rate of early GWG was determined as the ratio of GWG to weeks of gestation. Women also reported demographic and pregnancy-related information, and completed a semi-structured psychiatric interview.

On average, women gained 8.2 ± 13.0 lbs in early pregnancy and 28% ($n=55$) had met or exceeded guidelines established for total GWG. Women with pre-pregnancy obesity gained more early GWG (6.3 ± 9.5 vs 9.7 ± 15.1 , $p = .056$) than did women with pre-pregnancy overweight ($p = .001$). Non-white women ($p = .001$) and those with low income ($p = .004$) also gained more early GWG. However, there were no differences in lifetime history of psychiatric disorders, intentionality of pregnancy, perceived stress or current depressive symptoms between women who had and had not gained early weight. Further examination of women at the highest quartiles of early gestational weight gain suggests that some women gain 23.9 ± 12.1 lbs early in pregnancy at a rate of $1.6 \pm .9$ lbs weekly.

Women starting pregnancy at high risk for excessive GWG gain a large amount of their total gestational weight in the first half of pregnancy. Women in the highest quartiles of weight gain exceed the rate of weight gain suggested by the Institute of Medicine and have already exceeded IOM guidelines for 40 weeks of gestation within the first 20 weeks of pregnancy. Women who begin pregnancy with obesity and nonwhite women with low incomes may be at greatest risk for early weight gain but do not differ in psychological and psychiatric characteristics related to weight gain. Early GWG may be a critical target for intervention.

INTEGRATION OF TECHNOLOGY IN LIFESTYLE INTERVENTIONS
FOCUSED ON WEIGHT GAIN DURING PREGNANCY: A SYSTEMATIC
REVIEW

Alicia A. Dahl, MS, PhD (abd)¹, Marilyn Wende, BS, MSPH², Gabrielle Turner-McGrievy, PhD, MS, RD¹, Shan Qiao, PhD¹, Sara Wilcox, PhD¹, Jihong Liu, ScD¹, Rachel E. Davis, MPH, PhD¹

¹University of South Carolina, Columbia, SC; ²University of South Carolina, Cayce, SC

INTRODUCTION: Obesity rates among women of childbearing age are a growing public health concern. Nearly half of pregnant women in the U.S. enter pregnancy overweight or obese. Similarly, half of pregnant women exceed the Institute of Medicine guidelines for healthy gestational weight gain (GWG). Technology-mediated health interventions serve as a readily-accessible resource for delivering pregnancy weight-related information. This systematic review aimed to assess the impact of technology-mediated interventions on the prevention of excessive GWG.

METHODS: This review used the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. Three main MeSH terms were identified as critical components of this systematic review: technology, pregnancy, and weight outcomes. The second main search parameter was inclusion of randomized controlled trials (RCTs) only. Literature was collected through PubMed and Web of Science databases, and then reviewed and summarized from July 2016 through September 2017 by two reviewers. Only studies in which GWG was a measured outcome (collected by self-report or clinically-measured anthropometric data) were included.

RESULTS: Thirteen RCTs were selected for inclusion. The pooled RCTs included a total of 4,928 pregnant women, with seven studies based in the U.S. Ten of the studies relied on health coaches or registered dietitians for counseling support in the intervention. Telephone calls were the most commonly reported technology component ($n=6$, 46.2%) followed by text messages ($n=5$, 38.4%) and websites ($n=2$, 15.4%). Four of the studies reported significant differences in favor of the technology-mediated intervention groups, where participants gained less GWG compared to participants in the control groups.

DISCUSSION: We are unable to conclude whether technology-mediated lifestyle interventions are more successful in preventing excessive GWG than standard OB care, due to the varying demographic characteristics and sample sizes of the studies included in this review. Additionally, the diverse sources of technology used across these studies prevent us from concluding which methods are more or less effective in the prevention of excessive GWG. To address gaps in the literature, studies that examine the effect of different technology-mediated methods in lifestyle interventions, specifically among a powered sample of pregnant women, are needed to guide future e-Health interventions and resources.

11:15 AM-11:30 AM

MOBILIZING MHEALTH FOR MOMS: A REVIEW OF MOBILE APPS FOR TRACKING GESTATIONAL WEIGHT GAIN

Alicia A. Dahl, MS, PhD (abd)¹, Caroline G. Dunn, MS, RD², Alycia Boutte, MPH¹, Anthony Crimarco, MS¹, Gabrielle Turner-McGrievy, PhD, MS, RD¹

¹University of South Carolina, Columbia, SC; ²USC, Columbia, SC

INTRODUCTION: Almost one-half of all pregnant women in the U.S. exceed the Institute of Medicine's (IOM) weight gain guidelines. Mobile apps hold promise as a beneficial tool for facilitating healthy gestational weight gain (GWG). However, there is a need to examine apps on the market to determine if they provide users information consistent with IOM guidelines and behavioral strategies to help facilitate healthy GWG. The aim of this study was to review mobile apps on Apple and Android app stores that focused on GWG tracking and evaluate their features for meeting the IOM weight gain guidelines, as well as if they contained tools to encourage healthy nutrition and physical activity (PA) during pregnancy.

METHODS: App descriptions were reviewed for inclusion criteria. Trained research staff downloaded and conducted a review of apps that focused on tracking GWG. The apps were assessed by two reviewers, using a profile of an overweight pregnant woman at 12–13 weeks gestation. The reviewers entered predetermined weights daily for eight consecutive days. The weekly rate of weight gain was set above 0.6 lbs. per week, which exceeded IOM guidelines for healthy GWG for an overweight woman. Apps were independently scored based on presence of weight-related features and guidelines.

RESULTS: Initially 296 apps were screened for review. Among these apps, 196 were excluded from further review because they (1) did not have a pregnancy focus or option, (2) were not in English, or (3) were not able to be downloaded or were no longer available. Another 13 apps were excluded because of technical issues. The final review included 87 apps. Overall, 73 (84%) apps had a weight tracking feature, 19 (22%) apps provided accurate weight gain guidelines, eight (9%) apps included calorie (kcal) recommendations, and seven (8%) apps included exercise guidelines.

DISCUSSION: Overall, there is a paucity of apps for tracking GWG that use IOM guidelines and promote evidence-based healthy weight-related behaviors during pregnancy. This is a missed opportunity because currently available weight-tracking apps may not be effective in preventing excessive GWG without providing accurate, individualized GWG recommendations or behavioral modifications necessary for healthy weight gain. Furthermore, this review demonstrates the importance of health care practitioners' role in providing accurate information and behavioral support for achieving healthy weight in pregnancy.

Paper Session 8: Supporting the Health of Mothers During Pregnancy

11:30 AM-11:45 AM

TREATMENT FIDELITY OF A STRESS MANAGEMENT PROGRAM FOR PREGNANT WOMEN: THE SMART MOMS PROJECT

Guido Urizar, PhD¹, Menchie Caliboso, M.A.², Cassandra Gearhart, M.A.¹

¹California State University, Long Beach, Long Beach, CA; ²Long Beach Board of Health and Human Services, Long Beach, CA

Despite the adverse effects that elevated levels of prenatal stress and cortisol have on maternal and infant health outcomes, few studies have developed and evaluated behavioral interventions designed to reduce stress during this critical period of development. The current study examined the efficacy and treatment fidelity of the SMART Moms Project (a prenatal stress management intervention) on reducing stress levels (perceived stress, salivary cortisol), improving negative and positive mood states (PANAS), and increasing confidence to use relaxation and coping skills among 55 low-income pregnant women (71% Latina, 76% annual income < \$20K). Women attended weekly group-based sessions over an 8-week period in which a clinically trained researcher taught relaxation and coping skills. Treatment fidelity was assessed via videotaped class sessions that were then coded for enactment, delivery, and receipt of the intervention to determine which of these factors were associated with changes in treatment outcomes (stress, mood, confidence) over the 8-week period. Paired samples t tests demonstrated a significant reduction in stress and cortisol levels [$t(52) = 7.26, p < .001$], improvements in negative and positive mood states [$t(249) = 6.07, p < .001$], and feeling more confident in using relaxation and coping skills post-intervention. Regression analyses showed that the treatment fidelity factors of enactment (participant use of intervention skills; $\beta = .45, p < .05$) and delivery (instructor adherence to intervention content; $\beta = .41, p < .05$) were most associated with demonstrated improvements in treatment outcomes. These findings demonstrate the impact that prenatal stress management interventions can have in improving women's health outcomes and identify treatment fidelity factors to be considered when delivering these interventions in underserved communities.

Panel Discussion 1

12:45 PM-1:45 PM

DISCUSSION OF NIH SCIENTIFIC PRIORITIES FOR ADVANCING RESEARCH ON ADHERENCE TO TREATMENT AND PREVENTION REGIMENS

Janet S. de Moor, PhD, MPH¹, Susan M. Czajkowski, Ph.D.²

¹National Cancer Institute, National Institutes of Health, Rockville, MD; ²National Cancer Institute, National Institutes of Health, Bethesda, MD, MD

Improving treatment adherence is the top priority of the National Institutes of Health (NIH) Adherence Research Network. The persistent challenge of sub-optimal adherence to prescribed medication and other treatment and prevention regimens (hereafter referred to as treatment adherence) highlights the need for transformative research in this area. Poor treatment adherence is common, regardless of the condition targeted, type of treatment, or population studied. Evidence from many chronic conditions has demonstrated a relationship between poor treatment adherence and an increased risk of disease occurrence, progression and mortality. However, despite several decades of research in this area, sub-optimal treatment adherence remains a considerable problem and there is a lack of consensus about how to improve adherence in different clinical contexts. A critical public health need is to build upon the current evidence base to fully understand the conditions that precipitate poor treatment adherence and develop and implement interventions to improve treatment adherence and health outcomes. This one hour panel discussion will highlight NIH scientific priorities for understanding and addressing suboptimal treatment adherence and provide a forum for group discussion between representatives from the NIH Adherence Network and the audience. More specifically, the panel will review the state of the science of treatment adherence and discuss major knowledge gaps and methodologic shortcomings of prior research that need to be addressed. The panel will then describe the scientific priorities of the NIH Adherence Network (and participating Institutes and Centers) for research to address the pervasive problem of suboptimal treatment adherence across conditions, populations and clinical contexts. Because treatment adherence is a complex phenomenon, influenced by the interaction of factors operating at the level of patient, family, provider, healthcare system, community, and the broader societal context, the importance of and need for rigorous multi-level research will be discussed. To support audience members who intend to apply for funding, information will be provided about specific funding opportunities at NIH for supporting adherence research and strategies for applying for grant funding from NIH. Examples of successfully funded projects will also be shared. The panel will be concluded with a group discussion between the presenters and the audience about the material presented.

Panel Discussion 2 12:45 PM-1:45 PM**CREATING THE IMPACT YOU SEEK IN BEHAVIORAL MEDICINE'S RAPIDLY-EVOLVING PUBLISHING LANDSCAPE**David E. Conroy, Ph.D.¹, Kevin S. Masters, PhD², Suzanne M. Miller, PhD³, Rachel Warren, N/A⁴¹The Pennsylvania State University, University Park, PA; ²University of Colorado Denver, Denver, CO; ³Fox Chase Cancer Center, Philadelphia, PA; ⁴Oxford University Press, New York, NY

Behavioral medicine experts have more options than ever before for disseminating their ideas and empirical discoveries. The options can be dizzying with traditional peer-reviewed journal articles complemented by emergent opportunities for stimulating dialogue in open-access journals, blogs, social media, press releases and more. Authors can increase their productivity and the impact of their work if they understand how and when to leverage these tools. Yet it is difficult to keep track of developments brought about by advancing technology, an evolving publishing industry, and the open science movement. This session features brief presentations from leaders in the behavioral medicine publishing community: the editors for the Society's two peer-reviewed journals and a representative from the Society's new publishing partner, Oxford University Press. Each speaker will present brief (10 minutes) informal remarks followed by an open question-and-answer period for attendees to ask their questions about navigating this rapidly-evolving landscape. Topics will include perspectives on (1) keys for success in peer review, (2) the status and health of the journals, (3) visions for the future of publishing behavioral medicine scholarship, and (4) whatever other topics are on the audience's mind.

CORRESPONDING AUTHOR: David E. Conroy, Ph.D., The Pennsylvania State University, University Park, PA; conroy@psu.edu

Panel Discussion 3 12:45 PM-1:45 PM**EMPIRICAL APPROACHES FOR ADAPTING BEHAVIORAL INTERVENTIONS IN CANCER CONTROL AND PREVENTION FOR SEXUAL MINORITY POPULATIONS**Jennifer M. Jabson, PhD, MPH¹, Deborah Bowen, PhD², Charles Kamen, PhD, MPH³, Alicia Kaye. Matthews, Illinois⁴, John Pachankis, PhD⁵¹University of Tennessee, Knoxville, TN; ²University of Washington, Seattle, WA; ³University of Rochester Medical Center, Rochester, NY; ⁴University of Illinois at Chicago, Chicago, IL; ⁵Yale University, New Haven, CT

Background: Sexual minority (gay, lesbian, and bisexual) people experience disparities in cancer risk and cancer-related outcomes. Behavioral interventions that address these disparities across the cancer control and prevention continuum are one important aspect of a comprehensive approach for reducing and eliminating disparities. However, most behavioral interventions have been designed without consideration of sexual orientation or the unique barriers that may diminish intervention efficacy for sexual minority people. Behavioral scientists and practitioners have addressed this problem by adapting behavioral interventions for sexual minority people. Few empirical or conceptual resources inform what adaptations can be made and which cancer-related outcomes are sensitive to adaptations among sexual minority people. Using conceptual frameworks and empirically-based experiences, this panel will discuss the state of the science in behavioral intervention adaptation for sexual minority people across the cancer control and prevention continuum. It will identify persisting gaps and propose empirically based solutions.

Methods: Each of the panelists will discuss their experiences adapting behavioral interventions to reduce sexual minority people's cancer risk and improve health across the cancer control continuum. Behavioral interventions to be discussed include physical activity for LGB cancer survivors; mindfulness-based stress reduction for LGB people in Appalachia; cognitive behavioral therapy for gay and bisexual young men, and tobacco cessation for LGB persons.

Results: Behavioral interventions can be adapted to address the needs of sexual minority persons, and these adaptations can be based on established conceptual frameworks. Adapted interventions produce positive experiences for sexual minority people participating in research. Adaptation work best when they are based on empirically identified needs with the target population. Additional data is needed to identify these specific needs, develop a toolkit of specific adaptation approaches, and test additional behavioral intervention to improve cancer related outcomes for sexual minority people.

Conclusion: In-depth feasibility testing is essential for adapting behavioral interventions to the needs of sexual minority people across the cancer control and prevention continuum. Published frameworks and empirical evidence should guide future adaptations to behavioral interventions, with the aim of reducing cancer disparities.

Panel Discussion 4 12:45 PM-1:45 PM**CREATING WALKABLE COMMUNITIES WITH WAYFINDING: THE NEW ORLEANS PERSPECTIVE**Janet Fulton, PhD¹, Adrian P. Bell, MSc CMILT², Kurt Weigle, MUPL³, Ginny Frederick, MS⁴¹CDC, Atlanta, GA; ²Activator Planning, Vancouver, BC, Canada; ³New Orleans Downtown Development District, New Orleans, LA; ⁴Centers for Disease Control and Prevention, Athens, GA

Regular physical activity reduces the risk of several chronic diseases. To improve access to opportunities for physical activity, such as walking, the U.S. Surgeon General has released a Call to Action to Promote Walking and Walkable Communities. Improving walkability in communities can help improve safety, community cohesion, and economic vitality. Many strategies exist to improve walkability. While some may be resource-intensive, such as designing communities, others offer evidence-based options to those with fewer resources.

One way to improve walkability is to provide street-level information about walking times and directions throughout a city, commonly known as wayfinding. Wayfinding has been successfully implemented in several cities across the U.S., Canada, and Europe. One example of wayfinding is the Walk to Fly Study which used point-of-decision prompt signage in the Atlanta Airport to encourage travelers to walk to their departure gate instead of riding the train. The prompts provided walking time and direction and as a result, walking increased 11–17%, with roughly 800 more travelers per day choosing to walk. This strategy can extend beyond airports to other settings such as cities.

The design of maps, signs, and other tools that go into a wayfinding project are guided by a strategy. The strategy uses surveys and community engagement alongside research on the physical legibility, traveler needs and navigational tactics used locally. The effectiveness of the solutions can be evaluated to determine their impact on outcomes such as walkability, health, transportation, safety, community identity and cohesion, and economic vitality.

The city of New Orleans has some wayfinding in the downtown and is considering updating, coordinating, and expanding wayfinding across several communities. The purpose of this session is to discuss wayfinding as a strategy to improve walkability, describe the process of developing an effective wayfinding system, and provide insights from New Orleans. Presenters will describe the process of developing and implementing an effective wayfinding system with domestic and international examples. The panel discussion will also include an overview and update of the current wayfinding system development project being completed in New Orleans. This will allow attendees the unique opportunity to hear from city officials how wayfinding became a priority for New Orleans and how wayfinding to improve walkability could be applied more broadly.

Panel Discussion 5 12:45 PM-1:45 PM**OVERCOMING BARRIERS TO NIH FUNDING FOR OPTIMIZATION OF BEHAVIORAL AND BIOBEHAVIORAL INTERVENTIONS**Thelma Mielenz, PhD¹, Ahnalee Brincks, PhD², Angela Pfammatter, PhD³, Sara StGeorge, PhD⁴, David N. Cavallo, PhD, MPH⁵¹Columbia University Mailman School of Public Health, New York, NY; ²Michigan State University, East Lansing, MI; ³Northwestern Feinberg School of Medicine, Chicago, IL; ⁴University of Miami Miller School of Medicine, Miami, FL; ⁵Case Western Reserve University, Cleveland, OH

The primary objective of this forum is to discuss strategies for overcoming perceived barriers to applying for NIH funding for proposals with the goal of optimization of behavioral and biobehavioral interventions (OBBI). By optimizing on aspects such as treatment effect, cost, patient burden, etc., behavioral and biobehavioral interventions can realize a greater public health benefit.

Proposals focusing on research study frameworks, designs and approaches to create, optimize and then evaluate interventions are considered novel and innovative by NIH. Although a growing number of NIH funding announcements specifically request the use of the multiphase optimization strategy (MOST) framework, including specific approaches, such as full and fractional factorial experiments, sequential, multiple assignment randomized trials (SMARTs), and microrandomized trials (MRTs), being an early adopter is challenging and these challenges may be a perceived barrier to receiving funding.

To frame this discussion, we will draw on examples from our own research to outline challenges presented by OBBI proposals to NIH. The following topics will be covered, including: i) supporting rationale for use of the MOST Framework and SMART designs; ii) sample size considerations (e.g. SMART designs); iii) new clinical trial definition policy and its impact on OBBI; iv) K award and OBBI and v) overall limitations of OBBI designs

CORRESPONDING AUTHOR: Thelma Mielenz, PhD, Columbia University Mailman School of Public Health, New York, NY; tjm2141@columbia.edu

Panel Discussion 6**12:45 PM-1:45 PM****BEHAVIORAL MEDICINE CAREER TRANSITIONS: MAKING THE MOVE FROM POSTDOCTORAL FELLOWSHIP TO EARLY CAREER**Karen Oliver, Ph.D.¹, Karlene Cunningham, PhD², Carly M. Goldstein, PhD³, Marisa Sklar, PhD⁴¹Alpert Medical School of Brown University/Providence VA Medical Center, Providence, RI; ²Brody School of Medicine, East Carolina University, Greenville, NC; ³The Miriam Hospital/The Alpert Medical School of Brown University, Providence, RI; ⁴University of California San Diego, La Jolla, CA

Making the move from postdoctoral fellowship to an early career position marks one of the most exciting time points in one's career. Progressing from trainee status to junior faculty can be both highly rewarding and anxiety-provoking. There are considerable challenges and opportunities that occur as people adjust to the new roles and responsibilities of their position, including meeting the new demands of the position, finding mentorship, working independently, earning a salary, balancing work and family, and/or becoming a supervisor instead of a supervisee. This panel will discuss opportunities and challenges in transitioning from postdoctoral fellowship to a variety of early career positions, including research, teaching, and clinical work. Discussion will include panelists' personal experiences with the postdoctoral fellowship to early career transition points as well as strategies for successfully coping with challenges and capitalizing on opportunities. They will share "lessons learned" and provide strategies for audience members to consider when faced with their own unique career transition challenges. This panel is designed to be interactive and there will be time for questions and discussion.

CORRESPONDING AUTHOR: Karen Oliver, Ph.D., Alpert Medical School of Brown University/Providence VA Medical Center, Providence, RI; Karen_Oliver@brown.edu

Panel Discussion 7**12:45 PM-1:45 PM****TRAINING OPPORTUNITIES IN BEHAVIORAL RESEARCH WITHIN THE NATIONAL CANCER INSTITUTE**Richard P. Moser, PhD¹, Maria A. Rincon, MPH², Emily B. Peterson, PhD²¹National Cancer Institute, Bethesda, MD; ²National Cancer Institute, Rockville, MD

The National Cancer Institute (NCI) is the largest institute within National Institutes of Health and the one that leads the nation's cancer research program. One of the critical goals of the NCI is to train the next generation of cancer researchers, and each year NCI trains approximately 3,500 fellows. Cancer-related training opportunities are especially critical for those engaged in behavioral research given the vital role of behavior in reducing cancer burden for the public along the entire cancer continuum, from prevention to end-of-life. This panel will first provide a brief overview of NCI and then focus on a training program offered within the Division of Cancer Control and Population Sciences (DCCPS). DCCPS offers a multi-disciplinary research training program including concentrations in behavioral, epidemiological, surveillance and health care-related topics. This training program accepts trainees from a wide range of educational backgrounds ranging from high school students up to and including those with doctoral-level degrees (e.g., PhD; MD). Next, the panel will provide an overview of current training opportunities and mechanisms offered in DCCPS, including the Cancer Research Training Award program, the Cancer Prevention Fellowship and Health Communication Internship Program. This discussion will include the degree requirements, application process, and fellowship focus. Following this overview, two current DCCPS fellows—one a post-Master's, and one a post-doctoral (PhD) fellow, will each discuss their respective educational and training backgrounds, share how they obtained their fellowships, describe their research interests and current projects, discuss professional training and leadership development opportunities available for fellows, and provide helpful advice for those interested in obtaining a DCCPS fellowship. Following the presentations, time will be allotted for attendees to ask questions of the presenters and to learn more about the myriad fellowship opportunities within DCCPS.

Panel Discussion 8**12:45 PM-1:45 PM****DO TREATMENT EFFECTS LAST?**Lee M. Cohen, Ph.D.¹, Matthew R. Cribbet, Ph.D.², Michael G. Perri, Ph.D., A.B.P.P.³, C. Steven Richards, Ph.D.⁴¹University of Mississippi, University, MS; ²Texas Tech University, Lubbock, TX; ³University of Florida, Gainesville, FL; ⁴Dept of Psy Sciences, Texas Tech University, Lubbock, TX

Panel Discussion at SBM, 2018:

Do Treatment Effects Last?

Abstract: Treatment effects often do not last. This problem is of considerable importance to treatment programs, research efforts, theoretical developments, and strategies to improve behavioral medicine interventions and public health. This panel discussion will focus on three specific health topics, to discuss the issues of treatment maintenance and evidence-based ways to enhance the long-term maintenance of treatment effects. The first presenter will discuss these issues in the context of the long-term management of smoking-cessation efforts, including behavioral interventions and multi-disciplinary efforts. The second presenter will discuss these issues in the context of the long-term management of sleep disorders, again including behavioral interventions and multi-disciplinary efforts. Finally, the third presenter will discuss these issues in the context of the long-term management of obesity, yet again with a focus on behavioral interventions and multi-disciplinary efforts. The last 20 minutes of this 1-hour panel discussion will be reserved for questions and answers, and a general discussion, with the panel and members of the audience. The introductions, Q&A, and general discussion with the audience will be moderated by the panel chair. The long-term maintenance and management of treatment effects is one of the challenging issues in behavioral medicine and associated areas in public health. These panel presentations and discussions will focus on this issue—*Do Treatment Effects Last?*

CORRESPONDING AUTHOR: Lee M. Cohen, Ph.D., University of Mississippi, University, MS; leecohen@olemiss.edu

Panel Discussion 9**12:45 PM-1:45 PM****ENHANCING MEASURES SELECTION USING THE NATIONAL COLLABORATIVE ON CHILDHOOD OBESITY RESEARCH MEASURES REGISTRY AND USER GUIDES**Amanda I. Samuels, MS, MPH¹, Sharon Kirkpatrick, PhD², Leslie A. Lytle, PhD³, James F. Sallis, PhD⁴, David Berrigan, PhD⁵, Jill Reedy, PhD⁶¹FHI 360, Washington, DC; ²University of Waterloo, Waterloo, ON, Canada; ³University of North Carolina at Chapel Hill, Chapel Hill, NC; ⁴UC, San Diego, La Jolla, CA; ⁵National Cancer Institute, Bethesda, MD; ⁶NCI, Bethesda, MD

Selection of appropriate and robust measures for capturing individual-level diet and physical activity (PA) behaviors and the environmental forces that influence these behaviors is a critical element of studies within the field of behavioral medicine. The National Collaborative on Childhood Obesity Research (NCCOR) Measures Registry is a searchable data base of 1207 studies that shed light on the properties of measures of behavior and environmental factors relevant to childhood obesity research. Recently, NCCOR, with funding from The JPB Foundation, commissioned the development of four detailed User Guides introducing critical issues in measurement and designed to facilitate effective use of individual and environmental measures of diet and PA. The Guides include case studies illustrating use of the Registry to aid in the selection of appropriate high-quality measures for a variety of research and practice purposes.

In this panel, participants will hear brief summaries of the main features of the Measures Registry and User Guides. These summaries will be interspersed with hands-on exploration of the Registry and Guides (using user-supplied laptops) to consider cases. Case studies will cover a range of applications, including randomized experimental designs, implementation studies, collection of evidence to guide monitoring, and evaluation of programs. Cases will be selected with an eye to relevance to researchers and practitioners from multiple sectors. These activities will be complemented by discussions of critical issues in measures selection within the domains of diet and PA, which will emphasize practical considerations, such as tradeoffs between respondent burden and level of detail collected, as well as complementary uses of device-based versus self-reported measures of PA.

While the focus of NCCOR and its measurement tools is children, principles of measures selection apply across the life course, and environmental measures may be equally relevant to adults and children. In sum, this panel session will introduce participants to state of the art resources and guidance concerning measures selection, facilitated by leading obesity, diet, PA, and environment-oriented public health researchers.

Panel Discussion 10 12:45 PM-1:45 PM**ADVERSE COMMUNITY EXPERIENCES AND RESILIENCE - ADDRESSING THE ADDICTION EPIDEMIC**

Ruben Cantu, N/A, Sheila Savannah, MA

Prevention Institute, Oakland, CA

Substance abuse and addiction has been an issue in the U.S. for decades, with a devastating impact on individuals, families and entire communities. Lately, we have seen a heightened awareness of the severity of this impact as opioid addiction and related deaths have reached near epidemic levels and have touched a wider range of populations that had previously been less affected. Awareness however is most effective when it is accompanied with a deeper understanding of root causes and a commitment to comprehensive action. The factors that often lead to substance use, addiction and often untimely death have roots in what are becoming known as diseases of despair. To address the underlying conditions of this crisis, we must identify solutions that foster hope and opportunity for those who feel hopeless and disempowered due to lack of jobs, disinvestment in education and public infrastructure, strained social connectedness and negative social norms. While there has been much attention on individual trauma resulting from these conditions, there has been less focus on trauma at the community level. Responding to the kind of trauma that we see affecting communities as a whole requires not only trauma-informed care for affected individuals, but also community-level solutions to address the physical, social-cultural, and equitable opportunity environments.

This session will introduce the Adverse Community Experiences and Resilience (ACE|R) framework as a lens through which to examine the growing opioid epidemic from varying angles and by multiple sectors. The framework provides an understanding of community-level trauma, including symptoms that play out in communities which contribute to and reinforce opioid use, including a break-down of social networks, relationships, and positive social norms across the community – as well as a disinvestment in public spaces and the built environment – all of which would otherwise be protective factors. The framework has been used by groups as diverse as community-based organizations, health departments, and practitioners to understand trauma at a community level and identify and develop strategies to build resilience. We will also share promising multi-sector strategies from across the U.S., including newer policy and practice efforts in Ohio, for building resilience and healing.

The ACE|R framework was developed by Prevention Institute and Dr. Howard Pinderhughes, with funding from Kaiser Permanente Northern California Community Benefit, to understand and address Adverse Community Experiences.

CORRESPONDING AUTHOR: Ruben Cantu, N/A, Prevention Institute, Oakland, CA; ruben@preventioninstitute.org

Panel Discussion 11 12:45 PM-1:45 PM**PHQ-9: IS IT A GOOD MATCH FOR INTEGRATED PRIMARY CARE?**Jennifer S. Funderburk, PhD¹, Rodger S. Kessler, N/A², Kurt Kroenke, MD³, John E. Ware, Jr., PhD⁴, William Douglas Tynan, Ph.D.⁵, Kathryn Kanzler, PsyD, ABPP⁶

¹VA Center for Integrated Healthcare, Syracuse, NY; ²Doctor of Behavioral Health, Arizona State University, Phoenix, AZ; ³Indiana University School of Medicine, Indianapolis, IN; ⁴UMass Medical School, Bristol, RI; ⁵American Psychological Association, Washington, DC; ⁶University of Texas Health Science Center San Antonio, San Antonio, TX

The PHQ-9 has a strong empirical foundation, is available, and has become very popular to use as a screener for depression in primary care. However, there are questions about its utility and ability to meet the needs among patient groups with multiple health problems and mental health needs. This is especially true within integrated behavioral health primary care settings, where the goal is improving functioning and quality of life for a broad range of presenting concerns. The purpose of this panel is to generate discussion regarding the strengths and challenges of using the PHQ-9. This discussion will help move forward current thoughts regarding whether or not it is a good match for integrated primary care settings and stimulate future research and discussion. Dr. Kroenke, one of the original developers of the PHQ-9, will present a brief presentation on the original purpose of the PHQ-9 and his thoughts for its utility. Dr. Kessler, an expert researcher on integrated care, will briefly discuss the fit (and lack thereof) of the PHQ-9 with integrated primary care settings. Dr. Ware, an expert in outcomes research and developer of the SF-36, will briefly discuss the integration of generic health outcomes monitoring and depression screening using the PHQ-9. This will be followed by a brief summary and discussion led by Dr. Tynan, a leader within the American Psychological Association on integrated health care. This will be a highly engaging presentation with half of the time reserved for panel discussion fueled by attendees questions and comments.

Panel Discussion 12 12:45 PM-1:45 PM**PANEL DISCUSSION: INCORPORATING BASIC RESEARCH ON COGNITION AND AFFECT INTO CLINICAL GENOMICS**William Klein, PhD¹, Barbara Biesecker, PhD², Rebecca Anne Ferrer, PhD³, Jada G. Hamilton, Ph.D., M.P.H.⁴, Ellen Peters, PhD⁵, Jennifer M. Taber, PhD⁶

¹National Cancer Institute, Potomac, MD; ²National Human Genome Research Institute, NIH, Bethesda, MD; ³National Cancer Institute, Rockville, MD; ⁴Memorial Sloan Kettering Cancer Center, New York, NY; ⁵The Ohio State University, Columbus, OH; ⁶Kent State University, Kent, OH

The science of genetics and genomics continues to evolve rapidly and capture the attention of more junior scholars. A primary focus on single penetrance genes such as *BRCA1/2* for breast and ovarian cancer has been supplanted by a wealth of generation sequencing technologies such as whole genome sequencing, leading to population-scale efforts such as the *All of Us* initiative. These new technologies, while exciting, introduce a multitude of important social, psychological, ethical, behavioral, and communication issues. People may now be faced with a wealth of information about genetic predispositions for disease and other health outcomes (for themselves and their families), accompanied by choices about when, how, where, and under what conditions they might receive and act on the information. Given that decision making is influenced greatly by basic cognitive and affective processes, it is essential to understand the cognitive and affective factors that might play a role in how people engage with genomic information. Moreover, because genetic testing may involve recommendations for lifestyle changes, it is also important to understand how genetic information can best be communicated to individuals and their family members to promote engagement in behaviors that can potentially modify their disease risk and improve health outcomes. In this panel, basic behavioral scientists who have stretched their work on cognition and affect into the domains of genomic risk, testing, communication, and behavior change will briefly review their work with a focus on barriers to this area of research, methods for overcoming those barriers, and lessons learned about the most feasible, fundable, and clinically relevant research questions one might address in this area. Speakers on this panel have expertise in: health communication; decision making; risk perception; cognition, affect and health; genetic counseling; decisions about receiving genetic risk information; and behavior change. The discussion is sponsored by the NCI Cognitive, Affective, and Social Processes in Health Research (CASPHR) working group, the Theories and Techniques of Behavior Change Interventions SIG, and the Health Decision Making SIG. The CASPHR group recently published an article linking self-regulation theory to genetic testing (Cameron et al., 2017, *Social and Personality Psychology Compass*) and is more generally interested in forging stronger connections between basic behavioral science and behavioral medicine particularly with regard to cancer prevention and control.

REPORT FROM THE AST ADHERENCE TASK FORCE: REAL WORLD OPTIONS FOR PROMOTING ADHERENCE

Larissa Myaskovsky, PhD¹, Kristin Kuntz, PhD², Michelle Jesse, PhD³, Cynthia L. Russell, PhD⁴, Zeeshan Butt, PhD⁵, Mary Amanda Dew, PhD⁶, John Devin Peipert, PhD⁷, Nimisha Sulejmani, PharmD, BCPS⁸, Abbie Leino, PharmD, BCPS², Christina Spivey, PhD⁹

¹University of New Mexico, School of Medicine, Albuquerque, NM; ²The Ohio State University Wexner Medical Center- Columbus, Ohio, Columbus, OH; ³Henry Ford Health System, Detroit, MI; ⁴University of Missouri-Kansas City, Kansas City, MO; ⁵Feinberg School of Medicine, Northwestern University, Chicago, IL; ⁶University of Pittsburgh, School of Medicine, Pittsburgh, PA; ⁷David Geffen School of Medicine, University of California, Los Angeles, Los Angeles, CA; ⁸Henry Ford Hospital, Detroit, MI; ⁹University of Tennessee Health Science Center College of Pharmacy, Memphis, TN

Adherence to medication and other forms of medical regimen adherence is an important area of study in behavioral medicine. Solid organ transplant recipients must adhere to a complex post-transplant medical regimen to ensure the health of their donated organ and their own health and well-being post-transplant. Thus, promoting adherence in organ transplant recipients is an important area of study for behavioral medicine clinicians and researchers.

The proposed panel will present the two-year work of a task force organized by the American Society of Transplantation to develop a white paper that focused on clinically practical, evidenced-based interventions that transplant centers could implement to increase adherence to medication and behavioral recommendations in adult solid organ transplant recipients. The task force consisted of behavioral researchers, clinicians, and transplant pharmacists. The group focused on what centers could do in their daily routines to implement best practices to increase adherence in adult transplant recipients. We developed a list of strategies using available resources, clinically feasible methods of screening and tracking adherence, and activities that ultimately empower patients to improve their own self-management. Because adherence is not solely a patient-driven factor, we examined broader multi-level areas for intervention including provider and transplant program practices. However, we did not include policy-level systemic solutions to improve adherence such as better coverage of medication costs through long-term Medicare immunosuppression coverage, as this form of intervention would not be within the direct control of the transplant center. We focused on issues of feasibility for clinical application, scalability and dissemination because there are already a number of excellent published literature reviews on adherence in transplant patients. We sought to investigate how the findings from others' work translate to clinical applications, and whether they would easily translate into clinical practice. The group aimed to take lessons from the literature and then come to consensus about what these lessons indicated for best practices in adherence assessment and intervention.

We will present the white paper findings, and then use it as a springboard for a discussion of issues related to transplant adherence, including defining, measuring, and intervening on adherence. Ultimately, the task force aims to foster greater recognition, discussion, and solutions regarding transplant center needs, resources, cultural changes, and other best practices required for implementing practical interventions targeted at improving adherence.

INNOVATIONS IN INTERPROFESSIONAL MENTAL HEALTH INTEGRATION EDUCATION: DEVELOPMENTS FROM A MULTI-SITE VA PRIMARY CARE PROJECT

Joshua L. Ruberg, Ph.D.¹, Jennifer Manuel, PhD², Noel Quinn, Ph.D.³, Elizabeth Painter, PsyD⁴, Kerri Schutz, PsyD⁵, C. Scott Smith, MD⁶, Anna Strewler, MS, AGNP-BC⁷, Renee H. Lawrence, PhD⁸

¹VA San Diego Healthcare System, San Diego, CA; ²San Francisco Veterans Affairs/University of California, San Francisco, san francisco, CA; ³VA Connecticut Healthcare System, West Haven, CT; ⁴Louis Stokes Cleveland VA Medical Center, Cleveland, OH; ⁵Department of Veterans Affairs, Los Angeles, CA; ⁶University of Washington, Boise, ID; ⁷San Francisco VA Health Care System, San Bruno, CA; ⁸Louis Stokes Cleveland Veterans Affairs Medical Center, Cleveland, OH

An ever-increasing number of healthcare facilities nationwide are integrating mental health (MH) care into primary care settings. In 2010, the Department of Veteran's Affairs (VA) formed the team-based Patient Aligned Care Team (PACT) primary care program and required the co-location of at least one MH provider for every PACT clinic that serves at least 5000 Veterans. However, MH co-location has not yet ensured the functional integration of MH care into PACT, and many PACT clinics do not effectively deliver team-based MH care. This is due in part because, prior to working in this capacity, the majority of PACT providers do not receive training alongside integrated MH providers, which can promote competency in team-based delivery of MH care. Toward this end, Five Centers of Excellence in Primary Care Education (CoEPCE) were established in 2011 by VA with the aim of fostering the development of interprofessional curricula related to patient-centered primary care. In 2015, CoEPCE was expanded with a goal of developing an interprofessional curriculum for the delivery of MH services in PACT.

This panel will share innovations in interprofessional MH curricular design developed at our CoEPCE sites. The goal of this panel is to help trainees and clinicians in academic primary care settings (VA and non-VA alike) learn several approaches to interprofessional team-based learning. Attendees will better understand how this training model can improve team-based provider competence with the delivery of MH services while also improving patient outcomes. Panelists from three sites will discuss innovations in three domains of team-based learning: didactic instruction, reflective practice, and workplace learning. The first panelist will discuss advances in our Motivational Interviewing (MI) didactics. Our MI training curriculum has evolved over the years and has been adapted to include clinically-relevant learning, coaching, and feedback opportunities that are feasible within a demanding interprofessional primary care training environment. The second panelist will discuss the role and importance of reflective practice in interprofessional curricula and primary care, highlighting innovations that utilize narrative writing and video tape review of patient encounters. The third panelist will discuss PACT-Interdisciplinary Case Unit (PACT-ICU), a systematic case conference model for high-risk, high-needs primary care patients that has been formally developed by the Boise VA and disseminated to five other CoE sites. Variations will be presented based on the San Francisco and West Los Angeles versions that are tailored to their specific populations.

Finally, a previous CoEPCE trainee and now current faculty member and two national consultants to CoEPCE (a physician and psychologist) will lead a discussion on how to implement interprofessional MH education in academic primary care settings.

Thursday April 12, 2018 12:45 PM – 1:45 PM

(PANEL DISCUSSION 15) PANEL DISCUSSION 15: OFFICE HOURS WITH NIH PROGRAM DIRECTORS

Chair: William N. Elwood, Ph.D. – OppNet/Health-Scientist Administrator, National Institutes of Health

Discussant: William N. Elwood, Ph.D. – OppNet/Health-Scientist Administrator, National Institutes of Health

Chair: Erica E. Moore, BS – Communications Director, OFFICE OF BEHAVIORAL AND SOCIAL SCIENCES RESEARCH, NATIONAL INSTITUTES OF HEALTH

Co-Presenter: Karen Lee, MD MPH – NIH/NICHD

Co-Presenter: Annette Kaufman, PhD, MPH – Health Scientist/Program Director, National Cancer Institute

Co-Presenter: Lanay Mudd, PhD – Program Director, National Institutes of Health

Co-Presenter: Adelaida M. Rosario, PhD – Health Specialist, Div of Scientific Programs, Community Health and Population Science Branch, NIH/National Institute on Minority Health and Health Disparities

Co-Presenter: Catherine Stoney, PhD – Program Director, NHLBI/NIH

Co-Presenter: Wendy Weber, ND, PhD, MPH – Branch Chief, Division of Extramural Research, NCCIH/NIH

Co-Presenter: Dana L. Wolff-Hughes, PhD – Health Scientist Administrator, Office of Behavioral and Social Sciences Research, National Institutes of Health

Co-Presenter: Dawn A. Morales, Ph.D., Experimental Psychology – Health Scientist, National Institute of Dental and Craniofacial Research, National Institutes of Health

Co-Presenter: Susan M. Czajkowski, Ph.D. – Chief, Health Behaviors Research Branch, National Cancer Institute, NIH

NIH can seem daunting and mysterious to new investigators or experienced researchers looking to expand their horizons beyond the topics they traditionally have addressed. OBSSR hosts Office Hours to simplify the process of connecting researchers and NIH program directors.

Rather than a grantspersonship workshop, this session provides roundtable mentoring with at least one IC-based program director per table. If a laptop and projector are available, a timed PowerPoint presentation will provide application tips and funding opportunities throughout the session.

Participants who'd like tailored advice for their projects-in-development should bring at least five paper copies of a one- to two-page synopsis of the research aims, hypotheses, and methods. Participants interested in fellowship opportunities should bring a similar number of vitae/biosketches. NIH staff will provide participants with detailed feedback and advice. OBSSR representatives will provide overall scientific feedback and refer participants to ICs and program directors not represented at this meeting.

Symposium 18 2:00 PM-3:15 PM

SHAPING THE FUTURE OF PHYSICAL ACTIVITY PROMOTION: HIGHLIGHTS FROM THE 2018 PA GUIDELINES SCIENTIFIC ADVISORY COMMITTEE REVIEW

Abby C. King, PhD¹, David X. Marquez, PhD², Melissa A. Napolitano, PhD³, Matthew P. Buman, PhD⁴, Melicia Whitt-Glover, PhD⁵

¹Stanford Prevention Research Center, Palo Alto, CA; ²University of Illinois at Chicago, Chicago, IL; ³The George Washington University, Washington, DC, DC; ⁴Arizona State University, Phoenix, AZ; ⁵Gramercy Research Group, Winston-Salem, NC

As evidence for the positive health impacts of regular physical activity and reduced sedentary time continues to grow, there is increasing urgency to substantively address the physical inactivity epidemic in the U.S. and worldwide. Using a social ecological framework, this session will highlight the evidence reviewed by the 2018 Physical Activity Guidelines Scientific Advisory Committee of those intervention approaches with demonstrated efficacy as well as those which show promise in stemming the tide of inactivity at different levels of impact. Dr. Abby King (chair) will begin the session with an overview of the Scientific Advisory Committee's work across different levels of impact, including examples of effective interventions at the environmental and policy levels. Dr. David Marquez will present on efficacious approaches at the individual and community levels of impact. Dr. Melissa Napolitano will describe the current state of the evidence in the information technology arena, and Dr. Matthew Buman will overview the latest advances in reducing sedentary time. Finally, Dr. Melicia Whitt-Glover will highlight the most critical challenges, needs, and future directions required to significantly advance the physical activity promotion field.

Symposium 18A

EFFECTIVE PHYSICAL ACTIVITY PROMOTION AT INDIVIDUAL AND COMMUNITY LEVELS

Dr. David X. Marquez, PhD

For decades, behavioral scientists have been conducting physical activity (PA) research at various levels of impact, including individual-level interventions, which involve delivery of in-person PA advice, support, and/or other behavior change strategies, and community level interventions occurring in those locales where people gather for educational, housing, consumer-related, health-related, or social purposes. The purpose of this presentation is to highlight effective interventions at individual and community levels based on a recent evidence review. Individual-level interventions have occurred across the life course, and have often been theory-based. Promising cCommunity-level interventions have occurred in schools and childcare settings, as well as in community-wide, faith-based, nurse-delivered, worksite, and primary care settings. However, within both individual and community levels there is large variability related to study rigor and population targets. At the individual level, evidence was supportive of diverse interventions in youth and in different adult age groups, including, for the latter ages, those that were peer-led and theory-driven. For example, peer-led self-management interventions were found to be effective in older adults and individuals with chronic disease at producing small but meaningful increases in PA when compared with minimal/no-treatment controls. At the community level, evidence was particularly supportive of interventions in community-wide and school settings. For example, in schools, interventions that revise the structure of physical education classes have been effective for increasing PA in primary school-aged youth. Among recommendations for future research at the individual level are lengthening intervention and evaluation periods; examining the role of self-regulation techniques and related evidence-based strategies in more diverse populations across the age range; and examining which interventions are effective across life-course transitions. Among recommendations for research at the community level are conducting rigorous cluster-randomized designs; broadening enrollment targets to include more diverse sociodemographic groups; evaluating targeted uses of technologies in broadening potential reach and efficacy of such programs; and applying relevant behavioral theories to further guide intervention development and evaluation.

Symposium 18B

PHYSICAL ACTIVITY PROMOTION USING INFORMATION AND COMMUNICATION TECHNOLOGIES

Dr. Melissa A. Napolitano, PhD

Technological capabilities have enabled physical activity (PA) promotion interventions to be delivered via a variety of communication channels and strategies. The accessibility and reach of these technologies among US adults and youth have made them attractive platforms upon which to deliver PA interventions. A review of interventions using information and communication technologies (ICT) was conducted. To aid in review and future study, ICT interventions were subcategorized by delivery channel (e.g., telephone assisted, web-based or Internet delivered, social media, mobile phone, computer tailored print) or device (e.g., activity monitor, interactive video game). Within the seven subcategories, there is sufficient evidence to promote the use of activity monitors among adults and those with diabetes. Examining other devices, like interactive video games, yielded insufficient evidence for increasing physical activity for adults and children, primarily due to study quality and duration of outcomes measured. Despite this, there is some promise related to the use of interactive video games for settings such as schools or in settings to promote short term bouts of activity among older adults. There also is evidence to support the use of different channels for delivery of physical activity information and support, including telephone-assisted, web-based or Internet delivered, and mobile phone applications, with varied efficacy for each by population. Areas of future promise and further study include the use of social media, which had weaker evidence but was generally positive in terms of intervention effects. Finally, the use of computer tailored print, which involves technology support to deliver personalized messages and support also showed positive, but small effects for promoting physical activity among adults. Future studies in the information and communication technology arena should broaden reach to increase diversity and sample generalizability as well as employing new methods for evaluating information technology innovations (e.g., adaptive interventions). During this symposium, exemplars in each of the seven subcategories will be discussed along with additional recommendations for future areas that will continue to advance the physical activity field.

Symposium 18C

REDUCING SEDENTARY TIME IN YOUTH, ADULTS, AND OFFICE WORKERS

Dr. Matthew P. Buman, PhD

Behaviors done while sitting or reclining that require little energy expenditure (i.e., sedentary behaviors) are ubiquitous, habitual, and socially-reinforced in modern societies. Environmental, social, and individual-level determinants of sedentary behavior appear distinct from those associated with moderate-vigorous physical activity. Intervention strategies have recently emerged that have sought to target sedentary behavior in different contexts (e.g., schools, television viewing, and workplaces) and population subgroups (e.g., youth, adults, and office workers). The purpose of this presentation is to summarize the evidence on the efficacy of interventions for reducing sedentary time from a recent evidence review. There was substantial evidence to support small but consistent intervention effects for strategies targeting youth. These interventions varied in age group (i.e., 3–15 years), context (e.g., school, clinic, community), and intervention length (most > 6 months), but focused primarily on targeting reductions in television and screen-time behaviors. There was insufficient evidence for sedentary behavior focused interventions for reducing sedentary time in general adult populations due to few and poor quality studies. There was, however, small but consistent effects for “lifestyle” based interventions (i.e., intervention strategies simultaneously targeting sedentary and physical activity behaviors) for reducing overall sedentary time. The strongest evidence, with moderate to large effect sizes for workplace sedentary behavior, were observed among office workers. The most efficacious interventions were multicomponent in nature (i.e., inclusive of individual, social, and environmental elements) and included provision of a sit-stand workstation, walking workstation, or other activity-permissive environmental supports. Finally, there was little to no evidence overall for compensatory (e.g., reducing sedentary time during work will increase sedentary time outside of work) or cross-over (e.g., sedentary behavior interventions increasing moderate-vigorous physical activity) effects. Among recommendations for future sedentary behavior intervention research are more rigorous research designs, broadening interventions to more population subgroups (e.g., older adults, workers in diverse work environments), and the dissemination and implementation of evidence-based strategies to assess real-world effectiveness.

ACCEPTANCE-BASED APPROACHES TO BEHAVIOR CHANGE; APPLICATIONS TO WEIGHT CONTROL AND PHYSICAL ACTIVITY INTERVENTIONS

Margaret Schneider, Ph.D.¹, Jocelyn Rimmert, B.A.², Leah Schumacher, MS², Courtney J. Stevens, PhD³, Meghan Butryn, Ph.D.²

¹University of California, Irvine, Irvine, CA; ²Drexel University, Philadelphia, PA; ³Geisel School of Medicine at Dartmouth, Lebanon, NH

Acceptance-based behavioral treatments (ABT) targets behaviors for change (e.g., physical activity, diet, smoking) by providing individuals with the skills to accept the internal experiences (e.g., thoughts, feelings, physiological sensations) that may impede the behavior change and encouraging them to link behavioral goals with personal values. Relevant skills include accepting the experience of negative thoughts and sensations without letting these internal experiences dictate behavioral choices, being willing to engage in desired or valued behaviors that may come with uncomfortable internal experiences, and learning to “defuse” from the negative internal experiences (i.e., creating some separation between these experiences and behaviors). Interventions utilizing ABT to increase physical activity either as an end in itself or as a means to bring about weight loss have shown some promise. This symposium will present data from three independent intervention studies using ABT. A pilot study delivered in a middle-school setting found that 12 weekly ABT sessions increased physical activity and improved physical fitness among low-active adolescents compared to a control group. In a longer trial of ABT, 26 group sessions designed to target weight loss by increasing physical activity and modifying diet were found to increase food craving acceptance and physical activity acceptance among 283 adults with overweight/obesity. Although the ABT group did not show greater weight loss over the course of the intervention, greater increases in acceptance related to eating and physical activity were related to weight loss across all study groups. A third study of insufficiently active women delivered 2 ABT workshops and found a positive impact on physical activity acceptance. Moreover, higher physical activity acceptance at the end of the 30-day intervention predicted exercise maintenance at the 9-month follow-up. The overall findings from these three studies will be summarized by a discussant, who will address the lessons learned from these studies and the suggested directions for future research.

Symposium 19A

PILOT TEST OF AN ACCEPTANCE-BASED BEHAVIORAL INTERVENTION TO PROMOTE PHYSICAL ACTIVITY AMONG ADOLESCENTS

Jocelyn Rimmert, B.A.

Introduction: School-based interventions to date have had little success increasing adolescent physical activity (PA). New strategies are needed. Acceptance-based behavioral treatments (ABT) for PA encourage individuals to accept internal experiences (emotions, urges, physiological sensations) and not attempt to alter or suppress them, with the goal of uncoupling internal experiences from PA and instead linking PA to what is most important and personal: values. Studies of ABT for PA have demonstrated preliminary efficacy among adults; however, ABT for PA is untested among adolescents. This study reports the findings of a school-based pilot of an ABT intervention for PA.

Methods: Middle schoolers (n=20) who engaged in fewer than 60 min/day of moderate-to-vigorous physical activity (MVPA) completed assessments for cardiorespiratory fitness (cycle ergometer), body fat (skinfold), body mass (BMI percentile; height and weight), and waist circumference before and after a 12-week intervention. Students randomized to an ABT PA intervention (N = 10) received 12 weekly behavioral counseling sessions consisting of acceptance (i.e. willingness, defusion, values) and behavioral (i.e. goal setting, habit formation) skills. All participants wore a Fitbit Flex to assess PA throughout the intervention period (weeks 1–12). Descriptive data and effect sizes examined changes in fitness, body fat, BMI percentile and waist circumference. Multivariate linear mixed effect analysis evaluated the impact of the intervention on Fitbit steps and MVPA.

Results: The FitBit data showed a steady increase in steps (150 steps/day each week; $p < .01$) and MVPA (1 minute/day each week; $p < .001$) in the intervention group but not in the control group. At the end of 12 weeks, the intervention group had increased average daily steps by 1200 and average min/day of MPVA by 12 minutes. Compared to the no-intervention control group, the intervention group demonstrated improvements in measures of physical fitness, with medium to large effect sizes (cardiorespiratory fitness VO_2 ml/kg/min, $d=+4.38$; body fat, $d=-2.14$; BMI percentile, $d=-0.77$; and waist circumference, $d=-0.57$ cm).

Conclusion: A school-based intervention combining acceptance-based and behavioral skills showed preliminary evidence of efficacy among low-active middle-school students. After the 12-week intervention, the intervention group was more active and demonstrated changes in a positive direction on a range of fitness indices.

Symposium 19B

TARGET ENGAGEMENT AND MECHANISMS OF ACTION IN ACCEPTANCE-BASED BEHAVIORAL TREATMENT FOR ADULT OBESITY

Leah Schumacher, MS

Acceptance-based behavioral treatment for obesity has shown promise for improving weight loss outcomes. However, not all trials of this approach have demonstrated superior outcomes to traditional behavioral therapy (BT). Additional research on target engagement and hypothesized mechanisms of action in acceptance-based treatment is needed to inform further treatment development. This study examined change in several measures of psychological acceptance in a randomized trial evaluating the efficacy of an acceptance-based treatment for obesity. In this trial, a main effect of condition on weight loss was *not* observed. Participants were 283 adults with overweight/obesity ($M_{BMI} = 35.0 \text{ kg/m}^2$; $M_{age} = 53.2$; 78.8% women; 68.1% White) recruited from the community. Participants were randomized to receive 26 group sessions of traditional BT, BT with skills for managing the obesogenic environment (BT+E), or BT with environmental and acceptance-based skills (BT+EA) over 12 months. Participants were weighed and completed measures of general acceptance (Acceptance and Action Questionnaire-II), food-specific acceptance (Food Craving Acceptance and Action Questionnaire; FAAQ), and physical activity-specific acceptance (Physical Activity Acceptance Questionnaire; PAAQ) at 0, 6, and 12 months. Results revealed a main effect of time on all measures of acceptance ($ps < .008$), with greater acceptance observed at 6 and 12 months across conditions. Additionally, there was a significant time by condition interaction on FAAQ ($p = .03$) and PAAQ scores ($p = .04$), with participants in BT+EA exhibiting greater FAAQ and PAAQ scores at 6 and 12 months ($ps < .03$). Controlling for baseline levels of acceptance and BMI, greater increases in FAAQ and PAAQ scores from 0 to 6 months predicted greater weight loss from 6 to 12 months ($ps < .001$). Greater increases in FAAQ and PAAQ scores from 0 to 6 months and 0 to 12 months also were associated with greater concurrent weight losses ($ps < .001$). These findings suggest that acceptance-based treatment targets food- and physical activity-specific acceptance to a greater extent than treatment without these skills, though this may not translate into superior weight loss. However, greater increases in eating- and physical activity-specific acceptance (regardless of condition) are related to greater weight loss. Additional research is needed to determine what accounts for increases in acceptance in treatments that do not integrate these skills. Future studies also should examine differences in acceptance-based protocols that may affect their efficacy (e.g., emphasis on particular skills).

Symposium 19C

EXPERIENTIAL ACCEPTANCE AS A MECHANISM OF EXERCISE MAINTENANCE AND THE POSSIBLE ROLE OF WEIGHT STATUS ON INTERVENTION IMPACT: SUPPORTING EVIDENCE FROM THE GET ACTIVE! TRIAL

Courtney J. Stevens, PhD

Nearly half of American women are insufficiently active despite an enormous evidence base advocating the health benefits of regular exercise. Low rates of exercise adherence may be explained, in part, by the hedonic principle—"pursue pleasure, avoid pain." Exercise is associated with numerous aversive experiential factors, and obesity may contribute to exacerbation of those aversive factors. Acceptance-based behavioral interventions (ABBIs) promote participation in values-aligned behaviors (e.g., exercise) by increasing willingness to experience affiliated psychological and physical discomforts. The present investigation aimed to (1) test the impact of an exercise promotion ABBI on exercise behavior adoption and maintenance, (2) assess mechanisms of exercise behavior change (experiential acceptance), and (3) explore the role of weight status (obese, non-obese) across conditions.

$N = 119$ insufficiently active women aged 21–65 (BMI: 17–47 kg/m^2), were randomly assigned to 1 of the 3 interventions: (1) acceptance-based health coaching (ABBI), (2) education-based health coaching (EDUC), or (3) no-health coaching control (CTRL). The study was divided into 2 phases: Phase 1 "Adoption" (visit 1–visit 2), and Phase 2 "Maintenance" (3-, 6-, and 9-months follow up). During Phase 1, all participants completed a 30-day exercise program, and ABBI and EDUC participants received workshops at visits 1 and 2. All participants were contacted at 3-, 6-, and 9-months post-intervention to complete follow-up assessments.

The overall trend across Phases 1 and 2 was for ABBI participants to score highest on measures of exercise behavior. As expected, ABBI participants scored the highest on experiential acceptance at the end of Phase 1 controlling for acceptance scores at baseline, $F(1,106) = 7.17, p = .009$. Exploratory analyses revealed visit 2 experiential acceptance scores were highest among obese participants assigned to ABBI, $F(1,106) = 3.33, p = .071$. Finally, visit 2 experiential acceptance scores predicted exercise behavior at 3- ($b = .404, p < .001$), 6- ($b = .401, p < .001$), and 9-months follow up ($b = .306, p = .015$), suggesting experiential acceptance may be an important mechanism of exercise maintenance. This investigation builds on burgeoning work demonstrating the efficacy of exercise promotion ABBIs. Future work should more thoroughly assess the underlying reasons why obese participants may be particularly receptive to an acceptance-based approach.

Symposium 20

2:00 PM-3:15 PM

FAMILY COMMUNICATION OF CANCER GENETIC INFORMATION

Ashley Elrick, MA¹, Yelena P. Wu, PhD², Smita Banerjee, PhD³, Kimberly Kaphingst, ScD¹

¹University of Utah, Salt Lake City, UT; ²Huntsman Cancer Institute, University of Utah, Salt Lake City, UT; ³Memorial Sloan Kettering Cancer Center, New York, NY

For cancer genetic information, patients are expected to communicate their genetic test results or familial risk for cancer to biological family members so that family members can decide on genetic testing for themselves or make other medical and behavioral decisions. Genetics specialists (e.g., genetic counselors) can strongly encourage cancer patients to share information with their family, but healthcare providers cannot directly contact family members, which necessitates family communication (e.g., direct communication between family members). Therefore, better understanding of family communication processes and development and testing of family communication interventions is critical to improving outcomes among those at risk of cancer due to their family history. This symposium will present three papers, including a systematic review and two current intervention research that inform the mechanisms through which communication of genetic information may influence health behavior change within families. Presenter #1 will present findings from a systematic review of family communication interventions for genetic information and highlight research gaps identified by the review. The review emphasizes a lack of randomized control trials for intervention research and summarizes potential frameworks and considerations for future interventions. Presenter #2 will present findings from a novel educational intervention to communicate risk for melanoma and preventive recommendations for children who have a familial risk of melanoma. Parents and children who received the educational intervention reported that the intervention was acceptable. Further, children's reported adherence to recommended preventive behaviors increased significantly over time. Presenter #3 will then present baseline family communication findings from a study examining skin cancer genetic testing interest and uptake in a primary care population. Family communication about skin cancer risk was relatively high, and particularly high among those individuals with higher perceived risk and worry about skin cancer. The Discussant will synthesize implications from the presentations and identify next steps in research on family communication interventions. This symposium will therefore describe current and future approaches to interventions to increase family communication of cancer genetic information and improve behavioral outcomes among biological family members of those tested for cancer risk.

Symposium 20A

STATE OF THE EVIDENCE: FAMILY COMMUNICATION INTERVENTIONS FOR GENETIC INFORMATION

Ashley Elrick, MA

Successful family communication of genetic test results is critical for family members of those tested to make fully informed medical decisions. Prior research and reviews describe barriers and facilitators of family communication of genetic information. However, no recent reviews are available for family communication interventions to highlight effective strategies nor recommendations for future intervention development. This project reviews literature on interventions for family communication of genetic information and related studies that could directly inform future interventions. We conducted a comprehensive electronic literature search of articles published in six databases between January 2010 and January 2017. Articles were included if they described an intervention (e.g., randomized control trial, development, framework) or presented results that directly inform future interventions. Of the 9,259 unique papers screened for inclusion, 75 papers were independently reviewed by two authors with discrepancies resolved by a third author. Of the 34 included papers, six publications were identified that explained five family communication interventions. Four were identified as randomized control trials with a variety of delivery methods (e.g., telephone, one-on-one, group). There were limited quantitative data to show the interventions impacted family communication more than usual care. One intervention showed a statistically significant effect on family communication and another had a significant effect through indirect measures (e.g., medical record reviews). Furthermore, two had over 400 participants while the others had much smaller samples. The remaining 28 articles were development, frameworks, or results directly impacting interventions. Intervention development articles had very small pilot sample sizes with most under 20 participants. The majority of articles did not include a theoretical foundation and primarily focused on breast and ovarian cancer or general cancer risks. Overall, few family communication interventions have been published since 2010. More research is needed to test interventions in randomized controlled trials with adequate power and pilots with larger samples. Additionally, quantitative data and evaluations are needed in future studies to support an effect of the intervention on family communication. Implications of these findings for future interventions on the family communication of genetic information will be discussed.

Symposium 20B

A RISK COMMUNICATION AND PREVENTION INTERVENTION FOR CHILDREN AT RISK FOR MELANOMA AND THEIR FAMILIES

Dr. Yelena P. Wu, PhD

Children who have a parent with a history of melanoma are at increased risk for the disease. Melanoma preventive behaviors include use of sunscreen, protective clothing, and reducing ultraviolet radiation (UVR) exposure during peak hours (10 am–4 pm). Unfortunately, children are often sub-optimally adherent to these preventive behaviors. Our team designed a novel educational intervention for this population (Melanoma Education and Risk Information Team; MERIT). The intervention was provided to 18 families (33 children total) by 2 master's-level research assistants. It consisted of still slides and video lasting 30 minutes containing developmentally-appropriate information on children's elevated risk for melanoma based on their family history and demonstrated how preventive behaviors could mitigate this risk. Questionnaires assessed the acceptability of the educational materials, knowledge about key risk and prevention concepts, perceived risk for melanoma, and reported engagement in melanoma preventive behaviors and were completed immediately pre- and post-intervention, as well as 1 month post-intervention. On average, participants "agreed" to "strongly agreed" that the materials were useful, comprehensible and appealing. All participants demonstrated significant increases in knowledge about melanoma risk and prevention across time (all p 's $2(2)=15.4$, $p<.0001$). Per parent- and child-report, children's sunscreen use increased significantly ($F(1,21)=14.9$, $p<.05$; $F(1,30)=5.9$, $p<.05$), as well as shade-seeking ($F(1,21)=24.1$, $p<.05$; $F(1,32)=5.3$, $p<.05$). Only parents reported that children increased avoidance of peak UVR exposure ($F(1,21)=16.8$, $p<.05$). This pilot study of a novel educational intervention for children with an elevated familial risk for melanoma demonstrated that the intervention was acceptable to participants and was associated with positive effects across participants' knowledge, perceived risk, and engagement in preventive behaviors. If the present findings are confirmed in larger samples, attention could be given to identifying the best formats to deliver educational interventions for both parents and children and which components are particularly impactful in creating change in preventive behaviors.

Symposium 20C

“LET’S TALK ABOUT SKIN CANCER”: EXAMINING ASSOCIATION BETWEEN FAMILY COMMUNICATION ABOUT SKIN CANCER, PERCEIVED RISK, AND SUN PROTECTION BEHAVIORS

Dr. Smita Banerjee, PhD

Communicating about skin cancer (e.g., family history, detection and prevention behaviors, and increased risk) is important within families at high risk for skin cancer. However, we do not know if the amount and content of skin cancer risk communication occurs in families with low or average perceived skin cancer risk. As part of a randomized controlled trial examining behavioral outcomes associated with *MCIR* skin cancer genetic testing in primary care, we describe the baseline patterns of family communication about melanoma risk, specifically associations between patterns of family communication behaviors and perceived risk for skin cancer. Participants (N=600; 79% women, 48% Hispanic, mean age=53.8) were randomized 1:5 to usual care or an online *MCIR* test offer. At baseline, half had talked about skin cancer risk with their doctors (54%), followed by friends/coworkers (49%), spouse/partner (43%), other family members (39%), sister (36%), mother (36%), daughter (33%), son (32%), father (24%), and brother (22%). The content of these conversations focused on skin cancer risk (68% about personal skin cancer risk, 60% about family skin cancer history, and 59% about family’s skin cancer risk), sun protection behaviors (89% about using sun protection and 59% about time of day to avoid sun exposure), and going to the doctor for skin cancer examinations (57%). Bivariate analysis revealed that participants with heightened perceived skin cancer risk were more likely to have discussions about family skin cancer history ($r=.21, p<.01$), personal skin cancer risk ($r=.19, p<.01$), family skin cancer risk ($r=.16, p<.01$), and going to the doctor for skin cancer examinations ($r=.14, p<.01$), but less likely to have discussions about sun protection ($r=-.13, p<.01$). Further, participants who reported communicating about skin cancer topics were significantly more likely to engage in sun protection (i.e., using sunscreen, wearing hats, sunglasses, and long-sleeved shirts, and seeking shade, $p<.05$). High perceived skin cancer risk appears to be associated with increased discussions around skin cancer risk. Additionally, people who engage in these discussions also engage in increased sun protection behaviors. Implications will be discussed for sun protection campaigns and interventions that encourage discussions about skin cancer risk, sun protection, and skin cancer screening within the family in order to encourage adoption of sun-safe behaviors.

Symposium 21

2:00 PM-3:15 PM

RESEARCH FOUNDATIONS TO DISSEMINATION OF INTERVENTIONS IN CHRONIC DISEASE

Alexander Rothman, PhD¹, Annette L. Stanton, Ph.D.², Corinne Leach, PhD MS MPH³, Barbara L. Andersen, PhD⁴, Robert T. Croyle, Ph.D.⁵

¹University of Minnesota, Minneapolis, MN; ²Department of Psychology, University of California, Los Angeles, Los Angeles, CA; ³American Cancer Society, Atlanta, GA; ⁴The Ohio State University, Columbus, OH; ⁵National Cancer Institute, Bethesda, MD

More than 117 million people, or approximately 50% of all adults in the United States, have a chronic health condition. A number of meta-analyses document the efficacy of behavioral medicine interventions to address behavioral and psychosocial contributors to and sequelae of chronic disease. Experienced in intervention development and dissemination, the presenters and discussant in this symposium will address how such interventions can be honed to make them more efficient and effective, as well as to carry greater reach. The first presenter will consider the merits of adopting an experimental medicine approach to effective intervention development, which emphasizes experimental tests of targets (i.e., mechanisms of change) and programmatic research on altering those targets for effective behavior change. He will illustrate major points with his experimental trials to change health behaviors that cause chronic disease, including eating behaviors and smoking. The second presenter will address how theories and research foundations in behavioral medicine can inform the development of effective interventions. She will illustrate central points with new findings from theory-guided research with 460 women recently diagnosed with breast cancer, which make the case for targeting specific coping processes in order to prevent depression in the first year after diagnosis. The third presenter will describe the development and testing of an ehealth self-management intervention as a cooperative initiative of two large organizations. The fourth presenter will discuss the necessity to disseminate evidence-supported interventions. She will convey lessons learned from efforts to disseminate a large-scale psychological intervention to reduce stress and improve quality of life, health behaviors, and adherence for cancer patients. From the National Institutes of Health, the discussant will address implications of the presentations for extending the reach of evidence-based interventions in chronic disease as well as directions for research and application.

Symposium 21A

OPTIMIZING THE LINK BETWEEN THEORETICAL PRINCIPLES AND INTERVENTION STRATEGIES: TOWARD UNDERSTANDING WHAT WORKS WHEN AND WHY

Alexander Rothman, PhD

Abstract: How can we optimize the design and delivery of intervention strategies to promote behaviors that underlie the prevention and/or management of health problems? (Social) psychological principles have the potential to specify the factors that guide people’s behavior and delineate the conditions under which they operate. Thus, they provide a framework for delineating the mechanisms of change (i.e., targets) which need to be modified in order for intervention strategies to be effective and, in addition, the conditions under which these intervention strategies will and will not be effective. However, numerous commentators have noted that the benefits that should come from the guidance provided by theory have been surprisingly elusive. Looking across several programs of research designed to test and develop intervention strategies to promote healthy behavior (e.g., smoking cessation), I will examine how adopting an experimental-medicine approach to the study of health behavior change can generate the evidence-base needed to optimizing the connections between theoretical principles and the effective use of intervention strategies. In addition, I will discuss how an experimental-medicine approach has the potential to cultivate a “healthier conversation” between theory and intervention and, in particular, how it might help address the too frequent disconnect between what interventionists need to know and the guidance theorists have to offer.

Symposium 21B

RESEARCH ON CANCER-RELATED COPING PROCESSES AS A FOUNDATION FOR INTERVENTIONS

Dr. Annette L. Stanton, Ph.D.

Background: Informed via basic and applied research, an important step in the development of maximally effective interventions is to identify theoretically-grounded and malleable processes through which interventions can achieve their effects. The speaker will provide illustrations of such research, primarily focusing on new findings from a large-scale longitudinal study of recently-diagnosed breast cancer patients. In that study, cancer-related approach- and avoidance-oriented coping processes were investigated as predictors of depressive symptoms, depressive symptom trajectory classes (unremittingly high, recovery, consistently low), and major depressive episodes (MDEs) over 12 months in women with breast cancer.

Method: Women ($N = 460$) within four months of breast cancer diagnosis completed validated assessments of cancer-related coping strategies, depressive symptoms, and MDEs at seven points across one year.

Results: Beyond sociodemographic and medical variables, coping through avoidance of the cancer experience an average of two months after diagnosis was associated with likelihood of being in the high trajectory class and occurrence of a MDE during the year. Less decline in avoidant coping over time also predicted poor outcomes. In contrast, high initial engagement in approach-oriented coping was associated with lower depressive symptoms across assessments and likelihood of being in the recovery or low trajectory class, as were increases in the approach-oriented processes of coping through emotional expression and acceptance.

Conclusions: Sustained avoidance-oriented coping and sustained or increasing coping through acceptance and emotional expression over 12 months predicted recovery from initially high depressive symptoms in women recently diagnosed with breast cancer. Interventions targeted toward reducing cancer-related avoidance and fostering acceptance and emotional expression, among other approach-oriented coping strategies, could aid in preventing and lessening the burden of depression in this group and perhaps others undergoing life-threatening diseases. Centering interventions on these and other evidence-based targets promises to render interventions for depression in adults with chronic disease more efficient and effective.

Symposium 21C

BRINGING SELF-MANAGEMENT TO CANCER SURVIVORS THROUGH A MHEALTH PLATFORM: SPRINGBOARD BEYOND CANCER

Dr. Corinne Leach, PhD MS MPH

Background: In 2016, the American Cancer Society and the National Cancer Institute launched an online behavioral tool for cancer survivors. Springboard Beyond Cancer (SBC) is a free, customizable online tool leveraging behavioral science to help people self-manage physical and emotional symptoms, improve communication skills and lead healthier lives during and after a cancer diagnosis. SBC users can create printable, personalized Action Decks to identify cancer-related needs, set goals, create plans to achieve goals, monitor progress, and identify personally effective strategies.

Methods: Cancer survivors undergoing or post-treatment were recruited from clinical settings and community based organizations ($N=40$) to complete in-person usability tests of SBC. Participants explored the SBC site and then performed structured tasks to assess usability and understanding of the site. User comments and reactions were recorded and qualitative, thematic analyses were conducted. In addition, website metrics from Google Analytics were used to identify areas for website improvement, outreach and promotion opportunities. Key performance indicators tied to expected website outcomes were used to guide the analysis.

Results: Survivors, particularly those currently in treatment, found the information on the site to be clear, concise, and meeting their needs. However, survivors reported needing more instruction on how to best utilize Action Decks to prioritize their most pressing concerns. Once the action decks were explained, most felt they were a useful tool. From October 2016 to August 2017, SBC had 13,527 visits and 9,741 unique visitors. Metrics indicated that SBC was generally meeting engagement goals, but the action deck feature was being underutilized (14% of visitors used this feature). The top visited website content included the action deck page, symptoms overview, stress and mood management, and self-management basics pages. Engagement metrics such as average session duration (3:07), pages per session (3.16), returning users (29%), and mobile traffic (34% of visits are from mobile devices) exceeded initial goals.

Conclusions: Providing self-management content via an mHEALTH tool is feasible. Evaluation and web metrics data are guiding enhancements of SBC. SBC 2.0 will enhance user friendliness especially with action plans, and encourage engagement with interactive elements of the site.

Symposium 21D

DISSEMINATION AND IMPLEMENTATION OF CANCER CONTROL ESTS: PRESENT AND FUTURE

Dr. Barbara L. Andersen, PhD

Background: Hundreds of randomized controlled trials have tested psychological treatments and found them efficacious in reducing stress and improving quality of life and health, with selected demonstrations of enhanced immunity and reduced risk for recurrence or cancer death. Unfortunately, ESTs (Evidence-Supported Treatments) have not been disseminated from research settings where they were developed, with underutilization of ESTs across settings and a resultant gap in care. Even when clinicians receive dissemination education, usage may be modest. Models for addressing this problem will be reviewed, including continuing education, web based instruction, and education and support.

Method: The latter strategy was studied by offering 3-day institutes to mental health providers in cancer (N=123) to learn the Biobehavioral Intervention (BBI), an EST designed to help cancer patients cope with stress.

Results: Research showed that training was effective. Clinicians were then offered 6 months of implementation support (e.g. conference calls, web resources). They were assessed post-institute and 2, 4, and 6 months later on attitudes towards evidence-based practices and the BBI, self-efficacy to implement the BBI, and intentions to use the BBI. BBI usage logs were completed at 2, 4, and 6 months. Providers used BBI with 57–66% of their patients, with other data showing sustained implementation at 12 months. The research also used the Theory of Planned Behavior (TPB) to understand individual level variables in the prediction of EST implementation. Consistent with the TPB, prior attitudes toward BBI predicted intent to implement, and prior intent predicted BBI implementation. In addition to these data, lessons learned will be discussed.

Conclusion: These data illustrate how the success of a dissemination strategy that begins with multimodality education can leave providers engaged and motivated to use an EST to delivery psychological cancer care.

Symposium 22

2:00 PM-3:15 PM

DISSECTING THE “DIGITAL DIVIDE” - REACHING VULNERABLE POPULATIONS IN PAID MEDIA CAMPAIGNS

Sarah Field, BA, MA, Jamie Gray, BS Marketing, BS Psychology

ICF, Fairfax, VA

Background: The Smokefree.gov initiative (SFGI) is a large mobile health cessation program. Ensuring that the program reaches vulnerable populations is a challenge. Digital media may be especially effective in reaching these populations, as both general and vulnerable populations access digital channels with relatively equal frequency. In 2015, SFGI executed a \$1.2M digital paid media campaign to increase reach of and engagement with SFGI resources, prioritizing pregnant, teen, LGBT, and Spanish-speaking smokers.

Purpose: This study assesses the relative effectiveness of digital strategies in reaching vulnerable populations with smoking cessation resources.

Method: The performance of digital platforms was tracked and monitored using multiple tools: dashboards provided by paid media vendors, Google Analytics (website and mobile applications), and custom reports prepared by Smokefree's text messaging provider. Primary outcomes were engagement and signups/opt-ins to SFGI resources.

Results: This campaign resulted in 21 million impressions* with Spanish-speaking Hispanic smokers, 44 million impressions with teens, 29 million impressions with LGBT smokers, and seven million impressions with pregnant smokers. Compared across all campaign methods, email marketing performed particularly well for Hispanic smokers, Google and Bing paid search performed well for Hispanic and pregnant smokers, and programmatic online videos did well for LGBT smokers – more than half a million LGBT smokers watched our videos in full. The overall campaign's average cost-per-session (CPS) was low at \$1, but the more niche an audience was, the more expensive it was to drive web traffic to it. For example, CPS for pregnant smokers was \$10.43 and CPS for teen smokers was \$2.74. The cost-effectiveness of the campaign steadily increased over time, likely due to adjusting digital bids throughout the campaign's duration to optimize budgets and performance.

Conclusion: The results support the use of digital strategies to reach and engage vulnerable populations with cessation content. Smoking has increasingly become a health disparity issue, and the ability to target niche audiences will gain in importance for future campaigns. The advantages of digital, including the ability to optimize in real time and the efficient matching of content to subpopulation, support the use of these approaches.

Symposium 23

2:00 PM-3:15 PM

OPTIMIZATION EXPERIMENTS IN THE FIELD: THE MOST FRAMEWORK THROUGH 3 CLINICAL TRIALS

Bonnie Spring, PhD¹, Siobhan M. Phillips, PhD, MPH², Sara A. Hoffman, M.S.¹, Rachel A. Millstein, PhD, MHS³, Linda M. Collins, PhD⁴

¹Northwestern University, Chicago, IL; ²Northwestern University Feinberg School of Medicine, Chicago, IL; ³Massachusetts General Hospital, Boston, MA; ⁴Penn State, University Park, PA

Behavioral interventions often involve a “black box” approach, where a treatment package is provided to patients. Disentangling which components provide the greatest effect on outcomes of interest from the “black box” can be difficult. Interventions are also increasingly strapped for resources, and a gap exists between efficacious clinical trial findings and the ability to disseminate these findings with precision. The Multiphase Optimization Strategy (MOST) is an engineering-inspired framework for the optimization of behavioral and bio-behavioral interventions, and seeks to solve this issue by managing intervention resources effectively, using only those that provide the most benefit. MOST involves three phases: preparation, optimization, and evaluation. This symposium highlights the applicability of the MOST framework to complex questions in behavioral medicine, and outlines these phases through the lens of three different patient populations to underscore the utility of this framework for optimizing intervention treatment packages. The first presenter will overview the MOST optimization phase and discuss initial feasibility and recruitment for a new factorial experiment targeting physical activity in breast cancer survivors. The second presenter will discuss the end of the MOST optimization phase by describing 3-month outcomes and main effects of 5 behavioral components within a weight loss intervention, and will provide a brief synopsis of next steps to transition these findings to the evaluation phase of MOST. The final presenter will provide a linear overview of MOST by first discussing results from preparation phase experiments that informed a factorial trial for cardiac patients, and how the results of the optimization phase informed design and recruitment for a trial in the evaluation phase. The discussant will integrate each study into the MOST framework, discuss the utility of MOST to tailor factorial experiments to many patient populations, overview how randomized controlled trials (RCTs) are a key part of the MOST framework, and highlight future directions of this framework for behavioral interventions.

Symposium 23A

IMPLEMENTATION OF A NATIONWIDE REMOTELY-DELIVERED PHYSICAL ACTIVITY INTERVENTION AMONG BREAST CANCER SURVIVORS

Siobhan M. Phillips, PhD, MPH

An estimated 3 million breast cancer survivors live in the U.S. with this number expected to increase to 4 million over the next decade. Increased physical activity is associated with reductions in negative treatment-related side effects (e.g fatigue, depression), cancer recurrence and mortality and improved quality of life and survival. However, up to 70% of breast cancer survivors do not meet public health recommendations for physical activity. Although many factors contribute to survivors' low physical activity, an absence of accessible, effective physical activity programs is a major barrier. Most existing physical activity interventions are resource-intensive, on-site programs tested in controlled efficacy trials with limited potential to be translated into real-world practice. The primary objective of the Fit2Thrive study was to determine the effect of five remotely-delivered, technology supported intervention components on physical activity using Multiphase Optimization Strategy Trial (MOST) methodology. The five components to be tested include: (a) telephone support calls; (b) deluxe app; (c) Fitbit buddy; (d) online gym and (e) tailored text messages. All components have two levels: “on” versus “off”. This presentation will: (a) provide an overview of the theoretical framework; (b) highlight findings from initial pilot work that informed the design of the intervention; (c) explain trial implementation; and (d) describe key lessons learned from implementing a technology-supported intervention remotely, nationwide (i.e. without an in-person contact). Findings from the Fit2Thrive study will lead to an improved understanding of how to effectively change survivors' physical activity and could result in more scalable, effective physical activity interventions for breast cancer survivors to ultimately, improve health and disease outcomes.

Symposium 23B

A MOST FACTORIAL EXPERIMENT TO OPTIMIZE A WEIGHT LOSS INTERVENTION: 3-MONTH OUTCOMES OF THE OPT-IN TRIAL

Ms. Sara A. Hoffman, M.S.

The optimization phase of the Multiphase Optimization Strategy (MOST) framework involves the selection of components, and testing the effect of these components within a structured experiment. Opt-IN is a 6-month remote behavioral weight loss intervention that uses the MOST framework to examine which intervention components or component levels contribute to the greatest weight loss. Using a full factorial experimental design, the five components/component levels examined were: 12 vs. 24 telephone coaching calls, progress reports to a primary care provider (PCP), text messages, meal replacement (MR) recommendations, and training a “Buddy” to provide social support. Progress reports were sent to PCPs at follow-up assessments, and those receiving texts had the option to receive 1 text/day on 7 days, or 2 texts/day on 3 days with an additional weekend text. MR recommendations were given on coaching calls, and a 1-week MR supply was provided. Buddies who received training were asked to attend 4 online webinars. All participants received a CORE weight loss program, comprised of a study-specific smartphone app, daily calorie/fat intake goals, and a weekly physical activity goal that increased from 100–300 minutes. The dependent variable was change in weight from baseline to 3-months. Opt-IN participants (n=562; M age=38.7, SD=11.8) were primarily non-Hispanic/Latino (87%), White (74.2%) and female (81.7%), and had a BMI between 25–40 kg/m² (M BMI=32.3, SD=3.6). Retention at the 3-month assessment was 90.8%. A mixed model ANOVA testing for main effects of each intervention component at 3 months indicates that participants who attended the 3-month assessment (n=509) lost an average of 8.37 pounds (SD=7.4), or 4.26% (SD=3.62) of their original weight. There was a main effect of Buddy training on weight change (lbs.) at 3 months: participants who were assigned to Buddy training lost 1.3 more pounds than those not assigned to Buddy training (p=.046). No other main effects on 3-month weight change were found for the remaining components. Training a buddy on how to support a proband's weight loss efforts appears to enhance the proband's weight loss success. Going forward, this study will examine both main effects and interactions among the 5 behavioral components on 6-month weight loss to determine an optimally effective and cost efficient weight loss intervention.

Symposium 23C

A MULTIPHASE APPROACH TO OPTIMIZING A PSYCHOLOGICAL-BEHAVIORAL INTERVENTION IN CARDIAC PATIENTS

Dr. Rachel A. Millstein, PhD, MHS

Background: The Positive Emotions after Acute Coronary Events (PEACE) project aimed to use the multiphase optimization strategy (MOST) to iteratively optimize a positive psychology (PP) and motivational interviewing (MI) intervention. The overall goal of this intervention is to promote physical activity in post-acute coronary syndrome (ACS) patients.

Methods: The MOST preparation phase encompassed two development studies: PEACE I (n=34) involved a mixed (qualitative/quantitative) methods approach to gather input from post-ACS patients and customize the intervention for this population. PEACE II used a proof-of-concept trial of an 8-week phone-based PP intervention (n=23) versus treatment as usual (n=22), to assess feasibility and gather feedback about the PP intervention. The optimization phase, PEACE III (n=128), used a randomized, complete factorial design with eight study conditions in a 2x2x2 allocation to select the optimal intervention components, including both PP and MI. PEACE IV is an ongoing randomized controlled pilot trial (target n=40) to evaluate the efficacy of the optimized PP-MI intervention, versus an MI-informed control group, on physical activity.

Results: In PEACE I, higher optimism and positive affect following an ACS were associated with greater subsequent adherence to health behaviors, and participants indicated a preference for a brief (e.g., 8 weeks) phone-based intervention. In PEACE II, the PP intervention was found to be feasible, and PP participants had moderate pre-post improvements in positive affect, depression, and anxiety ($d_s = .47-.71$), but not dispositional optimism. In PEACE III, we modified the core intervention's content (PP only vs. PP-MI), intensity (daily vs. weekly exercises), and duration (with/without booster sessions) to generate the eight conditions. Booster sessions were associated with greater objectively measured physical activity ($\beta=8.58$, 95% CI: -0.49–17.65, $d=.43$; $p=.064$). MI was associated with overall self-reported adherence to health behaviors (e.g., diet, physical activity, medication adherence) ($\beta=0.95$, 95% CI: 0.02–1.87, $d=.39$; $p=.044$), and weekly exercise completion performed slightly better than daily on self-reported adherence. These findings, along with feasibility data, informed PEACE IV, a 12-week intervention.

Conclusions: Using MOST, we iteratively adapted an intervention to promote physical activity following an ACS, which is now being tested in a pilot randomized trial. MOST provided a logical and feasible process for efficient intervention development.

2:00 PM-3:15 PM

APPLICATIONS OF INTEGRATED SOCIAL COGNITIVE THEORIES IN PREDICTING AND CHANGING HEALTH BEHAVIOR

Kyra Hamilton, PhD¹, Derwin Chan, PhD², Dr. Ryan E. Rhodes, PhD³, Chun-Qing Zhang, Ph.D., M.Ed., B.Sc.⁴, Martin S. Hagger, PhD⁵

¹Griffith University, Mt Gravatt, Brisbane, Queensland, Australia; ²The University of Hong Kong, Pokfulam, N/A, Hong Kong; ³University of Victoria, Victoria, BC, Canada; ⁴Hong Kong Baptist University, Hong Kong, N/A, China (People's Republic); ⁵Curtin University, Perth, Western Australia, Australia

Modifying health behavior through intervention necessitates identifying target behavioral determinants and the accompanying mechanisms by which they guide the behavior. Motivational models such as theory of planned behavior have provided an extensive evidence base of salient antecedents and processes. However, there has been recognition that such theories have inherent limitations and models of greater complexity have been identified to encompass multiple predictors and processes. Models drawing from dual-phase and dual-process approaches such as health action process approach and reflective-impulsive model, in particular, have been foremost in informing this line of theory and research. Researchers have focused on extending these models to provide further insight into the complexities of health behavior change. The collection of papers in this symposium present new, innovative ways that integrated theoretical approaches and show how they have been adopted and applied to predict and explain health behavior. The symposium will showcase studies and research syntheses that highlight the multiple processes likely to impact health behavior derived from theory integration and provide suggestions on how these data can inform development of effective behavioral interventions.

Symposium 24A

PREDICTING HEAVY EPISODIC DRINKING IN YOUNG AUSTRALIAN UNIVERSITY STUDENTS: A DUAL PROCESS APPROACH

Dr. Kyra Hamilton, PhD

Objective: Australian national surveys indicate that young people aged 18–25 years are most likely to engage in risky single occasion drinking; this group is more likely to consume 11 or more standard drinks on a single occasion than people in any other age group. Dual process models that include both an explicit, conscious phase of motivation, as depicted by reasoned action models such as the theory of planned behavior, and an implicit, non-conscious route characterised by automatic, habitual responses are increasingly gaining support in their utility to explain variance in problem drinking behaviors. We applied a dual process model to identify predictors of heavy episodic drinking behavior in young university students.

Methods: Participants were undergraduates aged 18–25 years ($N = 200$, $M_{age} = 19.96$, $SD = 2.10$; 138 female). The study adopted a prospective correlational design with a four-week follow-up. At Time 1 (T1), participants completed measures of social-cognitive variables from the theory of planned behavior (attitude, subjective norm, perceived behavioral control, intention), self-reported habit, and past heavy episodic drinking behavior. Demographic information was also collected. At Time 2 (T2; $n = 152$), participants completed follow-up measures of habit and heavy episodic drinking behavior.

Results: Path analytic model testing proposed hypothesized relations of the dual process model exhibited a good fit to the data, accounting for 46.7% and 25.3% of the variance in intention and heavy episodic drinking behavior, respectively. Results showed significant direct effects of attitude, subjective norm, perceived behavioral control, and T1 habit, but not past behavior, on intention; and significant direct effects of T1 habit and past behavior on behavior, but no effects for intention and perceived behavioral control. There were also significant indirect effects of T1 habit on behavior mediated by T2 habit; and significant indirect effects of past behaviour on behavior mediated by T2 habit. No indirect effects were observed via the theory of planned behavior variables, supporting a non-intentional pathway to behavior.

Conclusions: Results indicate that students' heavy episodic drinking behavior tends to be governed more by non-conscious, automatic processes than by conscious, intentional processes. Future research should aim to address breaking problematic drinking habits to combat risky single occasion drinking in young university students.

Symposium 24B

STUDENTS' MOTIVATION AND BELIEFS IN SPORT INJURY PREVENTION: A QUALITATIVE INVESTIGATION OF THE TRANS-CONTEXTUAL MODEL

Dr. Derwin Chan, PhD

Objective: The present study is the first qualitative investigation of the trans-contextual model in the context of sport injury prevention among secondary school students. We aimed to gain an in-depth understanding of the content, meanings, and patterns of motivational and social cognitive factors of sport injury prevention in the in-school and out-of-school contexts.

Methods: We conducted 17 semi-structured focus-group interviews in secondary school students (total $N = 128$; $M_{age} = 13.76$, $SD = 1.15$, range = 12–16; 54% male). Qualitative data was analysed using thematic content analysis based on typological approach. To test the primary tenet of the trans-contextual model (i.e., autonomous motivation in-school is transferred into autonomous motivation out-of-school), chi-square test of independence examined the distribution of quote counts between motivational themes identified in the in-school and out-of-school contexts.

Results: The theoretical components of the trans-contextual model, such as motivation (autonomous and controlled) in-school and out-of-school contexts, and attitude (affective and instrumental), subjective norm (descriptive and injunctive), and perceived behavioral control (positive or negative), emerged as higher-order themes in the analysis. Chi-square test showed that autonomous motivation was more frequently reported than controlled motivation in the out-of-school context (Odd Ratio = 4.81, $c = 1.29$, p

Conclusions: Current findings identified themes that were consistent with the trans-contextual model, and students' autonomous motivation of sport injury prevention were more salient than controlled motivation in the out-of-school context than in the in-school context.

Symposium 24C

BRIDGING THE INTENTION-BEHAVIOR GAP IN PHYSICAL ACTIVITY: A REVIEW OF EVIDENCE FROM THE MULTI-PROCESS ACTION CONTROL FRAMEWORK

Dr. Ryan E. Rhodes, PhD

Objective: Theories in the social cognitive tradition have shown utility in changing physical activity, yet one of the most highlighted areas of concern is the established gap between intention and behavior, as these theories generally have limited explanation for intention-behavior discordance. Multi-process action control (M-PAC) was created as an organizing schematic to describe key reflective (affective judgments, opportunity), regulatory (plans, monitoring, enlisting support), and reflexive (habit, identity) constructs proposed to bridge the intention-behavior relationship across the initial adoption to ongoing maintenance of the physical activity. The purpose of this presentation is to provide a review of the current evidence for M-PAC.

Methods: Eligible studies were from English, peer-reviewed published articles that examined M-PAC in the context of physical activity. Searches were completed in July 2017 in five databases.

Results: Fifteen observational studies and five experimental trials, from independent data-sets, primarily of high quality, were identified that spanned different physical activity populations (e.g., cancer survivors, dog walking, families, children with disabilities, middle aged adults, college students). Results from the observational studies generally supported the proposed reflective (affective judgments supported in 9/11 tests; perceived control supported in 12/15 tests), regulatory (supported in 7/8 tests), and reflexive (habit supported in 4/4 tests; identity supported in 4/4 tests) constructs of M-PAC as moderators of intention-behavior relations. Experimental application of M-PAC is preliminary but early evidence is also generally supportive of the reflective (affective judgments supported in 2/2 tests; perceived control supported in 2/4 tests), regulatory (supported in 4/5 tests), and reflexive (habit supported in 2/2 tests; identity supported in 3/3 tests) constructs as potential mediators of physical activity change.

Conclusions: Overall, contemporary research on M-PAC demonstrate its constructs may act as a bridge of the intention-behavior gap and, thus, augment traditional social cognitive approaches with additional considerations of affect and opportunity, self-regulation, and habits and identity formation. Still, the temporal aspects of M-PAC, in terms of adoption and maintenance, have had limited empirical attention and a higher volume of studies in different contexts is needed to validate these initial findings.

Symposium 24D

A META-ANALYSIS OF THE HEALTH ACTION PROCESS APPROACH AND HEALTH BEHAVIORS

Dr. Chun-Qing Zhang, Ph.D., M.Ed., B.Sc.

Objective: The Health Action Process Approach (HAPA) serves as a self-regulation framework focusing on both motivational and volitional stages of behavior change. It has demonstrated utility in predicting changes in health-related behaviors in a variety of settings. The purpose of this meta-analysis was to explore the consistency of proposed relationships among HAPA constructs across health-related behaviors and investigate effects of demographic and conceptually-determined moderators of effects on the HAPA relationships.

Methods: Five electronic databases (PsycInfo, Medline, Embase, Web of Science, and Scopus) for studies of HAPA and health behaviors were systematically searched. After the records were screened and assessed for eligibility, 96 correlational and experimental studies (116 independent data sets) testing HAPA hypotheses were identified. Relations among each HAPA construct was synthesized using random-effects meta-analysis. Proposed relations among HAPA variables were tested using path analytic structural equation modeling.

Results: The majority of the included studies focused on physical activity and dietary behaviors, and most of them were prospective in design with self-reported measures of behavior. Consistent with HAPA propositions, positive and significant relations were revealed among key HAPA variables and behaviors, including: outcome expectancies, task self-efficacy, intention, maintenance self-efficacy, recovery self-efficacy, action planning, coping planning, action control, past behavior, and behavior. Specifically, there were medium-to-large-sized correlations between behavior and the task self-efficacy, intention, maintenance self-efficacy, recovery self-efficacy, action planning, coping planning, and action control constructs with smaller effects between behavior, including outcome expectancies and risk perceptions, and the other HAPA variables.

Conclusions: Patterns of relations among HAPA variables were consistent with predictions. Consistent with primary research, it seems that effects of self-efficacy, intention, and planning variables are more pervasive than risk perceptions in explaining variance in health behavior. Building on the current meta-analysis, future research needs to provide more evidence of the HAPA model in diverse health behaviors (e.g., condom use, sunscreen use, smoking, dental flossing). The use of experimental design and objective measures are also recommended.

Symposium 24E

PAST BEHAVIOR AND HABIT AND BEHAVIORAL AUTOMATICITY IN SOCIAL COGNITIVE MODELS: META-ANALYSIS AND TEST OF A PROCESS MODEL

Prof. Martin S. Hagger, PhD

Objective: Dual-process theories posit that health behavior is a function of automatic and deliberative processes. Inclusion of past behavior as a predictor in social cognitive theories has been purported to represent non-conscious processes, but has been criticized as lacking content and precision. Self-report measures of habit and automaticity have been proposed as an alternative approach to modeling non-conscious processes on health behavior in social cognitive theories. The current research examines past behavior and self-reported habit and automaticity as means to test non-conscious processes in social cognitive models of health behavior. To the extent that effects of past health behavior on future behavior reflects health habits, self-reported habit is expected to mediate the effect. The analysis is also expected to reveal the extent to which automaticity, as a specific component of habit, serves to account for past behavior effects.

Methods: A database search revealed 160 studies that measured self-reported habit or past behavior in social cognitive models applied to health behaviors. Based on data from included studies, meta-analytic structural equation modeling was used to test a dual-process model in which health behavior was predicted by a reasoned process involving intentions, attitudes, norms, and control beliefs, and a non-conscious process reflected by past behavior and habits. Effects of past behavior were proposed to be mediated by habit. Type of self-reported habit (habit vs. automaticity) was used as a moderator of habit and past behavior effects in the model.

Results: Models revealed independent effects of past behavior and intentions on health behavior. The direct effect of past behavior on behavior was mediated by habit, as predicted. However, past behavior had direct effects on behavior independent of the habit-mediated effect. Effects of past behavior and habit were not moderated by type of self-report habit measure, habit, or automaticity.

Conclusions: Current findings indicate that self-reported habit explains some of the effects of past behavior, even though a direct effect remained. Findings indicate that past behavior effects are, at least in part, due to habits. The remaining effect may account for implicit processes not modeled by habits, such as implicit attitudes. Current findings also indicate that habit mediated effects are not affected by whether the self-report measure reflects habits or automaticity alone.

Symposium 25

2:00 PM-3:15 PM

EXTENDING THE REACH OF MOTIVATIONAL INTERVIEWING IN HIV PREVENTION AND CARE: TAILORING DELIVERY AND TRAINING

Paula Bertone, MA¹, Tyrel J. Starks, PhD², Sylvie Naar, PhD³, Karen Ingersoll, Ph.D.⁴

¹Center for HIV Educational Studies & Training (CHEST), Hunter College of the City University of New York, New York, NY; ²Hunter College, CUNY, Brooklyn, NY; ³Florida State University, Royal Oak, MI; ⁴University of Virginia, CROZET, VA

The HIV epidemic in the U.S. disproportionately affects youth, particularly younger men who have sex with men (MSM) and racial and ethnic minority youth. Increasing evidence points to the salience of main (as well as casual or anonymous) partners as a context for HIV infection, particularly for young MSM. These epidemiological factors necessitate the development of targeted intervention strategies which reach those youth at greatest risk of HIV infection. Motivational Interviewing (MI) interventions have shown specific promise in improving HIV-related outcomes and reducing HIV-risk and related substance use.

This symposium focuses on strategies, challenges, and discoveries encountered in research which seeks to adapt MI delivery and training to novel formats and populations. The initial presentation discusses the challenges of translating an existing MI-based intervention developed for young MSM ages 18–29 – the Young Men's Health Project (YMHP) – from a traditional in-person format to one which is delivered online to adolescents aged 13–18. Qualitative analysis of session content identified modifications necessitated by the intervention format and developmental needs of clients. The second presentation discusses the extension of MI – traditionally as an individually delivered intervention – to HIV and substance use prevention work with gay male couples. Utilizing a grounded-theory approach to the analysis of session content, the presentation outlines a set of theoretical principles which might guide MI with couples. The final presentation reports the results of mixed methods research intended to enhance MI training. This novel work begins with quantitative analysis of interactions between HIV care providers and racial and ethnic minority youth to identify specific MI skills that efficiently elicit change talk from this under-served and high-need population. This is combined with provider feedback on challenges to MI implementation. From these data, a tailored implementation strategy was developed to enhance MI uptake at clinics serving HIV positive youth. Together, these three presentations illustrate diverse approaches to the challenge of extending the reach of MI across populations, format and setting. Attendees at this symposium will therefore be exposed to the full spectrum of intervention development and implementation research. They will leave with an understanding of how the theoretical foundations of existing interventions can inform the tailoring of novel applications which extend the scope of available services to critical populations.

Symposium 25A

ADAPTING A FACE-TO-FACE MOTIVATIONAL INTERVIEWING INTERVENTION FOR ONLINE DELIVERY TO HIGH-RISK ADOLESCENT MALES

Ms. Paula Bertone, MA

Background: Traditional face-to-face HIV prevention programs are often unable to reach a significant proportion of young men who have sex with men (YMSM) at risk for HIV, due to challenges with recruitment and engagement in treatment. The difficulty of reaching adolescent YMSM ages 13–17 is even greater. To address this problem, the adaptation reviewed here sought to revise and tailor an evidence-based HIV prevention intervention, The Young Men's Health Project (YMHP). The original YMHP, a face-to-face Motivational Interviewing (MI) intervention, successfully reduced sexual risk and substance use behaviors among YMSM ages 18–24. We adapted YMHP for delivery online with adolescent YMSM between the ages of 13 and 17.

Methods: Participants were recruited through advertisements posted on Facebook and Instagram and had to pass four milestones in order to be considered fully enrolled in the intervention. Milestone 1 was sending a survey link; milestone 2 involved completing the at-home baseline survey; milestone 3 was obtaining consent for the full study; and milestone 4 involved participating in the intervention. Of the 508 surveys sent, 250 attempted, and 201 completed and were eligible to participate. Of those, 70 were invited for the full study, 40 consented and 26 participated in the intervention. We identified the major points of revision to the original YMHP intervention and documented the protocol evolution through two rounds of adaptation. Six participants from the first round provided feedback that was captured and evaluated using qualitative interviews, and helped shape the adapted intervention in the second round.

Lessons Learned: This adaptation generated both developmental and technology-related insights. We learned that adolescent YMSM have a need for psycho-education around sex and that motivation to reduce HIV risk may be activated through conversations focused on general sexual health - including an exploration of the youth's sexual identity, dating habits, and relationship preferences. We addressed this by providing all participants in the second round with access to an online sexual education program developed for LGBT youth. We discovered a heightened salience of family factors (i.e., parents playing an active role in regulating their son's lives), and that finding partners and dating are priorities for this population, especially for youth in more rural areas. Remote service delivery (via phone, Skype, FaceTime) also presented initial challenges in establishing rapport and scheduling, which, with further adaptations in the second round, were able to be overcome through increased engagement with the youth.

Symposium 25B

EXTENDING MI TO COUPLES' HIV RISK AND RELATED SUBSTANCE USE: DERIVING AND ILLUSTRATING A THEORETICAL FRAMEWORK FOR PRACTICE

Dr. Tyrel J. Starks, PhD

Background: Main partners account for a substantial number of new HIV infections among gay and bisexual men (GBM). Relationship factors are also associated with drug use among GBM – enhancing HIV risk. Individually delivered Motivational Interviewing (MI) interventions have been effective in reducing drug use and sexual HIV transmission risk; however, research on couples generally – and GBM couples particularly – has been limited. The framework of MI has largely been articulated from an intra-individual perspective, and relatively little theoretical guidance has been offered for dyadic applications. The purpose of this formative study was to derive a framework informed by qualitative analysis of session content taken from MI sessions with GB couples targeting substance use and HIV risk reduction.

Method: Drawing upon existing MI-based approaches for individual GBM, the study's first author developed a 3 session intervention protocol for delivering MI to GBM couples. This protocol was administered to 10 GBM couples, in which at least one partner was aged 18–29; HIV-negative; and reported problematic alcohol use or the use of an illicit drug. Minimum relationship duration was 3 months. Masters and doctoral-level providers delivered all sessions, which lasted 50–75 minutes each. Session retention was 100%. We therefore reviewed transcripts from these 30 MI sessions. Utilizing a grounded theoretical approach, session content was coded for evidence of ambivalence toward the target behavior and MI processes (engaging, focusing, evoking, and planning). Codes were created to capture these processes at individual and interpersonal levels.

Results: Transcripts illustrated the potential for ambivalence to emerge at both the interpersonal and the intra-personal level. This allowed for the cultivation of change talk through therapist utterances directed at both the partners separately and the couple together. Relationship investment served as a catalyst for resolving interpersonal ambivalence in the direction of change. The process of resolving interpersonal ambivalence and developing a change plan for the couple can be understood as a special instance of the accommodation process conceptualized within Couples Interdependence Theory.

Conclusions: Brief MI is a feasible and acceptable strategy for addressing drug use and HIV-related risk with gay male couples. While the core concepts and skills of MI generalize to this work, it is necessary to conceptualize ambivalence and the processes of MI as dyadic rather than individual. The provider must interact with both the dyad and the individuals within it strategically to effectively elicit ambivalence and plan for change. MI providers working with couples must be open to the possibility that individual outcomes may be improved through improvements in dyadic functioning, which facilitates accommodation.

Symposium 25C

TAILORING MOTIVATIONAL INTERVIEWING FOR IMPLEMENTATION IN ADOLESCENT HIV CARE SETTINGS

Sylvie Naar, PhD

Background: Although MI is part of the clinical guidelines for HIV care and risk reduction, training healthcare providers to proficiency in MI is costly and not always successful. A key tension in implementing evidence-based practice is balancing strict fidelity with flexibility in adapting to context. The goal of this study was to utilize communication science and the dynamic adaptation process to tailor MI for implementation in adolescent HIV care settings with a specific focus on service delivery with racial and ethnic minority youth.

Method: For the communication science component, we analyzed 69 audio-recorded patient-provider encounters with racial and/or ethnic minority identified HIV-positive youth. Which were transcribed and coded using the Minority Youth Sequential Coding for Observing Process Exchanges. Encounters were randomly assigned to two coders with 20% co-coded for inter-rater reliability ($k=.684$). Sequential analysis was used to identify provider behaviors that elicited patient motivational language. For the dynamic adaptation process component, we conducted qualitative interviews with key stakeholders in two pilot sites utilizing the Exploration, Preparation, Implementation, Sustainment (EPIS) model. Interviewers completed rapid content analysis immediately following each interview to capture their impressions of themes in the interviewee's response content and observations of the interviewee for each EPIS category plus an overall summary. The interviewers' feedback was then compared across interviewees to identify recurrent themes.

Results: Provider questions (open and closed) were the communication strategy most likely to elicit change talk (CT) and commitment language (CL). Specifically, closed questions phrased to elicit CT did so 66% of the time and open questions did 57%. Closed questions phrased to elicit CL did so 71% of the time and open questions did 57%. Questions phrased to elicit counter change talk (CCT) were also likely to elicit CCT (closed 68%, open 73%) but reflections of ambivalence (75%) were more likely to elicit CCT and reflections of CCT were nearly as likely (53%). All $p<.05$. For the dynamic adaptation process component, major themes noted in the qualitative interviews were that the clinic environment was very busy and that intervention activities might be too time consuming. However, MI was a good fit for the staff, and planned implementation and sustainability strategies were well designed.

Conclusions: MI implementation strategies were adapted and feasibility tested using these data including workshop content and follow-up coaching plans. The resulting implementation intervention (TMI; Tailored Motivational Interviewing) is currently being tested in dynamic wait-list controlled design in 11 adolescent HIV clinics as part of the Adolescent Trials Network for HIV/AIDS Interventions.

Symposium 26

2:00 PM-3:15 PM

APPLYING DEVELOPMENTAL SCIENCE TO CHANGE HEALTH BEHAVIORS IN VULNERABLE CHILDREN

Sarah E. Domoff, PhD¹, Larissa N. Niec, PhD², Amanda E. Staiano, PhD³, Aaron D. Fobian, PhD⁴, Alan M. Delamater, PhD⁵, Alison Miller, PhD⁶

¹Central Michigan University and University of Michigan, Mount Pleasant, MI; ²Center for Children, Families, and Communities at CMU, Mount Pleasant, MI; ³Pennington Biomedical Research Center, Baton Rouge, LA; ⁴University of Alabama at Birmingham, Birmingham, AL; ⁵University of Miami Miller School of Medicine, Miami, FL; ⁶University of Michigan School of Public Health, Ann Arbor, MI

Engaging parents in health interventions is critical to initiate and sustain health behavior change in children and families. Reaching parents and achieving successful treatment completion is challenging, especially for families already experiencing barriers and service disparities. This symposium addresses the SBM 2018 Conference Theme, "Extending our Reach," by showcasing four interventions that specifically target parents and/or parenting processes to effectively reach vulnerable children and their parents and facilitate health behavior change.

The four papers in this symposium examine intervention development and effectiveness for children from four distinct stages of development: early childhood (Paper 1), late childhood/early adolescence (Paper 2), mid-adolescence (Papers 3 and 4), and late adolescence (Paper 3). Across papers, the interventions extend our reach by targeting a diverse group of historically underserved children and families (e.g., families from racial/ethnic minority backgrounds, living in rural regions of the US and in urban at-risk areas). Each paper will expand upon the integration of developmental science and theory into the design and implementation of interventions addressing important health domains such as childhood obesity (Paper 1), physical activity (Paper 2), sleep (Paper 3), and diabetes management behaviors (Paper 4).

Paper 1 will describe an innovative obesity prevention intervention informed by attachment theory and social learning theory. The authors will describe the importance of addressing the parent-child relationship as a novel obesity prevention target, especially for families with high stress and parent-child conflict, and will describe the adaptation of an innovative technique for eliciting behavior change that has demonstrated large effect sizes in its original format. Paper 2 will detail the GameSquad Study, which utilizes video chat and gaming exercise to promote physical activity in a racially diverse sample of overweight/obese children and their parents. Paper 3 will describe the effects of a group adolescent sleep intervention that integrates parents in the treatment. The final paper will describe a family-based self-management intervention program for minority adolescents with Type 1 Diabetes. In this intervention, effective parental communication, collaborative involvement, and problem-solving are facilitated to promote diabetes regimen adherence. The symposium will conclude with a discussion amongst the speakers and attendees about how to apply developmental science to improve our reach and close gaps in intervention dissemination.

Symposium 26A

UTILIZING PARENT-CHILD INTERACTION THERAPY TO PREVENT CHILDHOOD OBESITY: A NOVEL APPLICATION FOR HIGH-RISK FAMILIES

Dr. Sarah E. Domoff, PhD

Parents are critical to establishing healthy eating and activity behaviors in their children and preventing obesity (Birch & Ventura, 2009). Warm, responsive, and consistent parenting (i.e., authoritative parenting) is associated with a lower prevalence of child obesity (Anderson et al., 2012; Connell & Francis, 2014). Longitudinal studies have documented the links between parenting style and quality of parent-child interactions and child obesity status (Anderson et al., 2012). Improving how parents interact with children in general and in health salient (e.g., mealtime, feeding) contexts is especially critical for families experiencing ongoing stressors, such as unemployment and poverty. Parent-child conflict is higher in families with ongoing stressors, such as greater economic disadvantage (O'Connor et al., 2015). Therefore, prevention efforts that improve the parent-child relationship and parenting are particularly needed for children at higher risk.

In recent years, obesity prevention programs have begun to target general parenting practices to prevent obesity risk in children (Haines et al., 2016; Østbye et al., 2012). Despite growing involvement of parents in such prevention efforts, there has been limited evidence for preventing excess weight gain. A reason for the limited efficacy in obesity prevention programs may be *which* aspects of parenting are the target of the intervention. Although several obesity prevention programs have addressed parental *knowledge* of nutrition and physical activity guidelines (Skouteris et al., 2011) and a smaller number have addressed general parenting practices, (Gerards et al., 2011), none to our knowledge, have explicitly targeted improving the parent-child relationship via enhancing warm and responsive interactions in order to prevent obesity.

In this paper, we describe the development of an adapted version of Parent-Child Interaction Therapy (PCIT), an evidence-based behavioral family intervention designed to improve the behavior regulation of children ages 2.5 to 7 years, enhance parenting effectiveness, and improve the quality of the parent-child relationship. This adapted intervention, PCIT-Health, is informed by attachment theory and social learning theory (Eyberg & Funderburk, 2011; McNeil & Hembree-Kigin, 2010). During the first phase, Child Directed Interaction, parents learn child-centered interaction skills to enhance the parent-child relationship. During the second phase, Parent Directed Interaction, parents learn healthy, developmentally appropriate discipline skills. PCIT-Health, maintains all the core components of PCIT (e.g., behavioral assessment, in vivo coaching, relationship enhancement, and discipline skills), and adds an intervention module (Health Directed Interaction) to specifically target obesity risk.

Symposium 26B

ENGAGING PARENTS AND OVERWEIGHT/OBESE CHILDREN IN PHYSICAL ACTIVITY USING VIDEO CHAT AND GAMING TECHNOLOGY

Dr. Amanda E. Staiano, PhD

Background: Insufficient physical activity is a contributor to obesity, which affects one in five U.S. children. Given children spend on average 62 hours/week engaged in screen-time, leveraging digital screens to provide physical activity tools and virtual counseling support may be an innovative way to promote sustained moderate-to-vigorous physical activity (MVPA) among families.

Methods: The GameSquad study was a 6-month, 2-arm randomized controlled trial among 46 overweight/obese children (aged 10 to 12 years) assigned to a 6-month exercise intervention or a wait-list control group. The exercise intervention was grounded in social cognitive theory by reinforcing parental modeling and promoting children's self-efficacy. An exergaming console with four exergames and an exergaming curriculum were provided to promote family exergame play at home (3 hours/week), a fitness specialist did video chats with the parent-child dyad every 1–2 weeks, and children were provided with a FitBit for self-monitoring of physical activity. Children in the wait-list control received the exergaming console and games at the end of the 6-month period. Children completed psychosocial surveys and wore an Actigraph accelerometer for 7-days prior to and after the intervention. Minutes of MVPA were calculated from accelerometer data using Treuth cutpoints. Two-tailed t tests were used to examine difference scores between conditions in MVPA minutes/day and self-efficacy towards physical activity.

Results: Participants were predominantly male (54%) and African American (57%). Adherence to min/week of subscribed exergaming was 94.4%, and parent/child adherence to video chats was 85.5%. Most children (73%) reported usually exergaming with a parent or sibling/cousin. Compared to the control group, the intervention group significantly increased MVPA ($p=0.04$, +3.1 min/day vs. -3.7 min/day in the control group). Compared to the control group, the intervention group significantly increased self-efficacy towards physical activity ($p = 0.01$).

Conclusion: This video chat and gaming exercise intervention effectively engaged parents and children for a 6-month period and increased children's levels of MVPA. Screen-based technology offers an opportunity to support families in joint physical activity to promote healthy habits.

Symposium 26C

EFFICACY OF A GROUP ADOLESCENT SLEEP AND MEDIA USE INTERVENTION AND UTILIZING PARENTS IN TREATMENT

Dr. Aaron D. Fobian, PhD

Introduction: Research has shown that adolescents do not obtain adequate sleep, especially during the school week. Currently, few well-controlled studies assessing behavioral interventions for sleep in adolescents are available, and this study aims to assess the efficacy of an adolescent sleep intervention.

Methods: Twenty adolescents aged 15–17, who slept less than 8 hours on average were recruited (M age=16.05, SD=0.76; 65% female; 50% African American, 45% Caucasian, 5% Hispanic). Participants were randomly assigned to either a sleep intervention (n=10) or a study skills intervention (n=10). Each intervention consists of 4 group sessions consisting of 3–6 adolescents and their parents. The sleep intervention utilizes cognitive behavioral principles applied to sleep and media use. Because parents' behavior has been found to be strongly associated with adolescents' behavior, parents were significantly involved in the intervention. The study skills intervention taught evidence-based study skills and also included parental involvement. Sleep quality and quantity was measured by actigraphy at baseline, throughout the sleep intervention, and at follow-up. Change scores (post-pre) were completed to assess change in sleep for each participant. Independent samples t-tests were conducted to assess differences in change in sleep between participants in the sleep intervention and those in the study skills intervention. This is part of a larger study aimed at assessing the effects of increased sleep on metabolism and body composition. Participant recruitment is ongoing, and more data will be available at the time of presentation.

Results: Adolescents in the sleep intervention significantly increased their sleep by an average of 36 minutes as compared to the sleep of those in the study skills intervention, which decreased by 6.6 minutes on average, $t(18)=2.59$, $p=0.02$. There were no missing data.

Conclusions: A CBT-based sleep intervention that integrates parents is effective for increasing adolescents' sleep duration. The majority of adolescents do not obtain adequate sleep, and this short-term, group intervention is a cost effective way to target this problem. Additionally, this emphasizes the merit of utilizing parents in adolescent interventions. This intervention can be used to assess the impact of increasing adolescents' sleep on other health factors such as reducing obesity and risk for type 2 diabetes.

Symposium 26D

FAMILY-BASED SELF-MANAGEMENT INTERVENTION PROGRAM FOR MINORITY ADOLESCENTS WITH TYPE 1 DIABETES

Prof. Alan M. Delamater, PhD

Minority youth with type 1 diabetes are at increased risk for poor metabolic control. We developed a family-based intervention program utilizing motivational interviewing (MI) for youth and conducted a controlled pilot test of its efficacy. Exploratory focus groups and pre-testing informed program development. Six sessions were delivered over 12 weeks, with three monthly follow-up visits. Results of the pilot showed improvements for dietary behaviors ($p<.04$), management of hypoglycemia ($p<.03$), and blood glucose monitoring (BGM; $p<.04$). Although there were no significant changes in glycemic control, 54% of youth receiving the family-based MI program improved or maintained their glycemic control versus 31% of youth receiving standard care. Intrinsic motivation (IM) for diabetes management (DM) increased over time for youth in both groups ($p<.001$), and higher baseline IM predicted increased DM behaviors ($p<.01$) and better glycemic control ($p<.03$) six months later. These pilot findings demonstrated the initial efficacy of the family-based MI program and the importance of IM for DM.

The program focuses on youth making specific goals related to BGM, food intake, insulin use, and family communication about DM. Information is provided for youth and parents about these regimen components and effective parental communication, collaborative involvement and problem-solving. Youth select the issues they want to work on and set specific weekly goals; parents monitor and support goals for their children as well as their own goals to promote teamwork, with weekly tracking of success. With every goal, youth rate the importance and confidence they feel related to it, and the goal is linked to personally selected values to promote IM. The program addresses key DM behaviors shown to improve glycemic control, including increased frequency of BGM and bolusing of insulin, and accurate carb counting. The program also focuses on key psychosocial factors to promote these behaviors, including goal-setting, monitoring, and collaborative parental involvement.

The program's theoretical foundation is Social Cognitive Theory (SCT), in which behavior is determined by environmental, cognitive, and affective factors. Recent developments of interventions based on SCT include MI, which is based on self-determination theory. The intervention is also informed by intervention research to promote family teamwork and support by parents to their children in developmentally appropriate ways.

Symposium 27

2:00 PM-3:15 PM

INTERVENTIONS FOR CHRONIC PAIN IN PRIMARY CARE: A FOCUS ON EVALUATION

Jennifer S. Funderburk, PhD¹, Kathryn Kanzler, PsyD, ABPP², Gregory P. Beehler, PhD, MA³, Jeffrey Goodie, Ph.D., ABPP⁴, Alicia Heapy, PhD⁵

¹VA Center for Integrated Healthcare, Syracuse, NY; ²University of Texas Health Science Center San Antonio, San Antonio, TX; ³VA Western New York Healthcare System, Buffalo, NY; ⁴Uniformed Services University, Gaithersburg, MD; ⁵Yale University/VA Connecticut, West Haven, CT

More than 100 million Americans have chronic pain and most obtain care in primary care settings, where they do not usually receive evidence-based psychological treatments for pain. The increasing number of behavioral health providers embedded in primary care has led many systems to search for evidence-based treatments for chronic pain to implement. However, there lacks any brief evidence-based treatments targeting pain that fits typical models of integrated primary care service delivery. As a result, systems and integrated providers are developing treatments for pain to implement and there is an opportunity to conduct research on how they are approaching this problem. This symposium will have three presentations that will focus on how three different groups of people approached this issue, sharing their intervention for chronic pain, design of the evaluation, and outcome measures. Following introductions, the chair will introduce the idea for the need for greater participation by clinician innovators in conducting these evaluations and how these presentations provide glimpses into the types of designs and outcomes that can feasibly be used. The first presenters will discuss their research, involving a population-health based approach to studying treatment of chronic pain using Acceptance and Commitment Therapy in a primary care behavioral health clinic. Our second presenter will review their implementation study transporting brief Cognitive Behavioral Therapy (CBT) for pain within the Veterans Affairs primary care system. Our third presenter will review the design and methods of a proposed large-scale pragmatic trial in the Department of Defense healthcare system that utilizes diverse CBT interventions. Our discussant will focus on these projects in the context of dissemination and implementation science, allowing time for discussion and interaction with attendees.

Symposium 27A

EVALUATING ACT FOR CHRONIC PAIN IN INTEGRATED PRIMARY CARE WITH A POPULATION HEALTH-DRIVEN RCT

Dr. Kathryn Kanzler, PsyD, ABPP

Although internal behavioral health consultants in primary care have the skills to enhance treatment of chronic pain, research examining their effectiveness is lagging. While there are many techniques to study and intervene in primary care, we selected an RCT with a population health approach, which involves focusing on “the health outcomes of a group of individuals, including the distribution of such outcomes within the group” (Kindig & Stoddart, 2003). In this presentation, we will discuss our choice of clinical pathway intervention regarding the use of Acceptance and Commitment Therapy (ACT) for patients with persistent pain. Then, we will discuss our evaluation strategy using a grant-funded pilot RCT and the decisions regarding outcome measures, including challenges and successes using preliminary findings. We will recommend future steps to stimulate evaluation of evidence-based interventions in primary care, ultimately improving the quality of care and functioning for patients with chronic pain.

Symposium 27B

BRIEF CBT FOR CHRONIC PAIN: DEVELOPMENT AND IMPLEMENTATION OF A PROTOCOL FOR INTEGRATED PRIMARY CARE

Dr. Gregory P. Beehler, PhD, MA

Integrated primary care programs can play a key role in delivering biopsychosocial care for chronic pain. However, to date, there has not been a widely accepted protocol for CBT for chronic pain that is well-suited for integrated primary care settings. This presentation will describe the development and initial dissemination of Brief CBT for chronic pain (Brief CBT-CP) to Veterans Affairs (VA) integrated primary care clinics. Brief CBT-CP was adapted from the VA's full length gold standard CBT intervention to fit the Primary Care Behavioral Health model of integrated care. This protocol is shorter in duration (~3 hours total) than the original protocol (up to 12 hours) and includes six, 30-minute sessions. Brief CBT-CP strongly emphasizes measurement-based care to monitor response to treatment through the routine use of brief validated measures of pain and functioning. Immediately following protocol development, and in response to high demand for increased support for pain management in primary care, our team developed a clinical demonstration project to rapidly implement Brief CBT-CP in select VA integrated care clinics. We will describe the process of developing evaluation tools to support preliminary assessment of protocol feasibility and effectiveness as well as patient satisfaction. This project included the creation of an implementation plan designed to assist frontline providers with administering Brief CBT-CP. Integrated care providers attended a 60-minute orientation webinar that focused on the content and structure of Brief CBT-CP. Monthly Community of Practice calls were used for group discussion and provided a venue for technical assistance regarding implementation of the protocol. As-needed email and phone consultations were provided by the project team. We will review the results of evaluation data collected from providers at project mid-point and conclusion. These web-based surveys were used to identify barriers and facilitators impacting implementation of Brief CBT-CP and suggestions for future modification to the protocol and implementation approach. Lessons learned from patient satisfaction data from a subsample of Brief CBT-CP participants will also be discussed. In summary, this presentation will provide a real-world example of how to plan and execute a feasible approach for evaluating a rapid implementation of a new brief treatment for chronic pain in integrated primary care.

Symposium 27C

USING PRAGMATIC TRIAL DESIGNS TO EXAMINE IBHC INTERVENTIONS FOR CHRONIC PAIN IN PRIMARY CARE

Dr. Jeffrey Goodie, Ph.D., ABPP

Chronic pain is an increasing problem for beneficiaries in the Department of Defense. It is estimated that 50% of deployed military members are expected to return with pain conditions. Most (i.e., 84%) primary care clinics throughout the Department of Defense that have at least 3000 enrollees have an internal behavioral health consultant (IBHC). Although clear guidance for management and behavioral treatment of chronic pain in primary care settings by IBHCs has been disseminated, the effectiveness of these management strategies has not been examined. Our team recently proposed a multi-site pragmatic trial to evaluate the effectiveness of IBHCs in treating chronic pain using an advanced clinical pathway. Pragmatic trials are designed to examine the effects of an intervention under the usual conditions in which it would be implemented. For example, pragmatic trials encourage inclusion of any patients with the presenting problem while minimizing exclusion criteria, interventions are provided by a full range of practitioners, the implementation of the intervention is highly flexible, and measured outcomes are clinically meaningful to study participants. We will present our proposed study's rationale and unique design, including a stepped-wedge approach across sites, combining elements of population health interventions and team-based care, utilizing a pragmatic trial approach.

CORRESPONDING AUTHORS: Donald McGeary, Ph.D., University of Texas Health, San Antonio; mcgeary@uthscsa.edu; Kathryn Kanzler, PsyD, University of Texas Health, San Antonio; Kanzler@uthscsa.edu; Christopher Hunter, Ph.D., Patient-Centered Medical Home Branch, Clinical Support Division Defense Health Agency; christopher.l.hunter16.mil@mail.mil

Symposium 28

2:00 PM-3:15 PM

SPATIO-TEMPORAL MODERATORS OF HEALTH BEHAVIOR INTERVENTIONS: NEW METHODS AND RESEARCH EVIDENCE

Mark Hatzenbuehler, PhD¹, Blair T. Johnson, PhD², John Pachankis, PhD³, Allecia Reid, PhD⁴¹Columbia University, New York, NY; ²University of Connecticut, Storrs, CT; ³Yale University, New Haven, CT; ⁴Colby College, Waterville, ME

It is well known that individual-level factors (e.g., age, sex, personality characteristics) render health interventions more or less effective, but the contextual factors that impact the efficacy of these interventions are only beginning to be understood. Reid and colleagues (2014) conducted one of the first studies to demonstrate that intervention context exerts a powerful effect on intervention efficacy. The researchers re-analyzed a meta-analytic database with information on effect sizes from 78 HIV prevention interventions targeted toward African Americans, and took advantage of the fact that these interventions took place across the U.S. in communities that differed widely in terms of the level of structural stigma surrounding African Americans (operationalized via measures of anti-black attitudes). Interventions improved condom use only when communities had relatively positive attitudes toward African Americans. Conversely, the interventions did not reduce condom use when conducted in communities with high levels of anti-Black prejudice. This research opens up new avenues for exploring whether and why health behavior interventions flourish in some social contexts but often fail in others.

The goal of this symposium is to advance this evidence base on contextual moderators of intervention efficacy through three presentations. First, Dr. Johnson will discuss new methods for exploring contextual moderators of intervention efficacy, with a particular focus on the use of spatio-temporal meta-analyses. Second, Dr. Pachankis's study will examine whether structural stigma related to sexual orientation—including state laws targeting lesbian, gay, and bisexual (LGB) populations (e.g., lack of protections for sexual orientation in hate crime and employment non-discrimination statutes)—reduces the effectiveness of mental health treatments for LGB young adults, using new data from a large-scale study of mental health treatment across 154 college campuses. Third, Dr. Reid's study will examine whether the efficacy of interventions to improve African Americans' condom use depends on contextual features of the communities where interventions occurred (e.g., residential segregation). Following these presentations, the discussant will consider implications for future research and intervention development, such as the need for designing and testing modules that can be added to existing interventions to make them maximally responsive to diverse social contexts.

Symposium 28A

SPATIOTEMPORAL META-ANALYSIS AND HEALTH PROMOTION INTERVENTIONS: NEW METHODS AND FINDINGS

Prof. Blair T. Johnson, PhD

Individual health promotion interventions are studies conducted in particular places at particular times. Like all studies, they are distributed over time and space. The results of such studies manifest multiple processes, including those associated with individual, sample, intervention, study design, and environmental characteristics. Although extant meta-analyses of health promotion interventions routinely consider such study- and population-level factors to explain variability, they often neglect the environments where studies are conducted. This omission is ironic, as health phenomena cluster in space and times (e.g., the obesity epidemic). The settings in which study participants live, work, and play are characterized by such environmental factors such as prevalence of disease, weather trends, local and broad economic trends (e.g., income inequality), the built environment (e.g., parks, sidewalks), allostatic load due to all causes, and the level of stigmatization of minority groups. For example, the degree of stigma associated with being a racial or sexual minority varies widely over space and often over time within the same locale. **Spatiotemporal meta-analysis** endeavors to address heterogeneity in environments present in individual studies by combining information known about the locales when the studies were conducted. Logically, to the extent that relevant spatiotemporal information on environmental conditions is available and varies widely, it may explain variability in study results that is not explained by individual, sample, study, or intervention features: e.g., for obesity epidemics, safe neighborhoods, walkable roads and “food desert” areas are known important environmental factors. There are challenges in developing spatiotemporal meta-analyses, as it necessitates geocoding spatial information, which sometimes is not available in detail. Moreover, the strategy logically works best when there are many studies available and when theory supports clear hypotheses about which spatiotemporal factors relate to health outcomes. We discuss these challenges and future directions for this form of systematic reviewing methodology, such as the use of residuals plotted over space to diagnose unrecognized, but spatially clustered dependencies in the observations. Because the success of health promotion activities introduced in a particular locale are subject to forces in and surrounding that locale, both during and after the intervention has ceased, a spatiotemporal approach offers considerable heretofore unrecognized analytic potential not only in meta-analyses but also in original investigations.

Symposium 28B

THE INFLUENCE OF STRUCTURAL STIGMA ON PSYCHOTHERAPY OUTCOMES AMONG SEXUAL MINORITY COLLEGE STUDENTS

Dr. John Pachankis, PhD

While psychotherapy can improve the mental health of stigmatized populations, it is unknown whether the stigma present in the climate in which psychotherapy is delivered influences treatment efficacy. Sexual minority individuals (e.g., those who identify as LGBTQ) are at high risk for mental disorders and are three times as likely as heterosexuals to use mental health services. However, little is known about the efficacy of psychotherapy for this population. Even less is known about the influence of structural stigma (e.g., state homophobia) on psychotherapy outcomes for sexual minorities. In high-stigma locales, psychotherapy's effects might not be able to compete with the systemic and personal toll of pervasive discrimination. However, a lack of treatment outcome data from sexual minority clients across geographically diverse locales precluded examination of this possibility until recently. To address this knowledge gap, our team used a novel dataset from the Center for Collegiate Mental Health with outcome data for 15,811 students ($n = 1,969$ sexual minorities) who received psychotherapy at 116 college counseling centers across 38 states in the US, providing a rare opportunity to assess whether variation in structural climates surrounding sexual minorities in the US predicts geographic variations in the efficacy of psychotherapy for this population. Participants completed weekly assessments of depression, generalized anxiety, social anxiety, and alcohol use across treatment. State-level stigma was measured as laws affecting sexual minorities. To account for the nested data structure (i.e., repeated measures within participants within campuses and states), multilevel modeling will be employed to examine our hypothesis that structural stigma will moderate the effect of psychotherapy on mental health symptom trajectories across treatment, such that sexual minorities who receive treatment in structurally stigmatizing climates, compared to supportive climates, will experience lower benefit from treatment. We propose that this effect will be specific to sexual minorities, as structural climate is not hypothesized to affect treatment outcomes for heterosexual clients. Findings are expected to support the need for structurally supportive institutional climates, LGBTQ-affirmative trainings in college counseling centers, and LGBTQ-affirmative treatment adaptations to improve therapeutic outcomes among this vulnerable, underrepresented segment of the US population.

Symposium 28C

COMMUNITY-LEVEL RESOURCES AND SUCCESS OF HIV INTERVENTIONS FOR AFRICAN AMERICANS: A META-ANALYSIS

Allecia Reid, PhD

The Network-Individual-Resource Model proposes that the communities in which individuals live serve as negative or positive resources. Interventions are therefore less likely to succeed when participants must alter behavior in communities that lack important tangible or psychological resources, unless interventions explicitly address these needs. We examined the extent to which efficacy of interventions to improve African Americans' condom use practices depended on availability of community-level tangible and psychological resources, including unemployment and Whites' attitudes toward African Americans. A previously published meta-analytic database was updated and re-analyzed to examine whether community-level resources were associated with sexual risk reduction effect sizes. HIV prevention trials with samples that were at least 50% African American were included. County-level unemployment and Whites' attitudes were drawn from the U.S. Census and the nationally representative, American National Election Studies. For significant factors, we also examined whether intervention content that addressed the implied needs further moderated the effect.

Interventions were most successful when unemployment was lower and Whites' attitudes were more positive. Unemployment became non-significant in a combined model. Sensitivity analyses demonstrated that the effect of Whites' attitudes was especially pronounced among African American men but was significant for African American women. The effect of unemployment was consistent across groups. Intervention features that reduce African Americans' mistrust of providers may buffer against the influence of Whites' attitudes. Although utilizing African American facilitators to deliver the intervention did not moderate the effect, tailoring content to participants' values and needs buffered against the negative influence of Whites' attitudes. Residuals provided further information on factors associated with interventions for which efficacy deviated from expected results. Consistent with our focus on community resources, communities with interventions, compared to those without, had larger African American populations, lower median incomes for Blacks, higher income inequality, and higher unemployment. While promising that the communities most lacking in resources are receiving interventions, results highlight the role of community-level resources in maintaining racial/ethnic disparities in HIV and impeding the efficacy of health interventions.

NEW SOLUTIONS TO OLD PROBLEMS: IMPROVING WOMEN'S PERINATAL MENTAL HEALTH

Pamela A. Geller, Ph.D.¹, Mona Elgohail, M.S.², Emily C. Stasko, M.S., M.P.H.³, Christina DiSanza, MA¹, Sara Kornfield, PhD⁴

¹Drexel University, Philadelphia, PA; ²Drexel University, Atlantic Highlands, NJ; ³Drexel University, Albuquerque, NM; ⁴University of Pennsylvania Perelman School of Medicine, Philadelphia, PA

Women can experience a variety of adverse reproductive-related events surrounding the perinatal period. For many, the experience of achieving and maintaining pregnancy is largely uneventful, while others may confront considerable challenges such as infertility and preterm delivery. Moreover, the postpartum period, even following an uneventful pregnancy, can be a time of tremendous stress as women transition to their new role and seek to balance infant care, work, family, and self-care. Such perinatal experiences are accompanied by severe psychological distress for many women, with about 20% experiencing significant perinatal depression and anxiety. This rate is substantially higher for high risk populations, such as mothers of infants with a Neonatal Intensive Care Unit (NICU) hospitalization. Perinatal mental health problems can impact daily functioning, couple and family relationships, and maternal-infant attachment. While these issues are not new, there is growing recognition of the need to address this distress early and effectively to improve outcomes for women, children, couples and families.

This symposium introduces creative ways to alleviate perinatal distress for women through innovative psychosocial interventions. Four novel projects offer original perspectives on the implementation of protocols that can serve as models and extend our reach to diverse populations, address barriers to care, and promote the treatment of perinatal distress using relevant and unique approaches. The first presentation introduces an international project implementing an internet-based intervention utilizing religious cognitive behavioral therapy (iRCBT) to reduce depression in Muslim women experiencing infertility. The second presentation discusses Let's Get Sexy!—a program examining the impact of a new technology-driven intervention on intimacy and sexual satisfaction among women undergoing fertility treatment. This project expands the traditional focus on mental and physical dysfunction to address women's experiences of sexual agency, satisfaction, and intimacy while trying to conceive. The third presentation describes Mother Baby Connections — an intensive outpatient treatment program delivering interdisciplinary evidence-based services with an attachment focus that is newly developed for women experiencing depression and anxiety during the perinatal period. The fourth presentation describes Mindful NICU, a novel adaptation of a mindfulness-based stress reduction intervention integrated in a Level IV NICU. Together, these projects address ways to alleviate perinatal distress using innovative psychosocial interventions that can be integrated into outpatient practice, hospital, and collaborative care settings.

Symposium 29A

INTRODUCING MOTHER BABY CONNECTIONS: A MODEL OF CREATIVE PERINATAL MENTAL HEALTH PROGRAMMING

Dr. Pamela A. Geller, Ph.D.

Perinatal mental health problems are associated with significant morbidity and mortality among childbearing women. Approximately 20% of women experience mental health problems during the perinatal period, with higher rates among vulnerable populations; yet only 20 to 25% receive adequate treatment, warranting novel and creative approaches to provide accessible, perinatal-specific mental health treatment while reducing barriers to engagement in care. To meet this need in the greater Philadelphia area, we introduce *Mother Baby Connections (MBC)*, an innovative model of interdisciplinary, evidence-based, attachment-focused intensive outpatient perinatal mental health programming recently launched at Drexel University. *MBC* aims to reduce antepartum and postpartum psychiatric symptoms and improve maternal functioning through individual, couple and group treatment formats, including evidence-based Mother-Baby Interaction Therapy. This presentation will provide an overview of *MBC* and its components, highlighting the novel and unique factors that differentiate this program from traditional outpatient treatment. We also will discuss baseline to 4-week clinical outcomes (utilizing scores from reliable and valid scales) from the first 18 months of *MBC* operation. In sum, based on both parametric paired *t* and non-parametric Wilcoxon signed ranks tests, outcomes for 15 predominantly minority women with completed outcome measures showed significant improvements in maternal depression symptom severity, perceived stress, and emotional regulation. Effect sizes were medium to large (i.e., .50 to .89). The perinatal mental health training and research aspects of the program also will be described.

Symposium 29B

FAITH & FERTILITY: THE DEVELOPMENT OF A CBT-BASED INTERVENTION FOR MUSLIM WOMEN EXPERIENCING INFERTILITY

Mona Elgohail, M.S.

Infertility is a chronic health condition that affects millions of women each year, with many also suffering from depression. Depression may increase the risk of experiencing infertility, as well as decrease the success rate of infertility treatment. Our recent study of Muslim women living in western countries found that despite a high prevalence of infertility-related stress and depression in the sample, only 7% of participants reported that they were engaged in psychotherapy. Findings also suggested that this population often turns to religion/spirituality (R/S) to cope with emotional distress. This is consistent with previous research in which Muslims endorsed several barriers to seeking psychotherapy (e.g., fear of being stigmatized, lack of R/S integration). Consequently, Muslim women diagnosed with infertility need a psychotherapy that not only reduces depressive symptoms, but is private, convenient, and religiously integrated. Cognitive-behavioral therapy (CBT) has been effective in decreasing distress among Muslims and improving pregnancy rates among women with infertility. Thus, CBT that integrates R/S may be the most effective in alleviating distress in this population. The current study is the first to test an internet-based religious cognitive behavioral therapy to mitigate depression in Muslim women experiencing infertility and living in Australia, Canada, the United Kingdom, and the United States. This novel intervention will be described and preliminary data will be presented.

Symposium 29C

LET'S GET SEXTY! A NOVEL INTERVENTION TO IMPROVE SEXUAL SATISFACTION DURING FERTILITY TREATMENT

Ms. Emily C. Stasko, M.S., M.P.H.

It is well established in the literature that infertility is linked to numerous negative psychological sequelae, including anxiety, depression, stress, and overall distress (Domar, Broome, Zuttermeister, Seibel, & Friedman, 1993; Downey et al., 1989; Downey & McKinney, 1992; Freeman et al., 1985; Mahlstet et al., 1987). Women report that the medicalization of their bodies and sex lives is a cognitively distressing and often a dehumanizing ordeal. Unsurprisingly, both sexual and relationship satisfaction tend to diminish during struggles with infertility (Galhardo, Cunha, & Pinto-Gouveia, 2011; Pepe, & Byrne, 1991). Let's Get Sexy! is a program examining the effect of a new technology-driven intervention on intimacy and sexual satisfaction among women undergoing fertility treatment. By conceptualizing sexting (sending or receiving sexually suggestive or explicit messages, images, or photos through electronic means) as a form of sexual communication by which women undergoing infertility treatment may feel empowered and thereby improve their sexual satisfaction with their partners during a timeframe noted to be extremely stressful and challenging for women and couples. The proposed presentation describes the development, implementation, and findings from this novel 'Sext Education' intervention. Results will examine the connection between sexting, sexual communication, intimacy, and sexual satisfaction. This study expands the traditional focus on mental and physical dysfunction to address women's experiences of sexual agency, satisfaction, and intimacy while trying to conceive. For the large number of women experiencing infertility in the US annually, this program holds the potential to help focus behavioral interventions on women's experiences of pleasure and satisfaction during a psychologically challenging and sexually disruptive time period.

Symposium 29D

HERE & NOW: PARENTAL MINDFULNESS IN THE NICU

Christina DiSanza, MA

Rates of psychological distress, including depression, anxiety, and posttraumatic stress disorder, are substantially higher for parents of infants admitted to a neonatal intensive care unit (NICU). For parents of infants who've been discharged from a NICU, elevated symptoms of stress often persist as the child grows and develops. Parental stress, anxiety, depression and fatigue can negatively alter parenting behavior and perception of parental competence, ultimately impacting attachment and child development. At this time, there is a dearth of stress-reduction programs adapted and accessible for parents of infants who spend time in a NICU. Mindfulness-based interventions are efficacious at reducing stress among clinical and community samples, including perinatal populations. The current study examines the feasibility and acceptability of implementing, "Mindful NICU", a newly developed mindfulness-based program adapted for NICU parents and its preliminary impact on parental stress. Mindful NICU is a 6-session, 6-week, mindfulness-based program adapted for parents who have an infant in the Chronic Lung Disease Program in the Newborn/Infant Intensive Care Unit (N/IICU) at Children's Hospital of Philadelphia. The current study will report on two trials of Mindful NICU among 10 parents each. Parents will complete self-report measures of stress, mental health symptoms, and mindfulness-pre-and-post intervention. Infant chart reviews and infant health severity are conducted by staff to corroborate parental stress levels and to inform response to the program. The feasibility and acceptability of the program will be determined by assessment of attendance rates, exit surveys, and a 4-week follow-up exit interview. Descriptive analyses and bivariate correlations will be conducted on the primary variables (i.e. parental stress, NICU-related stress, mindfulness development). The current study will highlight the acceptability and promise of integrating mindfulness-based interventions within the NICU setting. These findings will help inform a larger randomized controlled trial of Mindful NICU as a means to assess the efficacy of this innovative program for reducing NICU parental distress.

Symposium 30

2:00 PM-3:15 PM

FROM BEHAVIOR TO BIOLOGY: EXPLORING LINKAGES BETWEEN HEALTH AND RISK BEHAVIOR AND BIOMARKERS OF DISEASE PROCESSES

Angela Bryan, PhD¹, Rebecca Ferrer, PhD², Emmanuel Mongodin, PhD³, William Klein, PhD⁴

¹University of Colorado Boulder, BOULDER, CO; ²National Cancer Institute/NIH, Rockville, MD; ³Institute for Genome Sciences, Baltimore, MD; ⁴National Cancer Institute, Potomac, MD

Lack of health behavior and engagement in risk behavior account for a staggering 40% of premature deaths in the United States, and approximately 75% of all current healthcare costs in the United States (\$1.5 trillion) are spent to ameliorate diseases and health problems that are preventable by behavior change. Though the association of health and risk behavior to disease states is clear, the mechanistic linkages between the two are not completely understood. Innovative transdisciplinary research that incorporates multiple levels of analysis, from psychological to physiological to genomic will be necessary to truly understand how it is that changes in behavior *lead to* changes in health and disease states. We present three innovative examples of research that attempts to explore and understand linkages between behavior and biology. Bryan will present data that test associations between cardiovascular fitness, body mass index, and dietary behavior with epigenetic variation in genes that are important for both inflammation broadly and breast cancer specifically. Ferrer will present data from the Midlife in the US (MIDUS) Biomarkers Project to examines emotion regulation (suppression and reappraisal), stress (PSS), sleep, and a suite of inflammatory and metabolic biomarkers. Mongodin will talk about his teams work to characterize the oral microbiota in smokeless tobacco users and cigarette smokers, compared to non-users. Taken together, these investigations highlight interesting and important mechanistic linkages between behaviors such as physical activity, sleep, and smoking and biomarkers of epigenetic change, inflammation, and the microbiome. Discussion will focus on how best to leverage these findings in order to develop better interventions to change health and risk behavior for optimal effects on biomarkers of disease processes.

Symposium 30A

TESTING BEHAVIORAL LINKAGES TO BREAST CANCER RISK VIA DNA METHYLATION: FITNESS, BMI, DIET AND EXERCISE BEHAVIOR CHANGE

Dr. Angela Bryan, PhD

Obesity and breast cancer are high-priority public health issues in the United States today. More than 1 in 3 adults in the US are obese, and about 1 in 8 women will be diagnosed with breast cancer in their lifetime. These two public health issues are strongly interrelated, as obesity puts one at risk for cancer. One important question regards whether increased body weight itself is most important in breast cancer etiology, or whether obesity-associated health behaviors, specifically, diet and exercise, also play an important role. A number of mechanisms have been hypothesized as potential pathways through which obesity, diet, and physical activity may influence breast cancer risk, and one of the most promising is their influence on DNA methylation. In this study, 276 women between the ages of 30 and 45 were recruited to participate in the study as part of a larger randomized controlled trial (RCT) examining the effects of exercise intensity and duration on DNA methylation, particularly of genes related to breast cancer. Body mass index, cardiovascular fitness (VO₂max), and fruit/vegetable consumption were measured at baseline, and then participants engaged in a 16 week supervised exercise intervention that varied in the intensity and duration of exercise bouts. DNA methylation was assessed at baseline and post exercise at CpG sites for a panel of cancer/tumor suppressor genes (BRCA1, RUNX3, GALNT9, and PAX6) and inflammatory genes (TLR4 and TLR6), and pyrosequencing was performed at EpigenDX (Worcester, MA). Methylation of inflammatory genes was strongly negatively related to methylation of cancer genes ($r = -.66$, p_{2max} were significantly associated with methylation of cancer genes. Fruit and vegetable consumption was not associated with methylation of either inflammatory genes or cancer genes. Preliminary analyses of follow-up data suggest that exercise may influence methylation of inflammation genes more strongly than inflammation of cancer genes. Specifically, increases in exercise behavior were associated with changes in TLR4 methylation ($p = .03$) and with an exercise session duration X intensity interaction on changes in TLR6 methylation ($p = .08$). Findings suggest that the obesity and cancer relationship may be impacted by inflammatory pathways that can be influenced by changes in exercise behavior.

Symposium 30B

DIRECT AND INDIRECT ASSOCIATIONS AMONG EMOTION REGULATION STRATEGIES AND BIOMARKERS OF DISEASE

Dr. Rebecca Ferrer, PhD

Objective: Effectively managing negative emotions is important for physical health, but some strategies for regulating emotions may be healthier than others. We examined the associations between habitually using cognitive reappraisal and emotion suppression as regulation strategies and biomarker indicators of health, and whether perceived stress and sleep quality mediated these relations.

Methods: Participants ($n = 1,255$) in the Biomarkers Project, a subcomponent of the Midlife in the United States (MIDUS) study, completed measures of emotion regulation, perceived stress, and subjective sleep quality. Twenty-four biomarkers were obtained from salivary, urine, and blood samples. Path analyses examined the direct and indirect associations of emotion regulation strategies to biomarkers through perceived stress and subjective sleep quality.

Results: Greater use of suppression was indirectly associated with riskier inflammatory and metabolic biomarkers and greater overall allostatic load. Reappraisal was indirectly associated with healthier biomarker profiles, including overall allostatic load, and inflammatory and metabolic systems specifically. Perceived stress and sleep quality mediated these associations, with suppression being adversely related to each, and reappraisal having beneficial relations to each.

Conclusions: This preliminary evidence suggests emotion regulation strategies may have downstream implications for physical health via stress, sleep, and biomarker expression. Changing which emotion regulation strategies are used habitually may have indirect health benefits by reducing perceptions of stress and improving sleep quality.

Symposium 30C

INFLUENCE OF BRAND, MENTHOLATION AND STORAGE ON TOBACCO-SPECIFIC BACTERIAL PATHOGENS: IMPLICATIONS SMOKERS' ORAL MICROBIOME

Dr. Emmanuel Mongodin, PhD

Complex bacterial communities that inhabit cigarettes may play a critical role in the generation of carcinogenic tobacco-specific nitrosamines (TSNAs) and in the health effects associated with cigarette smoking. However, the cigarette-associated microbiota, its dynamics, and its effects on the oral health on tobacco users, have been largely left unexplored. We conducted time-series experiments with five commercially-available brands of cigarettes that were either commercially-mentholated, custom-mentholated, user-mentholated or non-mentholated. Cigarettes were incubated for two weeks under three different temperature and relative humidity conditions to mimic pocket, refrigerator or room storage conditions. Metagenomic DNA was extracted, and the V3-V4 region of the 16S rRNA gene sequenced using Illumina MiSeq. Across all brands, bacterial communities were dominated by members of the *Pseudomonas*, *Pantoea*, and *Bacillus* genera, with levels of *Pseudomonas* relatively constant regardless of storage condition. Between-sample comparisons revealed bacterial composition differences by brand, mentholation state, as well as manufacturer's lots. Core bacterial operational taxonomic units (OTUs) were identified in all samples and included *Bacillus pumilus*, *Rhizobium* sp., *Sphingomonas* sp., unknown *Enterobacteriaceae*, *Pantoea* sp., *Pseudomonas* sp., as well as the opportunistic pathogens *Pseudomonas oryzae* and *Pseudomonas putida*. In addition to these experiments aimed at describing the microbiota in tobacco products, human studies were also performed to characterize the oral microbiota in smokeless tobacco users and cigarette smokers, compared to non-users. Our results show significant differences in microbiota composition between these 3 groups. Non-users possess a significantly smaller core of oral bacterial species compared to tobacco-users. Smokeless tobacco users and cigarette-users have a greater core of oral bacterial species. These differences can be partially explained by tobacco-associated bacteria that are transferred from the tobacco to the oral cavity of tobacco users. These data suggest that manufacturing, manipulations (i.e., mentholation) and storage conditions directly impact the cigarette microbiota as well as levels of TSNAs, which may have implications for exposure to both bacterial pathogens and TSNAs among cigarette users.

Paper Session 9: Improving Physical Activity in the Context of Cancer 3:30 PM-3:45 PM

A PILOT TRIAL OF PERSONAL TRAINING VS GROUP-BASED EXERCISE FOR INCREASING PHYSICAL ACTIVITY IN BREAST CANCER SURVIVORS

Heather J. Leach, PhD¹, Kelley Covington, B.S.², Corrine H. Voss, MS³, Steven Schuster, MD⁴

¹Colorado State University, Fort Collins, CO; ²Colorado State University, Fort Collins, CO; ³Colorado State University, Aurora, CO; ⁴University of Colorado Health, Fort Collins, CO

Background: Physical activity (PA) improves physical, psychosocial and mortality outcomes in breast cancer survivors. Previous studies have demonstrated the effectiveness of theory based PA interventions for increasing PA in breast cancer survivors. However, to date, the effectiveness of different face-to-face intervention delivery methods has not been assessed.

Purpose: To compare the effectiveness of an 8-week personal training (PT) or group-based exercise (GBE) intervention for increasing PA.

Methods: Breast cancer survivors ($N=27$, M Age= 52.0 ± 8.5) who had completed chemotherapy and/or radiation treatment within the previous year were randomly assigned to PT or GBE for 8-weeks. Participants exercised twice per week for 60 minutes, and received social cognitive theory based PA behavior change education/discussion sessions. Demographic (e.g. age, educational status, etc.) and medical (tumor stage, treatment) information was collected at baseline. PA was assessed at baseline and post-intervention. The International Physical Activity Questionnaire-short measured walking, moderate, vigorous and total PA (MET-hours per week), and a pedometer (Polar A300 Activity Monitor) measured steps per day. Baseline comparisons were performed using independent samples t-tests or chi-square analyses. Repeated measures t-tests examined within group PA changes from pre to post intervention. Analysis of covariance (ANCOVA) was conducted to compare differences in PA at post-intervention, controlling for the baseline value of the specific PA outcomes. Data were analyzed using SPSS version 24.

Results: 24 participants completed the intervention (GBE=12, PT=12). Reasons for drop out were a non-study related injury, and busy schedule/lack of time. Exercise session attendance was $M=15.8 \pm 0.5$ (99%) in PT, and $M=13.4 \pm 1.0$ (82%) in GBE ($p=.000$). At post-intervention, vigorous PA increased in PT ($\Delta 11.8$ MET-hr/week, $t(11)=-3.9$, $p=.002$) and GBE ($\Delta 15.7$ MET-hr/week, $t(11)=-5.2$, $p=.000$). Total PA increased in the GBE group ($\Delta 21.7$ MET-hr/week, $t(11)=-2.4$, $p=.034$). ANCOVA analyses revealed no differences in PA changes between groups.

Conclusion: Despite greater exercise session adherence in PT, GBE was equally as effective for increasing PA in breast cancer survivors, and may be a more cost-effective option. Due to the small sample size, these findings should be interpreted cautiously, and confirmation from a larger, adequately powered trial is needed.

Paper Session 9: Improving Physical Activity in the Context of Cancer

3:45 PM-4:00 PM

EFFECTS OF REPLACING SEDENTARY TIME WITH PHYSICAL ACTIVITY ON PATIENT REPORTED OUTCOMES IN BREAST CANCER SURVIVORS

Whitney A. Welch, PhD¹, Diane Ehlers, PhD², Susan Aguiñaga, PhD³, Kara L. Gavin, PhD, MPH¹, Alison Cottrell, B.B.A.⁴, Juned Siddique, DrPH¹, Edward McAuley, PhD⁵, Siobhan M. Phillips, PhD, MPH¹

¹Northwestern University Feinberg School of Medicine, Chicago, IL; ²University of South Carolina, Columbia, SC; ³University of Illinois at Urbana-Champaign, Aurora, IL; ⁴Northwestern University, Chicago, IL; ⁵University of Illinois at Urbana-Champaign, Urbana, IL

Physical activity can play an important role in alleviating the symptom burden of breast cancer survivors. However, it is unknown the extent to which decreasing time spent sedentary and replacing this time with more active behaviors might affect this symptom burden. Our aim was to determine the effect of substituting time between sedentary and active behaviors on patient reported outcomes in breast cancer survivors. We conducted a pooled analysis of 753 breast cancer survivors ($M_{age}=56.9 \pm 9.5$ yrs, $M_{BMI}=26.4 \pm 5.5$ kg/m²) from two observational studies in which participants wore the ActiGraph hip-worn accelerometer for 7 consecutive days and completed the Functional Assessment of Cancer Treatment-Breast (FACT-B) (physical, social, emotional, and functional well-being) and the Hospital Anxiety and Depression Scale. Isotemporal substitution models, were used to examine the effect of replacing time spent between sedentary and active behaviors on FACT-B, anxiety, and depression outcomes. Analyses controlled for age, body mass index, education, disease stage, treatment, and number of comorbidities. On average, participants engaged in 602.2 ± 74.3 minutes/day of sedentary time, 257.5 ± 69.2 minutes/day of light intensity, 22.7 ± 18.8 minutes/day of moderate intensity, and 1.5 ± 4.2 minutes/day of vigorous intensity physical activity. There was a significant change in physical well-being score when 30 minutes of moderate (mod) or vigorous (vig) activity replaced 30 minutes of sedentary (mod: $B=0.63$, $p=0.01$, vig: $B=2.22$, $p=0.032$) or light (mod: $B=0.57$, $p=0.03$, vig: 2.16 , $p=0.04$) activity. Functional well-being ($B=0.66$, $p=0.028$) and FACT-B total score ($B=2.37$, $p=0.029$) scores also improved when 30 minutes of sedentary time was reallocated to 30 minutes of moderate intensity physical activity. Replacing 30 minutes of sedentary time with 30 minutes of light intensity physical activity resulted in a significant increase in emotional well-being scores ($B=0.12$, $p=0.046$). There were no significant substitution of time effects on social well-being, anxiety, or depression scores. Substituting sedentary time with moderate intensity physical activity showed the greatest range of effect across patient reported outcomes (physical, functional, and FACT-B total score) among breast cancer survivors. These results can inform development of interventions to target specific behaviors for specific outcomes.

BREAST CANCER SURVIVORS' PREFERENCES FOR SOCIAL SUPPORT FEATURES IN A TECHNOLOGY-SUPPORTED PHYSICAL ACTIVITY INTERVENTION

Gillian Lloyd, BS¹, Sara A. Hoffman, M.S.², Whitney A. Welch, PhD³, Alison Cottrell, B.B.A.², Danielle Blanch-Hartigan, PhD, MPH⁴, Kara L. Gavin, PhD, MPH³, Lisa Cadmus-Bertram, Ph.D.⁵, Siobhan M. Phillips, PhD, MPH³

¹Northwestern University Feinberg School of Medicine, Denver, CO; ²Northwestern University, Chicago, IL; ³Northwestern University Feinberg School of Medicine, Chicago, IL; ⁴Bentley University, Waltham, MA; ⁵University of Wisconsin - Madison, Madison, WI

Despite known benefits, the majority of breast cancer survivors do not meet physical activity (PA) recommendations. Remotely-delivered, technology-supported PA interventions may be particularly useful in offering scalable PA programs for survivors. Incorporating peer and professional social support features into these programs may further increase their effectiveness. Because traditional face-to-face support is not possible in remotely-delivered PA interventions, it is necessary to first understand survivors' preferences for technology-enabled social features prior to intervention development. The purpose of this study was to elucidate breast cancer survivors' preferences for social support features (e.g. teams, discussion boards, exercise buddies) within a remotely-delivered, technology-supported PA intervention. Survivors [$N=96$; $M_{age}=55.8$ ($SD=10.2$)] self-reported demographic and disease characteristics, physical activity, and their interests in and preferences for social features for a remotely-delivered PA intervention via an online questionnaire. A subset of participants ($n=28$) were randomly selected to complete an audio-recorded, semi-structured phone interview. Questionnaire data were analyzed using descriptive statistics. Transcribed interviews were evaluated using a thematic content analysis approach and consensus review. Survey results revealed that the majority of survivors were interested in technology-enabled social features including a behavioral coach (77.1%), an assigned team (66.7%) and an exercise buddy (57.3%). Survivors endorsed sharing their activity data with their team (80.0%) and buddy (76.6%), yet only 44.8% were interested in a progress board. Most survivors (82.3%) were not interested/unsure about linking the intervention to their personal social media accounts. Three main themes emerged from interview data: (1) desire to connect with "survivors like me"; (2) aversion to competitive social features and (3) interest in study staff involvement/support. Preferences for social support features in the context of technology-supported exercise interventions varied among breast cancer survivors, yet data indicate that social features are of interest to survivors. Continued engagement of survivors in developing and implementing remotely-delivered, technology-enabled social features may greater inform future PA interventions.

Paper Session 9: Improving Physical Activity in the Context of Cancer 4:15 PM-4:30 PM

DO SOCIAL SUPPORT AND NEIGHBORHOOD WALKABILITY INFLUENCE PHYSICAL ACTIVITY DURING PREOPERATIVE PANCREATIC CANCER THERAPY?

Nathan Parker, MPH, PhD¹, An Ngo-Huang, D.O.², Rebecca E. Lee, PhD³, Daniel O'Connor, PhD⁴, Maria Q. B. Petzel, BS, RD¹, Keri Schadler, PhD⁵, David Fogelman, MD⁵, Linda Pang, MD⁵, Matthew HG. Katz, MD, FACS⁶

¹The University of Texas MD Anderson Cancer Center, Houston, TX; ²University of Texas MD Anderson Cancer Center, Houston, TX; ³Arizona State University, Phoenix, AR; ⁴University of HOuston, Houston, TX; ⁵MD Anderson Cancer Center, Houston, TX; ⁶UT MD Anderson Cancer Center, Houston, TX

Background: Home-based exercise programs may be prescribed to encourage physical activity among cancer survivors, but the socioecological factors influencing adherence have been incompletely characterized. We sought to examine the effects of social support and neighborhood walkability on physical activity among patients enrolled in a home-based exercise program concurrent with pancreatic cancer therapy.

Methods: Fifty enrolled patients with early stage pancreatic cancer [50% female, median age 67 (range 49–81)] were prescribed ≥ 60 min/week of moderate-intensity aerobic exercise (primarily brisk walking) and ≥ 60 min/week of full body strengthening with resistance tubes while receiving chemotherapy and/or chemoradiation. The abbreviated Neighborhood Environment Walkability Scale (NEWS-A) was administered prior to participation, physical activity was measured using daily logs and Actigraph GT3X+ accelerometers during the program, and the Social Support for Exercise Survey (SSES) was administered prior to and following participation.

Results: Median program duration was 13 weeks (range 5–45). On average, patients reported 126.4 minutes of aerobic exercise ($SD=82.8$) and 39.1 minutes of strengthening exercise ($SD=32.5$) per week and performed 139.0 minutes ($SD=132.7$) of accelerometer-measured moderate-to-vigorous physical activity (MVPA) per week. A positive association was observed between home neighborhood aesthetics and weekly minutes of moderate-to-vigorous physical activity after adjusting for relevant clinicodemographic covariates ($B=.30, p<.05$). Fifty six percent, 80%, and 51% of patients reported no change or increases in SSES subscale scores for family participation, family rewards and punishment, and friend participation, respectively. Patients who reported no change or an increase in family participation reported more weekly strengthening exercise (mean(SD) minutes 50.4(7.2) vs. 27.1(7.4), $Z(38)=-2.4, p=.02$). There were no other significant associations among socioecological factors and physical activity variables.

Conclusion: Social support and neighborhood walkability are important physical activity influences among patients undergoing preoperative treatment for pancreatic cancer. Oncologists, researchers, and exercise professionals should address these influences with patients to mitigate barriers, maximize support, and improve adherence to home-based exercise prescriptions.

SCALING UP A PHYSICAL ACTIVITY INTERVENTION FOR CANCER SURVIVORS: INSIGHTS FROM STAKE-HOLDERS

Bernardine M. Pinto, Ph.D.¹, Marissa Waldemore, DO², Cathy Hirsch, BA, JD³, Madison M. DeMello, Ph.D.¹

¹University of South Carolina, Columbia, SC; ²Thomas Jefferson University Hospital, Philadelphia, PA; ³The Frank and Clara Hirsch Foundation, Inc. and Reach to Recovery International Inc., Towson, MD

Behavioral lifestyle interventions that have empirical support for their efficacy are not often translated into practice. Successful implementation and widespread use may require assessment of the “market” for these interventions, assessment of the feasibility of adopting the intervention by the stakeholders in the market, and the development of a business model to support implementation. *Moving Forward Together* is a telephone-delivered peer-based physical activity intervention that has demonstrated efficacy in increasing physical activity adoption among cancer survivors. Regular physical activity has been recommended for cancer survivors to improve their functioning and well-being.

Method: To learn about how to scale up our intervention, we participated in the National Cancer Institute’s Speeding Research-Tested Interventions training program. We conducted 48 semi-structured interviews with cancer care organizations that had peer mentoring programs ($n=23$), peer mentors ($n=11$), cancer survivors ($n=12$) and other ($n=2$) to identify the stakeholder perspectives in building a viable business model and to identify appropriate customers for the intervention. The interviews were conducted via video/telephone and audio-taped. The notes were transcribed and themes extracted independently by three team members.

Results: Among our key insights, we learned that not all organizations identify physical activity as fitting their mission; however, a majority were interested in offering a program that was not gym-based. A majority endorsed a peer-based physical activity program as a “must have” or “nice-to-have” addition to their current services; all found that peers delivering the program was innovative and would make the program more effective for survivors. Interviews with peer mentors revealed that they were concerned about patient safety, location of programs and the need to individually tailor programs and be supportive of patients. Peer mentors were concerned about the location of their training.

Conclusions: Our qualitative work has demonstrated that there is a “market” for *Moving Forward Together* among cancer care organizations that have peer mentoring programs, and there is interest among peer mentors in extending their assistance to include physical activity promotion. To help scale up our intervention, we identified several features that are important to the cancer care organizations and to peer mentors. Similar research among potential customers can enhance efforts to extend the reach of efficacious behavioral lifestyle interventions.

CHANGES IN EATING BEHAVIOR AND APPETITE ARE ASSOCIATED WITH WEIGHT COMPENSATION IN THE E-MECHANIC TRIAL

Melissa Harris, MS, BS¹, S. Nicole Fearnbach, PhD², Neil M. Johannsen, PhD³, Timothy Church, MD, PhD⁴, Corby K. Martin, PhD⁵

¹Pennington Biomedical Research Center/Louisiana State University, Baton Rouge, LA; ²Pennington Biomedical Research Center, Baton Rouge, LA; ³Pennington Biomedical Research Center, Baton Rouge, LA; ⁴Pennington Biomedical, baton rouge, LA; ⁵Pennington Biomedican Research Center, Baton Rouge, LA

Physical activity is recommended for weight loss; however, aerobic exercise results in less weight loss than expected for a given exercise-induced energy expenditure. This is referred to as weight compensation. The Examinations of Mechanisms of Exercise-Induced Weight Compensation (E-MECHANIC) study was designed to compare the effect of two doses of aerobic exercise [recommended dose (8 kcal·kg⁻¹·wk⁻¹, 8 KKW) or weight loss dose (20 KKW),] versus to a no-exercise control group on the mechanisms of weight compensation in 198 sedentary, overweight/obese men and women. In this ancillary analysis, we assessed differential responses for energy intake and eating attitudes and behaviors between compensators (those who failed to lose the amount of weight expected from exercise) and non-compensators (those who lost the expected amount of weight), both of which are from the exercise groups only. The primary outcomes were assessed by doubly labeled water (DLW), retrospective appetite-related Visual Analog Scales (VAS), the Compensatory Health Beliefs Scale (CHBS), and the Eating Inventory (EI). The sample was primarily female (72.5%) and Caucasian (66.7%) with a mean (SD) age of 48.9 (11.4) year and BMI of 31.5 (4.7) kg/m². Compensators did not differ from non-compensators on age, weight, BMI or adherence (comp=96.64, non-comp=97.98, all *p*'s>0.45). Non-compensators lost 2.7 kg body weight, while compensators gained 0.8 kg. Compensators had greater increases in energy intake from baseline to week 24 (144.4 vs. 14.3 kcal/d, *p*<0.01), compensatory health beliefs (1.25 vs. -2.14, *p* = 0.01), and hunger (5.1 vs. -2.31, *p* = 0.03) and prospective food consumption (2.34, vs. -3.82, *p*=0.03) from retrospective VAS. Non-compensators had a greater reduction in disinhibition (-1.27 vs -0.28, *p*=0.02). After a controlled exercise intervention, compensators had more difficulty regulating appetite and eating behaviors resulting in increased energy intake, hunger, and prospective food consumption. Non-compensators had greater control of energy intake. These constructs should be targeted in future interventions to facilitate weight loss by preventing compensatory behaviors.

BASELINE EXECUTIVE FUNCTIONING PREDICTS WEIGHT LOSS AND PHYSICAL ACTIVITY OUTCOMES IN A LIFESTYLE MODIFICATION PROGRAM

Meghan Butryn, Ph.D., Fengqing Zhang, Ph.D., Jocelyn Remmert, B.A., Savannah Roberts, B.S., Evan Forman, Ph.D.

Drexel University, Philadelphia, PA

Emerging evidence indicates that executive functioning may have important and bi-directional relationships with weight control and physical activity. To better understand these relationships and their relevance to populations of interest, longitudinal research with adults seeking weight loss treatment is especially needed. The present study was designed to examine how baseline executive functioning predicted weight and physical activity outcomes after 6 months of behavioral treatment. Participants were overweight or obese adults enrolled in a behavioral weight loss program. At baseline, the Tower Test of the Delis-Kaplan Executive Function System was administered to assess inhibition, self-regulation, and planning. At baseline and 6 months, moderate-to-vigorous physical activity (MVPA) was measured with tri-axial accelerometers and weight was measured by research staff. Participants received 16 sessions of group-based treatment. Rule violations (*p* = .018) significantly predicted MVPA at 6 months, controlling for age, baseline MVPA, baseline BMI, and weight loss, such that participants with the fewest rule violations at baseline had the greatest MVPA at 6 months. Rule violations (*p* = .003) and completion time (*p* = .011) also significantly predicted 6 month weight loss controlling for age, baseline BMI and baseline or 6 month MVPA, such that participants with the fewest rule violations and fastest completion time had the most weight loss at 6 months. These patterns appeared clinically significant: among participants without any rule violations (*n* = 178), 6-month MVPA averaged 169.8 min/week and weight loss averaged 11.0%, while those with rule violations (*n* = 161) averaged 127.2 min/week of MVPA and 8.7% weight loss. Among those in the fastest quartile of completion time (*n*=86), weight loss at 6 months averaged 11.0%, while it was 8.9% for those in the slowest quartile (*n*=86). Total achievement score was not a significant predictor of outcomes (*p* < .05). These data are consistent with the hypothesis that some domains of executive functioning may facilitate or hinder lifestyle modification efforts in powerful ways. Experimental research is warranted that may, for example, determine if training that attempts to improve or compensate for below-average executive functioning might facilitate behavior change.

HABIT FORMATION IN AN OCCUPATIONAL THERAPY DIABETES SELF-MANAGEMENT INTERVENTION

Elizabeth Pyatak, PhD, OTR/L, CDE¹, Raymond Hernandez, MS, OTR/L¹, Kristine M Carandang, MS, OTR/L¹, Cheryl Vigen, PhD¹, Jeanine Blanchard, PhD, OTR/L¹, Jesus Diaz, OTD¹, Robin Whittemore, PhD, APRN, FAAN², Donna Spruijt-Metz, MFA, PhD¹, Anne Peters, MD³

¹University of Southern California, Los Angeles, CA; ²Yale University, School of Nursing, West Haven, CT; ³University of Southern California, Beverly Hills, CA

Introduction. Habit is a fundamental process by which behaviors are maintained over the long term. Yet, the vast majority of health behavior interventions focus primarily on consciously controlled behaviors and neglect to address habitual health behaviors. To address this gap, we developed and evaluated Resilient, Empowered, Active Living with Diabetes (REAL Diabetes), an occupational therapy diabetes management intervention which emphasizes habit.

Methods. We randomized 81 low-SES young adults with type 1 or type 2 diabetes to receive either the REAL Diabetes intervention or an attention control condition. Participants were 22.6 (± 3.5) years old, 63% female, 78% Hispanic/Latino, 75% with type 1 diabetes, and had baseline A1C levels of 10.8% ($\pm 1.9\%$). The REAL Diabetes intervention was comprised of 10–16 treatment sessions with an occupational therapist over 6 months in their homes or community settings. The intervention focused on developing and maintaining consistent diabetes self-care habits and routines through strategies such as environmental or sequential cues for checking blood glucose or taking medication. The attention control group received standardized diabetes education materials and biweekly phone calls. Blinded assessors collected data at baseline and 6 months; measures included A1C; frequency of diabetes self-care behaviors; habit strength for self-monitoring blood glucose (SMBG habit strength) and taking medications (SRBAI); diabetes distress; and diabetes-related quality of life (DQoL). Data were analyzed on an intention-to-treat basis using all available data in participants' originally assigned groups.

Results. Intervention participants, as compared to control group participants, had statistically significant improvements in A1C ($p=0.01$), DQoL ($p=0.04$); and SMBG habit strength ($p=0.05$). In examining correlations between change scores, participants with greater increases in SMBG habit strength had greater increases in medication adherence ($p=0.01$), and habit strength for taking medications ($p=0.01$), and decreases in diabetes distress ($p=0.04$). Furthermore, participants with greater increases in habit strength for taking medications also reported greater medication adherence ($p=0.005$).

Conclusion. The REAL Diabetes intervention was effective in changing participants' SMBG habit strength. Increases in habit strength for both SMBG and taking medications are associated with improvements in diabetes self-care behaviors and overall well-being.

Diabetes and Weight Control 4:15 PM-4:30 PM

BENEFIT OF SUPPORT FOR DAILY DIABETES MANAGEMENT DEPENDS ON SHARED ILLNESS APPRAISAL IN ADULTS WITH TYPE 1 DIABETES

Cynthia A. Berg, Ph.D.¹, Vicki Helgeson, Ph.D.², Caitlin S. Kelly, MA¹, Eunjin Lee, Ph.D.³, Meredith Van Vleet, Ph.D.², Jonathan Butner, Ph.D.¹, Michelle L. Litchman, PhD, FNP-BC, FAANP⁴

¹University of Utah, Salt Lake City, UT; ²Carnegie Mellon University, Pittsburgh, PA; ³University of Utah, salt lake city, UT; ⁴University of Utah College of Nursing, Salt Lake City, UT

Support from one's romantic partner in chronic illness management has been associated with benefits such as better mood and adherence to the illness regimen (Berg et al., 2007). For an illness such as type 1 diabetes, daily support from one's partner may be especially beneficial, as the disease requires the management of multiple tasks (testing, injecting insulin, food management) and individuals face challenges with failures in self-regulation to initiate such tasks. Yet, higher levels of partner support are not always linked with higher adherence. Whether support is beneficial for illness management may depend in part on how individuals appraise their illness (shared with partner versus own illness). To examine these issues 198 couples were recruited where one individual was diagnosed with type 1 diabetes for at least one year (52% females, average age 47 years, average duration of diabetes 27 years; average relationship length 19.4 years). Adults were asked at the end of the day for 14 consecutive days to 1) indicate how they appraised the illness "how you thought about diabetes today" with responses examined as "my issue" versus "shared," 2) rate ways in which their partner was involved (e.g., helped me to figure how to take care of my diabetes), 3) rate how frequently 8 self-regulatory failures occurred (e.g., testing my blood glucose kept slipping my mind), and 4) rate 7 adherence behaviors. Shared illness appraisal occurred on 24% of all days, and overall levels of support were low (2.1 on a 5-point scale). More shared appraisal and greater support across the 14 days were associated with greater reports of relationship quality and emotional and instrumental support from surveys, and shared appraisal as assessed in an interview. Multi-level models indicated that daily support was associated with better adherence for individuals who viewed their illness as more shared, but poorer adherence and more self-regulatory failures for individuals who viewed the illness as their own issue ($p < .05$). The results point to individual differences in the way individuals with type 1 diabetes appraise their diabetes, differences that are important for whether partner involvement in the illness is beneficial or not.

Paper Session 10: New Directions in Managing Diabetes and Weight Control 4:30 PM-4:45 PM

DIABETES DISTRESS AND GLYCEMIC CONTROL: THE DIRECT AND STRESS BUFFERING EFFECTS OF AUTONOMY SUPPORT FROM INFORMAL SUPPORTERS

Aaron A. Lee, Ph.D.¹, John Piette, PhD², Ann-Marie Rosland, MD MS³

¹VA Center for Chronic Disease Management, Ann Arbor, MI; ²University of Michigan School of Public Health, Ann Arbor, MI; ³University of Pittsburgh, Pittsburgh, PA

Objective: Adults with poorly controlled diabetes frequently experience diabetes related distress which contributes to worse glycemic control. Social support has been shown to buffer the negative effects of general stress on health outcomes. Autonomy support represents a particularly important form of social support which emphasizes individuals' agency in their disease self-management. Research indicates that autonomy support for diabetes self-management enhances intrinsic motivation, perceived competence, self-care behavior and, glycemic control. However, whether autonomy support from family members and friends can buffer the negative effects of diabetes distress has not been explored. We examined whether autonomy support for diabetes self-management from informal health supporters (i.e., family members and friends) moderated the association between diabetes distress and poorer glycemic control.

Methods: 308 Veterans with type 2 diabetes and one or more risk factors for diabetes complications completed a survey including measures of diabetes distress, and autonomy support from their main health supporter. Hemoglobin A1c (HbA1c) data from 12-months before and after the survey were extracted from participants' electronic medical records. Hierarchical linear regression models were used to examine the main and interaction effects of autonomy support and diabetes distress on repeated measures of HbA1c over the 12 months following the survey (clustered within participants), controlling for prior average 12-month HbA1c, time between the survey and HbA1c measurements, insulin use, age, and race/ethnicity.

Results: In adjusted models, there was a significant direct effect of greater autonomy support with lower HbA1c ($B = -.21$, $SE = .07$, $p = .005$). Autonomy support moderated the relationship between diabetes distress and HbA1c over the 12-months following the survey ($B = -.13$, $SE = .06$, $p = .027$). Specifically, greater diabetes distress was associated with higher HbA1c levels over the following 12 months at low ($B = .21$, $SE = .07$, $p = .002$), but not high ($B = .01$, $SE = .07$, $p = .890$), levels of autonomy support.

Conclusions: Autonomy support from individuals' main health supporters was linked to better glycemic control both directly and by buffering the negative effects of diabetes distress on glycemic control. Adults with high autonomy support from their main health supporters may be protected from the negative effects of diabetes distress on glycemic control.

Paper Session 11: Promoting Healthy Eating and Activity Among Children through Families and School 3:30 PM-3:45 PM

BARRIERS AND FACILITATORS TO IMPLEMENTATION OF COMPREHENSIVE AND COORDINATED HEALTH EDUCATION IN A LARGE URBAN SCHOOL DISTRICT

Rachael Dombrowski, PhD, MPH

Wayne State University, Detroit, MI

Background: Socioeconomic disparities are abundant among the nearly 400,000 CPS student population, as 87% are from low-income families and nearly 50% are overweight or obese. Chicago Public Schools (CPS) Office of Student Health and Wellness (OSHW) is working to address these disparities through provision of Comprehensive and Coordinated Health Education (CCHE) that is aligned with national standards, supports current efforts in nutrition and sexual health, and includes a connection to health services.

Intervention Description: The CCHE pilot project was implemented over the 2015–16 school year in 25 schools and engaged school administrators and teachers to effectively provide health education to all students grades PreK-12. A Health Education Leader was identified by each pilot school to ensure that the project was aligned with the CCHE Strategic Plan and Scope and Sequence. Schools were charged with providing health education instruction for at least 30 minutes per week centered around nine key health topics: alcohol and other drug-free lifestyle; healthy eating; mental and emotional health/social emotional wellness; personal health and wellness; physical activity; safety and injury prevention; sexual health; tobacco-free lifestyle and violence prevention. In addition, schools were required to collaborate with the CPS OSHW health providers for the provision of school-based health services for their students.

Methods: The CCHE pilot evaluation used a mixed methods approach to garner lessons learned from program implementation and effectiveness of CCHE delivery in pilot schools. The primary data sources for implementation outcomes included: a newly-administered, anonymous survey conducted with CCHE school staff; up to two classroom observations (pre and post) of health education lesson delivery in a subset of schools (N=10) and interviews among the school administrator and health education leader in all 25 pilot schools.

Results: Overall findings from the evaluation illustrated successful implementation of the CCHE project within the 25 schools. Key findings included a two fold increase in the number of schools providing health education instruction for 30+ minutes per week and double the amount of staff using the curriculum resources.

Conclusions: Conclusions will articulate successes and barriers in implementing CCHE throughout a large, urban school district. Lessons learned from partner and teacher training and health service coordination will provide a national model for other schools to implement CCHE.

EFFECTS OF A PHYSICAL ACTIVITY INTEGRATION COURSE FOR CLASSROOM TEACHERS ON STUDENT MOVEMENT AND TEACHER BEHAVIOR

Russell L. Carson, PhD¹, Brian Dauenhauer, Ph.D.¹, Peter T. Stoepker, M.A.², Lauren E. von Klingraeff, B.A.³, Michael Capps, B.S.¹, Ann C. Pulling Kuhn, BS, MS¹, Katie L. Hodgin, MPH, PhD⁴, Glenn Weaver, M.Ed. Ph.D.⁵

¹University of Northern Colorado, Greeley, CO; ²University of Northern Colorado, Greeley, CO; ³Colorado School of Public Health, Greeley, CO; ⁴University of Northern Colorado, Fort Collins, CO; ⁵University of South Carolina, Columbia, SC

Teachers are critical champions of physical activity (PA) in school settings (Hills et al., 2015). Findings from teacher training programs that have attempted to improve student school PA levels have been inconclusive (Carson et al., 2014). The purpose of this study was to explore the effects of an online, semester-long (16-week) course, designed to build teachers' capacity to integrate PA in the classroom, on student PA and teacher behavior. Four elementary teachers (100% female) from two public schools in the western United States participated in the study. The two teachers enrolled in the Spring 2017 course (intervention) selected a matched-grade level teacher from their school to participate (control). Kindergarten and first grade students (43 intervention, 42 control; 55.3% female) wore waist accelerometers at school during the last week of the online course (post-only design). On two separate days during the same week, the participating students' PA and teachers' behavior were systematically and reliably observed for two 60-minute class periods using SOSMART (Russ et al., 2017). Multilevel linear regression analyses indicated no significant difference in daily class time spent in accelerometer-derived moderate-to-vigorous PA (MVPA) between intervention ($M = 14.6$ minutes) and control students ($M = 13.2$ minutes, $p = 0.66$). Analyses of 721 SOSMART scans revealed students of intervention teachers were moving 19.5% more often during class than students of control teachers ($p = 0.01$), but control teachers were directing movement (e.g., leading an activity break) as often as intervention teachers ($p = 0.66$). After stratifying by sex, no differences existed in accelerometer-derived MVPA between intervention and control students for both males and females. In sum, teachers taking the online course in classroom PA integration may structure their classroom to support movement in general rather than explicitly direct MVPA opportunities. A 16-week online course format provides a unique and potentially promising approach to training classroom teachers in PA integration. Subsequent research will build upon this study's systematic methodology to determine the impact of the course in diverse school settings with objective control group sampling strategies.

Paper Session 11: Promoting Healthy Eating and Activity Among Children through Families and School 4:00 PM-4:15 PM

TEACHER-LEVEL FACTORS IMPACT IMPLEMENTATION OF AN ACTIVE LESSON INTERVENTION

Vanessa L. Errisuriz, PhD¹, Esbelle Jowers, Ph.D.¹, John Bartholomew, PhD²

¹The University of Texas at Austin, Austin, TX; ²The University of Texas at Austin, Austin, TX

Background: There is consistent evidence that active learning interventions increase children's daily physical activity (PA). Such classroom-based interventions rely on teachers for implementation, yet there is limited research examining factors that facilitate or impede teacher implementation of active lessons. This study investigates how teacher-level factors influence implementation of an active learning intervention, and the resulting intensity of student PA.

Method: Participants were 94 fourth grade teachers (93.5% female, 84.3% non-Hispanic white, $m_{age} = 39$ yrs) and 1,734 fourth grade students (47.4% female, 52.8% non-Hispanic white, 37.9% low SES) from 20 intervention schools of the Texas I-CAN! program. Teachers reported *attitudes* (Cronbach's $\alpha = .91$) and *PBC* ($\alpha = .92$) about implementation of I-CAN! lessons. A latent variable, *school climate*, was assessed with the supportive (e.g. "The principal goes out of his/her way to help teachers"), directive (e.g. "The principal monitors everything teachers do"), and restrictive (e.g. "Administrative paperwork is burdensome") subscales of the OCDQ-RE. For *Quality of Process*: frequency of teacher PA reinforcement ("Good high knees!") and technical instruction ("For push-ups, keep back straight") feedback was observed by staff observers. *Dose of implementation* was assessed through teacher self-report of the total number of lessons conducted over the school year. *Percent time in MVPA* during one active lesson was measured via accelerometry. Average percent time in MVPA was calculated for each class.

Results: A structural equation model examined the interrelatedness of teacher-level factors and impact on teacher implementation and PA. Results indicated relatively good fit (RMSEA = 0.06, SMSR = 0.06, CFI = 0.96). Primary findings include: School climate was positively related to PBC; attitudes and PBC were positively associated with implementation dose; PBC was positively associated with quality of process; while quality of process and dose of implementation were both associated with higher class PA intensity.

Conclusion: Findings indicate that teacher trainings for active learning should focus on enhancing PBC as well as on instructing teachers about the best types of feedback to give during lessons. Future research should investigate the various training strategies (e.g. model a lesson, role play, etc.) to increase PBC and use of PA-related feedback.

THE ASSOCIATION OF MATERNAL PERCEIVED STRESS WITH CHANGE IN CHILDREN'S HEALTHY EATING INDEX (HEI-2010) SCORE OVER TIME

Sydney O'Connor, BA¹, Jimi Huh, PhD¹, Susan M. Schembre, MS, PhD, RD², Nanette Lopez, PhD³, Genevieve F. Dunton, PhD, MPH¹

¹University of Southern California, Los Angeles, CA; ²The University of Texas MD Anderson Cancer Center, Houston, TX; ³University of Southern California, San Diego, CA

Background: Stress in mothers has been associated with higher body mass index (BMI) in their children. However, findings regarding the relationship between maternal stress and the quality of their children's dietary intake are mixed. Previous studies have been limited by a narrow focus on specific child dietary components (e.g., sugar sweetened beverages), use of maternal-only reports of children's dietary intake, and measurement of maternal stress and child diet at a single time point, preventing temporal analysis. This study examined the changes in child-reported diet quality over time, as well as the association between maternal stress at baseline and changes in overall dietary quality across time.

Methods: Mother-child dyads (n=174) participating in the Mothers' and their Children's Health Study completed three assessment waves separated by six-month intervals. At each wave, mothers (mean age at baseline=41.0 years, SD=6.1) completed the 10-item Cohen's Perceived Stress Scale (PSS). In the week following survey completion, children (52% female, mean age at baseline=9.6 years, SD=0.9) completed up to two telephone-based 24-hour dietary recalls, which were used to calculate each child's wave-specific Healthy Eating Index 2010 (HEI-2010) score. The HEI-2010 is a summary score of overall diet quality, ranging from 0–100, with higher scores indicating healthier diet. To account for the clustering of observations within dyads, multilevel models were used, and baseline PSS scores were centered to represent each mother's deviation from the group mean. In Model 1, wave was used to predict the change in child HEI-2010 across waves. In Model 2, a cross-level interaction term of baseline PSS and wave was created to test the effect of maternal stress over time on child HEI-2010, controlling for child sex.

Results: Model 1 revealed that, overall, there were no changes in child HEI-2010 over time (B= - 0.3906, p= 0.5021). However, controlling for child sex, there was a significant cross-level interaction effect of mother's baseline PSS with wave (B= -0.2194, p< 0.05), indicating that children of mothers who reported greater baseline stress experienced steeper decreases in diet quality over time, relative to children of mothers with average level of baseline stress.

Conclusions: Our analysis reveals that elevated maternal stress is associated with longitudinal decreases in the quality of their child's diet. Future research on child obesity should consider the potential benefits of maternal stress reduction in promoting children's healthy weight-related behaviors.

MONITORING AND MODELING FAMILY EATING DYNAMICS (M2FED): A SENSOR SYSTEM TO DETECT DIETARY MIMICRY IN FAMILIES

Brooke M. Bell, BA¹, Donna Spruijt-Metz, MFA, PhD², Abu Mondol, MS³, Ridwan Alam, MS³, John A. Stankovic, PhD⁴, John Lach, PhD², Kayla de la Haye, PhD²

¹Keck School of Medicine of University of Southern California, Los Angeles, CA; ²University of Southern California, Los Angeles, CA; ³University of Virginia, Charlottesville, VA; ⁴University of Virginia, Earlysville, VA

BACKGROUND: Evidence shows that family relationships and systems influence eating behavior and ultimately health risks (e.g., obesity). Child and adolescent eating habits and preferences are predominantly learned in family settings, although influence processes may be bidirectional. A key mechanism of interpersonal influence on eating behavior may be unconscious behavioral mimicry: when two or more people engage in the same behavior at the same time. There is evidence of dietary mimicry in strangers and mother-daughter pairs, but research has not yet explored dietary mimicry in entire families. This study examined whether family members mimicked the bites of each other in real time.

METHODS: M2FED is a cyber-physical system being developed to detect family eating behavior and other proximal determinants in the home environment with wearable and in-home sensors. To develop accurate algorithms for detecting eating via a smart watch, 22 participants from 7 families (7 parents: M age = 40 yrs; and 15 children: M age = 15 yrs) wore a smart watch on their dominant wrist and were videotaped while eating an unstructured meal with their family. Each videotape was coded for bite occurrence and bite time. These analyses test for associations in the number of bites and bite frequency among pairs of family members (n = 24 dyads, n = 1361 bites).

RESULTS: Significant differences in total bites and eating rates (bites per minute) were not found between parents and children. However, younger children had a faster average eating rate than older children (2.4 vs 1.9 bpm), and males took more total bites than females (78.6 vs 55.2). There was a significant positive correlation in total bites between dyad members ($r = 0.65$, $p < 0.001$) and a trend towards a significant positive correlation in eating rates ($r = 0.33$, $p = 0.10$). The extent to which dyads were similar in their total bites and eating rates did not differ between child-child dyads and child-parent dyads ($t = 0.60$, $p > 0.05$).

CONCLUSION: This pilot study provides preliminary evidence that the eating behaviors among pairs of family members are positively associated when they are co-engaged in an unstructured meal. These analyses will inform systems modeling of family eating dynamics over time (i.e., weeks, months) to identify temporal patterns of eating mimicry and broader synchrony of eating behaviors and other proximal determinants (mood, social interaction) using rich and contextualized data collected via our M2FED sensor system from multiple families in their homes.

Paper Session 12: Peer and Family Support in the Context of Cancer 3:30 PM-3:45 PM

“I FEEL GUILTY FOR NOT HELPING HER ENOUGH”: PSYCHOSOCIAL CORRELATES OF GUILT AMONG SPOUSES OF CHINESE WOMEN WITH BREAST CANCER

Nelson C. Y. Yeung, Ph.D.¹, Qian Lu, M.D., Ph.D.²

¹The Chinese University of Hong Kong, Hong Kong, N/A, Hong Kong;
²University of Houston, HOUSTON, TX

Background. Husbands of breast cancer survivors generally report challenges in multiple life domains when providing care to their spouses. Qualitative studies have suggested that guilt (i.e., perception of inadequacy in providing care to the recipient) is commonly experienced among husband caregivers of breast cancer survivors. However, little is known about the psychosocial correlates of caregiver guilt in the Chinese context.

Methods. This study recruited 176 Chinese husbands of women with breast cancer, recruited from two hospitals in Weifang, China. Participants' guilt, caregiving-related stressors, coping resources and strategies, and individual differences (e.g., endorsement of the “Masculinity strength” gender role norm (sample item: “A man should protect his loved ones”)) were measured in a questionnaire package.

Results. Hierarchical regression results showed that younger age ($\beta = -0.18$), lower endorsement of “Masculinity strength” gender role norm ($\beta = -0.42$), less protective buffering ($\beta = -0.18$), higher caregiving burden ($\beta = 0.31$), and higher social support seeking from spouse ($\beta = 0.16$) were associated with higher caregiving guilt (all $ps < .05$). Additionally, the “Masculinity Strength” gender role norm moderated the relationship between social support seeking from spouse and guilt ($\beta = 0.14, p = .03$), such that social support seeking from spouse was only associated with higher caregiver guilt for those having a stronger endorsement of such a norm (+1 SD) ($\beta = 0.29, p < .001$), but not among those with lower endorsement of the norm (-1 SD) ($\beta = -0.02, p = .89$). Marital satisfaction also moderated between protective buffering and guilt ($\beta = -0.15, p = .02$), such that lower protective buffering was associated with higher guilt only among those perceiving higher marital satisfaction (+1 SD) ($\beta = -0.36, p < .001$), but not those perceiving lower marital satisfaction (-1 SD) ($\beta = -0.06, p = .51$).

Conclusions. This study provided important information about the psychosocial correlates of caregiver guilt among husbands of Chinese breast cancer patients. Our findings seemed to support that interventions helping caregivers to reduce caregiving burden may decrease their guilt. The impacts of social support seeking and protective buffering on guilt may also differ according to caregivers' endorsement of gender role norms, marital satisfaction, and the broader cultural contexts. These findings could help researchers to design evidence-based interventions to serve specific needs of those husband caregivers, which may in turn facilitate well-being in both the caregivers and the patients living with breast cancer.

IT TAKES TWO TO MAKE A THING GO RIGHT: IMPACT OF HUSBANDS' PERCEPTIONS OF WIVES' SELF-EFFICACY FOR COPING WITH CANCER

Thomas V. Merluzzi, PhD

University of Notre Dame, Notre Dame, IN

Introduction: Spousal support is a crucial to positive adaptation to cancer and unsupportive behaviors can impair adjustment. In social learning theory, support can be traditional social support, but also persuasion, modeling, or shared perspectives of challenges. This study was a test of the shared perspective hypothesis.

Method: 72 women in treatment for breast cancer and their husbands completed measures of self-efficacy for coping (SEC) and quality of life (QOL). Performance status was obtained from medical records. Husbands completed the self-efficacy for coping (HSEC) measure based on their perceptions of their wives' coping efficacy. Correlations, regression, and mediation analyses were conducted to determine the contributions of husbands' (HSEC) and wives' perspectives (WSEC) to the wives' QOL.

Results: Interestingly, the correlation between WSEC and HSEC was .207. However, in regression analyses both WSEC ($B = .393, p = .001$) and HSEC ($B = .243, p = .026$) contributed significantly to the wives' QOL. Models were tested to determine the nature of the relationship between WSEC and HSEC: discrepancy model = WSEC-HSEC; aggregate model = WSEC+HSEC; multiplicative model = WSEC X HSEC. The discrepancy model was not related to wives' QOL, however the aggregate ($B = .494, p < .001$) and multiplicative ($B = .408, p < .001$) models equally and significantly predicted wives' QOL. In a double mediation model, both HSEC and WSEC fully mediated ($B = -.371, p = .032$) the relationship between performance status and QOL.

Discussion: Though based on a similar construct, husbands' perception of their wives' efficacy made a distinct contribution to their wives' QOL, and both WSEC and HSEC mitigated the negative effects of disease impact on QOL. Thus, it is the aggregate of the two distinct perceptions of efficacy expectations that is critical in determining QOL. Future research will be needed to determine the quality of the differences between HSEC and WSEC in order to develop interventions to optimize the impact of these two perspectives on coping.

Cancer is the second leading cause of death in the United States. Evidence supports peer support (PS) as an effective strategy for enhancing prevention and control of cancer. However, there is a need to understand the opportunities that exist in the use of PS in cancer to inform future interventions and programming. Thus, this systematic scoping review examines the range and variety of interventions reported in recent peer-reviewed literature on the use of PS across the cancer care continuum. Our population of interest included adult populations or families of adults affected by cancer. Our search was conducted in PubMed, SCOPUS, and CINAHL to identify relevant peer-reviewed literature published from 2011–2016. To survey the breadth of literature in this area we used a broad definition of PS and 44 search terms including variations of “promotora,” “community health worker,” and “peer educator.” We screened the title and abstracts of 2087 articles, followed by full-text screening of 420 articles, resulting in a final sample of 242 articles of which the most recent 100 articles were reviewed. Many of the cancers addressed by the PS interventions were breast (54% of all papers, percentages not summing to 100% because of overlap), gynecological (31%) and colorectal cancer (29%). In contrast, few papers focused on other cancers (e.g., only 5% on lung cancer). This suggests the need to better disseminate PS methods and practices to address more cancer types. Moreover, 50% of interventions focused solely on women, whereas 7% focused solely on men. Other areas needing more attention include the provision of PS at late stages in cancer care (4% palliative or end-of-life care). Many interventions (40%) targeted multiple outcomes, with the most common being patient engagement (75%) and psychosocial health (48%); less common were behavioral risks (10%) and cancer progression (3%). Many interventions sought to address racial or ethnic disparities in cancer outcomes (62%), but few studies focused on geographic disparities (8%). Despite the important, yet challenging work of peer supporters, few studies (4%) examined the positive or negative impacts on those providing PS. Attention to the wellbeing of peer supporters is critical for program quality and the sustainability of this often volunteer-based workforce. Our review highlights PS as a promising approach to addressing needs across the cancer care continuum. While well developed in many areas, there are important opportunities to expand the use of PS to all cancers, in palliative and end-of-life care, where geographic disparities exist, and to address the effects on those providing support.

Paper Session 12: Peer and Family Support in the Context of Cancer 4:15 PM–4:30 PM

MEASURING THE DEGREE OF CLOSENESS TO THE CANCER EXPERIENCE: REVISITING THE CONNECTION TO THE EXPERIENCE OF CANCER SCALE -CONNECS

Juan L. Rodriguez, MPH, MS¹, Nikki Hawkins, PhD¹, M. Elizabeth Hodgson, PhD², Lucy Peipins, PhD¹

¹Centers for Disease Control and Prevention, Atlanta, GA; ²Social and Scientific Systems, Inc., Durham, NC

The experience of cancer in one's family can have a significant impact on a person's perceived risk of developing cancer, which may then affect their medical decisions and engagement in health behaviors. However, there are few scales to assess one's lived experience with and proximity to cancer. A scale to measure the degree of closeness to a cancer experience, CONNECS, was previously developed and initially validated. Although results indicated a well-fitting three-factor model, several limitations were noted. We sought to address these limitations by modifying the response set and adding items to better discriminate between high and low levels of closeness to the cancer experience. The 11-item CONNECS was administered to participants in the Sister Study, a prospective cohort study of women with at least one sister diagnosed with breast cancer (n=19,540), as part of a CDC-sponsored survey. The sample was randomly split into two sub-samples. An exploratory factor analysis (EFA) with varimax rotation was conducted on subsample 1 (n1=9770) and a confirmatory factor analysis (CFA) was conducted on subsample 2 (n2=9770). Scale reliability was assessed using Cronbach's alpha for the overall scale as well as for each subscale. Results of the EFA indicated a four-factor model with items clustering into: 1) general closeness, 2) resemblance, 3) cognitive processing, and 4) caregiving. Results of the CFA confirmed a good fit of the four-factor model (RMSEA= 0.060; CFI= 0.967; TLI= 0.944; SRMR= 0.031; X²= 1129.24, p<0.001). Reliability analysis of the overall scale indicated good internal consistency (alpha= 0.807). Reliability analysis of each subscale indicated that general closeness, cognitive processing, and caregiving subscales had moderate to good internal consistency (0.805, 0.706, and 0.850, respectively), and the resemblance subscale having poor internal consistency (0.540). Findings provide additional evidence for the reliability and construct validity of CONNECS in measuring an individuals' lived experience with cancer. Factors associated with general closeness, and cognitive processing (talking about and time spent thinking about cancer) were consistent with our previous findings. However, additional item development and testing is likely needed for the resemblance subscale. The revised CONNECS may be a useful tool for understanding the impact of the cancer experience on risk perception, cancer worry, and decision-making.

Background: Breast cancer (BC) mortality is higher for African-American women (AAW) than for any other race or ethnicity. Increasing uptake of genetic counseling among AAW with increased BC risk is a key step in reducing racial disparities in BC. We are developing a culturally-sensitive intervention that provides educational information designed to motivate AAW with genetic risk for BC to engage in genetic counseling. To identify themes that are culturally relevant and salient to the target population, multiple qualitative methods were used to identify barriers, motivating factors, and familial experiences related to BC that impact the desire and ability of AAW to access genetic counseling.

Methods: Women at high risk for BC, previously recommended for genetic counseling, were recruited at a Federally Qualified Health Center in Chicago to participate in semi-structured, one-on-one interviews and in story circles. Interviews focused on barriers, motivating factors, and knowledge related to genetic counseling. Story circles focused on familial experiences related to cancer. Thematic analysis of both methods was conducted using primary and secondary coding with Atlas software and detailed field notes.

Results: Interviews (n=20) were followed by story circle sessions with a subset of participants (n=11). Women expressed barriers related to psychosocial concerns and healthcare system navigation. They also discussed challenges associated with familial secrecy due to shame or guilt; fatalistic spiritual and cancer beliefs; high medical costs, discrimination, fragmented care in the healthcare system; and limited cancer-related knowledge. Women expressed a desire for more education related to cancer; a desire to disrupt generational patterns of secrecy; and to hear testimonials of “like” others who have undergone genetic counseling. Data will be presented comparing findings from interviews and story circles to define the contributions of each methodology.

Conclusion: Use of multiple qualitative methods represents an innovative, culturally sensitive approach that provides comprehensive exploration of factors associated with uptake of genetic counseling in high risk populations. Data will inform the creation of an educational intervention by incorporating the “lived experiences” of AA families with BC.

LONG-TERM RESULTS OF PEDIATRIC TRIAL TO REDUCE CHILD SECONDHAND SMOKE EXPOSURE AND PROMOTE SMOKING CESSATION

Stephen J. Lepore, Ph.D.¹, Bradley Collins, PhD¹, Uma Nair, PhD², Jonathan Winickoff, MD, MPH³, Donna Coffman, PhD¹

¹Temple University, Philadelphia, PA; ²University of Arizona, Tucson, AZ; ³Mass General Hospital, Boston, MA

Secondhand smoke exposure (SHSe) harms children’s health, yet effective interventions to reduce child SHSe have been difficult to implement in pediatric practice. We addressed this problem using a multilevel intervention combining pediatrician advice with telebased behavioral counseling. The intervention, Kids Safe & Smokefree (KiSS), was tested in a randomized controlled trial (N = 327) with two-groups and three measurement periods: pre-intervention, end-of-treatment (EOT) and 12-month follow-up. Smoking parents of children < 11-years-old were recruited from urban pediatric clinics. All parents received clinic-level intervention from pediatricians. Messages were embedded in electronic health record systems to prompt pediatricians during clinic visit to “Ask” about child SHSe, “Advise” about SHSe harms, and “Refer” smokers to cessation resources (AAR). After AAR, consented parents were randomized to a 3-month tele-based intervention condition that used support, education and cognitive-behavioral skill building to promote reduction in child SHSe and parent smoking cessation (COUNSELING) or an attention control nutrition education condition (CONTROL). Healthcare providers and assessors were blind to group assignment. Primary outcomes at EOT were parents’ self-reports of child SHSe and their own smoking status. Analyses of parent reported outcomes at EOT (in press) suggest that counseling reduced children’s exposure and increased quit rates significantly relative to the control condition. The present paper examines heretofore unreported findings using more objective bioverified data collected at 12-month follow-up, including child SHSe verified using urinary cotinine levels and parent 7-day point prevalence abstinence from smoking verified using salivary cotinine levels. Participants were predominantly unmarried (59%), African American (84%), female (84%), and living below poverty (79%). Intention-to-treat analyses showed a significant effect of intervention on 12-month quit rates: the counseling group was 2.46 times more likely to have quit than controls (p<.05). Average child cotinine levels dropped significantly in both groups from baseline to 12-month follow-up (p<.001), but there were no differences between groups. These findings suggest that a multilevel-pediatric intervention effectively reaches high-risk children, pediatrician advice may improve parent protections of children from SHSe, and relatively intense intervention is necessary to help parents to quit smoking.

PEER MENTORING AND AUTOMATED TEXT MESSAGES FOR SMOKING CESSATION: A RANDOMIZED PILOT TRIAL

Justin S. White, PhD¹, S F. Toussaert, PhD², Johannes Thrul, PhD³, Lorien Abroms, ScD⁴, JOHANN L. Westmaas, PhD⁵, Jeuneviette Bontemps-Jones, MPH, CHES⁵

¹University of California, San Francisco, San Francisco, CA; ²London School of Economics, London, England, United Kingdom; ³Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; ⁴GWU SPH, Washington, DC; ⁵American Cancer Society, Atlanta, GA

Background: Peer mentoring delivered by lay coaches who provide emotional and informational support is an essential component of popular health promotion programs like Alcoholics Anonymous and Weight Watchers. For smokers who want to quit, automated text messaging programs also provide encouragement and information for quitting and have proven helpful. However, existing interventions for smoking cessation have not tested a combination of these effective approaches.

Methods: In February and March 2017, 200 smokers who were planning to quit were recruited online and randomly assigned to receive smoking cessation support for 6–8 weeks via (i) automated text messages similar to NCI's SmokefreeTXT program (control group) (n=99), or (ii) automated text messages plus personalized texts sent from trained mentors who were former smokers (n=101).

Results: After three months, 7-day point prevalence abstinence was 40% in the mentored group (22/55) versus 21.4% (12/56) in the control group ($p=0.03$). Results based on an intent-to-treat (ITT) analysis were similar (22% versus 12%, $p=.07$). Controlling for socio-demographic and smoking-related variables, the average treatment effect was 19% (ITT: 13.9%, $p=0.05$). Moreover, 78% of the mentored group felt someone cared if they quit versus 51% in the control ($p=0.01$). Biochemical validation at follow-up to be reported.

Implications: Text-based peer mentoring from former smokers holds potential as an acceptable, effective, and engaging smoking cessation intervention.

Paper Session 13: Progress in Smoking Cessation Interventions 4:00 PM–4:15 PM

COMPUTER-FACILITATED 5A'S FOR TOBACCO USE DISORDERS: USING TECHNOLOGY TO IMPROVE SCREENING AND BRIEF INTERVENTIONS

Jason Satterfield, PhD

UCSF, San Francisco, CA

Background: Clinical practice guidelines recommend that primary care providers (PCPs) deliver the 5A's (*ask, advise, assess, assist, and arrange*) at every clinical encounter for the treatment of tobacco use disorders. Unfortunately, while most clinicians "ask" and "advise," adherence to the "assist" and "arrange" steps remains low due to time, confidence, and skill limitations. Innovative service delivery models are needed to improve 5A's adherence and coordinated tobacco cessation efforts.

Objective: To evaluate effectiveness of a computer-facilitated 5A's (CF-5A's) intervention to improve PCP 5A's adherence. Primary outcomes include adherence to each "A" and to the 5A's as a whole.

Materials and Methods: PCPs from 3 clinics (HIV primary care, safety net, and academic health center) were randomized into the CF-5A's intervention or to usual care (UC). Adult patients who had smoked at least 100 lifetime cigarettes and at least one cigarette in the past 7 days were recruited in primary care waiting rooms and assigned to their provider's condition. Intervention patients completed the CF5A's and two tailored clinical summaries were generated – one for the provider and one for the patient. UC patients completed an eligibility survey and consent only. Within 72 hours of the appointment, patients completed a post-visit interview about their receipt of the 5A's during their PCP encounter. Patients could participate up to three times within the yearlong study period.

Results: N=221 providers saw n=961 patients (n=412 intervention; n=549 UC) in n=1,340 total encounters with n=1,011 completed post surveys (75.4% response). After accounting for 4-level nesting effects, GEE models showed intervention PCPs 32% more likely to "Assess" (OR 1.32; 95% CI, 1.01–1.72), 45% more likely to "Assist" (OR 1.45; 95% CI, 1.08–1.93), and 72% more likely to "Arrange" in the first visit only (OR 1.72; 95% CI, 1.23–2.40), and 104% more likely to complete all 5A's during the first visit (OR 2.04; 95% CI, 1.35–3.07).

Conclusion: A computer-facilitated 5A's delivery model was effective in improving the fidelity of provider-delivered 5A's to diverse PC patients. This relatively low cost, time-saving intervention has great potential for smoking cessation and other health behaviors. Future studies should identify ways to promote and sustain technology implementation including seamless integration with electronic health records and other digital tools.

ORAL HEALTH 4 LIFE: A RANDOMIZED SEMI-PRAGMATIC TRIAL CONDUCTED WITH STATE TOBACCO QUITLINES

Jennifer B. McClure, PhD¹, Terry Bush, PhD², Melissa L. Anderson, MS³, Paula R. Blasi, MPH¹, Ella E. Thompson, BS¹, Jennifer C. Nelson, PhD⁴, Sheryl Catz, PhD⁵

¹Kaiser Permanente Washington Health Research Institute, Seattle, WA; ²Optum (formerly Alere Wellbeing), Seattle, WA; ³Kaiser Permanente WA Health Research Institute, Seattle, WA; ⁴Kaiser Permanente Washington Health Research Institute, Seattle, WA; ⁵UC Davis, Sacramento, CA

Smokers are at increased risk for oral disease, and those seeking treatment through state-funded tobacco quitlines are at particularly high risk since many lack dental insurance and access to affordable dental care. Interventions are needed that can promote dental care utilization and smoking cessation in this high-risk population. Thus, we developed a novel program (Oral Health 4 Life, OH4L) that integrated oral health promotion content into the standard multi-call quitline program. The program referred smokers to local, low-cost dental providers and encouraged positive oral health behaviors (flossing, chewing xylitol gum, etc.) as strategies for managing cravings to smoke. Using a semi-pragmatic design to balance experimental control and generalizability, we recruited callers (n = 718) from the LA, NE, and OR quitlines. Participants were randomized to standard care (SC) or SC + OH4L and followed for 6 months to assess use of professional dental care and smoking cessation. Participants were racially diverse (42% non-white), low-SES, 71% reported fair/poor oral health, and all were overdue for routine dental care. At 6-month follow-up, use of professional dental care and smoking abstinence were not significantly different in the primary analysis with missing outcome values imputed as no dental care/current smoker. 18% in each arm sought dental care (OR 1.03 [0.69–1.53], P=0.94). Smoking cessation rates were 30.3% in SC vs. 33.8% in SC+OH4L (OR 1.29 [0.93–1.78], P=0.13). In a complete case sensitivity analysis dental care outcomes were unchanged, but cessation rates were significantly higher in the SC+OH4L arm at 2 months (39.1% control vs. 46.4% OH4L, OR 1.42 [1.01–2.00], P=0.04) and approached significance at 6 months (40.8% control vs. 46.9% OH4L, OR 1.37 [0.95–1.96], P=0.09). Fidelity to the intervention protocol was very good and there was no evidence of treatment contamination. The strong design provides confidence that OH4L did not increase use of professional dental care or smoking cessation compared to standard care, but the findings suggest oral health counseling may offer some advantage to smokers when quitting. The study is important because it: 1) demonstrates behavioral interventions can be integrated with standard quitline care without negatively impacting cessation, 2) is a model for conducting semi-pragmatic randomized trials, and 3) is a model for partnering with quitlines to address high-risk behaviors other than smoking.

4:30 PM-4:45 PM

A MULTIDISCIPLINARY, MULTILAYERED PROGRAM FOR VETERANS AND SMOKING CESSATION: VETS KICK BUTTS

Daniel DeBrule, Ph.D.¹, James Broussard, Ph.D.²

¹Houston VA / Baylor Medical College, Houston, TX; ²Michael E. DeBakey VA Medical Center, Houston, TX

Tobacco use among Veterans is a primary cause of disease, disability, and compromised quality of life. While many VA Medical Centers possess a Health Behavior Coordinator (HBC) responsible for tobacco programming across a Facility, there may often be times in which the HBC is unavailable due to leave, serving a detail, or the position being vacant. During these times, few if any cessation interventions are offered despite the immense need, particularly in our VA that serves well over 100,000 Veterans as the most medically complex in the nation. Furthermore, Veterans tend to report better engagement and outcomes when cessation programs include many disciplines that can share their expertise, and connect ongoing care from a Patient Aligned Care Team in Primary Care to the tobacco cessation program. Our team also decided to create a visible, memorable logo and name for our program that Veterans could connect with: Vets Kick Butts. This paper will outline the many advantages of our Multidisciplinary Program that is highly sustainable due to the multitude of staff who oversee and conduct psychoeducational classes (Psychologist, Psychology trainees, Social Workers, Registered Nurses) as well as optional Nicotine Replacement sessions (Physicians, Pharmacists, Physician Assistants) following each class. Our implementation strategy, process, and navigation of barriers experienced over the past four years will also be outlined. The aim of our current project was to create a sustainable, comprehensive smoking cessation program complete with educational materials to best serve the needs of our veterans. Borrowing heavily from evidence-based programs already existing in VHA, our team also created a 70 page workbook complete with guidance on nicotine replacement and e-cigarettes consistent with VHA policy. This paper will present our model and reflections from implementation across the past four years both in our main Facility and nine community clinics. Outcome data from our program indicate that cessation rates are comparable to similar cessation programs and nicotine replacement (30–40%) but also highlight the need for ongoing care and structure beyond our 5 session protocol. The support group that was borne out of this need will also be outlined, as well as methods that address enduring challenges to our program: how best to orient and train staff, ways of integrating technology into content delivery/aftercare, and how best to engage Veterans into treatment from within Primary Care and from Mental Health. Presentation will conclude with an overview of how Motivational Interviewing is disseminated among various staff in Primary Care from the presenter, including how MI and health coaching have become our primary means of delivery in the Vets Kick Butts program.

VALUES CLARIFICATION EXERCISES IMPROVED PARENTAL DECISION MAKING ABOUT NEWBORN GENOMIC SEQUENCING

Susana Peinado, PhD¹, Ryan S. Paquin, PhD², Megan Lewis, PhD³, Christine Rini, PhD⁴, Myra Roche, M.S.⁵, Rita M. Butterfield, Ph.D.⁶, Jonathan Berg, MD, PhD⁷, Cynthia M. Powell, MD⁸, Donald Bailey, Ph.D.⁹

¹RTI International, Montecito, CA; ²RTI International, Minneapolis, MN; ³RTI International, Seattle, WA; ⁴John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, NJ; ⁵University of North Carolina at Chapel Hill, Chapel Hill, NC; ⁶University of North Carolina, Chapel Hill, Chapel Hill, NC; ⁷UNC Chapel Hill, Chapel Hill, NC; ⁸The University of North Carolina at Chapel Hill, Chapel Hill, NC; ⁹RTI International, Research Triangle Park, NC

Purpose: Genomic sequencing may be used in the future as a component of newborn screening, introducing complex issues surrounding parental consent and decision support. Using an online decision aid we developed to help parents make informed decisions about genomic sequencing for their newborn, we tested our prediction that adding a values clarification exercise to educational content would improve decision making outcomes.

Methods: As part of an online randomized experiment, women and men ages 18–44 who were either currently pregnant, had a partner who was pregnant, or were preparing to get pregnant in the next two years were randomly assigned to view either decision aid content that included only educational information about genomic sequencing for newborns or content that included both educational information and a values clarification exercise about sequencing. Analyses were conducted using ANCOVA, including sex, health literacy, and experience with genetic testing as covariates. Moderation analyses were conducted using Hayes' PROCESS macro.

Results: Of the 1,000 participants who completed the decision aid, those who completed the values clarification exercise experienced less decision regret ($M = 1.95$, $SD = 0.72$) than those who viewed only educational content ($M = 2.05$, $SD = 0.73$), $F(1, 995) = 5.09$, $p = .020$. Participants who completed the values clarification exercise were also clearer about their personal values (a subscale of the decisional conflict scale) ($M = 4.00$, $SD = 0.85$) than those who did not ($M = 3.87$, $SD = 0.83$), $F(1, 995) = 6.39$, $p = .010$. Moderation analyses revealed that the benefit of the values clarification exercise on decision regret was particularly evident among participants with lower health literacy ($\beta = -.21$, $SE = .06$, $t = -3.49$, $p < .001$) and no prior genetic testing experience ($\beta = -.11$, $SE = .05$, $t = -2.05$, $p = .040$). Additionally, the effect of the values clarification exercise on decisional conflict was only significant among those with lower health literacy, $\beta = -0.17$, $SE = 0.06$, $t = -2.72$, $p < .01$.

Conclusion: Adding values clarification to educational content in decisional aids for expectant and future parents deciding whether to have genomic sequencing for their child may produce a better decision making experience. Completing a values clarification exercise in addition to educational content appears to provide the greatest benefit to individuals with lower health literacy and no prior genetic testing experience.

Paper Session 14: Advances in Medical Decision Making 3:45 PM-4:00 PM

DECISIONAL CONFLICT ABOUT TREATMENT IS PERSISTENT IN MEN WITH LOW-GRADE PROSTATE CANCER AND THEIR CLOSE ALLIES AFTER DIAGNOSIS

Kelly Shaffer, Ph.D.¹, Elizabeth Schofield, MPH¹, Michael A. Diefenbach, Ph.D.², Christian Nelson, PhD¹

¹Memorial Sloan Kettering Cancer Center, New York, NY; ²Northwell Health, Manhasset, NY

Purpose: Men diagnosed with low-grade prostate cancer and their close allies report significant uncertainty making the decision between pursuing treatment or active surveillance. This study explored if decisional conflict (DC) between patients and partners was related and resolved over time.

Methods: Men recently diagnosed with low-grade prostate cancer eligible for active surveillance (N=150) and their close allies (N=70, 83% spouses; dyads N=64) completed the Decisional Conflict Scale at baseline and again three months later. Total and subscale scores (Information, Value Clarity, Support, and Uncertainty) were examined, with higher scores indicating greater conflict. Correlations and paired-samples t-tests compared scores of patients and allies at each time point. Stability-influence modeling using actor-partner interdependence modeling (SI-APIM) examined the stability of patients' scores controlling for the influence of their allies' scores from baseline to follow-up (and vice versa: stability of allies' scores controlling for patients' scores).

Results: For patients, total DC and all subscale scores declined from baseline to follow-up ($ps < .001$). For allies, total DC and all subscale scores declined from baseline to follow-up ($ps < .02$), except for decisional support ($p = .14$). At baseline, total DC and uncertainty scores were positively related between patients and their allies ($ps < .02$), and patients reported receiving more decisional support than allies ($p = .01$). At follow-up, there were no associations or differences between patients' and their allies' DC scores. SI-APIM revealed that, for total DC and all subscale scores, one's own higher score at baseline was related to higher scores at follow-up (stability effect; $ps < .001$); however, there were no effects of one's partner's baseline score on follow-up scores (influence effect; $ps > .10$).

Conclusions: DC declines across the early post-diagnosis period among both men and their close allies. Those experiencing the highest DC, however, show slower reductions in conflict, regardless of their partner's conflict. Findings suggest clinical attention to reduce DC is warranted for men with low-grade prostate cancer with high DC at diagnosis, along with their allies.

SHARED DECISION-MAKING AND SOURCES OF INFORMATION AMONG PERSONS WITH RARE DISEASES: AN ONLINE SURVEY WITH A U.S. SAMPLE

Veronica Irvin, PhD, MPH, Kathleen Bogart, PhD

Oregon State University, Corvallis, OR

Most people with rare diseases (defined as prevalence <200,000 Americans) report receiving insufficient information and support through the healthcare system and report turning to rare disease organizations for these needs. Shared decision-making is central to patient-centered care and improves with access to and understanding of health information, but it has not yet been studied in rare diseases. The objective of this presentation is to examine the relationship of shared decision making with sources and trust of health information among persons with rare diseases.

Methods. We conducted a cross-sectional online survey of adults living in the U.S. diagnosed with a rare disease. The National Organization of Rare Disorders and Coordination of Rare Diseases shared recruitment materials. A total of 1473 participants representing 232 different rare diseases completed the survey between December 2016 and May 2017 and 1185 were retained in this analysis. Shared decision making was assessed with a standardized 9-item scale with a range from 0 - 100. Sources and trust of information items were adapted from the Health Information National Trends Survey. Multivariate analyses regressed shared decision making on sociodemographics, disease characteristics, and use and trust of information from rare disease organizations, support groups, and physicians, and health literacy measures.

Results: The sample was comprised of 77% female, 55% married, 60% college degree, 94% White and mean age 51. Participants searched for information through multiple sources –rare disease website (70%), rare disease organization (personal contact made) (46%), doctor (66%), support groups (46%) and complementary and alternative medicine (16%). Over 70% trusted information from rare disease organization websites as compared to trusting information from physicians (57%), support group (40%), complementary and alternative medicine (2%). Higher shared decision-making was related to higher use, satisfaction and trust of information from rare disease websites, support groups, and doctors as well as ease in finding and understanding information. In multivariate linear regression models, higher shared decision-making was related to contacting a rare disease organization and turning to and trusting a physician for information after controlling for socio-demographics and rare disease characteristics. Health literacy variables were insignificant in the model, but persons who reported more frustration searching for information reported less shared decision-making.

Conclusions: Both the physician and the specific rare disease organization are central points for information for persons with rare disease. Our group is planning future work to expand types and availability of information from rare disease organization to better prepare client and physician for the shared decision making process.

Paper Session 14: Advances in Medical Decision Making 4:15 PM–4:30 PM

REPRODUCTIVE DECISION MAKING AMONG POSTPARTUM HIV-INFECTED WOMEN IN RURAL SOUTH AFRICA

Deborah L. Jones, PhD, MEd¹, Suat Babayigit, MEd¹, Antonio Chahine, BS in Biochemistry; Current MPH student², Violeta Rodriguez, MEd³

¹University of Miami Miller School of Medicine, Miami, FL; ²University of Miami, Miami, FL; ³University of Georgia, Miami, FL

Objectives: Despite pregnancy spacing recommendations, women in sub-Saharan Africa often become pregnant within 12 months postpartum. Planned pregnancy among women living with HIV (WLHIV) is essential to optimize health outcomes among mothers and neonates. This study examined reproductive decision making among postpartum WLHIV. It was hypothesized that pregnancy intentions would primarily be influenced by the risk of mother-to-child transmission (MTCT) of HIV, partners' and families' preferences, and community opinion.

Methods: WLHIV in rural South Africa (n = 165) were assessed at 12 months postpartum regarding demographics, medical history, fertility desires, intimate partner violence (IPV), depression, and knowledge of prevention of MTCT (PMTCT) and HIV. A conjoint survey was used to estimate the relative importance of factors hypothesized to be associated with reproductive decision-making when factor-associated scenarios occurred.

Results/Hypotheses: Women were a mean of 28 years old (SD = 5.71), having a monthly household income of ~USD\$70. Using conjoint analysis, decision paths associated with reproductive intentions were explored. Risk of MTCT of HIV (Mean = 0.43; SD = 0.33) had the greatest impact on decision making, followed by partners' desires (M = 0.22; SD = 0.18), family preferences (M = 0.18; SD = 0.13), and community opinion (M = 0.17; SD = 0.13). PMTCT was most important to women with greater HIV and PMTCT knowledge, who placed less emphasis on partner, family, and community preferences. In contrast, those who had been diagnosed with HIV for a longer period of time placed more emphasis on partner preference and community opinion, and less importance on MTCT risk. PMTCT was less important to women experiencing psychological IPV, and those experiencing psychological and physical IPV gave more importance to community opinion. Those reporting clinically significant depression also placed less importance of PMTCT and more on community opinion (all *p* values < 0.05).

Conclusions: Findings highlight the impact of knowledge, maternal depression and IPV on reproductive decision making, and the need for individually tailored, focal perinatal interventions to support the unique circumstances of women living with HIV. Results underscore the need for perinatal preconception counselling for women during follow up and routine HIV care; physicians should consider inclusion of families and/or partners in the process.

DECISION-MAKING UNDER CLINICAL UNCERTAINTY: PROVIDER PERSPECTIVES ON ADJUVANT CHEMOTHERAPY FOR STAGE II COLON CANCER

Rachel Shelton, ScD, MPH, Laura Brotzman, MPH

Columbia University Mailman School of Public Health, New York, NY

Objective: In light of the lack of consensus and evidence supporting benefit and use of adjuvant chemotherapy, guidelines from the National Comprehensive Cancer Network (NCCN) recommend that providers discuss risks and benefits, supporting evidence, associated morbidity, and high-risk characteristics of adjuvant chemotherapy with stage II colon cancer patients when presenting treatment options. However, little is known about the factors impacting provider decision-making and recommendations for use of adjuvant chemotherapy in the context of clinical uncertainty.

Methods: Providers were recruited from eight US institutions on the East Coast using convenience sampling. Actively practicing health care providers who interact with or participate in the care of stage II colon cancer patients were eligible. Providers completed a 30–45 minute phone interview. Interviews were transcribed, and transcripts were coded for qualitative analysis.

Results: A total of 42 providers were interviewed. Oncologists (51%), surgeons (21%), and nurses (14%) were the most common provider types, with a mean of 16 years experience. Providers varied in how they made recommendations for treatment and involved patients in the process. Though most providers were aware of NCCN guidelines, their use in practice varied from “living and breathing” the guidelines to questioning their validity. While some providers made great effort to involve patients in decision-making, others felt their role was to give a recommendation. Overall, providers were consistent in prioritizing clinical information over patient preferences or circumstances (i.e. cultural beliefs) when making a recommendation. Patient knowledge and interest in treatment options were identified as key facilitators of patient involvement in the decision-making process, while time constraints, health literacy, and language differences were commonly reported barriers.

Conclusions: Findings suggest that providers are not consistently involving patients in treatment decision-making or following recommended guidelines for discussing the benefits and risks of adjuvant chemotherapy among this patient population. Given the critical role that provider communication and recommendation plays in shaping patient treatment decisions, particularly in the context of clinical uncertainty, more research and efforts are needed to enhance provider education, patient-provider communication, and patient involvement in the decision-making process.

LATINO ADVANCED CANCER PATIENTS' AND THEIR CAREGIVERS' PREFERENCES FOR ADVANCE CARE PLANNING COMMUNICATION

Megan J. Shen, PhD¹, Cyndi J. Gonzalez, BS², Benjamin Leach, MD³, Paul Maciejewski, PhD¹, Holly Gwen. Prigerson, PhD¹

¹Weill Cornell Medicine, New York, NY; ²Weill Cornell Medicine, Astoria, NY; ³City of Hope, Los Angeles, CA

Background: Advance care planning (ACP) is associated with better quality of life at the end of life (EoL) among advanced cancer patients; it has also been shown to be associated with patients being more likely to receive care consistent with their preferences. Unfortunately, Latino advanced cancer patients engage in ACP at much lower rates than their non-Latino counterparts. To improve Latino advanced cancer patients' engagement in ACP, it is critical to understand what patients' and caregivers' preferred methods of communicating about ACP.

Methods: A mixed-methods approach was used in the present study. In the quantitative phase of the study, Latino advanced cancer patients (n=20) and their caregivers (n=9) completed a brief survey assessing rates at which they engaged in discussions around EoL care and advanced directives (DNR orders, living will, health care proxy). In the qualitative phase, patients and caregivers were interviewed about cultural, religious, and familial beliefs that influence engagement in ACP and their preferences for communication of ACP.

Results: Quantitative results indicated that Latino advanced cancer patients engage in ACP discussions with their family members at much higher rates (30–50%) than with their doctors (10–45%). Qualitative findings highlighted two key themes. First, Latinos' cultural, religious, and familial beliefs influenced their engagement in ACP. Namely, Latino study participants held medical advice from their doctors in high regard, preferred family members to be involved in ACP discussions, and often held optimistic religious beliefs that were antithetical to ACP approaches to being instructed on how to discuss EoL care preferences.

Conclusions: Key cultural, religious, and familial beliefs and dynamics influence whether Latino advanced cancer patients and their caregivers engage in ACP. Promising next directions for improving communication around and engagement in ACP may be through addressing cultural and religious beliefs in ACP discussions, providing information about ACP from the doctor, recognized involvement of family members in ACP discussions and decision-making, and instructions on how to engage in EoL care and ACP discussions.

AN EXPLORATION OF STRUCTURAL AND CONTEXTUAL PATTERNS IN FAMILY HEALTH HISTORY KNOWLEDGE AMONG AFRICAN AMERICAN ADULTS

Sula Hood, PhD, MPH

Indiana University Richard M. Fairbanks School of Public Health, Indianapolis, IN

Background: Family health history (FHH) is a strong risk factor for many chronic diseases. Ethnic minorities have been found to have a low awareness of their FHH, which may pose a contributing factor to health disparities.

Purpose: The purpose of this mixed-methods study was to identify structural and contextual patterns in African American adults' knowledge of their FHH.

Methods: Thirty-two African American adults (mean age=42.7 years) completed individually administered family network interviews. Participants' 3-generation family pedigree served as a visual aid to guide their interview. Participants identified biological relatives who, to their knowledge, had ever been diagnosed with any of the following: cancer, diabetes, kidney disease, hypertension, heart disease, and mental illness. To contextualize quantitative findings, participants were asked to discuss *how* they learned about the health history of the relatives they identified during their family network interview.

Results: Average network size was 29.4 relatives (SD=15.6; Range= 10–67). Participants, on average, only reported FHH information for 9.3 relatives, less than a quarter (24.1%) of their familial network. The most commonly reported diagnosis was hypertension (mean= 4.6 relatives), followed by cancer (mean=2.6 relatives), diabetes (mean=2.3 relatives), heart disease (mean=2.1 relatives), mental illness (mean=1.8 relatives), and kidney disease (mean=0.8 relatives). Participants were more likely to report knowing their maternal FHH (30.0%) than their paternal FHH (22.0%). Logistic regression results show that participants were more likely to know the health history of relatives who were older (OR=1.04, $p<0.001$) and who discussed their health concerns with the participant (OR=4.89, $p<0.001$). Participants primarily reported knowing about one or more health conditions for their parents (65.0%), followed by their grandparents (54.1%), aunts/uncles (40.4%), siblings (28.2%), and cousins (7.6%). Qualitative contextual data suggests that FHH information is commonly transmitted during caretaking activities (ex. attending medical appointments and providing medication assistance), during a relative's illness, and after a relative's death. FHH knowledge is also facilitated by open, direct communication among relatives, and commonly occurs during gatherings such family reunions and holiday celebrations. Mothers, grandmothers, and female matriarchs were frequently described as being FHH information sources, in both maternal and paternal networks.

Conclusions: African Americans' FHH knowledge is limited, especially regarding paternal FHH, siblings, and extended relatives. More culturally and contextually meaningful public health efforts are needed to promote FHH sharing within African American families.

Paper Session 15: Family Context and Health 4:00 PM-4:15 PM

FAMILY HEALTH HISTORY KNOWLEDGE AMONG PARTICIPANTS IN THE DR. SUSAN LOVE RESEARCH FOUNDATION'S THE HEALTH OF WOMEN (HOW) STUDY™

Megan C. Roberts, PhD¹, Melinda Krakow, PhD MPH¹, Michelle I. Silver, PhD, ScM²

¹National Cancer Institute, Bethesda, MD; ²National Cancer Institute, Rockville, MD

Introduction: Increasingly, individualized and risk-based approaches to disease prevention and screening are being leveraged. An important component to these risk-based approaches is a patient's ability to recall family health history (FHH); however, studies indicate that recall of FHH is low. While research has measured general knowledge of FHH, few studies have characterized patterns and gaps in FHH that patients are or are not able to accurately report. This study aimed to examine the extent to which individuals can recall comprehensive information about FHH and whether this ability varies by the type of disease or the type of relative.

Methods: This analysis leverages a large dataset of over 50,000 individuals with and without breast cancer from Dr. Susan Love Research Foundation's The Health of Women (HOW) Study™ to evaluate the extent to which respondents are able to report their FHH for multiple diseases including, breast, ovarian and colon cancer, as well as Crohn's disease, ulcerative colitis, diabetes, asthma, high blood pressure, high cholesterol, stroke, migraine, Parkinson's disease, multiple sclerosis, lupus and scleroderma. We included women who completed the family history module of the study (n=22106). We used (1) paired t-tests to compare the proportions of individuals who did not know their FHH by disease type and type of relative (son, daughter, brother, sister) and (2) multivariable regression to examine the association between sociodemographics and recall of FHH for breast cancer.

Results: We found that individuals' ability to recall FHH was lower than for personal health history and varied by disease area. Participants were least likely to report not knowing FHH of breast cancer (3.1%), and were most likely to report not knowing their FHH of high cholesterol (24.6%). Further, participants were less likely to recall the extent of family history for breast and colon cancer among male relatives (i.e., sons and brothers) than female relatives. In our multivariable model, education, race/ethnicity, insurance status, and sexual identity were associated with breast cancer FHH recall.

Conclusions: Findings from this study indicate that individuals need additional support to collect FHH information about certain common heritable diseases (e.g., high cholesterol) and from male family members. Publicly available resources, such as the Surgeon General's My Family Health Portrait, may be useful tools for improving FHH recall.

FACTORS ASSOCIATED WITH REACH OF INFORMATION ABOUT RISK AND RELATIVE'S HEALTH IN FAMILIES AFFECTED BY ALZHEIMER'S DISEASE

Laura Koehly, Ph.D.¹, Sato Ashida, Ph.D.², Jennifer Cleary, B.S.¹, Christopher Marcum, Ph.D.¹

¹National Human Genome Research Institute, National Institutes of Health, Bethesda, MD; ²College of Public Health, University of Iowa, Iowa City, IA

Background: Little is known about communication patterns in families affected by common yet complex conditions where family history confers increased risk. One example is Alzheimer's disease (AD), a condition in which family members negotiate both informal caregiving roles and shared AD risk. In this context, we investigate how AD family history, discussion partner attributes, and interpersonal ties shape communication patterns about AD. As well, we explore race differences in these patterns.

Methods: Seventy-two respondents from 30 families with a relative affected by AD enumerated family members and important others and indicated with whom they discuss AD, the health of their affected relative, and their family risk of AD. Analyses focus on adult family and important others enumerated in families with multiple participants, resulting in 777 total relational ties. Logistic regressions were fitted with GEE adjustment for within family clustering.

Results: Forty-three percent of respondents indicated family history of AD beyond their affected relative, with no difference due to race. Discussion participation varied with 60%, 55%, and 20% of enumerated network members on average involved in conversations about AD generally, their affected relative's health, and AD family risk, respectively. Race differences were observed only for family risk discussions, with white participants reporting more discussion than black participants (27% vs. 3%, $p < .001$). Regardless of discussion topic, there was a tendency for information to flow between biologically related family members (ORs from 3.62 to 5.72, $ps < .001$) and with emotional supports (ORs from 2.54 to 4.13, $ps < .01$). General discussions about AD were more likely to involve spouses (OR=3.60, $p < .01$) and social kin (OR=3.10, $p < .001$). Discussions about the affected relative's health occurred among those of the same generation, rather than those in older and younger generations (OR=0.31 and OR=0.36, respectively; $ps < .03$). Discussions about AD family risk involved spouses (OR=2.76, $p = .02$), tangible supports (OR=2.03, $p = .04$), and were more likely to occur in families with a family history of AD (OR=3.35, $p = .03$).

Conclusions: Results suggest important nuances in how discussion partners are chosen based on content. Network characteristics identified here can inform future health education programs to address potential barriers to communication, thus extending the reach of AD information in at-risk families.

PARENTING STYLES, FOOD-RELATED PARENTING PRACTICES, AND CHILDREN'S HEALTHY EATING

Nanette Lopez, PhD¹, Susan M. Schembre, MS, PhD, RD², Britni R. Belcher, PhD, MPH³, Sydney O'Connor, BA³, Jaclyn P. Maher, Ph.D.⁴, Reout Arbel, Ph.D.⁵, Gayla Margolin, Ph.D.³, Genevieve F. Dunton, PhD, MPH³

¹University of Southern California, San Diego, CA; ²The University of Texas MD Anderson Cancer Center, Houston, TX; ³University of Southern California, Los Angeles, CA; ⁴University of North Carolina at Greensboro, Greensboro, NC; ⁵University of Haifa, Haifa, Israel

Parents exert a strong influence on their children's diet. While authoritative parenting style is linked to more healthful dietary outcomes in children, little is known about the mechanisms that mediate this relationship. This study examined whether parenting styles (authoritative, authoritarian, and permissive) were associated with three specific food-related parenting practices (mealtime structural practices (e.g., eating meals as a family), parent modeling of healthy food, and household food rules) and whether these food-related parenting practices mediated the association between individual parenting styles and children's dietary outcomes. Participants were 202 mother-child dyads. Among mothers (67% married, 82% college graduates), mean age was 41 years ($SD = 6.1$). Children (51% female) had a mean age of 10 years ($SD = 0.9$). Mothers reported on their parenting style using the Parenting Styles and Dimensions Questionnaire. Children's diet was assessed with two telephone-based 24-hour dietary recalls. Dietary outcomes included the Healthy Eating Index (HEI)-2010 score, calorie-adjusted daily servings of combined fruit and vegetables, and mean daily added sugars (by total sugars). Correlations tested initial associations between the variables of interest. Using PROCESS, multiple mediation cross-sectional analyses with parallel mediators using 10000 bootstraps were performed. After controlling for relevant covariates, partial correlations indicated authoritative parenting style was positively associated with mealtime structural practices ($r = .219, ps < .05$). Mealtime structural practices was positively associated with children's HEI-2010 score ($r = .270, ps < .01$). Additional correlations among the parenting styles and food-related parenting practices were significant for mealtime structural practices and parent modeling of food rules ($r = -.184$ to $-.294, ps < .05$). No significant associations emerged among the three parenting styles and children's dietary outcomes. Mealtime structural practices mediated the relationship between authoritative parenting and HEI-2010 score ($B = 6.020, p = .018, CI = [0.0047, 0.1134]$). No other mediating relationships were significant. Mealtime structural practices may be an effective way for authoritative parents to provide a healthy diet for their children. Further examination of the features by which mealtime structural practices serve as a mechanism for parents to support healthy eating among their children may improve children's diet quality.

YOGA AND MINDFULNESS BASED INTERVENTION FOR STRESS AND QUALITY OF LIFE IN THIRD-GRADE STUDENTS

Christopher Anderson, MSPH¹, Jeanette Gustat, PhD, MPH², Alessandra N. Bazzano, PhD, MPH¹

¹Tulane University, New Orleans, LA; ²Tulane University School of Public Health and Tropical Medicine, New Orleans, LA

Background: Stress is increasingly perceived as an issue that needs to be managed in educational settings. Yoga/mindfulness curricula may be a tool that can be used to teach children to manage stress and improve their sense of wellbeing.

Purpose: This study aimed to assess the impact of a yoga curriculum in an elementary school on student quality of life.

Methods: A randomized controlled trial was used to assess the impact on quality of life on third-grade students from a public school in New Orleans, Louisiana who screened positive for stress at the beginning of the school year. Students were randomized to an intervention group of 20 students receiving small group yoga/mindfulness activities for 8 weeks with an instructor from a local organization using Yoga Ed curriculum, and a control group of 32 students receiving care as usual.

The Brief Multidimensional Students' Life Satisfaction Scale- Peabody Treatment Progress Battery version (BMSLSS-PTPB) was used to assess life satisfaction and the Pediatric Quality of Life Inventory (PedQL) was used to assess quality of life in baseline, midline and endline surveys.

The intervention and control groups were compared at baseline. Differences were tested, in frequencies for categorical variables with chi-square or Fisher's exact tests, and in means for continuous variables using t-tests. Generalized estimating equations (GEE) were used to model the repeated measurement of the continuous scores. The models were adjusted for the time at which the outcome was assessed, homeroom teacher assignment and student interest in yoga at baseline.

Results: Of the participants, 52 percent were male, 53 percent were white, 60 percent of had prior experience with yoga, 65 percent thought yoga would help them feel calm, and 34 percent reported being very interested in doing yoga. Only baseline interest in yoga differed between the intervention and control groups (p-value 0.01).

In GEE models adjusted for time, the yoga based intervention was associated with a 14.17 unit increase in student emotional PedQL (p-value 0.001) and a 7.43 unit increase in student psychosocial PedQL (p-value 0.01). These results were not attenuated by further adjustment.

Conclusions: The intervention in this study was associated with a significant improvement in emotional and psychosocial quality of life when compared to the control group, suggesting that yoga/mindfulness interventions may improve stress management skills among students.

OXYTOCIN: A NOVEL BIOMARKER RELATED TO INFLAMMATION AND QUALITY OF LIFE IN OVARIAN CANCER

Michaela Cuneo, M.A.¹, Lauren Z. Davis, PhD², Angela Szeto, Ph.D.³, Michael Goodheart, MD⁴, Premal Thaker, MD⁵, Philip M. McCabe, Ph.D.⁶, Anil Sood, M.D.⁷, Susan Lutgendorf, Ph.D.¹, Armando J. Mendez, Ph.D.⁸

¹University of Iowa, Iowa City, IA; ²VA Ann Arbor Healthcare System, Ann Arbor, MI; ³University of Miami, Miami, FL; ⁴University of Iowa Hospitals and Clinics, Iowa city, IA; ⁵Washington University School of Medicine, St. Louis, MO; ⁶University of Miami, Coral Gables, FL; ⁷MD Anderson Cancer Center, Houston, TX; ⁸Division of Endocrinology, Diabetes and Metabolism, Miami, FL

Research on the central and peripheral hormone oxytocin (OT) has primarily focused on neurohypophyseal OT and its role in human social behavior, bonding and the stress response. Less research has examined the psychosocial consequences of peripheral OT. OT is synthesized and produced locally by multiple peripheral organs, including the ovary. *In vitro* and *in vivo* studies suggest a protective role for OT in ovarian cancer via anti-inflammatory and anti-tumor effects. However, no studies have examined relationships between peripheral OT, inflammation and psychosocial variables that may be influenced by inflammation (e.g. quality of life) in a cancer population. This study examines endogenous OT from the tumor microenvironment (ascites fluid) and its potential relationship with quality of life (QOL) outcomes in ovarian cancer. OT was measured in the ascites fluid of 108 ovarian cancer patients and relationships between OT, markers of inflammation (IL-6) and QOL were examined. High levels (> 200 times circulating levels in healthy, non-pregnant women) of naturally occurring OT were observed in the ascites fluid of ovarian cancer patients (mean=191.2 pg/mL; range=1.7-2,383 pg/mL). Ascites OT was inversely related to both ascites IL-6 ($\beta=-.27, p=.007$) and plasma IL-6 ($\beta=-.20, p=.055$), suggesting anti-inflammatory activity. To test the hypothesis that OT inhibits inflammatory activity in ovarian cancer, *in-vitro* studies were performed and revealed basal OT secretion from four ovarian cancer cell lines, and a direct inhibitory effect of OT on IL-6 (IL-6 levels reduced by 40%; $p=.03$). Given known relationships between inflammation and poorer QOL in cancer patients, we examined whether ascites OT was associated with QOL via its relationship with IL-6. Path analyses indicated that higher levels of ascites OT were associated with higher patient total QOL (FACT-G; $\beta=.20, p=.02$), higher ovarian cancer specific QOL (FACT-O [subscale]; $\beta=.29, pp=.02$), controlling for age, stage, and correlations among the outcome variables. In bootstrapped mediation analyses, the effect of ascites OT on overall QOL ($\beta=.07, 95\% \text{ CI}=.01, .12$) and patient-rated disability ($\beta=-.06, 95\% \text{ CI}=-.11, -.01$) was found to be fully mediated by IL-6. The effect of ascites OT on higher ovarian cancer specific QOL was only partially mediated by IL-6 ($\beta=.06, 95\% \text{ CI}=.002, .12$). This research identifies OT as a novel biomarker in the ovarian tumor microenvironment with both direct anti-inflammatory effects and relevance for patient QOL. Ongoing research is investigating the source of OT in the ovarian tumor microenvironment and examining potential top-down processes that may contribute to individual differences in OT in the tumor microenvironment.

TRENDS IN RACIAL/ETHNIC DISPARITY OF HEALTH-RELATED QUALITY OF LIFE IN MEDICARE ADVANTAGE BENEFICIARIES (1998–2012)

Maria A. Rincon, MPH¹, Mandi A. Yu, PhD¹, Ashley Smith, PhD, MPH¹, Erin E. Kent, PhD²

¹National Cancer Institute, Rockville, MD; ²ICF International, Rockville, MD

Background: Hispanic, Non-Hispanic Asian/Pacific Islander (NH-API), and Non-Hispanic Black (NH-Black) cancer survivors often report poorer health status compared to Non-Hispanic Whites. Recent data pooled from 1998–2007 from the National Cancer Institute (NCI)'s SEER-MHOS (Surveillance, Epidemiology and End Results-Medicare Health Outcomes Survey) on Medicare Advantage (MA) beneficiaries reveal differences in health-related quality of life (HRQoL) by race/ethnicity. We conducted a trend analysis using SEER-MHOS data to determine if differences in HRQoL by race/ethnicity are increasing, decreasing or plateauing among MA beneficiaries with cancer as compared to non-cancer controls.

Methods: We sampled adults ages 65+ included in SEER-MHOS (1998–2012). HRQoL measures included the Physical and Mental Component Scores (PCS/MCS), harmonized from the Medical Outcomes Short Form (SF-36) (1998–2005) and the Veteran's RAND 12-Item Survey (VR-12) (2006–2012). We compared PCS/MCS by race/ethnicity among individuals with/without cancer, adjusted for comorbidities, gender and region, and further adjusted by time since/stage of diagnosis for those with cancer. Absolute (between-group variance; BGV) and relative (mean log deviation; MLD) indices of disparity were generated from the NCI's Health Disparity Calculator. JoinPoint was used to calculate annual percent changes (APC) in PCS/MCS and test disparity trends over the study period.

Results: Both cancer (NH-White=61,676; NH-API=5,676; NH-Black=6,655 and Hispanic=6,512) and non-cancer cohorts (NH-White=239,988; NH-API=32,377; NH-Black=30,700 and Hispanic=41,135) consisted predominantly of NH-White beneficiaries. NH-Blacks and Hispanics reported significantly lower PCS than NH-Whites/NH-Asians over the entire study period. MCS among NH-Blacks/NH-Asians/Hispanics decreased between 1998–2012. Difference in MCS among race/ethnicity groups increased over the study period in beneficiaries with [BGV APC=13.67; C.I (9.9, 17.6); MLD APC= 13.71; C.I (9.9, 17.6)] and without cancer [BGV APC=34.25; C.I (0.1–80.1); MLD APC=15.7; C.I. (12.4, 19.0)]. Increases in both BGV and MLD indices for PCS were only evident in those without cancer [BGV APC=11.82; C.I (8.2,15.6); MLD APC=12.77; C.I (8.6,17.1)].

Conclusions: Our analysis suggests rising disparities in mental HRQoL by race/ethnicity in older adults with cancer. Future research should continue to follow trends in HRQoL and explore racial/ethnic disparities in unmet health care needs.

FINANCIAL STRAIN AND QUALITY OF LIFE IN BREAST CANCER

Laura M. Perry, BS¹, Michael Hoerger, PhD, MSCR¹, Katherine Seibert, BS², James I. Gerhart, PhD³, Sean O'Mahony, MB, BCh, BAO³, Paul R. Duberstein, PhD⁴

¹Tulane University, New Orleans, LA; ²Albert Einstein College of Medicine, New Orleans, LA; ³Rush University Medical Center, Chicago, IL; ⁴University of Rochester Medical Center, Rochester, NY

Objective: To assess the cross-sectional association between financial strain and key elements of physical and emotional quality of life among women with breast cancer.

Method: Across two samples, 175 women with breast cancer completed online surveys as part of NIH-funded research. Participants completed validated measures of financial strain, physical quality of life (symptom burden, perceived health, and functional status), and emotional quality of life (emotional functioning, depression, and anxiety). Analyses controlled for key covariates that included age, education level, marital status, presence of metastases, and time since diagnosis.

Results: Results showed that 33.7% of women experienced financial strain, which was associated with worse physical and emotional quality of life. Financially strained women reported worse physical symptom burden ($p < .001$), perceived health ($p < .001$), and functional status, including spending >3 additional days in the past month mainly in bed ($p = .005$). They also reported worse emotional functioning ($p = .001$), and worse depression symptom severity in particular ($p < .001$), but not worse anxiety. Effect sizes were clinically significant (Cohen's $d = 0.49–0.85$).

Conclusion: The present investigation illustrates the importance of financial strain in breast cancer. Clinicians are encouraged to explore financial stressors and strains in their depressed patients.

Paper Session 16: Influences on Quality of Life Across the Lifecourse 4:30 PM-4:45 PM

IMPROVING PARENTS & CHILDREN'S ASTHMA-RELATED QUALITY OF LIFE

Sharon D. Horner, PhD

The University of Texas at Austin, Austin, TX

Background: Asthma is a major public health problem in childhood with heavier burden experienced among members of racial/ethnic minority groups. Frequent symptomatic days requiring urgent management, disturbed sleep, and limitations in daily activities due to asthma contribute to worsening quality of life (QOL) in children who have asthma and in their parents.

Methods: Children (7–12 years old) were randomly assigned to treatment or comparison groups. The intervention was designed to improve children's asthma self-management knowledge, skills, problem-solving. Data on QOL were collected from children at baseline and again at 12 months. QOL was measured with Juniper's scales for children and their caregivers.

Sample: A total of 257 children and their parental caregiver completed the 12-month study and included 163 boys (63.6%), 94 girls (36.4%); of which 58% were Hispanic, 21% were Black, and 19% were non-Hispanic white (white). The children's mean age was 8.82 years (SD=1.2).

Results: The groups were not significantly different at baseline (sample demographics: gender, age, race/ethnicity; and QOL). After the intervention, QOL was significantly improved in the treatment group. **Children's QOL:** QOL total score, $F=7.53$, $p=.007$; QOL emotional functioning, $F=4.05$, $p=.02$; and QOL asthma symptoms, $F=3.28$, $p=.04$. In terms of activity limitations due to asthma, there were no between treatment group differences – both groups had fewer days with limited activity. **Parents' QOL:** QOL total score, $F=7.29$, $p=.007$; QOL emotional functioning, $F=3.27$, $p=.04$; and QOL family activities, $F=5.29$, $p=.006$.

When comparing racial/ethnic groups, additional information is revealed. There were significant differences at baseline in children's QOL: The mean scores for children's total QOL scores at baseline were significantly worse for Blacks - 62.30, followed by Hispanics - 52.34, and best for whites - 48.86 [$F=7.05$, $p=.001$]. The children's QOL improved after the intervention, but there continued to be significant differences between racial/ethnic groups 12 months later: QOL total score, $F=3.62$, $p=.03$.

Discussion: The intervention significantly improved the treatment groups' QOL. It is important to note that the treatment and comparison group were composed of equivalent groups in terms of gender and race/ethnicity. The further examination of QOL by racial/ethnic group did reveal significant differences in QOL for children who are members of racial/ethnic minority groups. Nevertheless, their scores also improved after the intervention. While this is a positive finding, the continued differences in QOL reported by children who are ethnic/racial minority group members should be noted. Interventions may require tailoring to address specific issues of concern to parents and children with asthma who are members of racial/ethnic groups.

CANCER-RELATED PROBLEMS AND SLEEP QUALITY IN LONG-TERM CANCER SURVIVORS: A REPORT FROM THE STUDY OF CANCER SURVIVORS-1

Sara Strollo, MPH, Elizabeth Fallon, MPH, Ph.D., Tenbroeck Smith, MA

American Cancer Society, Atlanta, GA

Introduction: Poor sleep is a top five unmet need among cancer survivors, resulting in lower physical, emotional, and cognitive functioning. While cancer-related problems are known to effect sleep quality within the first 5 years of survivorship, less is known about long-term survivors (> 5 years). This study assessed the association between cancer-related problems and sleep quality among long-term survivors.

Methods: Data from the third survey of the American Cancer Society's Study of Cancer Survivors (SCS-1) was used for this study. The nationwide sample (N=1,979) includes survivors of 10 cancers (30% Breast; 20% prostate), 9 years (M=8.9 sd=0.6) post-diagnosis, and was mostly female (62%), non-Hispanic white (90%), with a mean age of 55.5 (sd=11.1) years. Sleep quality was assessed by dichotomizing the 1-item component score of the Pittsburgh Sleep Quality Index. Cancer-related physical distress, emotional distress, employment and financial problems, and fear of recurrence were measured with the Cancer Related Problems in Living Scale. Adjusting for medico-demographics, behavioral factors, and sleep medication use, multivariable logistic regression determined the association between cancer-related problems and poor sleep quality.

Results: Almost 20% (n=388) reported poor sleep quality, of which 51% (n=196) reported sleep medication use. The highest rates of poor sleep quality were reported among survivors of non-Hodgkin lymphoma (30.4%), kidney cancer (27.3%), and lung cancer (27.0%). Survivors with greater cancer-related physical distress (OR=1.18; 95% CI=1.11, 1.25) and greater fear of recurrence (OR=1.08; 95% CI=1.01, 1.15) had significantly higher odds of poor sleep quality after adjusting for covariates and sleep medication use. Sensitivity analyses revealed the stability of the effect of cancer-related physical distress on poor sleep quality when removing sleep medication from the model (OR=1.18; 95% CI=1.1, 1.3) and excluding participants with sleep medication use (OR=1.19; 95% CI=1.1, 1.3).

Implications: Cancer-related problems continue to impact sleep quality among cancer survivors 9 years post-diagnosis. Clinicians should assess and treat cancer-related physical distress as a possible underlying cause of poor sleep quality among patients with a cancer history. Future research will determine specific cancer-related factors interfering with long-term survivor sleep quality to improve symptom management and health outcomes.

GOAL COGNITIONS, FATIGUE, PAIN, AND FUNCTIONAL WELLBEING IN LUNG CANCER PATIENTS

Laurie E. Steffen, PhD¹, Jennifer S. Cheavens, PhD², Kevin Vowles, PhD³, Bruce W. Smith, PhD³

¹Wake Forest School of Medicine, Winston Salem, NC; ²The Ohio State University, Columbus, OH; ³University of New Mexico, Albuquerque, NM

Background: Because lung cancer is usually diagnosed in an incurable stage, symptom management is a large component of patient care. Fatigue and pain are two of the most common, disruptive, and distressing symptoms to patients. These symptoms can negatively affect patients daily, interfering with their routines and eroding their sense of value to daily life. Prior work has identified the centrality of personal goals to wellbeing during illness and suggested a cross-sectional association between goal cognitions and symptoms among lung cancer patients. The aim of the present longitudinal study was to evaluate the relation between goal cognitions and daily fatigue, pain, and related aspects of wellbeing.

Methods: Multilevel modeling was used to analyze 1,029 reports (M per person = 20.3, SD = 1.34) of fatigue and pain (FACT-L), functional wellbeing (FACIT-Pal), and goal cognitions (State Hope Scale) from 50 lung cancer patients (21 males; M age = 69 yrs, SD = 8.8 yrs; 72% advanced disease) enrolled in a 21-day diary study. Goal cognitions were disaggregated into individual-level averages. Models adjusted for age, baseline depression, physical functioning, and treatment type.

Results: People who perceived more pathways to their goals reported less daily fatigue and pain, adjusting for covariates ($Est.$ = $-.26$, p = $.035$). This effect was maintained in models that adjusted for the previous day's level of fatigue and pain ($Est.$ = $-.14$, p = $.031$). People who reported higher agency in meeting their goals reported higher daily functional wellbeing ($Est.$ = $.27$, p = $.027$). This effect trended in the model that adjusted for the previous day's level of functional wellbeing ($Est.$ = $.11$, p = $.058$).

Conclusions: Results provide longitudinal evidence that how patients think about their personal goals and plans affects their daily experience of fatigue and pain and related aspects of wellbeing such as perceived independence, usefulness, and ability to make each day count. Interventions that help patients perceive pathways to personal goals and build agency for working on those goals may help address these prominent physical symptoms and related aspects of wellbeing.

NOVEL BIOMARKERS OF CHEMOTHERAPY-INDUCED MUSCLE DAMAGE, CANCER-RELATED FATIGUE AND EXERCISE: A RCT IN 350 CANCER PATIENTS

Karen Mustian, PHD, MPH¹, Anita Peoples, PHD, MPH¹, Po-Ju Lin, PhD, MPH, RD², Ian Kleckner, PhD¹, Luke Peppone, PhD, MPH¹, Michelle Janelins, PhD, MPH¹, Matt Asare, PHD¹, Julia E. Inglis, PhD, RD¹, Jessica Miller, BA, CCRP³, Jeffrey Giguere, MD⁴

¹University of Rochester Medical Center, Rochester, NY; ²University of Rochester Medical Center, Wilmot Cancer Institute, Rochester, NY; ³MMCORC, St. Louis Park, MN; ⁴Greenville Health System Cancer Institute, Greenville, SC

Background: Chemotherapy may lead to systemic muscle damage. Up-regulation of developmental myosin light chain 5 (MYL5) and myosin heavy chain 8 (MYH8) genes is required for normal muscle regeneration in response to damage. However, secretion of MYL5 and MYH8 proteins into the serum suggest degradation of muscle, which, in turn, may lead to cancer-related-fatigue (CRF). In this study, we investigated (1) the effect of an exercise intervention, Exercise for Cancer Patients (EXCAP), on mRNA gene expression and serum protein levels of MYL5 and MYH8 and (2) the association of these novel biomarkers with CRF.

Methods: Chemotherapy naïve cancer patients ($N=350$; mean age = 55.7) from 39 community oncology practices throughout the U.S. affiliated with the URCC NCORP Research Base participated in this nationwide, multi-center, phase III RCT. Patients were randomized into 2 groups: (1) chemotherapy and (2) chemotherapy plus a 6-week aerobic and resistance exercise prescription-EXCAP. Gene expression and protein levels of MYL5 and MYH8, as well as CRF were assessed pre- and post-intervention from whole blood by qPCR, from serum by Luminex assays, and from patient-report by the Multidimensional Fatigue Symptom Inventory, respectively.

Results: T-tests show MYL5, but not MYH8, mRNA levels were significantly up-regulated from pre- to post-intervention in exercisers and controls (all $p \leq 0.01$) with no significant group difference. Additionally, MYL5 and MYH8 serum protein levels significantly increased from pre to post in controls (all $p \leq 0.05$), but remained stable in exercisers. Significant group differences in these serum proteins ($p \leq 0.01$) suggest greater muscle degradation in non-exercisers. Pearson correlations revealed trends suggesting increases in MYL5 and MYH8 serum proteins are associated with increases in CRF ($r = 0.09$ and $r = 0.11$, respectively, all $p \leq 0.10$).

Conclusions: Results suggest EXCAP exercise is protective from chemotherapy-induced muscle damage via its effects on MYL5 and MYH8, and changes in these novel biomarkers may mediate changes in CRF. Further research is needed to confirm these findings.

WEIGHT-BASED STIGMA IS ASSOCIATED WITH SLEEP QUALITY AMONG EMERGING ADULTS

Kristina Decker, Masters Degree¹, Idia B. Thurston, Doctorate¹, Rebecca Kamody, Masters Degree², Caroline Kaufman, B.A.¹, Andrew Paladino, BA¹, Girardin Jean-Louis, PhD³

¹University of Memphis, Memphis, TN; ²The University of Memphis, New Haven, CT; ³New York University, New York City, NY

Background: Weight-based stigma is both pervasive and socially accepted in U.S. culture. Recent research has illuminated associations between greater weight stigma and poorer health outcomes. Research is limited on the association between weight-based stigma and sleep; however, literature on race-based stigma suggests that poor sleep quality drives the association between perceived stigma and worse health. We explored associations between external and internal weight stigma (e.g., hearing disparaging remarks about one's weight, believing oneself to be lazy because of weight) and sleep quality, accounting for associations with depression and Body Mass Index (BMI).

Methods: 436 emerging adults (59% White, 18% Black, 10% Hispanic, 6% Asian, 5% Multiracial, 3% Other; 74% female) enrolled through Amazon Mechanical Turk and a university subject pool. These 18-25-year-olds ($M_{age}=21.59$, $SD=2.32$) completed measures of depressive symptoms (Center for Epidemiologic Studies Depression Scale), internal weight stigma (Weight Self-Stigma Questionnaire), external weight stigma (Stigmatizing Situations Inventory), and sleep quality (Pittsburgh Sleep Quality Index). Reported height and weight were used to calculate BMI (kg/m^2), which ranged from 13.93–64.15 ($M_{BMI}=26.0$, $SD=6.63$). A hierarchical linear regression was conducted across 3 steps to predict sleep quality. Sex and race/ethnicity were entered in Step 1; BMI and depressive symptoms in Step 2; and external and internal weight stigma in Step 3.

Results: The final step of the model was significant ($F(10, 425)=23.97$, $p<.001$, $Adj.R^2=.36$) with being female ($B=-1.07$, $SE=.31$, $p<.001$), having greater depressive symptoms ($B=-.14$, $SE=.01$, $p<.001$), and perceiving greater external weight stigma ($B=-1.13$, $SE=.36$, $p<.01$) associated with poorer sleep quality. On average, Hispanic ($B=1.10$, $SE=.46$, $p<.05$), Asian ($B=1.45$, $SE=.58$, $p<.05$), and "Other race" ($B=2.06$, $SE=.86$, $p<.05$) participants had better sleep quality than White participants. BMI and internal weight stigma were not significant predictors.

Discussion: Findings highlight a unique association between external weight stigma and sleep quality, which align with race-based stigma research. Future research should verify such associations with objective sleep measures as derived from actigraphy. Results also underscore the important need for policies that safeguard against weight stigmatization across multiple external domains such as: school, work, clinic, and community settings.

Paper Session 17: Sleep and Fatigue in the Context of Chronic Disease 4:30 PM-4:45 PM

EVALUATION OF PROMIS SLEEP MEASURES IN ETHNICALLY DIVERSE OVERWEIGHT OR OBESE PRIMARY CARE PATIENTS WITH AND WITHOUT DEPRESSION

Jun Ma, MD, PhD¹, Nan Lv, PhD², Lan Xiao, PhD², Lisa Rosas, MPH, PhD², Mark Snowden, MD, MPH³, Megan Lewis, PhD⁴, Elizabeth M. Venditti, PhD⁵, Andrea Goldstein-Piekarski, PhD⁶

¹University of Illinois at Chicago, Chicago, IL; ²Palo Alto Medical Foundation Research Institute, Palo Alto, CA; ³University of Washington, Seattle, WA; ⁴RTI International, Seattle, WA; ⁵University of Pittsburgh, Pittsburgh, PA; ⁶Stanford University, Stanford, CA

Objective: Reliable and valid, simple measures of sleep disturbance (quality) and sleep-related impairment (sequelae) may improve characterization and management of overweight and obese patients, including those with comorbid depression, in primary care.

Methods: Baseline data on the PROMIS sleep disturbance and sleep-related impairment short forms (8 items each) and on psychosocial and biobehavioral measures from two ongoing randomized trials were analyzed separately: RAINBOW, 409 adults of mixed race and ethnicity with comorbid obesity and depression; Vida Sana, 189 Latinos who were overweight or obese and at high risk of type 2 diabetes. We tested the reliability of both sleep measures using item correlations and Cronbach's alpha, and examined their validity using ANOVA and χ^2 tests of associations with other measures.

Results: RAINBOW participants (70% female, 71% non-Hispanic White, 51.0 [SD, 12.1] years) had mean (SD) BMI 36.7 (6.4) kg/m^2 , PHQ9 depression score 13.8 (3.1), and T scores of sleep disturbance 52.7 (3.4) and impairment 56.9 (6.8). Vida Sana participants (62% female, all Latino, 50.3 [12.2] years) had BMI 32.5 (5.7), PHQ9 5.4 (4.5), sleep disturbance 51.6 (8.9), and impairment 51.2 (9.2). Item correlations ranged 0.22–0.70 in RAINBOW and 0.22–0.87 in Vida Sana for both sleep measures, all with high Cronbach's alpha (0.86–0.92). In both studies, higher sleep disturbance and impairment were significantly associated with greater depressive symptoms, stress, anxiety, and poorer health-related quality of life; higher sleep impairment was associated with younger age. In RAINBOW, higher sleep disturbance was significantly associated with older age and lower physical activity, while higher sleep impairment was associated with greater disability and more negative problem-solving orientation and more avoidance tendency. In Vida Sana, higher sleep disturbance and impairment were significantly associated with lower food security, lower self-efficacy with weight control and exercise.

Conclusions: Both PROMIS sleep measures showed good scale reliability and convergent validity with related health risk measures in two independent, ethnically diverse samples. Impaired sleep quality and resulting daytime symptoms are common in primary care patients with excess weight and comorbid depression or other cardiometabolic risk factors. The PROMIS sleep short forms may have clinical utility in primary care settings.

Paper Session 18: Insights into Disordered Eating 3:30 PM-3:45 PM

THE RELATION BETWEEN PERSISTENT PROBLEMATIC EATING AND HEALTH STATUS AMONG ADULTS AT HIGH RISK OF HOSPITALIZATION

Andrea E. Kass, PhD¹, Ilana Engel, BA², Lauren Wiklund, BA¹, Andrea Flores, MA¹, Jennifer Wildes, PhD¹, David Meltzer, MD, PhD¹

¹University of Chicago, Chicago, IL; ²University of Chicago Medicine, Biological Sciences Division, Chicago, IL

Background: Persistent problematic eating, such as under- or overeating, increases risk for eating disorders or obesity, is associated with distress, and can onset or worsen with increased stress, such as when experiencing complex medical problems. This study examines the relation between persistent problematic eating, health status, and future hospitalization among adults at high risk of hospitalization.

Methods: Participants were 2,000 adults (age=63 ± 16y; 86% Black; 63% female) enrolled in a RCT comparing a hospital-based intervention to standard care, who had been hospitalized in the past year or were recruited while in the emergency department. Participants were assessed every three months. At intake, participants answered the question, “In the past two weeks, how often have you been bothered by poor appetite or overeating?” For this study, persistent problematic eating referred to poor appetite or overeating that occurred nearly every day (vs more than half, several, or no days); non-responders (*n*=11) were excluded from analyses.

Results: At intake, 17% endorsed persistent problematic eating. Compared to their counterparts, individuals with persistent problematic eating were more likely to be female, endorse worse ratings of overall health, and have greater impairment in activities of daily living (ADL) and instrumental ADL (*ps*<.001); they also endorsed worse ratings of overall mental health and greater anxiety symptoms, psychosomatic complaints, and disordered personality traits (*ps*<.001). There were no between-group differences in age, race, ethnicity, income, education level, or whether they were hospitalized or number of hospitalizations in the past year (*ps*>.10). Among the subset of participants (67%) who were alive one year after enrollment and reported hospitalizations in each of the 3-month follow-ups (responses from which were aggregated into one variable of “future hospitalizations”), individuals with persistent problematic eating, compared to those without, were more likely to be hospitalized over one year, controlling for study condition and whether they were hospitalized in the year prior (OR=1.5; 95% CI=1.1–2.1).

Conclusions: Persistent problematic eating is associated with poor physical and mental health and may portend worsening health (i.e., hospitalization). Results highlight the importance of identifying and addressing these behaviors, particularly among individuals with complex medical problems and high health care utilization.

Paper Session 18: Insights into Disordered Eating 3:45 PM-4:00 PM

IMPULSIVITY AND AFFECT REACTIVITY PREDICT DISORDERED EATING ATTITUDES OVER TIME: A 6-YEAR LONGITUDINAL STUDY

Brittney Evans, BA¹, Julia Felton, PhD², Stephanie Manasse, PhD¹, Adrienne Juarascio, Ph.D.¹

¹Drexel University, Philadelphia, PA; ²Michigan State University, Detroit, MI

Introduction: Eating disorders (EDs) are associated with significant psychological and physical comorbidities and increased risk for mortality. Impulsivity and changes in negative affect (i.e., affect reactivity) are hypothesized to contribute to the development of EDs, and adolescence is a particularly high-risk time for the emergence of ED pathology. However, no studies have examined these prospective relationships in adolescents. The current study examined the relationship between impulsivity and affect reactivity as predictors of the development of ED-attitudes in adolescents over time.

Methods: 206 adolescents (ages 11–15 years) participated in a longitudinal study examining the development of psychopathology. ED-attitudes were assessed via the College Eating Disorders Screen (COEDS). Affect reactivity was measured as change in negative affect before and after a laboratory stressor using scores on the Positive and Negative Affect Schedule for Children (PANAS-C). Impulsivity was measured via the Eysenck Impulsivity Inventory.

Results: Results of latent growth modeling using an unconditional model suggest that ED-attitudes increase over time. When affect reactivity, impulsivity, and their interaction were added (controlling for baseline negative affect and sex), the model fit the data well: $\chi^2_{(df=41)} = 69.64, p = 0.004$; CFI = .96; TLI = .96; RMSEA = 0.05 (90% CI = 0.03 – 0.08). The interaction between impulsivity and affect reactivity significantly predicted the slope of ED-attitudes (std. est. = -.60, *p* = .033), such that for youth with greater affect reactivity, increases in impulsivity were more strongly related to increases in ED-attitudes over time, relative to less-affectively reactive youth.

Discussion: Findings suggest that greater levels of affect reactivity and impulsivity are key risk factors for the development of ED-attitudes in youth, and that youth high in both affect reactivity and impulsivity may be especially susceptible to developing ED-attitudes. Subsequent research should examine the relation between affect reactivity and impulsivity in predicting objectively measured ED-behaviors to better understand the link between these factors and the development of ED symptoms in addition to ED-attitudes. Further investigation may implicate affect reactivity and impulsivity as important targets for early intervention to prevent later onset of ED symptoms in adolescents.

Paper Session 18: Insights into Disordered Eating 4:00 PM–4:15 PM

THE ASSOCIATION BETWEEN INTUITIVE EATING AND BODY PRE-OCCUPATION IS INDEPENDENT OF OBJECTIVE WEIGHT STATUS

Natalie Keirns, BS, Misty Hawkins, PhD

Oklahoma State University, Stillwater, OK

Background: Intuitive eating (IE) is an adaptive style of eating based on following the body's signals of hunger and fullness. IE is associated with many positive psychological factors, including body appreciation/acceptance, emphasis on body function over appearance, and lower body dissatisfaction and avoidance behaviors. The goal of this project was to extend previous literature by determining whether IE was associated with preoccupation with body shape and weight after adjusting for objective weight status in a diverse sample of adults.

Method: 192 adults (age: 36 ± 15 years, female: 138(72%), non-white: 86(45%), body mass index; BMI: 32 ± 7 kg/m²) completed a battery of self-report measures. The IE total score and its subscales were measured with the Intuitive Eating Scale-2. Shape and weight preoccupation were measured with the Shape Concern (SC) and Weight Concern (WC) subscales of the Eating Disorder Examination-Questionnaire. Objective weight status was assessed using measured BMI. Model covariates included age, gender, race, and BMI.

Results: Linear regressions revealed that greater IE was associated with lower SC ($\beta = -.47, p < .001$) and lower WC ($\beta = -.49, p < .001$) after adjusting for BMI and other covariates. Subscale analyses revealed that only the Unconditional Permission to Eat and Eating for Physical Rather than Emotional Reasons subscales were uniquely associated with SC ($\beta = -.30, p < .001$; $\beta = -.42, p < .001$) and WC ($\beta = -.26, p = .002$; $\beta = -.49, p < .001$). BMI was not associated with SC or WC in the model with total IE ($\beta = .03, p = .788$; $\beta = .08, p = .391$) or its subscales ($\beta = .01, p = .897$; $\beta = .07, p = .446$).

Discussion: Higher levels of IE were associated with lower levels of shape and weight concerns – independent of BMI – such that eating more intuitively was related to less preoccupation with body shape and weight. Giving oneself permission to eat ad libitum and eating based on hunger instead of emotion(s) appear to be the most important aspects of IE in this relationship. BMI was not related to shape or weight concerns. These findings suggest a person may be better able to minimize eating restrictions and to utilize hunger signals when he/she is less concerned with weight and shape, regardless of his/her actual weight status. This conclusion, however, is limited by our cross-sectional design. Future research should investigate the directionality of this relationship and its implications on mindful and disordered eating as well as on obesity development or progression.

ORTHOOREXIA TRAITS ARE ASSOCIATED WITH INTERFERENCE WHEN EATING BEHAVIOR DOES NOT CONFORM TO HEALTHY EATING BELIEFS

Hana F. Zickgraf, MA¹, Jordan Ellis, MA², Jamal H. Essayli, PhD³

¹Pennsylvania State University College of Medicine & University of Pennsylvania, Harrisburg, PA; ²East Carolina University, Greenville, NC; ³Penn State University College of Medicine, Harrisburg, PA

Background. Orthorexia nervosa (ON) is characterized by obsessions about eating healthily and rigid adherence to a perceived healthy diet. This study investigated the relationship between self-reported ON symptoms, self-reported food intake, clinical impairment, and body mass index (BMI).

Methods. ON symptoms were assessed in 451 adult participants, recruited on Amazon's Mechanical Turk, using the Eating Habits Questionnaire, which includes factors representing rigid healthy eating beliefs (RB), as well as positive affect (PA) and interference (INT) related to these behaviors. Using multiple regression, we explored the differential relationships of ON symptomatology dimensions, self-reported daily fruit/vegetable (FV) and discretionary food (snack and dessert) intake, BMI, and the Clinical Impairment Assessment (CIA), a validated measure of impairment due to disordered eating behavior.

Results. ON dimensions were highly intercorrelated; thus, z-scores were used to generate four variables representing the variance shared by the three factors and variance unique to each factor. Variance shared by the ON dimensions predicted higher FV intake ($\beta = .42$) and lower discretionary food intake ($\beta = -.22$), whereas variance unique to INT had the opposite relationship with intake of both FV ($\beta = -.11$) and discretionary food ($\beta = .27$). While RB was not related to FV or discretionary intake, it was the only ON dimension uniquely, and negatively, associated with BMI ($\beta = -.12$). A model including an interaction term of shared ON variance and discretionary food intake significantly predicted scores on the CIA, indicating that eating-related clinical impairment is associated with greater discretionary food intake in the context of more pronounced ON traits (Interaction $\beta = .14$).

Conclusions. Individuals with features of ON report rigid healthy eating beliefs and intentions, but the functional impact of ON may depend on individuals' ability to enact these beliefs. Participants who consume more "unhealthy" foods appear to report greater ON-specific and eating disorder-related impairment, whereas those who report rigid healthy eating behaviors may experience protection against weight gain. However, self-reported interference may not reflect true impairment, for example, if successfully orthorexic individuals lack insight into the social and potential health impacts of their rigid eating.

DO YOU KNOW HOW MANY CALORIES YOU NEED? PREDICTORS AND CORRELATES OF CALORIC NEED AWARENESS

Morgan S. Lee, PhD, MPH, CPH¹, Kelly Prigge, BSN, MS², Ann O. Amuta, TEXAS³

¹University of Colorado - Colorado Springs, Colorado Springs, CO; ²USAF Academy medical group, Colorado springs, CO; ³TEXAS WOMAN'S UNIVERSITY, Denton, TX

Background: Despite mixed evidence regarding its effectiveness, calorie labeling on restaurant menus has become a popular public health intervention in efforts to combat the obesity epidemic in the United States. A potential weakness of this approach is that it assumes people have at least a basic knowledge of their caloric needs. However, limited research to date indicates caloric need awareness may be low. The present study explored predictors and correlates of caloric need awareness.

Method: A nationally representative sample of 501 male and female adults (53% female, mean age: 44.22 years, mean body mass index (BMI): 28.06) completed self-report measures of demographic characteristics, perceived weight status and activity level, fast food consumption, calorie intake monitoring and limiting, weight-related goals, and estimated daily calorie intake needs to maintain current weight. A participant's caloric needs estimate was considered accurate if it was within 10% of their Estimated Energy Requirement, which was calculated using a standardized formula.

Results: Females (versus males) and unmarried (versus married) participants were more likely to accurately estimate their caloric needs ($p < .01$). Participants who perceived themselves as sedentary (versus moderately or vigorously active) were more likely to estimate accurately ($p = .02$). Participants who were trying to maintain their weight (versus trying to lose weight, not doing anything regarding their weight, etc.) were most likely to estimate accurately ($p < .01$). Ability to estimate accurately did not vary based on race, ethnicity, income, education, BMI, perceived weight status, or frequency of fast food consumption. For calorie intake monitoring and limiting, a trend was observed such that participants who were neither monitoring nor limiting their intake were more likely to estimate accurately ($p = .17$). A trend was also observed for age, whereby increasing age was associated with greater likelihood of estimating accurately ($p = .13$).

Conclusions: Commonly emphasized predictors such as race, socioeconomic status-related variables, and BMI may be of limited utility in identifying target groups for education campaigns related to caloric needs. Future research should investigate the mechanisms underlying the observed relationships for factors that were associated with caloric need awareness and develop interventions to increase caloric need awareness in groups where this knowledge is particularly low.

BRIEF, SHORT-TERM PRENATAL MENTAL HEALTH INTERVENTION FOR PTSD: A PILOT STUDY IN LOW-INCOME, MINORITY WOMEN

Sara Kornfield, PhD¹, Brendan McGeehan, M.S. Statistics², Stephanie Criniti, M.S.², C. Neill Epperson, MD³

¹University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; ²University of Pennsylvania, Philadelphia, PA; ³Penn Center for Women's Behavioral Wellness, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA

Introduction: It is estimated that more than half of women will experience a traumatic event in their lifetime, with rates as high as 86% among African-American, urban-dwelling women. Women are twice as likely as men to meet diagnostic criteria for PTSD, and over four times as likely to experience chronic PTSD. It is therefore not surprising that many women struggle with PTSD or subthreshold trauma related symptoms during pregnancy. Studies have shown rates of PTSD are higher in pregnant compared to non-pregnant women. Stress hormone regulation necessary for appropriate development of the fetus and timing of parturition may be disrupted by heightened maternal physiological arousal which is a hallmark symptom of PTSD. Though PTSD during pregnancy has been associated with sub-optimal birth outcomes, pregnant women with subthreshold or even full PTSD may not seek out treatment due to cultural/environmental norms, or simply the inconvenience of attending another appointment given the burden of prenatal care. Therefore, this study aimed to test the effectiveness of a brief, short term psychological intervention for trauma related symptoms which could be delivered in tandem with prenatal care to women who were symptomatic yet non-treatment seeking.

Method: Pregnant women were recruited from the waiting room of an urban prenatal clinic. After evaluation and screening for PTSD symptoms, those who met inclusion criteria (PCL score > 40) were invited to participate in a brief, 4-session treatment within the context of a larger study. The 4 sessions focused on psychoeducation, behavioral activation to address avoidance, and mindfulness training. Participants completed the PCL-C, EPDS, and PSS at Baseline, session 2, session 4, Post-treatment Follow-up, and Postpartum Follow-up (10–14 weeks post-partum).

Results: Twelve (12) pregnant women completed the treatment and follow-up sessions. Linear modeling was used. Overall, self-reported scores showed a significant decrease from Baseline to Post-treatment Follow-up, on the PCL-C ($\beta = -4.708$, $SE = .580$, $p = 2.18e-9$), EPDS ($\beta = -1.0093$, $SE = .2844$, $p = 1.38e-09$), and PSS ($\beta = -1.0817$, $SE = .2861$, $p = 1.4e-09$). These improvements were maintained at the 10–14 week postpartum follow-up assessment.

Discussion: Brief, short term psychotherapy targeting avoidance and arousal in pregnant women with PTSD is effective in decreasing symptoms of both PTSD and depression. Gains were maintained into the postpartum which is significant as many women with mental health disorders during pregnancy are at higher risk for worsening in the postpartum.

Paper Session 19: Addressing Trauma and PTSD 4:00 PM-4:15 PM

RESISTANCE TRAINING REDUCES ANXIETY IN INDIVIDUALS WITH POSTTRAUMATIC STRESS DISORDER

Christopher T. Webster, MA¹, James W. Whitworth, MA², Nicholas J. SantaBarbara, MS, CSCS², Sanaz Nosrat, MA, CSCS¹, Mark E. Louie, Ed.M.¹, Joseph Ciccolo, PhD¹

¹Teachers College, Columbia University, New York, NY; ²Teachers College Columbia University, New York, NY

Background: Individuals with posttraumatic stress disorder (PTSD) frequently experience comorbid symptoms of anxiety and depression. Research has shown that these symptoms can poorly affect and exacerbate PTSD. Despite the well-known positive effects of exercise on anxiety and depression, few studies have examined how it can impact the anxiety and depression faced by individuals with PTSD. Additionally, no study has explored the potential benefits of resistance training (RT; i.e., weight lifting) on anxiety and depression in this population.

Purpose: This pilot study tested the effects of RT on anxiety and depression among a community sample of individuals with PTSD.

Method: 22 adults (ages 19–62, mean=33.0 ± 13.3; 81.1% female) who screened positive for PTSD, using the Posttraumatic Diagnostic Scale for DSM-5 (PDS-5; cutoff score ≥28), were randomly assigned to 3 sessions/week of RT for 3 weeks (n=11) or a time-matched, attention Control (n=11). Anxiety and depression were assessed using the State-Trait Anxiety Inventory and the Center for Epidemiologic Studies Depression Scale, respectively. Nineteen participants completed baseline and follow-up assessments (RT=9, Control=10). Differences in anxiety and depression were assessed using repeated-measures ANOVA, and effect sizes were calculated using Cohen's *d*.

Results: There were no significant group differences at baseline. At follow-up, there was a significant main effect of group for anxiety ($F=5.3$, $p=0.03$). Additionally, there was a significant group X time interaction for anxiety ($F=6.8$, $p=0.02$), such that the RT group significantly improved from baseline to follow-up (pre 54.7 ± 11.5 vs. post 46.2 ± 12.6) relative to the Control (pre 48.3 ± 11.8 vs. post 48.8 ± 13.8). Effect size calculations showed that RT had a larger beneficial effect on anxiety relative to the Control ($d=-0.70$ vs. 0.04). There were no significant differences between RT and the Control for depression ($p>0.05$). However, the effect size for RT and the Control on depression were $d=-0.59$ and $d=0.06$ respectively.

Conclusion: These findings suggest that 3 weeks of RT can help reduce anxiety in individuals who screen positive for PTSD. The lack of a significant effect of RT on depression was unexpected. However, these findings may be explained by the small sample size. Thus, additional adequately powered studies testing the effects of RT on anxiety and depression in those with PTSD are needed.

UNDERSTANDING HISTORICAL TRAUMA AMONG INDIGENOUS ADULTS AT RISK FOR DIABETES TO INFORM BEHAVIORAL INTERVENTIONS

Luis C. Garcia, MS¹, Jan j. Vasquez, MPH, CHES², Randall S. Stafford, MD, PhD, MHS³, Ida Sallas, Bachelor of Arts, Lifetime Teaching Credential, Masters in Education - Social Science and Reading⁴, Adrian E. Kendrick, B A Management⁵, Lisa Rosas, PhD, MPH⁶

¹Stanford University School of Medicine, Stanford, CA; ²Pathways to American Indian & Alaska Native Wellness (PAAW), San Jose, CA; ³Stanford University, School of Medicine, Stanford, CA; ⁴Pathways to American Indian and Alaska Native Wellness, san jose, CA; ⁵Pathways to American Indian and Alaskan Native Wellness (PAAW), Fremont, CA; ⁶Stanford University, Palo Alto, CA

Introduction: Culturally-specific behavioral interventions to address chronic conditions like diabetes among indigenous groups in the US, such as American Indian/Alaska Natives, are urgently needed. To develop effective interventions, the historical experiences of indigenous communities must be considered. Specifically, historical trauma—the transgenerational experience of group-wide trauma that manifests as emotional and psychological suffering—is critical given its impact on mental and physical health. However, little is known about historical trauma and associated symptoms among indigenous adults at risk for chronic disease.

Methods: Information on historical trauma was gathered using the Historical Loss (HL) and Historical Loss Associated Symptoms (HLAS) scales from 207 indigenous adults in California at risk for diabetes. We used separate HL scales for those with ancestry from the US/Canada and for those with ancestry from Mexico/Central/South America to reflect differences in historical traumatic experiences. Wilcoxon-Rank-Sum and Kruskal-Wallis tests were used to evaluate relationships between participant characteristics and HL and HLAS scores.

Results: Participants had a mean age of 52 (SD=13.3), a mean Body Mass Index of 37 (SD=6.1) and were primarily female (79%). Participants were indigenous to the US/Canada (57%) and Mexico/Central/South America (34%). Among participants with ancestry from the US/Canada, 49% thought about at least one historical loss, such as “the effects of loss of land on our people,” weekly, daily, or several times a day. Among participants with Mexican/Central/South American ancestry, 32% thought about at least one historical loss weekly, daily, or several times a day. Among all participants, 62% reported experiencing associated symptoms sometimes, often, or always. Indigenous ancestry from the U.S. or Canada ($p<.001$), depression ($p<.001$), and greater participation in cultural ($p<.001$) and spiritual ($p=.003$) activities were positively associated with HL scores. The same characteristics were positively associated with HLAS scores. Food insecurity was positively associated with HLAS scores ($p=0.003$).

Conclusion: Indigenous adults from the US and Canada who participated more frequently in culturally-relevant activities had higher HL and HLAS scores than their peers. Partnering with indigenous communities to identify and incorporate culturally-specific strategies into behavioral interventions has the greatest potential for effectiveness.

TRAUMA-INFORMED PRIMARY CARE PSYCHOLOGY: PREVALENCE OF SELF-REPORTED TRAUMA AND ITS RELATIONSHIP TO ANXIETY AND DEPRESSION

Sarah Griffin, MS, Allison B. Williams, M.S., Samantha Mladen, B.S., Sarah Braun, M.S., Bruce Rybarczyk, PhD

Virginia Commonwealth University, Richmond, VA

Introduction: Primary care is a critical access point for screening and treatment of depression and anxiety, particularly for low-income patients. Given the high prevalence of trauma exposure (and its mental/physical health sequelae), universal screening for trauma is recommended for primary care. However, in practice, clinicians often rely on patients to self-report trauma. To date, little research has investigated how frequently patients self-identify trauma as a problem area or how self-identified trauma influences common mood disorders and their treatment trajectories. Using a sample of low-income, primary care patients the present study aims to: 1) define prevalence of patients self-identifying trauma as a problem area, 2) analyze the effect that self-identified trauma has on depression/anxiety treatment at baseline and on the frequency of follow-up sessions, and 3) review other factors that may influence the relationship between depression/anxiety and trauma.

Methods: Data from patients ($n=927$; 31% male, 69% female; 32% White, 48% Black, 20% Other) who received primary care psychology services from 2012–2017 were analyzed using linear and logistic regressions. Patients self-reported trauma as a problem area and depression and anxiety were assessed with the PHQ-9 and GAD-7 respectively. Patients were categorized as white or of color for analyses due to sample size constraints.

Results: A total of 50 patients (7.5%) self-identified trauma as a problem area. Patient-identified trauma was associated with higher depressive symptoms ($b = 3.58$, $t(1) = 2.71$, $p < .01$) and more follow-up visits ($b = .86$, $t(1) = 2.23$, $p < .05$) when controlling for race, gender, and age. Patient-identified trauma was not a significant predictor of anxiety symptoms ($ps > .05$). Patients with self-reported trauma tended to be younger ($M = 40.39$) than participants who did not report trauma ($M = 46.85$; $\chi^2(1)=8.0$, $p < .01$); there were no significant differences due to race (white v people of color; $p = .57$) or gender ($p = .32$).

Conclusion: The prevalence rate of self-identified trauma was substantially lower than in studies with universal screening of trauma, suggesting that patients under-report trauma independently. Trauma was also shown to be associated with increased baseline depressive symptoms and increased follow-up visits. The present study's findings underscore the importance of systematic trauma screening and trauma-informed treatment in primary care.

Paper Session 20: Promoting the Health of Sexual and Gender Minorities 3:30 PM-3:45 PM

VALIDATING THE SYNDemic THREAT SURROUNDING SEXUAL MINORITY MEN'S HEALTH IN A POPULATION-BASED STUDY

Richard Bränström, PhD¹, John Pachankis, PhD²

¹Karolinska Institutet, Stockholm, Stockholms Lan, Sweden; ²Yale University, New Haven, CT

Background: Accumulating research on the syndemic health threats facing sexual minority men suggests that the vastly elevated risk of HIV among this population co-occurs with other health disparities, such as poor mental health and substance abuse. Identifying syndemic correlates of HIV infection among sexual minority men can spur the development of comprehensive interventions targeting these co-occurring vulnerabilities. Yet previous investigations into sexual minority men's syndemic health threats are limited in that they 1) rely on non-representative sampling, therefore potentially biased by self-selection, 2) rely on self-reported exposures, potentially conflated with disease outcome, 3) do not include a heterosexual comparison, thereby precluding comparison of disease comorbidity – a central tenet of syndemic theory, and 4) only assess sexual minority status as a function of behavior (i.e., MSM), rather than identity (e.g., gay, bisexual), which is more susceptible to the minority stress factors hypothesized to ultimately drive the syndemic threats facing this population.

Purpose: To conduct the first population-based examination of clinically assessed syndemic predictors of HIV infection among gay/bisexual, compared to heterosexual, men.

Method: The sample was comprised of adult males in the Stockholm Public Health Cohort 2010. In the cohort, a total of 29,328 (91.9%) self-identified as heterosexual, 535 (1.7%) as gay, and 396 (1.2%) as bisexual. We linked survey responses to health registry data.

Results: Gay men had vastly elevated risk of HIV infection (>150 times) compared to heterosexuals. Gay men also had an elevated risk of all psychosocial syndemic conditions (i.e., depression, substance abuse, lifetime suicide, and assaults) compared to heterosexuals. Bisexual men had 16 times higher risk of being HIV-positive than heterosexual men. Number of psychosocial syndemic conditions was significantly associated with HIV infection among gay men (adjusted odds ratio [AOR] = 1.51; 95% confidence interval [95% CI]: 1.03, 2.22), but not among bisexual and heterosexual men (AOR = 0.72; 95% CI: 0.12, 4.24; AOR = 1.57; 95% CI: 0.64, 3.86).

Conclusions: In the first study to investigate syndemic production using population-based sampling, clinically-derived disease indicators, and self-identified sexual orientation, results suggest that gay-identified men are significantly more likely to be diagnosed with HIV, and to experience co-occurring psychosocial conditions, than heterosexual or bisexually-identified men. This study confirms emerging research evidence for the existence of syndemic health threats affecting sexual minority men, finds stronger evidence for syndemics among gay compared to bisexual men, and suggests the need for HIV-prevention interventions that comprehensively address the co-occurring disparities affecting this group.

Paper Session 20: Promoting the Health of Sexual and Gender Minorities 3:45 PM–4:00 PM

ENGAGING SEXUAL AND GENDER MINORITIES IN IDENTIFYING STRATEGIES TO INCREASE PREP UPTAKE AND ADHERENCE IN THE MID-SOUTH

Latrice C. Pichon, PhD, MPH¹, Shanell McGoy, PhD, MPH², Velma McBride Murry, MS., PhD³, Donald Alcendor, MS, PhD⁴, Paul Juarez, PhD⁴

¹The University of Memphis School of Public Health, Memphis, TN; ²Tennessee Department of Health, Nashville, TN; ³Vanderbilt University, Nashville, TN; ⁴Meharry Medical College, Nashville, TN

Background: Increasing access to HIV prevention services and the promotion, uptake, and adherence of pre-exposure prophylaxis (PrEP) is paramount to ending the epidemic of HIV in the Mid-South among sexual and gender minority youth and young adults. The purpose of this qualitative pilot study was to explore strategies needed for and barriers to PrEP uptake and adherence among members of populations experiencing HIV disparities.

Method: Sexual and gender minority youth and young adults (n=20) at least 15 years of age from the Memphis, TN metropolitan area participated in 3 focus group discussions using a semi-structured discussion guide. Topics included motivations, barriers, and facilitators to PrEP use; sexual decision-making; and PrEP delivery personnel. Each focus group was audio recorded, transcribed verbatim, and session transcripts were analyzed using theme analysis strategies.

Findings: The majority of participants self-identified as HIV-negative (100%), Black/African American (95%), men who have sex with men (95%), and currently prescribed PrEP (80%). Emerging themes identified by participants to increase uptake and adherence included involvement of primary sexual partner, trusted and relatable healthcare provider (e.g., HBCU trained, LGBTQ), and use of social media for PrEP awareness. Addressing PrEP-related stigma, mislabeling of PrEP as promiscuity promoting, and limitations with PrEP marketing (e.g., solely LGBTQ) were recognized as barriers and perpetuating stigma.

Conclusions: These results will benefit community-academic research partnerships in efforts to improve strategies used by state and local health departments to increase PrEP uptake and adherence. Our data suggest extending PrEP awareness and training to medical providers matriculating at HBCUs; working closely with couples; and crafting PrEP messaging for broader audiences. Findings may inform the development of public health interventions for sexual and gender minority youth and young adults and help facilitate HIV prevention efforts to other groups disproportionately affected by HIV in the Mid-South.

Paper Session 20: Promoting the Health of Sexual and Gender Minorities 4:00 PM–4:15 PM

HOUSING INSECURITY AND HOMELESSNESS AMONG GENDER MINORITIES

Jennifer Glick, PhD¹, Miranda Pollock, MPH², Katherine Theall, PhD³

¹Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; ²Tulane University School of Public Health, New Orleans, LA; ³Tulane School of Public Health and Tropical Medicine, New Orleans, LA

Background: Housing is well understood to be an important social determinant of physical and mental health and well-being. Gender minorities are more likely to experience homelessness and housing discrimination than their cisgender counterparts. Housing insecurity, not just homelessness, is associated with barriers to health care and increased use of acute-care services. This study explores homelessness and housing insecurity among gender minority individuals.

Methods: Utilizing targeted ethnography, we conducted 41 semi-structured key-informant interviews with gender minority individuals throughout the USA. Interviews queried life stressors, particularly around homelessness and housing insecurity, and included personal experiences and community accounts, connections to other aspects of life, and coping strategies. Interviews were audio recorded and transcribed. Data was coded and analyzed for key themes using NVIVO 11.

Results: Respondents discussed an array of housing challenges throughout the gender minority community. About half of respondents reported personal stories; the others frequently shared peer accounts. Overwhelmingly, financial barriers were discussed regarding accessing secure housing, though family rejection and gender-related housing discrimination were discussed. Financial barriers focused on pervasive discrimination, which limited access to stable employment. Discrimination stories increased whenever the respondent was non-white, or trans-feminine, leading to even more financial barriers and insecure housing for these populations. Housing insecurity was linked to hygiene and health challenges, overall stress, and trouble maintaining work. Respondents discussed social support and alternative family structures as coping resources, as well as substance use.

Conclusions: Nearly all respondents discussed housing challenges as an issue in the gender minority community, and its link to other social wellbeing indicators, such as race based discrimination and maintaining employment, which then further destabilizes housing security. The study supports increased resources towards gender minority housing access and interventions into the cyclical discrimination, housing, and employment issues this population faces.

EXAMINING A BEHAVIORAL MODEL OF HEALTHCARE DELAY AMONG TRANSGENDER AND GENDER-NONCONFORMING ADULTS IN THE UNITED STATES

Megan Sutter, PhD

Moffitt Cancer Center, Brooksville, FL

Transgender and gender-nonconforming (TGNC) individuals have reported increased mental, behavioral, and physical health needs, as well as unique barriers to healthcare, largely due to stigma. TGNC individuals have also reported being denied medical care and postponing seeking care due to fear of discrimination, which may increase complications and severity of illness, and result in increased hospitalizations and healthcare costs. The current study examined robust associations among stigma-related stressors (i.e., vicimization and discrimination), personal and physician-related enabling factors, health needs, and past-year healthcare delay among an online convenience sample of 109 TGNC adults in the United States. A series of simple mediation models and serial mediation models were run using the Hayes Process Macro for SPSS to examine the indirect associations with delay as the outcome. Victimization and discrimination were significantly associated with delay through mental health ($ps < .05$). Also, victimization ($b = .24, p < .05$) and discrimination ($b = .32, p < .05$) were indirectly associated with delay through a cascade of indirect effects: TGNC-inclusive care → negative expectations → mental health → perceived behavioral control → delay. Lacking a TGNC-inclusive provider may exacerbate the effects of stigma on internalization, such as negative expectations about the future or fear of rejection, and worse mental health. These findings highlight the need for TGNC-friendly healthcare providers, which may serve as a buffer between exposure to victimization/discrimination and subsequent HCU delay. Internalization of stigma and resultant mental health problems may diminish perceived behavioral control through a cycle of social avoidance and isolation, resulting in avoidance of healthcare when needed. These findings highlight the need to address both TGNC individuals' timely use of care, and the quality of care they receive. It is imperative that future research takes a multi-level approach by creating and testing evidence-based interventions to improve both healthcare providers' competency, as well as for TGNC individuals' ability to coping with stressors.

INCORPORATING PATIENT-LEVEL PREFERENCES OF SEXUAL MINORITY MEN INTO PATIENT-PROVIDER INTERACTIONS ABOUT HIV PREVENTION

Eva N. Woodward, PhD¹, Jessica Cunningham, BA², Anthony WP. Flynn, BA³, Ethan Mereish, Ph.D.⁴, Sara Landes, Ph.D.⁵, JoAnn Kirchner, MD⁶, David W. Pantalone, Ph.D.⁷

¹Central Arkansas Veterans Healthcare System, North Little Rock, AR; ²Simmons College, Randolph, MA; ³U.S. Department of Veterans Affairs, Lake Balboa, CA; ⁴American University, Washington, DC; ⁵University of Arkansas for Medical Sciences, Little Rock, AR; ⁶VA QUERI for Team Based Behavioral Health, North Little Rock, AR; ⁷University of Massachusetts, Boston, Boston, MA

The objective of this study was to identify behaviors of healthcare providers that sexual minority men deemed to be helpful and unhelpful regarding HIV prevention. This is important because significant health disparities exist between sexual minority (e.g., gay, bisexual) and heterosexual men, especially regarding HIV infection. One factor that may contribute to health disparities is poor patient-provider interactions, which can lead to patient disengagement in healthcare. Although some work has been done on patient-provider interactions with marginalized groups, no patient-provider interaction models have been tailored for sexual minority men and HIV prevention. Providers are left without clear guidelines on what constitutes helpful or unhelpful behaviors regarding promoting HIV prevention behaviors among sexual minority male patients.

We recruited a sample of 20 HIV-negative sexual minority men who endorsed at least one psychosocial HIV risk factor (e.g., mental health problems, childhood sexual abuse) from online venues in the U.S. (e.g. listservs, social groups). We conducted individual interviews using the audio call feature of Skype. Among our sample, 55% identified as White and 65% reported annual incomes less than \$39,999 (Mean age = 28.45, SD = 7.68). A coding team of four coders used a type of qualitative analysis known as conventional content analysis and double checked results for accuracy through participant follow-up interviews.

Findings suggested that, from the perspective of sexual minority male patients, some providers are knowledgeable about sexual minority health and HIV prevention and yet, continue to contribute to poor patient-provider interactions (e.g., stereotyping patients, judgmental behaviors about sex). Also, some providers are knowledgeable and tailor treatment accordingly (the preferred interaction). Preferred interactions with sexual minority men regarding HIV prevention involved: providers (a) knowing about and being comfortable talking about sexual health, (b) knowing some information about sexual minority people and employing it routinely in practice (e.g., gay or bisexual health brochures, inclusive intake forms), (c) maintaining confidentiality, (d) creating comprehensive treatment plans, (e) providing education about treatment plans, and (f) providing care that is affordable and easy to access, and (g) treating psychosocial HIV risk factors (e.g., mental health problems), that indirectly helped participants remain HIV-negative. By integrating these findings with existing literature on patient-provider interactions for sexual minority people, we will present a preliminary model of patient-provider interactions that reflects preferences of sexual minority men regarding HIV prevention.

¹University of New South Wales, Randwick, New South Wales, Australia; ²University of New South Wales, Sydney, Australia, Sydney, New South Wales, Australia; ³University of New South Wales, Randwick, New South Wales, Australia; ⁴UNSW Sydney, Sydney, New South Wales, Australia; ⁵NHMRC Centre of Research Excellence in Mental Health and Substance Use, Sydney, New South Wales, Australia; ⁶Université de Montréal, Montreal, PQ, Canada

Background: Alcohol use and associated harms are among the leading causes of burden of disease among young people, highlighting the need for effective prevention. The Climate and Preventure (CAP) study was the first trial of a comprehensive approach to alcohol use prevention which combined a universal intervention (delivered to an entire school year group) with a personality-targeted selective intervention (delivered to high-risk students only).

Method: A cluster randomized controlled trial was conducted between 2012–2015 with 2190 students (mean age: 13.3yrs) from 26 Australian high schools. Participants were randomized to receive one of four conditions; universal prevention for all students (Climate); selective prevention for high-risk students (Preventure); combined universal and selective prevention (Climate and Preventure; CAP); or health education as usual (Control). All students were followed up for 3 years post-baseline and a longer-term follow is currently underway. This longer-term follow-up will extend over a critical risk-period as students transition from school to early adulthood, spanning 7 years post baseline and assessing drinking, drug use, and other risk behaviours.

Results: Analyses up to 3-years post baseline demonstrate the effectiveness of universal, selective and combined approaches in preventing harmful alcohol use among both low- and high-risk adolescents, as well as reducing mental health symptoms in the high-risk students. Compared to control group, effect sizes for the universal, selective and combined interventions ranged from $d = -0.21$ to $d = -0.56$ ($p < 0.05$), and Number Needed to Treat (NNT) values ranged from 6 to 12. These compare extremely favourably to other alcohol prevention programs. These results will be presented along with the study protocol of the long-term follow-up.

Conclusion: Results support the effectiveness of universal, selective and combined approaches to alcohol prevention up to 3 years post baseline. As very little is currently known about the effectiveness of school-based prevention programs beyond age 17, the longer-term follow-up of the CAP study which is underway will address a crucial knowledge gap. We hope the findings will indicate which prevention approaches are most sustainable long-term, vital information to inform policy nationally and internationally, as economic modelling suggests substantial societal benefit can be gained from even modest reductions in alcohol use.

Paper Session 21: Understanding and Addressing Alcohol Use 3:45 PM-4:00 PM

POSITIVE CHOICES: ADDRESSING THE EVIDENCE-PRACTICE GAP IN ALCOHOL AND OTHER DRUG PREVENTION

Lexine A. Stapinski, PhD, M.ClinPsych, BPsych(Hons)¹, Nicola C. Newton, PhD², Lucinda R. Grummitt, Bachelor of Arts (Psychology)³, Cath Chapman, PhD², Maree Teesson, BSc Psych(Hons), PhD²

¹University of New South Wales, Sydney, Australia, Sydney, New South Wales, Australia; ²UNSW Sydney, Sydney, New South Wales, Australia; ³National Drug and Alcohol Research Centre, Lavender Bay, New South Wales, Australia

Background. Onset of alcohol and other drug use typically occurs during adolescence; thus preventative initiatives need to occur early on, prior to exposure. Schools are an ideal place to implement harm prevention strategies, with the potential for broad-ranging impact and tailoring of messages to suit students' developmental level. In parallel, parents require guidance about how they can protect against harms associated with drug use. There is increasing evidence that the risk of alcohol and other drug harms among teenagers can be reduced substantially with the right prevention strategies. Despite this, evidence-based drug prevention approaches are not widely implemented.

Objectives. The Positive Choices project aims to address a known evidence-practice gap in the implementation of alcohol and other drug prevention approaches.

Method. The Positive Choices portal was developed to provide a central resource where school staff, young people and their parents could easily access evidence-based drug information and prevention strategies. The portal was developed in consultation with drug and alcohol experts, as well as target users in Australia. Research literature and drug education websites were systematically reviewed to identify resources meeting pre-specified inclusion criteria for relevance and evidence quality. A post-launch evaluation was conducted, guided by the Reach, Effectiveness, Adoption, Implementation and Maintenance (RE-AIM) model, with school staff ($n=107$) and parents ($n=50$) post-launch to assess the success of the initiative and determine progress towards evidence-based practice.

Results. In the two years since launch, the Positive Choices portal and accompanying webinar series have been accessed by over 85,000 users across Australia and internationally. Evaluation feedback from teachers and parents indicated that the games, videos and factsheets were the most accessed drug prevention resources on the site. Eighty four percent of respondents said they would continue to use the portal, and 89% said they would recommend Positive Choices to a friend or colleague. There was evidence that use of the portal changed respondents attitudes and intentions to implement evidence-based prevention strategies.

Conclusion: This study represents the first implementation and evaluation of a national drug prevention initiative in Australia. Findings suggest *Positive Choices* has achieved broad reach, and increased awareness and future intentions to implement evidence-based prevention strategies.

Paper Session 21: Understanding and Addressing Alcohol Use 4:00 PM-4:15 PM

THE 'REIGN OF ERROR' IN ADOLESCENTS' PERCEPTIONS OF PEER DRINKING NORMS IN US SECONDARY SCHOOLS

Jessica M. Perkins, PhD¹, H. Wesley Perkins, PhD², David Craig, Ph.D.³

¹Vanderbilt University, Nashville, TN; ²Hobart & William Smith Colleges, Geneva, NY; ³Hobart and William Smith Colleges, Geneva, NY

Past work on social norms and alcohol use among college students has found pervasive overestimations of peer drinking norms and that the frequency and quantity a student believes peers to drink predicts personal consumption. Few studies have examined whether similar phenomena are found among middle school and high school students. Yet, students' perceptions of peer norms within the school context may be an important determinant of adolescent alcohol use as youth look to peers for social cues on what to believe and how to behave during an important development period. This study distinguishes between perceived and actual peer norms for alcohol use among 27,545 students in grades 6–12 across 63 schools in 11 states from 1999 to 2014. Data were collected via anonymous online surveys on students' perceptions of the most common drinking behaviors among same-grade same-school peers as well as data on personal drinking behaviors, which determined actual norms. Within 83% of grade-school cohorts (179 out of 216), the majority of students rarely consumed alcohol (never or only 1-2x per year). This peer norm of abstinence/rare use was misperceived, however, by two-thirds of the students in these grade cohorts who thought that their peers typically consumed alcohol more frequently. Further, one-third of students in these cohorts erroneously believed most peers drank weekly or more often. In the other 37 cohorts where monthly alcohol use was the actual norm, overestimations of this peer norm were equally pervasive. Overall 83% of students believed consumption to be more frequent than the actual cohort norm. Other measures of consumption demonstrated similar disparities between actual and perceived norms across all cohorts. Misperceptions were pervasive across racial groups, school socio-economic status, size of grade-school cohort, and time periods within this study. Misperceiving frequent drinking as the norm and misperceiving drinking large quantities as the norm among cohort peers strongly predicted personal drinking. Perceptions of the norm were a stronger predictor of personal behavior compared to several other individual and school-level factors, including actual peer norms. Researchers should design experiments to assess causal direction while also testing interventions to reduce misperceptions, and presumably reduce actual alcohol use. Practitioners could begin to explore comprehensive ways to promote the awareness of positive actual norms among students.

Paper Session 21: Understanding and Addressing Alcohol Use 4:15 PM-4:30 PM

ETHNIC DIFFERENCES IN THE RELATIONSHIP BETWEEN CHILDHOOD ADVERSITY AND SUBSTANCE USE AMONG UNDERGRADUATE COLLEGE STUDENTS

Myriam Forster, PhD, MPH¹, Joshua Manlutac, N/A², Christopher Rogers, BS³, Stephanie M. Benjamin, Ph.D., M.P.H.², Marla Eisenberg, Sc.D. M.P.H.⁴

¹California State University, Northridge, Santa Monica, CA; ²California State University, Northridge, Northridge, CA; ³California State University, Northridge, Castaic, CA; ⁴University of Minnesota, Minneapolis, MN

Introduction: Despite evidence that suggests college students have high rates of substance use and misuse and a high prevalence of adverse childhood experiences (ACE), whether ACE related substance use patterns vary across ethnic groups remains unknown. However, the increasing size and diversity of college populations calls for research that can determine if ACE-related substance use behaviors are similar or different across ethnic groups and whether college communities would benefit from the development of culturally-informed prevention services for at-risk students. The present study, using an ethnically diverse sample of undergraduates from two states, examined the prevalence of ACE exposure; marijuana, tobacco, and alcohol use; and if the association between individual and accumulated ACE and substance use varied across ethnic background.

Methods: Data are student responses (N=7,184) on a standardized college health surveillance instrument administered in 2016 in west-coast and mid-west colleges. A series of multivariable logistic regression models assessed the direct associations between individual ACE and substance use (adjusting for age, gender, state, depressive symptoms), and the graded effects of ACE for substance across non-Hispanic White, Hispanic, African American, African, Asian/Pacific Islander, and multiracial students.

Results: Across the two states, 22% of students reported using marijuana, 29% had smoked tobacco, 75% had used alcohol, and 30% acknowledged binge drinking. There were significant differences in the prevalence of substance use and ACE across ethnic groups ($p < 0.01$) and in the strength and significance of the graded relationship between ACE and use of each substance. The increase in odds of substance use associated with every additional ACE reported by students was especially pronounced among ethnic minority students (OR range 1.21 - 2.51, $p < .001$).

Conclusions: Our results, using data from a large cross section of college students, comport with preliminary studies suggesting that many students may be using substances to cope with ACE related distress. The variability in ACE related substance use patterns across ethnic groups highlights the need for research that can advance our understanding of how ethnicity and culture influence trauma response and the role of campus communities in the development of culturally informed prevention services.

ANXIETY, DRINKING TO COPE, AND THE TRANSITION TO HIGH RISK ALCOHOL USE IN EARLY ADULTHOOD

Lexine A. Stapinski, PhD, M.ClinPsych, BPsych(Hons)¹, Jon Heron, PhD², Andrew Baillie, PhD, M.ClinPsych³, Nicola C. Newton, PhD⁴, Liam Mahedy, BA Psychology, PhD², Gemma Hammerton, PhD², Alexis Edwards, BS, PhD⁵, Kenneth Kendler, MD, PhD⁵, Maree Teesson, BSc Psych(Hons), PhD⁴, Matthew Hickman, BSc(Lanc), MSc(Aberd), PhD(Lond)²

¹University of New South Wales, Sydney, Australia, Sydney, New South Wales, Australia; ²University of Bristol, Bristol, England, United Kingdom; ³University of Sydney, Sydney, New South Wales, Australia; ⁴UNSW Sydney, Sydney, New South Wales, Australia; ⁵Virginia Commonwealth University, Richmond, VA

Background. Anxiety and alcohol use disorders commonly co-occur, and if left untreated, can fuel each other in a feed-forward cycle. The transition from adolescence to adulthood is a key risk period for onset of both disorders, yet little is known about the developmental unfolding of these disorders over young adulthood, or how best to prevent their escalation.

Aims. This research aims to i) examine the relationship between anxiety, coping-motivated drinking and transition to hazardous alcohol use over this important developmental period; and ii) inform the development of an early intervention for young adults to prevent the escalation of anxiety and alcohol use problems.

Methods: At ages 17 and 21, participants (n = 2,148) from a UK birth cohort reported their alcohol use and related problems, anxiety symptoms, and use of alcohol to cope with emotional symptoms. Latent transition analysis was used to identify alcohol use subtypes at each timepoint, and examine the effect of anxiety and coping motives on transition from low- to high-risk use over this period.

Results: Three distinct profiles were identified. At age 17, the majority of participants were classified as “low-risk” drinkers, with a smaller “binge” class (22%) reporting binge-drinking at least monthly. By age 21, the binge-drinking group had grown to 36% and a third “high-risk” class (8%) emerged, showing markedly increased rates of alcohol-related harm. Anxiety disorder and drinking to cope were associated with higher risk alcohol use at both waves. Young people who reported coping-motivated drinking were at increased risk of moving from low-risk to high-risk alcohol use over the transition to adulthood. A one standard deviation increase in drinking to cope at age 17 was associated with a doubling of the odds of transitioning from a low-risk to high-risk state (OR = 2.01, 95% CI=[1.51, 2.69]) and increased risk of moving from a low-risk to bingeing state (OR = 1.42, 95% CI=[1.16, 1.74]).

Implications: Anxiety, and in particular drinking to cope with anxiety, is associated with adverse drinking patterns in early adulthood. Results will be discussed with a focus on implications for development of a novel youth-focused intervention, the “inroads” program, to address harmful alcohol use occurring in the context of anxiety symptoms.

Paper Session 22: Innovations in Supporting the Healthy Veterans 3:30 PM-3:45 PM

PROMOTING PARTICIPATION: OUTCOMES INDICATIVE OF A QUALITY PHYSICAL ACTIVITY EXPERIENCE FOR VETERANS WITH A DISABILITY

Celina Shirazipour, PhD¹, Amy Latimer-Cheung, PhD²

¹Dalhousie University, CALGARY, AB, Canada; ²Queen's University, Kingston, ON, Canada

Background: Individuals with disabilities have a basic right to full participation in society – a right not currently experienced in physical activity (PA). One main knowledge gap in promoting full PA participation is a comprehensive understanding of the concept of quality participation. As a result, researchers are currently aiming to develop a model of quality PA participation by identifying the components of quality participation. To date, while the precursors and elements of quality participation have been identified, the outcomes indicative of a quality participation experience remain undefined.

Purpose: The current study aimed to fill this gap by determining what outcomes are indicative of a quality PA experience within a specific population: military veterans with a physical disability. PA programs have proliferated internationally as a way of supporting veterans post-injury. Unfortunately, there is no evidence to support optimal program development and delivery or program evaluation. Understanding the outcomes that veterans desire from quality PA experiences is key to building this evidence base and, thus, improving programs and participant experiences.

Methods: Eighteen veterans (15 men, 3 women) with a physical disability (e.g. amputation, spinal cord injury) who participate in PA programming (e.g. sport, therapeutic recreation, physical challenges) took part in semi-structured interviews. An inductive thematic analysis was conducted to identify patterns indicative of quality outcomes.

Results: Four overarching themes were identified: (1) Physical health and fitness outcomes (i.e. achieving and maintaining optimal physical health); (2) Psychological outcomes (i.e. mental healing, a sense of accomplishment, enjoyment, and a boost in mood state); (3) Social outcomes (i.e. building a social network, protecting against stigma, and having a prosocial influence); and (4) Life opportunities (i.e. new avenues including employment, and certifications).

Discussion: The first three overarching themes have previously been identified in the literature. However, the value of the findings lies in the unique sub-themes, which identify specific outcomes which veterans with a disability link to quality experiences. The results are also beneficial in identifying novel outcomes which have not been previously explored, including stigma, prosocial behaviours, and opportunities that emerge beyond PA.

Conclusion: This research contributes to the development of a model of quality PA participation for individuals with disabilities – particularly veterans. Through these contributions, researchers can support PA program staff by providing evidence as to how programs can provide quality experiences, and ultimately promote the basic human right to full participation in society.

PREDICTORS OF INFORMATION SHARING IN A MILITARY MENTAL HEALTH STIGMA REDUCTION INTERVENTION

Emily A. Schmied, PhD, MPH¹, Cynthia Simon-Arndt, MA, MBA², Colleen McBrien, Psy.D³, Rosemarie Subala, MPH², Renee Dell'Acqua, BA², Jennifer Belding, PhD², Isabel Altarejos, MPH², Suzanne Hurtado, MPH²

¹Naval Health Research Center, LEIDOS, San Diego, CA; ²Naval Health Research Center, San Diego, CA; ³LEIDOS consultant, San Diego, CA

Background: Military service members face increased risks for mental health issues. Because mental health stigma is associated with adverse mental health outcomes, it is critical to develop interventions that reduce stigma and increase support-seeking behavior. Research suggests stigma can be reduced through media campaigns and by encouraging individuals to talk about mental health; however, it is unknown if individuals who view stigma reduction materials will talk to others about what they learn. The objective of this study was to examine predictors of health information sharing among service members participating in a stigma reduction intervention.

Methods: Participants included 85 Marines (87.1% male; age =25.4; SD=6.7) who completed one of two interventions. Both study groups viewed a 35-minute video designed to demystify mental health treatment by describing various aspects of treatment (e.g., types of providers and treatments, parameters of confidentiality). One study group also engaged in a 15-minute in-person discussion about the video with a clinical psychologist. Participants completed a self-report questionnaire at baseline, immediately following the intervention, and 6 weeks later. Demographic and military service characteristics, mental health symptoms, and stigma toward mental health treatment seeking were assessed at baseline, the immediate follow-up survey assessed video ratings and reassessed stigma; information sharing (yes/no) was assessed at the 6-week follow-up.

Results: After 6 weeks, 61.4% of participants had shared what they learned from the video with at least one person. Bivariate analyses revealed several predictors of information sharing, including female sex, higher rating of the video, lower stigma, and participation in the discussion. A multivariable model including all variables significant at the univariate level showed women (OR=18.7, $p=0.05$).

Discussion: Engaging participants in active discussions regarding mental health treatment may increase the likelihood thereby increasing the reach of the message and potentially reducing stigma. Future stigma interventions should incorporate active discussions and explore methods for increasing information sharing among men.

Paper Session 22: Innovations in Supporting the Healthy Veterans 4:00 PM-4:15 PM

EFFECTS OF SOCIAL SUPPORT DURING AND AFTER DEPLOYMENT ON HAZARDOUS ALCOHOL USE AMONG ARMY RESERVE AND NATIONAL GUARD COUPLES

Erin Anderson Goodell, S.M.¹, D. Lynn Homish, BS², Gregory G. Homish, PhD²

¹Johns Hopkins University, Bloomberg School of Public Health, Ormond Beach, FL; ²University at Buffalo- State University of New York, Buffalo, NY

Background: Research suggests that interpersonal support is beneficial to military personnel and families in curbing deployment-related mental health issues. However, there is limited research examining the deployment timeline and crucial periods where support might be more protective against negative outcomes. This research examines the effects of support during and after deployment on hazardous alcohol use by both military personnel and civilian partners.

Methods: Data are from the baseline assessment of Operation: SAFETY (Soldiers And Families Excelling Through the Years), an ongoing longitudinal study of Army Reserve and National Guard soldiers and their partners. Logistic models examined relationships between current hazardous alcohol use (AUDIT ≥ 8) and experiences of social support both during and after most recent deployment (DRRI score and average closeness to past-year social ties, respectively). Separate models are examined for 248 male soldiers who have been deployed and 130 female civilians whose current partner had been deployed during their relationship. Models controlled for partner's alcohol use and combat exposure severity during deployment.

Findings: For male soldiers, higher DRRI scores are associated with lower unadjusted odds of hazardous alcohol use (OR=0.94 [0.91–0.98], $p=0.004$), while the unadjusted relationship for average closeness and alcohol use is non-significant. When simultaneously assessing the effects of both support types, higher DRRI scores continue to be inversely related to alcohol use (OR=0.94 [0.90–0.98], $p=0.003$), and average closeness is non-significant.

For female partners, as with male soldiers, the unadjusted likelihood of current hazardous alcohol use is inversely related to higher DRRI scores (OR=0.95 [0.90–1.00], $p=0.033$), and alcohol use is not related to average closeness. However, when assessing the two types of support together, findings now show a significant inverse relationship between average closeness and likelihood of hazardous alcohol use (OR=0.25 [0.10–0.65], $p=0.005$), with DRRI no longer being significant.

Conclusions: Support during deployment may be protective for male soldiers, whereas higher levels of closeness with social ties post-deployment may be protective for female partners. These findings have implications for timing and strategy when providing or supplementing deployment support to curb negative health outcomes. Future efforts should focus on the role of support in marital partnerships with female soldiers.

Supported by R01-DA034072 and T32-DA007292.

Paper Session 22: Innovations in Supporting the Healthy Veterans 4:15 PM-4:30 PM

IS SOCIAL MEDIA A VENUE FOR HELP-SEEKING AMONG MILITARY VETERANS WITH MENTAL HEALTH PROBLEMS?

Alan R. Teo, M.D., M.S.¹, Heather Marsh, M.A.², Samuel B. L. Liebow, N/A¹, Christopher W. Forsberg, M.S.², Christina Nicolaidis, M.D., M.P.H.³, Steven K. Dobscha, M.D.²

¹Oregon Health & Science University, Portland, OR; ²VA Portland Health Care System, Portland, OR; ³Portland State University, Portland, OR

Background: The media has devoted significant attention to anecdotes of military veterans and other individuals who post messages on Facebook prior to suicide. However, it is unclear to what extent social media is perceived as a source of help, or how it compares to other sources of potential support for mental health problems.

Methods: This was a cross-sectional study of 270 adult military veterans with probable major depression. Help-seeking intentions were measured with a modified General Help-Seeking Questionnaire, with choices ranging from 1 (“Extremely unlikely”) to 7 (“Extremely likely”). Facebook users and non-users were compared via t-tests, chi-square tests, and mixed effects regression models. Associations between types of help-seeking among Facebook users were examined using mixed effects models.

Results: The majority of participants were users of social media, primarily Facebook (n=162). 76% (n=206) endorsed having at least one source of help they intended to use if having suicidal thoughts. Mean help-seeking intentions for each included help source were similar between Facebook users and non-users, even after adjustment for potential confounders. Facebook users were very unlikely to turn to Facebook as a venue for support when experiencing either an emotional problem (mean score 1.67) or suicidal thoughts (mean score 1.41). Compared to help-seeking through Facebook, they had significantly higher help-seeking intentions for formal sources such as psychologists (mean scores 4.42 for emotional problem, 4.16 for suicidal thoughts; $p < .001$), informal sources such as friends (mean scores 3.69 for emotional problem, 3.18 for suicidal thoughts; $p < .001$), and phone help lines (mean scores 2.89 for emotional problem, 3.33 for suicidal thoughts; $p < .001$). Results did not substantially change when examining individuals who frequently used or actively posted on Facebook.

Conclusions: Without interventions that modify health attitudes or behaviors, the typical military veteran with major depression in the United States appears unlikely to seek help for emotional problems or suicidality via social media.

OPTIMIZING FACEBOOK ADS TO REACH AND RECRUIT MILITARY VETERANS IN RESEARCH: A FACTORIAL DESIGN

Alan R. Teo, M.D., M.S.¹, Samuel B. L. Liebow, N/A¹, Benjamin K. Chan, M.S.², Steven K. Dobscha, M.D.³, Amanda L. Graham, PhD⁴

¹Oregon Health & Science University, Portland, OR; ²OHSU-PSU School of Public Health, Portland, OR; ³VA Portland Health Care System, Portland, OR; ⁴Truth Initiative, Washington, DC

Background: Prior research has demonstrated the feasibility of recruiting research participants through Facebook ads, but less is known about the effectiveness of Facebook ads in reaching military veterans with health problems who are not engaged in VA care. This study tested the effectiveness of 15 ads in reaching this target population.

Methods: Facebook ads tailored to military veterans ran for 6 weeks, beginning January 2017. The call to action was completing an online health survey. Using a full 3x5 factorial design, ads varied imagery (person taking a survey; veteran with his family; soldiers marching) and headlines informed by behavioral economics principles (social norms; altruism; empowerment; incentive; and sharing). Reliable and valid self-report tools were used to screen for mental health problems (PC-PTSD, AUDIT-C, PHQ-2, and DSI-SS). Outcomes were click-through rate (CTR), survey completion, and cost per survey completed. Negative binomial models incorporating the full factorial design were used to compare image and headline main effects and interactions on each outcome.

Results: Overall, advertisements produced 827,918 impressions and 9,527 clicks (CTR=1.20%). 710 individuals were eligible for the survey, and 587 completed the survey (83% response rate). One hundred fifty-five participants (26%) had never been enrolled in the VA, and 322 (55%) had not used VA health care services in the prior year. Participants frequently screened positive for current mental health problems, including PTSD (52%), problematic drinking (51%), major depression (28%), and suicidality (22%). Total ad expenditure was \$11,427, yielding an average cost per completed survey of \$19.47.

The soldiers marching image had a higher CTR than other images ($p < 0.001$). “Sharing” and “incentive” headlines had higher survey participation than social norms ($p < 0.001$ and $p = 0.008$, respectively). Half of survey participants (n=285) were recruited by just 2 of the 15 ads: soldiers marching with an “incentive” headline and “sharing” headline. These two ads were also the most cost effective, at \$4.88 and \$5.90 per participant, respectively.

Conclusions: Facebook ads are effective in rapidly and inexpensively reaching military veterans, including those at-risk for mental health problems who are not receiving VA healthcare. Features such as images of soldiers, and headlines mentioning incentives or a request to share the ad with others may help optimize effectiveness of ads.

Symposium 31

3:30 PM-4:45 PM

FUNCTION FOCUSED CARE: CHANGING BEHAVIOR IN CAREGIVERS AND COGNITIVELY IMPAIRED OLDER ADULTS

Barbara Resnick, PhD, CRNP, Sarah Holmes, MSW, Elizabeth Galik, PhD, CRNP, Barbara Resnick, PhD, CRNP

University of Maryland, Baltimore, MD

Residents in long term care environments engage in limited amounts of physical activity and decline functionally more rapidly than would be expected based on disease. Reasons for decline are multifactorial and include resident factors (e.g., comorbidities, age, cognition) and setting factors (e.g., caregivers, environments and policies), among others. Environments in long term care settings impose barriers, particularly for cognitively impaired residents that minimize opportunities for physical activity. Depending on the settings, some may have limited open space for physical activity, and ambulation is discouraged because direct care workers and families fear residents will fall. Residents and families expect that direct care workers will complete necessary care tasks (e.g., the resident will be bathed and dressed) and often become distressed if direct care workers just provide encouragement, cueing or minimal assistance needed to assure that residents walk, dress and bathe at their highest level. Once residents are no longer allowed or encouraged to perform an activity, they lose the ability and motivation to do so. To address this persistent decline in functional and physical activity, we implement function focused care. Function focused care teaches caregivers to optimize the residents' participation in all activities. Examples of function focused care interactions include: modeling behavior for residents (e.g., oral care); providing verbal cues during dressing; walking a resident to the dining room; and providing recreational physical activity (e.g., Physical Activity Bingo). Implementation of Function Focused Care includes a four step approach: (1) Evaluation of Policies and Environments; (2) Education; (3) Evaluation of resident capability and goal setting; and (4) mentoring and motivating. Implementation of Function Focused Care improves resident function, physical activity and mood among and decreases transfers to the hospital. For caregivers, exposure to Function Focused Care consistently resulted in an increase in knowledge related to function focused care and the amount of function focused care provided. This session will review the impact of the environment on function focused care, innovative approaches for how to provide function focused care to those with moderate to severe cognitive impairment and the testing of an approach to disseminate and implement function focused care to 100 assisted living settings.

Symposium 31A

DISSEMINATION AND IMPLEMENTATION OF FUNCTION FOCUSED CARE 100 SETTINGS AT A TIME

Ms. Barbara Resnick, PhD, CRNP

There are resident and setting level challenges to dissemination and implementation of Function Focused Care in assisted living. Resident challenges include medical events, advanced age; sociodemographic characteristics; comorbidities; cognitive impairment and behavioral symptoms; lack of motivation; culture; pain; fear of falling; body mass index; and polypharmacotherapy. Setting level challenges include environments and policies that seek to minimize risk by limiting opportunities for physical activity and limited resources. To disseminate and implement Function Focused Care into 100 settings we identified resident and setting challenges, optimized use of available resources and provided direct care workers with ways in which to overcome these challenges using a theoretic approach that involves four steps: 1. Evaluation of the environment and policies; 2. Education; 3. Resident goals; 4. Mentoring and motivation. Social cognitive theory (SCT) was combined with the Social Ecological Model and the Evidence Integration Triangle (EIT). The SEM includes intrapersonal, interpersonal, environmental, and policy factors that influence behavior. SCT guides the interpersonal interactions that motivate direct care workers and residents. Self-efficacy and outcome expectations, the main components of social cognitive theory, are dynamic and enhanced by four mechanisms: (1) successful performance of the activity; (2) verbal encouragement; (3) seeing like individuals perform the activity; and (4) elimination of unpleasant physiological and affective states associated with the activity. We taught direct care workers to use SCT approaches to overcome many of the resident level challenges. The pragmatic EIT process begins and ends with engagement of local stakeholders. Guided by the EIT we involved a stakeholder team, selected by the setting, to be part of the implementation and evaluation process. Use of EIT integrates evidence with practical approaches and measures and assures continual feedback from stakeholders. We built off available resources within each setting (e.g., develop direct care workers as champions). The findings from our dissemination and implementation activities to 100 settings resulted in reaching over 1,000 residents, and improving policies and environments to facilitate function and physical activity among residents and resulted in a decrease in falls and hospital transfers. Findings from our first cohort of a second dissemination and implementation study will also be presented to reflect additional resident outcomes. Although behavior change in long term care is particularly challenging as it involves a two tiered approach that includes changing behavior among staff as well as residents, the use of the SEM, SCT and EIT is successful in making behavior change a reality.

Symposium 31B

THE IMPACT OF ENVIRONMENT ON FUNCTION AND PHYSICAL ACTIVITY

Sarah Holmes, MSW

Physical activity is important for health, well-being, and life-satisfaction of older adults in long term care settings. However, little is known about how the environmental influences and helps motivate residents in these settings to engage in physical activity. The purpose of this study was to examine factors that influence physical activity among residents in Assisted Living environments. We hypothesized that controlling for depression, cognition, comorbidities, and gender, residents who reported higher levels of satisfaction with their environment would be more likely to engage in physical activity. This was a secondary data analysis using baseline data from an intervention study testing the impact of function focused care in Assisted Living. A total of 171 residents from four Assisted Living facilities were included. Demographic information, mood, cognition, life satisfaction, time spent in physical activity based on the Physical Activity Survey for Long-Term Care (PAS-LTC) and social support for physical activity were obtained. Structural equation modeling was used to test the proposed model. The majority of participants were female (N=136, 80%) and Caucasian (N=160, 94%) with a mean Mini Mental Status Exam score of 23.2 (SD=4.9). Depression, satisfaction with staff and activities, and social support for exercise were directly associated with time spent in physical activity. Gender, cognition, depression, and number of comorbidities were indirectly associated with time spent in physical activity and accounted for 13% of the total variance in physical activity. These findings indicate that, although mood, cognition and gender influence physical activity, residents' satisfaction with staff and staff encouragement are novel factors influencing time spent in physical activity and should be the focus of future interventions.

Symposium 31C

TRICKS OF THE TRADE FOR BEHAVIOR CHANGE AMONG COGNITIVELY IMPAIRED OLDER ADULTS AND STAFF

Elizabeth Galik, PhD, CRNP

To optimally change behavior among staff and cognitively impaired residents we use a four step approach that includes first the assessment of policies and the environment to assure that there are no barriers to engaging residents in functional tasks and physical activity. Further we encourage instituting new policies that will assure residents are physically active, regardless of cognitive deficits. For example, we facilitate the implementation of Walk-to-Dine programs, the placement of weights at tables for residents to use while waiting for meals, and the development of open outside areas to walk. The second step is education of staff which is done in a way that best fits with the work flow and educational patterns of the setting. For some, we do one-on-one education on the unit and use a multiple choice test to complete the teaching. Formal group education is also done with testing to assure that information at least didactically has been increased such that there is an overall mean score of 80% on the Knowledge Tests for Function Focused Care. The third step is the completion of a capability assessment of the residents which is taught to staff. Assessment of capability involves evaluation of the resident's cognition and ability to follow commands as well as underlying physical ability related to range of motion, balance and ambulation. From this assessment, appropriate functional and physical activity goals are developed with the resident as he or she is able. Lastly we focus on motivation and mentoring of staff and residents. For staff motivation, we implement contests which include such things as sit-to-stand contests or wheelchair race contests so they experience what the residents' challenges might be. In addition, we have contests to see who can provide the best ideas for engaging residents in physical activity related to a holiday or outdoor activities. Lastly, we provide ongoing mentoring and motivating by providing a weekly Tidbit with ideas for how to engage residents in physical activity in innovative ways such as through household tasks. We have established techniques such as use of less touch and less talk as ways to engage residents. Findings support the value of function focused care with cognitively impaired older adults as a way to maintain and improve function and time spent in physical activity.

A SMARTPHONE-BASED APPROACH TO GATHERING TWICE-DAILY REPORTS OF COMMUNICATION AND MOOD AMONG COUPLES COPING WITH CANCER

Shelby Langer, PhD¹, Michael Todd, PhD¹, John Burns, PhD², Joan M. Romano, Ph.D.³, Niall Bolger, Ph.D.⁴, Jonathan B. Bricker, PhD⁵, Karen Syrjala, PhD⁵, Francis Keefe, PhD⁶, Timothy J. Strauman, PhD⁷, Neeta L. Ghosh, MA, MPH⁵, Blair Puleo, BA⁶, Julie Gralow, MD³, Veena Shankaran, MD, MS⁸, Kelly Westbrook, MD⁹, Yousuf Zafar, Associate Professor¹⁰, Laura Porter, PhD⁶

¹Arizona State University, Phoenix, AZ; ²Rush University Medical Center, Chicago, IL; ³University of Washington, Seattle, WA; ⁴Columbia University, New York, NY; ⁵Fred Hutchinson Cancer Research Center, Seattle, WA; ⁶Duke University Medical Center, Durham, NC; ⁷Duke University, Durham, NC; ⁸University of Washington; Fred Hutchinson Cancer Research Center, Seattle, WA; ⁹Duke University School of Medicine, Durham, NC; ¹⁰Duke Cancer Institute, Durham, NC

Questionnaire-based studies of couple communication in cancer indicate that avoidance of disclosure is associated with psychological distress but this work is largely cross-sectional and retrospective. We examined concurrent and lagged associations between communication and negative affect (NA) using a smartphone application to gather *ecological momentary* data based on standard questionnaire items: protective buffering (4 items), holding back (3 items), responsiveness and perceived partner responsiveness (3 items each; to what extent did you support/ understand/ criticize your partner; to what extent did your partner support/ understand/ criticize you), and NA (9 items). Participants were persons with stage 2–4 breast or colorectal cancer, and their partners. Patients and partners independently received 2 smartphone notifications/ day for 14 days. To date, 30 patients and 29 partners have provided data: M (SD) age = 51.0 (11.7), 60% female, 83% Caucasian, and 7% Hispanic [patients]; M (SD) age = 50.6 (11.4), 45% female, 83% Caucasian, and 3% Hispanic [partners]. 1284 (82%) of 1567 prompts were responded to. For patients, afternoon and evening holding back ($bs = 0.09$ and 0.19) and evening protective buffering ($b = 0.21$) were associated with greater concurrent NA, $ps < .01$; afternoon perceived partner responsiveness was associated with lower concurrent NA ($b = -0.12$, $p = .001$). Lagged analyses adjusting for afternoon NA approached significance, with afternoon protective buffering ($b = 0.07$, $p = .083$) and holding back ($b = 0.06$, $p = 0.05$) predicting greater evening NA. In cross-lagged analyses, afternoon NA predicted greater evening protective buffering and holding back ($bs = 0.28$ and 0.39 , $ps < .01$). For partners, afternoon and evening protective buffering ($bs = 0.15$ and 0.08) and holding back ($bs = 0.15$ and 0.14) were associated with greater concurrent NA, $ps < .05$. Afternoon and evening responsiveness ($bs = -0.19$ and -0.23) and perceived partner responsiveness ($bs = -0.21$ and -0.23) were associated with lower concurrent NA, $ps < .001$. In lagged analyses, afternoon holding back ($b = 0.09$, $p < .01$) and protective buffering ($b = 0.08$, $p = 0.059$), adjusted for afternoon NA, predicted greater evening NA. Cross-lagged models predicting NA from communicative behaviors were not significant for partners. These findings, although preliminary, underscore the critical role of both enacted and perceived partner communication on mood as well as possible reciprocal relationships across time between communicative behaviors and affect. Data collection is ongoing; analyses will be updated prior to the presentation with an expected sample size of 60 couples.

RURAL HEALTH DISPARITIES: WHAT DO WE KNOW?

Kelly Hirko, PhD, PhD¹, Sabrina Ford, Ph.D.²

¹Michigan State University, College of Human Medicine, Traverse City, MI;

²Michigan State University, College of Human Medicine, East Lansing, MI

Various definitions have been used to delineate rural from urban populations in the U.S., based primarily on population size and proximity to urban areas. The lack of consistency in defining rural populations poses unique challenges for researchers interested in rural health disparities. Moreover, a better understanding of the diversity in health behaviors and outcomes within rural settings is needed. Rural areas are often underrepresented in research; although rural health disparities have been well documented. For example, compared to urban counterparts, those living in rural areas of the U.S. are more likely to be obese, have activity limitations due to chronic health conditions, and have a lower overall life expectancy. While people in rural America tend to get cancer less often than those in urban settings, they die from cancer at higher rates. Rural areas also tend to have higher incidence of and death rates from cancers related to tobacco use and cancers that can be prevented by screening. For example, compared to women living in urban areas, rural women are less likely to meet recommendations for mammography and are more likely to be diagnosed with breast cancer at a later stage of disease. The underlying causes of rural health disparities have been largely attributed to barriers in healthcare access, socioeconomic status, and certain health behaviors, such as higher rates of smoking, alcohol abuse, physical inactivity and obesity. Interventions to address the root causes of these health behaviors in rural areas are needed.

THE LAY OF THE LAND: CANCER HOT SPOTS

Michelle Martin, PhD¹, Sabrina Ford, Ph.D.², Laura Q. Rogers, MD, MPH³, Shannon M. Christy, PhD¹

¹University of Tennessee Health Science Center, Memphis, TN; ²Michigan State University, College of Human Medicine, East Lansing, MI; ³University of Alabama at Birmingham, Birmingham, AL

Rural cancer control is often been overlooked as a health equity issue. Those living in rural areas of United States (U.S.) such as Appalachia, Mississippi Delta, Plains, and Pacific Northwest (herein referred to as rural) have difficulty accessing health care providers due to geographic distance and in turn obtaining quality treatment. This is because of sparse populations in rural areas that cannot support locally accessible healthcare providers. This is particularly a problem for cancer diagnosis, treatment, and follow-up. In addition, despite the fact that overall cancer morbidity has been decreasing in the United States, it has been decreasing at a much slower rate in rural areas. These trends point to widening disparities in cancer in rural locales over time. In this presentation, we will describe cancer “hotspots” and the characteristics of special populations that live therein. Geographic cancer clusters or “hot spots” are locales where cancer incidence rates are higher than the national and state averages. The CDC reports that lung, colorectal and cervical cancers are more prevalent in rural America than the U.S. as a whole. Contributors to rural cancer hotspots are much more varied than in urban areas where lifestyle and toxins can often be generalized. Higher rates of cancer incidence and mortality in rural areas is more challenging to understand because of the large variation and interaction of multilevel factors. These multilevel factors include individual and family, health provider and system issues, and community and environmental contributors. We will explore five distinct rural geographic hotspots and multilevel influences that contribute to increased incidence and mortality. We will also suggest strategies and interventions that can be useful to address rural cancer disparities.

CULTURALLY COMPETENT EDUCATIONAL INTERVENTIONS FOR PROSTATE CANCER SCREENING AMONG LATINO MEN

Kathleen Scura, EdD, RN¹, Maryelena Vargas, PhD, RN², Ji-Young An, PhD, MPH³¹Fairleigh Dickinson University, Carlsbad, CA; ²Fairleigh Dickinson University, Teaneck, NJ; ³Rutgers University, Camden, NJ

Background: Prostate cancer is the second leading cause of death in men and the most commonly diagnosed cancer among Latino men. Prostate cancer is curable if detected early but it can go undetected since it is pain free. Screening tests for prostate cancer are controversial, and experts recommend discussions with primary care providers (PCP) on an individual basis.

Purpose: This study aimed to explore if a nurse-led culturally competent educational program and a short video “Dos Amigos” developed for this pilot project increase knowledge, influence health attitudes/beliefs and practices (KAPs) of prostate health and the risks of prostate cancer in Latino men.

Methods: A mixed method design was employed including a pre/post survey questionnaire and focus group interviews. Convenience sampling was utilized (n=63; mean age=55.82 ± 5.56). The educational materials used were culturally sensitive and at an appropriate literacy level in English and Spanish. The content combined information regarding diet and exercise. A five-minute video in Spanish was utilized to increase KAPs in regards to preventive and early detection methods for prostate cancer, followed by focus groups in Spanish. G*Power 3.1, SPSS 24 and NVIVO 10 were used for data analyses.

Results: The majority were high school graduates (55.7%) and married (47.1%). The reliability (Cronbach’s α) of the KAP Questionnaire was .77 for pre-test and .87 for post-test. KAPs showed a significant difference between before and after the program ($t=2.71$; $d.f.=61$; $p=.009$). Age ($r=.342$; $p=.006$) and education ($r=.298$; $p=.018$) had a statistically significant effect on the post-test, respectively. Recommendations for prostate screening by PCPs and screening tests examined in the past did not show any statistically significant effect on either the pre-test and the post-test. Audiotaped focus group data were transcribed verbatim, and descriptive terms were openly coded, contrasted and compared. The discussion included how to locate Spanish speaking PCPs and financial coverage for their services via community resources.

Conclusions: The main contribution of this research is the culturally competent video intervention to reach and educate vulnerable populations that otherwise may not be reachable. The results demonstrate that the intervention was very effective in regards to increasing level of KAPs. Therefore, clinicians and researchers should be aware of the importance of understanding KAPs of Latino men. These factors influence behaviors necessary for preventive self-care practices and prevents utilization of more expensive tertiary modes of treatment.

DISTRESS AMONG PATIENTS WITH CANCER: THE INFLUENCE OF SOCIOECONOMIC FACTORS

Amy M. Williams, PhD¹, Michael Ryan, PsyD², Theodoros Varkas, LMSW², Wendy Goldberg, MSN, NP²¹Henry Ford Health System, Beverly Hills, MI; ²Henry Ford Health System, Detroit, MI

Cancer related distress is known to be under-recognized and under-managed. Identifying distress is a necessary first step in order to develop resources to address those needs. Previous research has found differences in distress based on urban compared to suburban residence, regardless of race. The current study seeks to further understand the diversity of distress across race/ethnicity and more objective measures of socioeconomic status.

Zip-code level socioeconomic data were merged with cancer distress screening data (n=717) to provide a marker of SES. Demographic data was gathered via chart review. These data were also included for unscreened patients who were eligible for screening (n=449). Descriptive and univariate analyses were conducted.

1166 patients receiving cancer care at a large, tertiary care cancer center. There were no significant differences in demographics between screening cohorts. Overall, non-whites lived in zip codes with lower household incomes and educational attainment, higher rates of poverty and rates of rented homes. Concerns about weight loss was more common in patients with lower household incomes, < HS education, and those living at

This is the first study that we know of to examine distress related to cancer care and objective markers of socioeconomic status. The current study extends the current research examining racial differences in distress and initiates the examination of distress beyond the simple grouping of race. Race is often seen as a proxy of SES in research examining health disparities, however it has been determined to not be the best measure and is often confounded by true socioeconomic variables. These more objective measures of SES, such as household income, education, housing, warrants incorporation in future research and use of race alone as a proxy of SES should be avoided.

EFFECTS OF CHRONIC STRESS ON MENTAL AND PHYSICAL HEALTH OF CANCER CAREGIVERS

Valentina Bolanos, MPH, Hannah-Rose Mitchell, MPH, Youngmee Kim, PhD

University of Miami, Coral Gables, FL

Family and friends of cancer patients (caregivers) have elevated health risk due to the strain imposed by their caregiver role. Among cancer caregivers, those with chronic financial and social stress may be at particular risk for negative health outcomes as early as the time of the patient’s diagnosis. We aimed to examine the association between chronic stress (i.e., financial, marital, and parental) and caregiver quality of life (i.e., mental and physical health) in caregivers of recently diagnosed colorectal cancer patients.

Caregivers (N=85) of newly and recently diagnosed colorectal cancer patients (Stage I-IV) participated in the study (M=50 years old; 57% Hispanic; 71% female; 3-months post-diagnosis; 56% low income; 44% patient’s spouse). Caregiver self-reported mental and physical health (MOS SF-12) were outcomes. Predictors were financial, marital, and parental chronic stress (Chronic Stress Scale). Age, ethnicity, gender, and household income served as covariates.

Caregivers reported levels of mental and physical functioning below the 25th percentile and around the 50th percentile of the US norms, respectively. General linear modeling simultaneously predicting mental and physical functioning revealed that low income ($B=-4.17, p<.01$), older age ($B=-.12, p=.02$), and male sex ($B=-4.61, p<.01$) related to caregiver lower self-reported physical health. No covariates significantly reported to caregiver self-reported mental health. After controlling for the effects of covariates, caregivers’ higher chronic financial ($B=-2.52, p=.05$) and parental ($B=-2.78, p=.04$) stress related to their lower self-reported mental health. Caregivers’ higher financial stress also related to their lower self-reported physical health ($B=-2.04, p=.03$).

Results suggest chronic financial and parental stress as sources of health disparities in cancer caregivers manifested as early as the time of the patient’s diagnosis and initiation of treatment. Family members entering the caregiver role with chronic stress may be at a heightened risk for the deleterious health effects of caregiving. Longitudinal research is required to examine the role of chronic stress in caregiver health over time. Findings also suggest multi-level caregiver interventions targeting structural and individual level stress management.

HEALTH LITERACY, ANXIETY, AND RISK OF HOSPITALIZATION IN MEN ON ACTIVE SURVEILLANCE FOR LOW-RISK PROSTATE CANCER

James Rogers¹, Brittany D. Cullen, MA², Joel Epling², Oliver Sartor, MD², Jonathan Silberstein, MD², Allison Feibus, MS², Michael Hoerger, PhD, MSCR²¹Tulane University, Monroe, NY; ²Tulane University, New Orleans, LA

Objective: Men with low-risk prostate cancer are increasingly managing their illness through active surveillance, and health literacy may be associated with patient outcomes. The purpose of this study was to evaluate whether health literacy was associated with health-related anxiety and hospitalization frequency among patients on active surveillance for prostate cancer.

Method: Participants were men with low-risk prostate cancer receiving active surveillance at the Tulane Cancer Center in New Orleans, Louisiana. The present analyses use baseline data from ongoing longitudinal data collection in which 45 participants to date have completed surveys on demographics, comorbidities, cancer symptoms, health literacy, health-related anxiety, and hospitalizations. Health literacy was evaluated using the Rapid Estimate of Adult Literacy in Medicine-Revised (REALM-R) test. Descriptive statistics and correlational analyses were used to characterize the sample and examine whether health literacy was associated with patient outcomes.

Results: We found that 35.6% (16/45) had clinically significant health illiteracy concerns according to established REALM-R criteria. As well, 30.2% (13/43) reported clinically-significant health-related anxiety, and 20.0% (9/45) reported having been hospitalized in the past year. Increased health literacy was associated with lower health-related anxiety ($r = -.316$, $p = .039$) and fewer hospitalizations ($r = -.325$, $p = .029$).

Conclusion: Health literacy concerns are prevalent and may be related to health-related anxiety and risk of hospitalization in men on active surveillance for low-risk prostate cancer. Findings suggest the need for further longitudinal research involving large samples as well as the need to consider how healthcare systems can support patients with low health literacy to improve their care.

HISPANIC ORIENTATION AND CANCER-RELATED KNOWLEDGE GAPS IN CHILDHOOD CANCER SURVIVORS

Cynthia Ramirez, MPH¹, Alix G. Sleight, PhD, OTD, OTR/L², Joel Milam, PhD³, Kimberly Miller, PhD, MPH¹¹University of Southern California, Department of Preventive Medicine, Los Angeles, CA; ²National Cancer Institute, Los Angeles, CA; ³University of Southern California, Los Angeles, CA

Background: Despite an increased risk for poor health outcomes throughout the lifespan, childhood cancer survivors (CCS) commonly report cancer-related information needs that are associated with poorer mental and physical health.¹ In addition, very little is known about cancer-related knowledge gaps among Hispanic CCS, who are both underserved in healthcare and underrepresented in the literature. Acculturation in Hispanics is a complex process and has been associated with both protective and deleterious health outcomes. Previous research has found greater Hispanic orientation to be associated with increased cancer-related knowledge in cancer survivors.² Acculturation may therefore be an important covariate when measuring cancer-related knowledge gaps in CCS.

Objective: Describe cancer-related knowledge gaps in a diverse sample of CCS and, among Hispanic CCS, assess relationship of cancer-related knowledge gaps with orientation towards Hispanic culture.

Sample: 193 Los Angeles County CCS diagnosed between 2000 and 2007 (54% Hispanic; average age 19.9 ± 2.8 years; age at diagnosis, 12.1 ± 3.0 years; time since diagnosis, 7.8 ± 2.0 years).

Methods: Self-report surveys were used to assess cancer-related knowledge, demographics, and clinical factors. Descriptive statistics were utilized and univariate and multivariable logistic regression analyses were conducted to determine relationships among variables.

Results: CCS in this study demonstrated several substantial gaps in knowledge regarding plans for their ongoing medical care as lifelong cancer survivors. 45% of participants reported being unaware that they will require follow-up care throughout the lifespan. 67% reported never receiving a written summary of their cancer treatment, and 42% reported never discussing future oncology-related follow-up care plans with their doctors. Hispanics with higher orientation toward Hispanic culture were significantly more likely to be aware of a need for future follow-up care ($r = 0.28$; $p = 0.004$).

Conclusions: Targeted education is necessary in diverse groups of CCS to improve cancer-related knowledge, particularly regarding the need for lifelong follow-up care. Among Hispanics, orientation toward Hispanic culture may offer protection against cancer-related knowledge gaps. Potential mechanisms behind this relationship require further research.

OPTIMISM PREDICTS LONG TERM SURVIVAL FOLLOWING AUTOLOGOUS STEM CELL TRANSPLANTATION

Sarah R. Thilges, PhD, James I. Gerhart, PhD, Rebecca Hunter, PhD, Henry Fung, MD, Stevan Hobfoll, PhD

Rush University Medical Center, Chicago, IL

As hematopoietic stem cell transplants (HSCT) increase, attempts continue to be made to identify modifiable variables which may predict, and if intervened on, influence survival although complexities between physical and psychosocial relationships make survival analysis difficult. This study seeks to understand psychosocial variables which influence five-year survival among patients who received HSCT. Based on review of the literature, cancer related variables including anxiety, depression, PTSD and trait optimism were investigated.

Participants: A total of 63 patients who underwent autologous HSCT participated. Mean age was 56 years ($SD = 12$), 24 were female (38.1%) and the most common diagnosis was Multiple Myeloma ($N = 28, 44.4\%$).

Measures: Measures were collected as part of a longitudinal study assessing psychosocial variables throughout HSCT from admission to 90 days post-transplant. Demographics, medical variables, the HADS, PCL-C, LOT-R and Brief Copc were administered.

Analysis: Univariate Cox Regression Models were used to regress survival time on Depression, Anxiety, PTSD, and Optimism. Significant predictors from the planned analyses were retained and plausible confounders including age, clinician rated risk status, cancer diagnosis, and ECOG status at the time of discharge were entered as covariates.

Results: Twenty participants (31.7%) were deceased at five-years. Depression, Anxiety, and PTSD were unrelated to survival. Optimism was significantly associated with survival ($\text{Exp}(B) = .87, p = .013$) such that each unit increase in optimism was associated with a 13% reduction in hazard. The adjusted model with plausible confounders of age, gender, medical risk, and discharge ECOG status did not significantly improve the model fit ($\chi^2 = 7.95, p = .094$). Optimism remained a significant predictor of survival ($\text{Exp}(B) = .89, p = .049$) with each unit increase in Optimism predicting an 11% reduction in hazard.

Conclusion: Contrary to expectations, negative valence including depression, anxiety and PTSD were unrelated to survival. These findings suggest that patients who look for good in the face of adversity were able to fair better in the long run. Although the relationship is unclear, it may be that patients who “feel better”, reflecting underlying physical health, have increased optimism. There also may be indirect relationships with optimistic individuals including improved social support, better relationships with providers and greater likelihood of commitment to pro-health behaviors. Future studies should examine the complex relationship between mediating psychological and cognitive variables, especially “positive psychology” domains.

PHYSICAL ACTIVITY, SEDENTARY BEHAVIOR, AND ALCOHOL USE AMONG BREAST CANCER SURVIVORS

Jenna Gilchrist, PhD¹, David E. Conroy, PhD², Catherine Sabiston, PhD³¹The Pennsylvania State University, Toronto, ON, Canada; ²The Pennsylvania State University, UNIVERSITY PARK, PA; ³University of Toronto, Toronto, ON, Canada

Multiple health behaviors impact breast cancer survivors'; quality of life during survivorship. Physical activity (PA) decreases the physical and psychological complications associated with breast cancer while sedentary behaviors (SED) may increase them. Alcohol consumption has been associated with increased breast cancer risk yet alcohol consumption is also positively associated with physical activity. This study examined associations between weekly alcohol use, physical activity, and sedentary behavior in a sample of 197 post-treatment breast cancer survivors ($M_{age} = 55.01, SD_{age} = 10.96$). Participants were initially diagnosed an average of 11.37 months prior to study enrollment ($SD = 4.36$), and the mean time since treatment completion was 3.98 months ($SD = 3.07$). The majority of participants (82%) were diagnosed with stage I and II cancers. Participants wore an accelerometer and provided daily self-reported alcohol intake for 7 days every 3 months for 5 measurement bursts. On average, alcohol consumption was positively associated with both duration of PA ($r = .19, p = .01$) and SED ($r = .16, p = .01$). Age was not associated with any of the health behaviors and did not moderate associations between PA/SED and alcohol consumption. Multilevel analyses indicated that breast cancer survivors consumed more alcohol on weeks when they were more physically active than usual ($b = .001, p = .02$). Sedentary behavior was not related to alcohol consumption at either the between- or within-person level ($p > .05$). Further research on the dynamics of multiple health behaviors is warranted, particularly to understand changes on fast time scales (e.g., within days). Researchers should also consider various domains of sedentary behavior that may be differentially associated with alcohol intake.

POSITIVE PSYCHOLOGICAL FACTORS PREDICTING SEVERE SLEEP DISTURBANCE AMONG CAREGIVERS OF CANCER PATIENTS

Alaina Lea. Carr, BA¹, David Avram, MA¹, Lacey Clement, MA¹, Elizabeth Kessler, MD², Matthew Golub, BA³, Kristin Kilbourn, PhD, MPH¹¹University of Colorado Denver, Denver, CO; ²University of Colorado School of Medicine, Aurora, CO; ³University of Colorado Anschutz, Denver, CO

Background: Informal caregivers (CGs) of cancer patients often experience sleep disturbances as a result of their caregiving role. Sleep disturbances are linked to measures of carer anxiety and depression, but the potential relationship between anxiety, depression, positive psychological factors and sleep disturbances remains unexamined in cancer patient caregivers.

Objectives: This study explored the link between resilience, hope, depression, anxiety and severe sleep disturbance (SSD) in a large sample of cancer CGs.

Research Design: An online Qualtrics survey assessed quality of life and psychosocial metrics in 467 self-identified cancer CGs. Sleep disturbance was assessed using the PROMIS sleep disturbance short form that was transformed into a binary variable. CGs with a t-score ≥ 60 were coded as 1 (SSD); those with t-score

Results: Mean age was 43 ($SD = 15.4$), a majority of participants were married (77 %) and female (61%), and 34% identified as a spousal CG. The primary cancer diagnoses were breast (21%), lung (15%), gastrointestinal (15%), and hematological (8%); 43 CGs reported SSD (9%). Male gender ($OR = 2.29, 95\% CI, 1.04-5.05$) resilience ($OR = 1.13, 95\% CI, 1.03-1.24$) and higher depression scores ($OR = 1.11, 95\% CI, 1.04-1.19$) were associated with an increased odds of SSD. Older age ($OR = 0.94, 95\% CI, 0.90-0.99$) was associated with a decreased odds of SSD. Non-significant predictors of SSD included marital and employment status, years caregiving, hope, anxiety and CG burden.

Conclusion: Caregivers who report higher levels of resilience are more likely to report sleep disturbance. These results are consistent with resilience theory which indicates that a positive adaptation to chronic stress is domain specific, and the presence of resilience does not imply a global absence of maladaptive functioning. In addition, these findings suggest that those who are older, male and who report higher levels of depression experience more sleep disturbance suggesting the need for more targeted interventions to populations at high risk for SSD.

Future Plans: Further research exploring the relationship between sleep disturbance, positive psychological factors, and caregiver-related stressors is warranted.

READINESS FOR WELLNESS PROMOTION - A SURVEY OF 100 AFRICAN AMERICAN CHURCH LEADERS IN SOUTH LOS ANGELES

Annette E. Maxwell, DrPH¹, Rhonda Santifer, M.Min.², Aziza Lucas-Wright, M.Ed.², Juana Gatson, Ph.D.², Roberto Vargas, M.D.³, Cindy Chang, M.S.², Loretta Jones, Th.D.⁵

¹University of California Los Angeles, Fielding School of Public Health, Los Angeles, CA; ²Charles Drew University, Division of Cancer Research and Training, Los Angeles, CA; ³UCLA David Geffen School of Medicine, Los Angeles, CA; ⁴University of California Los Angeles, Los Angeles, CA; ⁵Healthy African American Families, Los Angeles, CA

Background: South Los Angeles has a large proportion of African American residents, 38%, compared to 7% in California. It has the highest rate of obesity in the Los Angeles area and among the highest mortality due to diabetes, coronary heart disease, stroke, lung, breast, cervical and colorectal cancer. These disparities exist in a setting of disproportionate rates of poverty and limited access to care. Faith-based centers are an important asset and a trusted resource in the African American community. Prior to launching a large-scale partnership, we surveyed 100 church leaders in South LA to gain a better understanding of the readiness of churches to actively engage in health promotion.

Methods: With input from church leaders, we developed a theory-based capacity assessment survey. Capacity refers to factors that increase the success of implementing a health promotion program, including the community's *awareness* of the health problem, its *readiness and resources* to address it. At the organizational level, capacity speaks to the agency's *leadership, commitment, size and structure*. We also assessed *barriers* to implementing wellness activities and the type of *support* churches would require. We started surveys with churches to which our research team had existing relationships and used snowball sampling thereafter.

Results: Interviews were conducted face to face (34%) or by telephone (66%) with senior pastors at Baptist (52%), non-denominational (16%) or Methodist churches (13%). About half (54%) had ever partnered with an academic institution to promote wellness at their church. Many churches had been involved in wellness activities in the last 12 months that addressed cancer (44%), coronary vascular disease/stroke (31%), physical activity (29%), nutrition (22%) and diabetes (17%). Additionally, many were extremely interested in addressing violence in the community (73%) and in the family (59%) and in preventing STDs (61%). Based on a modified Implementation Leadership Scale, church leaders were moderately involved in supporting wellness activities. Most church leaders (88%) did promote physical activity or good nutrition from the pulpit, but only 35% had established health or wellness policies or had guidelines for healthy church meals. Although 58% of churches had a person appointed for health-related activities and 41% had a health/wellness ministry, only 31% had a budget for health related activities and of those, 90% stated that it was insufficient.

Discussion: Many churches in South Los Angeles are actively engaged in health promotion activities, despite a general lack of resources. We will discuss church leaders' needs regarding resources, their preferences regarding health promotion activities and correlates of churches' readiness for wellness promotion. Findings will guide our future collaborative health research in South Los Angeles.

STRATEGIES TO IMPROVE ADHERENCE TO TREATMENT FOR PATIENTS WITH CANCER: INNOVATIVE USE OF PATIENT PORTALS

Kendall Powell, BS¹, Karen E. Wickersham, PhD, RN¹, Irene Soybelman, RN, MS, CNL², Catherine O'Malley, MS, RN², Eun-Shim Nahm, PhD, RN, FAAN³

¹University of Maryland, Baltimore, Baltimore, MD; ²University of Maryland Greenebaum Comprehensive Cancer Center, Baltimore, MD; ³University of Maryland School of Nursing, Baltimore, MD

Background: Patient portals (PPs) are secure websites where patients can view their electronic health records (e.g., medications, laboratory results), send providers eMessages, and request medication refills and appointments. Most PPs also include other functions, such as reminders for laboratory tests, and grant caregivers proxy access. PPs are freely available to patients from their healthcare providers; however, adoption has been slow.

Objective: To collect pilot data on clinic patients' use of the Internet and the PP using an anonymous survey.

Method: Prospective, descriptive study design using anonymous surveys. Participants were recruited by the research team from the waiting areas of the outpatient clinic. The survey was administered in paper format over a two-week period and included questions about patient socio-demographics, such as age, race/ethnicity, gender, level of education, and native language; type of cancer, current stage of cancer, and current stage of their treatment of cancer (i.e., post-diagnosis but before treatment, active treatment, completed active treatment); and experience with computers, the Internet, PPs, and personal health records, as well as their experiences with patient-clinician communication and self-efficacy to use MyPortfolio (PP used by the hospital system). Descriptive statistics were computed to describe the data distributions, characterize the study sample, and describe patient Internet and PP use.

Findings: The participant sample (N=85) was 50.6% male, 63.5% white, and well-educated (80% with some college, college degree, or graduate degree). The mean age was 57.1 years (SD 13.4; range 23 – 62 years). English was the native language for 94.1% (n=80) of the participants. The types and stages of cancer varied greatly among the participants; the most common cancers included breast (4.7%), leukemia or lymphoma (29.0%), multiple myeloma (18.8%), and lung (6%). All patients used the Internet, and the majority of participants used a smartphone (e.g., iPhone, Galaxy; 90.6%). Thirty-six (42.4%) participants had used the PP prior to completing the survey. Given that all of the participants in our study used the Internet and 42.4% had used the PP, there is great potential for using PPs to deliver information tailored to the need of cancer patients and cancer survivors in this group.

Funding: This research was funded by a research facilitation grant through the University of Maryland, Baltimore, School of Nursing, Biology and Behavior across the Life Span Research Center of Excellence.

THE IMPACT OF COMORBID DIABETES ON THE SYMPTOMS OF BREAST CANCER SURVIVORS

Susan Storey, PhD, RN, AOCNS, Andrea Cohee, PhD, RN

Indiana University School of Nursing, Indianapolis, IN

Background. Studies have noted women with diabetes have a 23% higher risk of developing breast cancer (BC) than those without diabetes. Breast cancer and diabetes share common symptoms including decreased physical function, cognitive function, fatigue, depression, and pain contributing to decreased quality of life. Research in other cancers, has demonstrated that survivors with comorbid diabetes have increased symptoms, and poor health outcomes, however, a similar body of research as it relates to breast cancer survivors (BCS) with comorbid diabetes is lacking. The purpose of this study was to determine if differences exist between BCS with self-reported comorbid diagnoses of diabetes on physical function, attention function, sleep and fatigue; and to examine if there was a relationship between symptom severity among BCS with/without a diagnosis of diabetes.

Methods. This descriptive study used data from a larger quality of life study. BCS stages I-IIIa, 3 to 8 years post diagnosis and treatment, with no recurrence at the time of recruitment; and treated with chemotherapy.

Sociodemographic variables included age, income, education and marital status. Medical history included diabetes (yes/no), breast cancer staging and treatment, and BMI. Physical function was measured by the *Physical Function-10*. *Attention Function Index* measured attention function. *The Pittsburg Sleep Quality Index*, measured sleep. The *Functional Assessment of Cancer Therapy Fatigue Subscale* (FACT-F) a 13-item instrument measured fatigue. Independent *t* tests compared the means of symptoms (physical function, attention function, sleep and fatigue) of BCS with/without diabetes. Separate regression analyses were ran to assess the relationship of diabetes on each of the dependent variables (physical function, attention function, sleep and fatigue).

Results. 121 BCS identified as having diabetes. BCS were primarily Caucasian, married and well educated. BCS with diabetes were older, had a higher BMI, lower education and income.

Independent *t* tests demonstrated BCS with diabetes reported poorer physical and cognitive function, less sleep and greater fatigue. Regression analysis found significant relationships between BCS with diabetes and physical function ($p = .000$) and attention function ($p = .017$). Indicating BCS with diabetes have poorer physical and attention than BCS without diabetes. In this sample, BCS with diabetes did not report increased sleep disturbance ($p = .149$) or greater fatigue ($p = .098$).

Conclusion. This study indicates that BCS comorbid diabetes experience higher levels of symptom severity specifically poorer physical and attention function than BCS without comorbid diabetes. Baseline assessments of these symptoms at initial diagnosis, prior to initiation of and throughout treatment are important to assess to determine the impact of diabetes on the symptom severity.

CANCER SURVIVORS' FATALISTIC BELIEFS AND MENTAL HEALTH INDICATORS

Emily P. Rabinowitz, N/A¹, Aisha T. Langford, PhD, MPH²¹New York University, New York, NY; ²NYU School of Medicine, New York, NY

The National Cancer Institute (NCI) estimates that there are 15.5 million cancer survivors in the United States, a population that is slated to increase by 31% by 2026, thus demonstrating the need for more understanding of this unique population. The following study uses NCI's 2014 Health Information National Trends Survey 4 (HINTS 4) Cycle 4 data to examine the psychology of the cancer survivor and patient population. Of the total 3,677 respondents, 542 majority white, middle aged ($M=66.08$, $SD=13.70$), survivors of any type of cancer were included in this analysis. Cancer fatalism, the belief in the inevitability of cancer diagnosis and subsequent death, was assessed in four likert scale questions (recoded into agree and disagree) that assessed the extent that participants adhered to certain statements. Half (50.92%) of cancer survivors agreed with statement one: "It seems like everything causes cancer;" about a third (29.34%) agreed with statement two: "There is not much you can do to lower your chances of getting cancer;" over two thirds (69%) agreed with statement three: "There are so many different recommendations about preventing cancer, it's hard to know which ones to follow;" and almost half (43.73%) agreed with statement four: "In adults, cancer is more common than heart disease." Cancer survivors' experiences of mental health indicators using the PHQ4 (little interest, hopelessness, worry, and nervousness) ranged between 11.07% (of those frequently experiencing hopelessness) to 13.10% (of those frequently experiencing worrying), but almost a third (26.94%) reported being previously diagnosed with depression or anxiety. This analysis reveals a paradoxical belief system among cancer survivors who simultaneously believe that cancer is preventable, but that there are too many prevention recommendations. Nearly half of these survivors are also likely to believe that everything causes cancer, a belief closely related to feelings of worry and hopelessness. Interestingly, these beliefs of hopelessness and anxiety, do not carry over into the measures of mental health, perhaps suggesting that uncovering mental health difficulties in cancer survivors requires new methods, especially considering the high prevalence of previously diagnosed anxiety and depression. Because the belief systems that survivors hold are critical determinants of their responses to care, these findings demonstrate a need for further understanding of how cancer survivors perceive their risk and rate of cancer survival.

A MULTIVARIATE APPROACH TO EXAMINING POTENTIAL COMPONENTS OF INTERVENTIONS FOR CANCER PATIENTS

Thomas V. Merluzzi, PhD, Errol J. Philip, PhD

University of Notre Dame, Notre Dame, IN

I

Introduction: In a stress diathesis approach to conceptualizing adjustment to cancer, there are exacerbating variables, generically called Stressors, which may be related to poorer Outcomes, and there are Resource variables (e.g., coping, social support) that may inhibit the impact of Stressors on Outcomes such as emotional or functional well-being. In order to optimize facilitating forces and positive outcomes, it may be prudent to critically analyze, in a multivariate approach, the typical variables that constitute the diathesis in which one class of variables, that is Stressors, may be evaluated relative to another class of variables such as Resources or Outcomes. The purpose of this study was to critically analyze the relationship between classes of Stressors, Resources, and Outcomes to discover the most important variables in these sets relative to a criterion, the canonical (i.e., multivariate) correlation between these sets. This approach may set the stage for more powerful interventions that take into account the most dynamic stressors and resources in order to facilitate positive outcomes.

Method: 550 persons with cancer were given measures of 1) Stressors: life events, problems (e.g., financial, familial), symptoms (e.g., pain, fatigue), and serious comorbidities; 2) Resources: coping skills, social support, and satisfaction with care; 3) Outcomes: emotional well-being and functional well-being. Canonical correlation analyses (CCAs) were used to evaluate the relationship between each variable and the linear combination of two sets of variables (Stressors and Outcomes; Resources and Outcomes), that is the canonical variate.

Results: Based on eigenvalues one canonical variate accounted for over 90% of the variance in both CCAs. Based on the correlation of each Stressor with the Stressor-Outcome canonical variate, Problems ($r=-.59$) and Symptoms ($r=-.44$) emerged as the most critical variables. In the Resources-Outcomes CCA, the most critical variable in terms of correlation with the canonical variate was Coping ($r=.77$). These correlations are based on standardized canonical coefficients, thus an increase in 1SD for Problems would result in a .59 SD decrease in well-being outcomes. Also, a 1SD increase in coping skills would result in a .77 SD increase in well-being.

Discussion: These results indicate that with respect to the canonical relationship of Stressors with Outcomes, problems and symptoms are much more troublesome than life events or comorbidities. Moreover, with respect to Resources and Outcomes, coping, by far, was the most critical, compared to support and satisfaction with care. This type of analysis may help hone the components of interventions to zero in on the most critical problems and the most fruitful target of an intervention in order to have powerful, short term treatments that meet patient needs.

ANALYSIS OF ONE-CARBON NUTRIENTS AND THE DEVELOPMENT OF PANCREATIC CANCER

Andrew Marley, MPH¹, Kristin Anderson, MPH, PhD², Jianjun Zhang, MD, PhD¹¹Indiana University Richard M. Fairbanks School of Public Health, Indianapolis, IN; ²University of Minnesota, Minneapolis, MN

Background: Pancreatic cancer is one of the most fatal cancers. It is biologically plausible that one-carbon nutrients, such as folate, vitamin B₆, vitamin B₁₂, and methionine, are associated with pancreatic cancer risk. The present study was conducted to investigate these associations in a population-based case-control study.

Methods: Cases (n=150) were recruited from all hospitals in the metropolitan areas of the Twin Cities and the Mayo Clinic, Minnesota. Controls (n=459) were randomly selected from the seven-county metropolitan communities of the Twin Cities and were frequency matched by age and (within 5 years) and sex. Logistic regression was used to estimate odds ratios (OR) and 95% confidence intervals (95% CI) for pancreatic cancer risk.

Results: After adjustment for confounders, dietary intake of folate was associated with a reduced risk of pancreatic cancer [OR (95% CI) for quartile (Q) 4 vs. Q1: 0.31 (0.12–0.78)]. An inverse association was also observed for dietary intake of vitamin B₆ [OR (95% CI) for Q4 vs. Q1: 0.58 (0.34–0.97)]. No significant associations were seen for intakes of vitamin B₁₂ and methionine. The observed inverse associations for dietary folate were more pronounced among ever smokers and ever drinkers compared with never smokers and never drinkers, respectively.

Conclusion: The present study suggests that high intake of folate and vitamin B₆ conferred some protection against pancreatic cancer risk and that these beneficial effects were modified by cigarette smoking and alcohol drinking.

ANXIETY SENSITIVITY'S IMPACT ON PHYSICAL ACTIVITY IN A COHORT OF ENDOMETRIAL CANCER SURVIVORS

Sarah Thomas, MA¹, Adriana M. Coletta, Ph.D. R.D.², Micheal Robertson, M.P.H.², Jaejoon Song, Ph.D.², Yue Liao, MPH, PHD³, Cindy L. Carmack, Ph.D.², Karen Basen-Engquist, Ph.D., M.P.H.²

¹The Ohio State University, Columbus, OH; ²The University of Texas MD Anderson Cancer Center, Houston, TX; ³University of Texas MD Anderson Cancer Center, Houston, TX

Background: Anxiety sensitivity (AS) is defined as the fear of physical symptomatology associated with anxiety. AS has been linked with energy balance factors such as physical activity levels. Additionally, self-efficacy has been linked to both physical activity, as well as anxiety sensitivity as a key determinant of health behavior. The role of AS on physical activity among cancer survivors is particularly relevant because cancer and treatment related physical symptoms may contribute to poor adherence to physical activity guidelines in this population. To date, few physical activity interventions have targeted endometrial cancer survivors and no interventions have explored the relationship between AS, determinants of physical activity such as exercise self-efficacy, and physical activity behavior among this population.

Present Study: AS encompasses a fear of a variety of somatic sensations such as tightness of chest, shortness of breath, rapid heartbeat, and these sensations are often associated with physical activity. We hypothesize that AS may moderate self-efficacy's effect on physical activity.

Method: Secondary data analysis of a behavioral intervention for endometrial cancer survivors was conducted ($N = 100$). Participants were predominantly diagnosed at stage I ($n = 80$), II ($n = 16$), or IIIa ($n = 4$), and predominantly white ($n = 75$).

Analysis: Baseline data physical activity measured right after baseline assessment were analyzed. Multiple linear regression and PROCESS macro for SPSS was used to assess moderation effects. Johnson-Neyman curve was utilized to assess conditional effects.

Results: The effect of exercise self-efficacy on physical activity was significant ($b = 4.91$, $se = 2.38$, 95% CI [.15, 9.66], $p = .04$), but the effect of AS was not. However, a conditional interaction was detected between AS and exercise self-efficacy. The Johnson-Neyman Curve analysis suggests a range of conditional effects, such that self-efficacy was positively related to physical activity when AS was low, but not when it was high.

Conclusion: While results indicate self-efficacy has a positive relationship with physical activity, this may be limited to survivors with low to moderate AS. Future interventions may consider tailoring materials for those with high baseline AS, teaching cognitive coping strategies for accurately appraising physical activity induced physiological sensations, which in turn, may increase their self-efficacy for engaging in physical activity.

BENEFIT FINDING BUFFERS THE IMPACT OF CANCER-RELATED MASCULINE THREAT ON DISTRESS IN YOUNG AND OLDER ADULT MEN WITH CANCER

Ashley Wang, PhD¹, Michael A. Hoyt, PhD²

¹Hunter college, CUNY, New York, NY; ²Hunter College & The Graduate Center, City University of New York, New York, NY

Objective: Benefit finding (BF) involves perceptions of significant positive changes within one's self, social relationships, ability to cope, and sense of life purpose as a result of adverse experiences such as cancer. While BF has been well studied in female cancer survivors, few studies focused on men with cancer. In breast cancer samples, BF's direct relationship with well-being has been inconsistent; suggesting that BF may instead act as a buffer against negative psychological influences related to cancer. Men diagnosed with cancer often feel vulnerable to cancer-related masculine threat (CMT), especially when their experience is inconsistent with their masculine self-image. In prostate cancer patients, CMT is associated with reduced emotion-regulation and worse health outcomes, including worse sexual and urinary function over time. The current study examined BF as a possible buffer against the CMT on psychological distress in young adults with testicular cancer (TC) and older adults with prostate cancer (PC), to examine these relationships across the lifespan.

Methods: Men treated for localized PC ($N = 66$; age range = 42–87, $M = 65.8$, $SD = 9.0$) within the prior 2 years and young adults with a history of testicular cancer ($N = 171$; age 18–29, $M = 25.2$, $SD = 3.3$) completed questionnaires, including the Benefit Finding Scale (Tomich & Helgeson, 2004), the Cancer-Related Masculine Threat scale (Hoyt et al., 2013), the Positive and Negative Affect Schedule (NA; Watson et al., 1988), and the Center for Epidemiologic Studies Depression Scale (CESD; Radloff et al., 1977). Multiple linear regression was used to test hypotheses.

Results: Men with TC reported higher BF, CMT, and depressive symptoms than older men with PC. Within both groups, CMT, and not BF, was positively associated with negative affect (NA) and depressive symptoms ($r = .52$ and $.57$ for TC patients; $r = .50$ and $.50$ for PC patients). However, BF buffered these relationships only in the young adult group, such that CMT demonstrated a stronger association with NA and depressive symptoms in men reported low BF (CESD: $\beta = 7.35$, $t = 5.76$, $p < .001$; NA: $\beta = 12.76$, $t = 6.28$, $p < .001$), compared to those reporting high BF (CESD: $\beta = 3.65$, $t = 3.24$, $p = .001$; NA: $\beta = 4.85$, $t = 3.214$, $p = .03$).

Conclusions: Men who experience masculine threat from cancer are at risk for poor adjustment, though perceiving social and psychological benefits from cancer might protect young men from its harmful impact. At younger ages, masculine identity might be more malleable whereby threats are more easily repaired. It might also be that threats to masculinity are more dynamic after TC (versus PC). Longitudinal data will be important for intervention development.

BUSTING THE “GOOD CANCER” MYTH: THYROID CANCER PATIENTS’ SYMPTOMS AND EXPERIENCES AFTER RADIOACTIVE IODINE THERAPY

Kristi D. Graves, Washington, DC¹, Charlene Kuo, MPH², Stearns Selma, N/A³, Jacqueline Jonklaas, MD⁴¹Georgetown University - Washington, DC, Washington, DC; ²Georgetown University/Lombardi Comprehensive Cancer Center, Washington, DC; ³Oxford University, Kensington, MD; ⁴Georgetown University, Washington, DC

Background: Differentiated thyroid cancer (DTC) has the fastest rising cancer incidence in the U.S., yet remains vastly underexplored in terms of quality of life and survivorship experiences. Favorable outcomes after diagnosis of high-risk DTC may be largely due to use of radioactive iodine (RAI) therapy; RAI often does not provide benefit for low risk DTC. The range and impact of post-RAI side-effects are not well documented. The purpose of this study was to identify the range of symptoms experienced by patients after RAI.

Methods: We conducted focus groups with patients diagnosed with DTC treated with RAI within the past 10 years. Two trained facilitators guided participants’ discussion using semi-structured guides. Discussions were audiotaped and transcribed by team members. Two trained raters coded transcripts using content analysis and grounded theory methods with iterative refinement of the emerging codes.

Results: We enrolled 47 individuals into 8 separate focus groups (78.7% women; Mean age=52.1 Years; Range=28–89 years). The average time since diagnosis was 3.9 years and most participants had papillary thyroid cancer. Five primary themes emerged: Mouth/Salivary symptoms; Nasal Symptoms; Eye Symptoms; Functional Impact; and Uncertainty/ Communication. Examples of symptoms that participants reported within these five themes include extreme dry mouth, swollen or painful salivary glands, tooth sensitivity to hot and cold, changes in taste; blocked tear ducts, excessive tearing of eyes, dry eyes; sinus congestion, runny nose; cognitive ‘fogginess’; and uncertainty regarding whether symptoms were due to RAI or not. Participants reported that symptoms remained years after RAI treatment; for some, their diagnosis was ‘a shadow’; or a ‘life-long worry.’; A number of participants commented that they would not necessarily have RAI if they were to make the decision again. Almost all participants reported that they were unprepared for the range, type, or severity of symptoms they experienced after RAI. Strikingly, many participants also noted that their physicians were unfamiliar with what patients might expect after RAI.

Discussion: Results suggest many patients diagnosed with DTC and treated with RAI experience burdensome and impactful symptoms years after treatment. Study findings have implications for patient-physician communication and treatment decision-making, especially for patients with low risk DTC.

CHANGES IN BELIEFS ABOUT COMORBID DIABETES FOLLOWING NEW DIAGNOSIS OF CANCER

Kimberly A. Muellers, MPH, Juan P. Wisnivesky, MD, DrPH, Jenny Lin, MD, MPH

Division of General Internal Medicine, Icahn School of Medicine at Mount Sinai, New York, NY

Background: With improved survival and prognosis for many cancers, it is increasingly important to understand how a cancer diagnosis may impact patients’ perception of other comorbid illnesses, both immediately after cancer diagnosis and long-term following treatment. We undertook this study to assess the effect of cancer diagnosis on beliefs about comorbid diabetes over time.

Methods: We recruited patients with type II diabetes who were newly diagnosed with early-stage breast, prostate, lung or colorectal cancer and enrolled age-, gender- and hemoglobin A1c-matched diabetes patients. All patients completed the Beliefs and Illness Perceptions Questionnaire (BIPQ) for diabetes. Non-parametric analyses were used to compare cancer and non-cancer patients’ beliefs about diabetes at the time of enrollment and at 3-month and 9-month follow-ups. We used Wilcoxon’s signed rank test to compare changes in beliefs about diabetes within the two groups from enrollment to 3 months and enrollment to 9 months.

Results: Our sample included 173 participants, 75 of whom had a new diagnosis of cancer. The average age was 62 years and 53% were male. At the time of enrollment, subjects with cancer were less likely to report “I am always not feeling well because of my diabetes” compared to non-cancer participants (mean score: 1.39 vs. 2.74, $p=0.020$). Compared to non-cancer patients, cancer patients were less concerned about their diabetes at 3-month follow-up (mean score: 6.79 vs. 7.79, $p=0.016$) and less likely to report that diabetes caused them to feel unwell at 9-month follow-up (mean score 1.14 vs. 2.55, $p=0.013$). Among non-cancer participants, there was a decrease in the average score of how much diabetes affects them emotionally over time 3.73 at baseline vs. 2.87 at 9 months; $p=0.008$); other beliefs did not change. Among cancer participants, several beliefs about diabetes changed over time: concern about diabetes decreased at each time point (7.66 at baseline vs. 6.86 at 3 months [$p=0.037$] and 6.45 at 9 months [$p=0.023$]) and reported impact of diabetes on participants’ lives decreased from baseline to 9 months (4.12 at baseline vs. 3.22 at 9 months, $p=0.013$).

Conclusion: Diabetes beliefs differ for patients with and without a new cancer diagnosis. Cancer patients also demonstrate more changes in their beliefs about diabetes over time, while beliefs remain stable for non-cancer patients. Further research should investigate the effect of these changes in diabetes beliefs on patient’s diabetes management and control.

CHEMOTHERAPY-INDUCED NEUROPATHY AND THE BRAIN: AN FMRI STUDY OF 50 BREAST CANCER PATIENTS

Richard Aslin, PhD¹, Charles Heckler, PhD², Michelle Janelsins, PhD, MPH², Nimish Mohile, MD², Matt Asare, PHD², Calvin L. Cole, PhD², Po-Ju Lin, PhD, MPH, RD³, Karen Mustian, PHD, MPH², Vikram Rao, MS⁴, Shelli Kesler, PhD⁴, Ian Kleckner, PhD²

¹University of Rochester, Rochester, NY; ²University of Rochester Medical Center, Rochester, NY; ³University of Rochester Medical Center, Wilmot Cancer Institute, Rochester, NY; ⁴MD Anderson Cancer Center, Houston, TX

Background: Over half of patients receiving taxane, platinum, and vinca alkaloid chemotherapy experience chemotherapy-induced peripheral neuropathy (CIPN), which involves numbness and neuropathic pain in the hands and feet. CIPN has no effective treatments partly because its etiology is poorly understood. We theorize that CIPN symptoms are partly caused by impairment of interoceptive brain circuitry, which processes bodily sensations via the posterior insula and anterior cingulate cortex (ACC). We investigated whether CIPN is associated with altered connectivity in interoceptive brain circuitry.

Methods: Fifty women with breast cancer (50 ± 9 years) reported CIPN symptoms (CIPN-20) and underwent resting fMRI one or more times: before surgery, one month after completion of chemotherapy, and one year after chemotherapy. We used an *a priori* seed-based investigation of connectivity between the posterior insula and ACC. We compared connectivity between 31 patients without CIPN symptoms (≤ 10 CIPN-20-Sensory), 19 patients with CIPN symptoms (> 10 CIPN-20-Sensory), and 280 healthy adults (174 women, 19.3 years) from another study.

Results: Patients with CIPN symptoms had significantly reduced connectivity between the posterior insula and the ACC compared to patients without CIPN symptoms ($p=0.01$, $d=0.73$). Connectivity between the posterior insula and the ACC was negative in patients with CIPN symptoms but positive in both healthy adults and patients without CIPN symptoms.

Conclusions: CIPN is characterized by reduced connectivity in interoceptive brain circuitry. Interoceptive networks may be a target for behavioral interventions known to activate interoceptive brain circuitry (exercise, meditation) to prevent or treat CIPN. Future work will assess causal relationships between CIPN symptoms and reduced connectivity.

CORRESPONDENCE BETWEEN OBJECTIVE AND SELF-REPORTED ENDOCRINE THERAPY ADHERENCE AMONG WOMEN WITH BREAST CANCER

Emma E. Bright, M.A.¹, Annette L. Stanton, Ph.D.²

¹University of California, Los Angeles, Los Angeles, CA; ²Department of Psychology, University of California, Los Angeles, Los Angeles, CA

Endocrine therapies (i.e., tamoxifen, aromatase inhibitors) lower the likelihood of recurrence in the approximately 70% of women with hormone receptor-positive breast cancers. However, rates of non-adherence to endocrine therapies among women with breast cancer remain high. In this prospective study, we examined correspondence between self-reported and objective adherence to endocrine therapies among survivors of breast cancer. Participants with breast cancer ($N = 130$) receiving their initial endocrine therapy prescription were recruited from a community oncology clinic. Participants took part in three interview sessions at the clinic at prescription initiation (T1), one month (T2), and four months later (T3). Questionnaires addressed women's self-reported adherence, among other variables. At the initial appointment, participants were provided a Medication Event Monitoring System (MEMS) cap to assess adherence; the MEMS cap was collected at T3. At T2, 63% of women reported never forgetting their medication, 80% of women reported never forgetting a pill in an average week during the past month, and 78% of women reported forgetting no pills during the past week. At T3, 51% of women reported never forgetting their medication, 72% of women reported never forgetting a pill in an average week during the past month, and 78% of women reported forgetting no pills during the past week. Across all time points (T1-T3), MEMS measurements revealed that only 7% of women were 100% adherent. The MEMS indicator percent correct (i.e., the number of days a dose was taken/the number of days the participant had the pill bottle) was significantly negatively correlated with the T2 self-reported non-adherence measurements of occasionally forgetting ($r = -.31$, $p r = -.34$, $p < .001$), and non-adherence in an average week in the past month ($r = -.33$, $p < .001$). MEMS percent correct and T3 self-reported adherence measurements were negatively associated: occasionally forgetting ($r = -.42$, $p r = -.49$, $p r = -.55$, $p z = 0.94$, $p = 0.347$) nor the correlation change between non-adherence in the past week and MEMS at T2 and T3 ($z = 1.35$, $p = 0.177$) was significant. However, the correlation change between non-adherence in an average week in the past month and MEMS at T2 and T3 was significantly different ($z = 2.13$, $p = 0.033$). The significant difference in correlations between T2 and T3 in combination with the larger magnitude of the correlation at T3 may indicate that assessing adherence over a longer period of time is necessary to obtain a more accurate self-report of adherence. These results suggest moderate correspondence between objective and self-report measures, however, self-reported measures of adherence may overestimate actual adherence. Furthermore, measurement of adherence to endocrine therapies over at least four months is recommended.

DEPRESSION, PRO-INFLAMMATORY CYTOKINES, AND RAGE-ASSOCIATED S100A8/A9 LEVELS IN BREAST CANCER PATIENTS

Erica R. Nahin, B.A., B.S.¹, Marc E. Lippman, MD², Barry I. Hudson, PhD², Laura C. Bouchard, Ph.D.³, Chloe Taub, M.A.¹, Charles S. Carver, PhD¹, Alain Diaz, Ph.D.⁴, Bonnie B. Blomberg, Ph.D.⁵, Michael H. Antoni, PhD¹

¹University of Miami, Coral Gables, FL; ²University of Miami, Miami, FL; ³Northwestern University, Chicago, IL; ⁴University of Miami School of Medicine, Miami, FL; ⁵University of Miami Miller School of Medicine, Miami, FL

Introduction. The link between depression and breast cancer outcomes has been a topic of great interest for a decade. Up-regulated inflammatory signaling may be one of the biological mechanisms at play. The purpose of this study was to examine the relationship between depression severity levels, pro-inflammatory cytokines IL-1 β , IL-6, and TNF- α , and ligands associated with the receptor for advanced glycation end products (RAGE). Activation of RAGE by ligands S100A8/A9 can trigger pathways that promote inflammation. To date, no study has linked depression with RAGE ligands in breast cancer patients.

Method. Women in South Florida (ages 32–69) with Stage 0-III breast cancer were recruited 2–10 weeks post-surgery between December 1998 and February 2005 as part of a randomized controlled trial of a stress management intervention. They completed the Hamilton Rating Scale for Depression (HRSD) and provided blood samples before initiating adjuvant chemotherapy or radiation. Participants in this sample (N= 59) were predominately non-Hispanic white (72.9%), followed by Hispanic (20.3%) and Black (5.1%).

Results. Using linear regression, we found that after controlling for age, stage, body mass index (BMI), time since surgery, and type of surgery (mastectomy versus lumpectomy), depression severity related to significantly greater levels of S100A8/A9 ($p = .038$), IL-1b ($p = .011$) and TNF-a ($p = .026$) and marginally with IL-6 ($p = .062$).

Conclusion. These data suggest that depression may relate to multiple markers of inflammation in breast cancer patients at an early point in their treatment. Because inflammatory processes may increase odds of metastasis, addressing depression early in the post-surgical period may have future health effects in breast cancer patients.

DOCTOR-PATIENT COMMUNICATION IN THE BRCA-PATIENT EXPERIENCE: 'EVEN THOUGH IT'S SPECIALIZED CARE, IT'S NOT PERSONALIZED CARE'

Aliza K. Phillips-Stoll, Ph.D.¹, Lisa R. Rubin, Ph.D.²

¹Joslin Diabetes Center; Harvard Medical School, Boston, MA; ²New School for Social Research, New York, NY

Genomic or personalized medicine promises to individualize medical treatment to a patient's unique genetic makeup. However, in focusing on the minutia of the body, this treatment risks contributing to the fragmented culture of medicine in which a person's body is split between multiple care providers and the psychological self is divided from the body. This qualitative study investigated the provider-patient experiences of 19 women who carry a BRCA 1/2 genetic mutation, which predisposes them to breast and ovarian cancer. Using Grounded Theory to analyze the interviews, the study identified the theme of fragmented health care in the BRCA-patient experience. This theme appeared in two ways: 1) fragmentation of medical care, in which patients experience their treatment and body parts as split up among providers and 2) fragmentation of self, in which patients experience medical encounters as paying more attention to physical symptoms than to psychological and subjective experiences of health and illness. The study also identified a "holding environment," that mediated the participants' experience of fragmentation. Two types of holding environments were noted: 1) Concrete holding, which included integrated care among providers wherein the providers discussed and shared treatment of the patient and 2) Metaphoric holding, wherein providers focused not on patients' bodies alone but also on their emotional experiences. These findings suggest that the least fragmented medical encounter for patients with BRCA 1/2 mutation should include an integrated model of care through which treating clinicians work together in a coordinated manner and pay attention to the patient's body, thoughts, and feelings.

EFFECT OF AN ONLINE TRAINING PROGRAM ON PRIMARY CARE PHYSICIANS' KNOWLEDGE, BELIEFS AND ATTITUDES ABOUT CANCER CLINICAL TRIALS

Carma Bylund, PhD¹, margo michaels, MPH², Elisa S. Weiss, PhD³, Thomas A. D'Agostino, PhD⁴, M. Diane McKee, MD⁵, Maria Christina Binz-Scharf, PhD⁶

¹University of Florida, Gainesville, FL; ²Health Care Action and Access Consulting, NEWTON HIGHLANDS, MA; ³The Leukemia & Lymphoma Society, Rye Brook, NY; ⁴Albany Stratton VA Medical Center, Saratoga Springs, NY; ⁵Albert Einstein College of Medicine, Bronx, NY; ⁶City University of New York, New York, NY

Introduction: Participation in cancer clinical trials (CCTs) is critical to improving cancer treatments and quality of care. However, rates of patient participation remain low, particularly among racial and ethnic minorities. Research has shown that a trusted physician recommendation is important to the decision to enroll in a CCT. Patients generally have high levels of trust in their primary care physicians (PCPs). However, PCPs' knowledge is limited and attitudes and beliefs about CCTs may inhibit recommendations. Improving PCPs' knowledge, attitudes, and beliefs about CCTs is a promising potential path for improving CCT participation, especially for minority patients.

Methods: Forty-one PCPs in the New York City area who treat minority patients participated in a 1-hour online pilot training session on cancer clinical trials. The objectives of the training module were to (1) educate the PCPs about clinical trials, with a focus on overcoming misconceptions; and (2) discuss roles of PCPs in partnering with oncologists to help patients gain access to clinical trials. The training module included didactics, audio excerpts and case descriptions. Participants completed a pre-test immediately before taking the course, a post-test immediately after taking the course, and a 3-month post-course survey. All three assessments included: a general T/F knowledge test, a 7-item attitude/belief scale, and a knowledge test focused specifically on local resources and access for clinical trials.

Results: Forty-one PCPs completed the module and the pre-post course surveys. Eighty percent (33/41) also completed the three-month post-course survey. Pre-post mean comparisons showed that general knowledge, attitudes/beliefs, and local knowledge all increased significantly.

Conclusions: A brief online course showed significant and sustained improvement in PCPs' general and local knowledge about cancer clinical trials, which translated into self-reported behavior change. Future dissemination of the course and further research into its impact are planned.

EFFICACY IN PATIENT-PHYSICIAN INTERACTIONS AND CANCER SURVIVORSHIP CONFIDENCE IN WOMEN ENDING TREATMENT FOR BREAST CANCER

C. Crocker, B.A.¹, S. Creamer, B.S.¹, P. Lazar, B.S.¹, E. Keating, MS, APRN-BC¹, S. Feltus, B.A.², T. Harralson, PhD³, E.L. O'Hea, PhD⁴¹UMass Medical School, Worcester, MA; ²Stonehill College and UMass Medical School, Fitchburg, MA; ³Tridium, Wayne, PA; ⁴Stonehill College and UMass Medical School, Easton, MA

Cancer patients have unique health care needs as they transition from active treatment to survivorship. Confidence levels in the ability to manage survivorship varies among patients. The relationship between patients and providers is an important factor that may influence confidence as patients move into survivorship. As part of an ongoing Randomized Control Trial (RCT) examining the impact of Breast Cancer (BC) survivorship planning on patients' Quality of Life, we examined the relationship between patient efficacy in their interactions with providers and confidence related to entering survivorship. We gave patients the Confidence in Survivorship Information (CSI) and the Perceived Efficacy in Patient-Physician Interactions (PEPPI) scales at the end of active treatment for breast cancer. The CSI provides an overall confidence scale and subscales for confidence in knowledge of 1) diagnosis and treatment, and 2) prevention and treatment of long-term effects. Scores for the CSI range from 1–3, with higher scores indicating greater confidence. The PEPPI measures patients' self-efficacy in obtaining medical information and attention to medical concerns from physicians. Scores for the PEPPI range from 1–5, with higher scores indicating higher confidence. Patients (n=64) were non-metastatic, predominantly White (94%) and married (61%), with a relatively high education level (61% 4-year college degree or beyond) and a mean age of 60 years old. Most patients had been diagnosed within 9 months (94%) and were diagnosed with stage 1 or 2 (77%). The overall average for the CSI was 2.34 (.43), and the subscales were 2.86 (.24) and 2.19 (.53), respectively. On average, patients scored 4.47 (.66) on the PEPPI. Analyses showed that higher overall confidence in self-efficacy for patient-provider interactions was significantly correlated with higher overall confidence for survivorship ($r = .52$), as well as subscale 1 ($r = .47$) and 2 ($r = .48$). Results indicate that patients that feel efficacious in their relationships with their providers also tend to feel more confident in their knowledge as they enter survivorship. The patient-provider relationship as it relates to confidence, then, may be a key factor in supporting cancer survivors.

ESTIMATION OF PHYSICAL ACTIVITY CUT-POINTS USING ACCELEROMETRY IN BREAST CANCER SURVIVORS AND AGE-MATCHED CONTROLS

Linda Trinh, PhD¹, Robert W. Motl, PhD², Sarah A. Roberts, MSc¹, Trisha Gibbons, MSc¹, Edward McAuley, PhD¹¹University of Illinois at Urbana-Champaign, Urbana, IL; ²University of Alabama at Birmingham, Birmingham, AL

Background: Measuring physical activity (PA) is important to accurately characterize PA patterns and the strength of association between PA and disease outcomes in cancer survivors. Accelerometers are a valid measure of overall PA in cancer survivors, but there is no evidence on the validity of accelerometer cut-points for quantifying moderate-to-vigorous PA (MVPA) in breast cancer survivors (BCS) compared with the general population. The assumption of a strong association between accelerometer output and energy expenditure has been tested in the general healthy population, but not in BCS.

Purpose: To examine the association between the rates of accelerometer activity counts and energy expenditure during walking in BCS compared to age-matched healthy controls, and examine possible differences in cut-points for MVPA.

Methods: Using a case-control design, 19 BCS who have completed primary treatment and 19 age-matched women without a cancer diagnosis completed 6 minutes of resting energy expenditure and 5-minute periods of walking at speeds of 1, 2, 3, and 4 mph on a treadmill. Participants wore an accelerometer (i.e., GT3X+) and breath-by-breath analysis of expired gases was conducted using an open-circuit spirometry system to measure energy expenditure (i.e., VO_2). Repeated measures analysis of variance was conducted on activity counts and VO_2 . Independent samples t-tests were conducted to compare the magnitude of association, slope, and intercept.

Results: Significant differences were found in metabolic rate where BCS had higher energy expenditure compared to controls for the walking speeds ($p < .001$), and accelerometer counts ($p < .001$). There was a strong linear association between accelerometer activity counts and energy expenditure overall, with a mean $R^2 = 0.90 \pm 0.16$. The magnitude of the linear association did not differ between BCS and controls for the R^2 ($p = 0.62$) or slope ($p = 0.43$), but differed in terms of the intercept ($p = 0.01$). This resulted in different cut-points for MVPA: $1,439 \pm 761$ counts·min⁻¹ in BCS and $1,937 \pm 639$ counts·min⁻¹ in controls.

Conclusions: The findings support the application of different accelerometer cut-points for quantifying PA in BCS. Energy expenditure and accelerometer activity counts differed between the groups despite using the same exercise stimuli. The cut-point for controls overlaps with those provided in the general literature thereby validating our approach. Such data are essential for accurately characterizing PA necessary for prescription, monitoring, and better health outcomes in PA programs for BCS.

FACTORS AFFECTING BEHAVIORAL INTENTIONS TO OBTAIN SCREENING FOR CRC IN HISPANICS OF MEXICAN DESCENT

Karoline Sondgeroth, MPH, MSW¹, Joe R. Padilla, Bachelors in Science², Clara Reyes, BA¹, Camilla Champion, BS¹, Rebecca Palacios, PhD¹

¹New Mexico State University, Las Cruces, NM; ²New Mexico State university, Canutillo, TX

Background/Purpose. Colorectal cancer (CRC) is the second most commonly diagnosed cancer and the third leading cause of cancer-related deaths among Hispanic men and women in the US. While Hispanics in the U.S. show favorable outcomes for CRC compared to all other racial ethnic groups, Hispanics residing along the U.S. Mexico Border exhibit disparities in both CRC incidence and mortality. Several risk factors may account for these late CRC stage diagnoses and mortality rates. The purpose of this study was to examine general (e.g., confidence to obtain screening) and cultural beliefs (e.g., fatalism) that may increase or reduce behavioral intentions to participate in CRC screening among Hispanics of Mexican descent.

Methods. Study participants included 153 Hispanic adults, who had never been screened/diagnosed for CRC, were at least 50 years old, and lived in the U.S.-Mexico border region (e.g., Dona Ana, NM and El Paso, TX counties). Women composed 73% of the sample. Factors assessed in this study included 1) perceived benefits of screening 2) self efficacy to obtain screening, 3) subjective (injunctive) norms for screening, 4) fear of screening, 5) cancer fatalism, 6) acculturation, 7) machismo and 8) behavioral intentions to get screened. All measures were assessed via a self-report survey in the participants preferred language. Pearson correlations were calculated.

Results/Findings. Perceived benefits of screening, self efficacy to obtain screening, and subjective (injunctive) norms for screening were all positively related (all r 's $> .38$, $p < .05$) and acculturation and machismo were negatively related (both r 's $> .17$, $p < .05$) to behavioral intentions to screen for CRC. Interestingly, cancer fatalism and fear demonstrated no significant relation to behavioral intentions.

Discussion. Hispanics of Mexican descent would benefit from interventions that target those belief systems that promote CRC screening. It is important to address culturally-related beliefs acting as barriers to cancer screening and prevention.

FEASIBILITY AND EFFICACY OF HIGH-DOSE VITAMIN D SUPPLEMENTATION ON BONE DENSITY IN OLDER PROSTATE CANCER PATIENTS: A PHASE II RCT

Luke Peppone, PhD, MPH¹, Julia E. Inglis, PhD, RD¹, Eva Culakova, PhD, MS¹, Michelle Janelsins, PhD, MPH¹, Charles Kamen, PhD, MPH¹, Matt Asare, PHD¹, Sarah Kerns, PhD, MPH¹, Karen Mustian, PHD, MPH¹, Jennifer Reschke, MS¹, Chunkit Fung, MD², Hong Zhang, MD¹, Supriya Mohile, MD¹

¹University of Rochester Medical Center, Rochester, NY; ²University of Rochester, Rochester, NY

Background: Use of androgen deprivation therapy (ADT) for prostate cancer (PCa), which can cause rapid bone loss, has greatly increased over the past decade. Vitamin D (VITD) may protect against bone loss; however it remains unclear if the recommended daily allowance (RDA) of VITD is sufficient to reduce bone loss or whether higher doses are needed. The aim of this phase II RCT was to collect preliminary data on the effect of high-dose VITD on bone mineral density (BMD) and bone biomarkers in ADT-treated PCa patients compared to the RDA of VITD.

Methods: Older PCa patients (≥ 60 years old) with VITD insufficiency (< 32 ng/ml), beginning ADT with 6 more planned months of ADT were randomized 1:1 to high-dose VITD (hVITD; 600 IU/daily plus 50,000 IU/weekly) or RDA of VITD (rVITD; 600 IU/daily plus placebo weekly) for 24 weeks. All subjects received 100% of the RDA for calcium (1,000 mg/day). BMD was assessed at the total hip (TH) and lumbar spine (LS) via DXA at pre- and post-intervention. ANCOVA tested the change from baseline in BMD and biomarkers between groups.

Results: 59 PCa patients were accrued (85% white; mean age = 67.6). Serum analyses confirmed compliance in both groups (25-OH VITD change: hVITD = +32.0 ng/ml vs rVITD = +4.3 ng/ml; $p < 0.01$). Hypercalcemia was limited to 1 subject. Bone loss was significantly reduced for the hVITD group compared to rVITD group for total hip (BMD% change: hVITD = -1.5% vs rVITD = -4.1%; Cohen's $d = 0.21$; $p = 0.02$), with a trend for the femoral neck (BMD% change: hVITD = -1.7% vs rVITD = -4.3%; Cohen's $d = 0.19$; $p = 0.06$). There was no difference in LS BMD loss between groups. A biomarker of bone formation increased in the hVITD group (Osteoprotegerin: Cohen's $d = 0.27$; $p = 0.09$) as did biomarkers of bone resorption (NTX: Cohen's $d = 0.55$; $p < 0.01$; CTX: Cohen's $d = 0.49$; $p = 0.02$).

Conclusions: The rate of BMD loss within this sample population was substantial. Even with the high rate of BMD loss in this population, hVITD supplementation produced significantly greater reductions in hip BMD loss compared to rVITD. hVITD increased formation biomarkers as expected. hVITD also significantly increased resorption levels, which could be related to the current use of ADT or could support a different mechanism of action than current bone drugs, which are anti-resorptive; future research is needed to further understand these mechanisms. Clinically, higher doses of VITD may be necessary to effectively prevent ADT-induced BMD loss. A definitive phase III RCT is needed to confirm these findings.

HEALTH BEHAVIORS IN INDIVIDUALS WITH INHERITED OR FAMILIAL RISK FOR PANCREATIC CANCER

Meghan Underhill, PhD, CRNP¹, Traci Blonquist, MS², Janette Z. Lawrence, MS, LCGC³, Fangxin Hong, Ph.D.²

¹DFCI, Boston, MA; ²Dana-Farber Cancer Institute, Boston, MA; ³Massachusetts General Hospital, Winchester, MA

Background/Significance: Individuals at high risk for inherited pancreatic cancer cared for within a comprehensive cancer center are encouraged to meet national recommendations for healthy lifestyle and to undergo annual surveillance with MRI or endoscopic ultrasound (EUS). There has been limited literature evaluating patient engagement or receptivity to lifestyle modification, behavioral change, or surveillance. In preliminary qualitative research completed by the study team, participants reported actively seeking information and ways to “do something” to manage their risk and avoid similar death experiences witnessed within the family. More information is needed to understand current health beliefs and behaviors in this population to guide future clinical and research interventions.

Purpose: Evaluate participant outcomes and the relationships between demographic and personal factors (age, gender, family history, cancer risk perception, pancreatic cancer specific distress) and behaviors (alcohol intake, smoking behavior, pancreatic cancer surveillance behavior or experience) in adults at risk for pancreatic cancer.

Methods: A multi-site cross-sectional survey study guided by the Health Belief Model including high risk adults with no personal history of pancreatic cancer. All variables were summarized with descriptive statistics. Wilcoxon rank sum test, Fisher’s exact test were used to assess univariate associations.

Results: Of the 132 respondents, 92(70%) report undergoing surveillance which was associated with older age ($p=0.001$) and having lost a family member to cancer ($p=0.05$), and 89% intend to continue. 36% and 51% report that MRI or EUS were uncomfortable, respectively. Of those who report alcohol consumption ($n=88$); 15% consume 1 or more drinks daily and alcohol consumption was associated with higher distress scores ($p=0.02$). 30% ($n=40$) of the sample reported smoking in their lifetime and 6 were current smokers, 5 of which intend to quit in the next 6 months.

Discussion/Conclusions: In this study, most participants were engaging in pancreatic cancer surveillance. Alcohol intake was moderate and tobacco use was minimal. Age, family experience, and distress were related to behaviors and provide information regarding modifiable factors to target for future intervention research.

HEALTH-RELATED QUALITY OF LIFE AS A DETERMINANT OF EHEALTH ACTIVITY FREQUENCY AMONG CANCER SURVIVORS

Hayley S. Thompson, Ph.D.¹, Nicole Senft, PhD², Anne Katz, RN, Ph.D.³, Deborah Charbonneau, PhD³, Judith Abrams, PhD⁴, Elisabeth Heath, MD²

¹Wayne State University -Karmanos Cancer Institute, Detroit, MI; ²Wayne State University/Karmanos Cancer Institute, Detroit, MI; ³Wayne State University, Detroit, MI; ⁴Karmanos Cancer Institute, Detroit, MI

There has been dramatic growth in the number of eHealth interventions specific to cancer care, including cancer survivorship. Yet, little is known about the determinants of eHealth activity in this patient population. Uses and Gratifications (U & G) Theory posits that eHealth activity is not random or passive, but a strategic choice based on one’s needs. The current study investigates health-related quality of life (HRQOL) as a determinant of eHealth activity in a population-based sample of 284 African American and white cancer survivors (breast, prostate, and colorectal). Participants were recruited from the Metropolitan Detroit Cancer Surveillance System (MDCSS), part of the National Cancer Institute’s Surveillance, Epidemiology, and End Results (SEER) program. The mean age of participants was 61 years; 68% identified as female and 32% identified as male; 54% were African American and 46% were white. Participants completed the eHealth Activity Assessment (eAA), a mixed methods interview examining 17 eHealth activities across 5 domains: informational, communal, self-care, expert care, and transactional. The eAA included assessment of the frequency of each activity, ranging from 1=never to 5=at least once a day. Participants also completed the Functional Assessment of Cancer Therapy – General (FACT-G), which includes subscales measuring physical well-being (PWB), social well-being (SWB), emotional well-being (EWB), and functional well-being (FWB). Multivariate regression analyses revealed that, after controlling for significant demographic and clinical covariates of mean eHealth frequency (specifically, race, age, household income, employment status, and extent of insurance coverage), the FACT-G was independently and negatively associated with mean frequency of eHealth activity ($p<.002$), along with income ($p<.002$) and employment status ($p<.005$). PWB ($p<.0003$), EWB ($p<.006$), and FWB ($p<.05$) were also negatively associated with frequency, with race and insurance coverage no longer significantly associated with activity frequency in all multivariate models. Findings support U&G Theory and suggest that low HRQOL among cancer survivors may drive their eHealth activity and digital efforts to address their needs. Increasing the availability and accessibility of high-quality eHealth resources may be an effective intervention strategy to support survivors who seek to improve their well-being.

6:15 PM-7:15 PM

ILLNESS PERCEPTIONS AND BREAST CANCER RISK-REDUCTION INTENTIONS: THE COMMON-SENSE MODEL APPROACH

Claire Conley, MA¹, Doreen Agnese, MD², Barbara L. Andersen, PhD²¹The Ohio State University, Cleveland, OH; ²The Ohio State University, Columbus, OH

Objective: Leventhal's Common Sense Model (CSM) is a conceptual framework for understanding health decision making. The CSM proposes that illness perceptions guide self-management of health. The present study examines the CSM in the context of BC risk management. Women at high risk for breast cancer (BC) must cope with the likelihood of severe future illness and take actions to mitigate risk. Using the CSM, we hypothesized that higher levels of all illness perceptions (consequences, timeline, personal control, treatment control, identity, concern, understanding, emotions) would be related to greater intentions for risk management behaviors.

Methods: A single group, cross-sectional design was used. Women at elevated BC risk (N=103) completed the Brief Illness Perceptions Questionnaire (BIPQ) and reported intentions ("yes," "no," or "unsure") for risk-reducing behaviors (mastectomy, oophorectomy, chemoprevention, lifestyle changes). Intentions were combined into a single composite variable; higher scores represent greater intentions for risk reduction. Hierarchical linear regression tested illness perceptions in relation to global intentions for BC risk management. Control variables were empirically selected and included Gail Model score, age, partner status, education, and employment status.

Results: Consequences ("How much does your risk affect your life?", $\beta=0.25$, $\Delta R^2=0.08$, $p=0.02$) and identity ("How much do you experience symptoms as a result of your risk?", $\beta=0.30$, $\Delta R^2=0.09$, $p=0.01$) were significant predictors of intentions for BC risk reduction. No other illness perceptions demonstrated significant effects (all p 's >0.05).

Conclusions: Consequences and identity were related to risk-management intentions. As these items assess the impact of BC risk on present functioning, intentions for future behavior may be best predicted by present experience rather than impending health threats. These findings suggest that interventions among women at high risk of breast cancer, including genetic counseling, may benefit from bringing the long-term consequences of risk to present awareness.

INCREASING THE CAPACITY TO PROMOTE CANCER SCREENING IN AFRICAN AMERICAN CHURCHES IN SOUTH LOS ANGELES

Annette E. Maxwell, DrPH¹, Aziza Lucas-Wright, M.Ed.², Juana Gatson, Ph.D.², Rhonda Santifer, M.Min.², Cindy Chang, M.S.³¹University of California Los Angeles, Fielding School of Public Health, Los Angeles, CA; ²Charles Drew University, Division of Cancer Research and Training, Los Angeles, CA; ³University of California Los Angeles, Los Angeles, CA

Background: Churches are important assets in the African American community and many are interested to engage in engaging in health promotion. We are conducting a 3-year pilot study with African American churches to gain a better understanding of what it takes for churches to implement an evidence-based program to promote cancer screening among parishioners.

Methods: We are aiming to increase the capacity of 10 African American churches in South Los Angeles to promote cancer screening by training Community Health Advisors (CHAs) at each church. Training workshops include (1) general information on national cancer screening guidelines and on evidence-based strategies to promote cancer screening and (2) training and practice of the study protocol, in which CHAs learn to recruit and consent participants, screen for eligibility of study participants (age 50–75; baseline non-adherent to screening guidelines for breast, cervical, or colorectal cancer or never discussed PSA test with physician); and provide one-on-one counseling on cancer screening tests that are needed. Trainings are evaluated with pre- and post-tests to assess CHAs'; knowledge of human subjects protection rules (5 items) and colorectal cancer screening guidelines (4 items) and perceived self-efficacy for performing specific tasks of the study protocol (13 items, Cronbach's alpha $> .90$). In addition, we are assisting each church to develop SMART objectives (Specific, Measurable, Achievable, Realistic, Time-bound) that specify organizational activities the church will implement to promote screening.

Results: We trained 51 CHAs from 10 churches (80% female, average age 63 years, 49% had a health care background). CHAs'; knowledge scores on human subjects protection rules increased from 4.5 to 4.7 on a 5 point scale ($p<.02$), their knowledge score on CRC screening guidelines increased from 2.1 to 3.4 on a 4 point scale ($p<.001$) and their self-efficacy increased from 8.6 to 9.3 on a 10 point scale ($p<.0001$). Post training scores were unrelated to demographic characteristics of CHAs. SMART objectives centered around publishing personal interest stories (e.g. testimonies of cancer survivors); organizing worship services that will feature a health theme in the sermon or dedicating one Sunday per month to health promotion; and presentations to inform parishioners about the study. To date, CHAs have recruited 376 participants and provided counseling to 169 participants (45%) who were non-adherent to at least one cancer screening guideline.

Discussion: Our findings suggest that African American churches and church volunteers in South LA are willing and able to promote cancer screening. CHAs with a wide range of educational and professional background achieved similar training outcomes. We will present additional results regarding changes in CHAs' knowledge and attitudes about evidence-based programs.

MODELING THE RELATIONSHIP BETWEEN LIFE STRESS AND SICKNESS BEHAVIOR IN WOMEN WITH SUSPECTED GYNECOLOGIC CANCER

Kelly A. Hyland, BA¹, Aasha I. Hoogland, PhD², Ashley M. Nelson, MA¹, Navdeep Chahal, BA³, Brian D. Gonzalez, Ph.D.², Brent Small, PhD³, Brittany Kennedy, BS Public Health BS Biomedical Sciences⁴, Yvelise Hyland, BA², Paul B. Jacobsen, PhD⁵, Heather Jim, FL²

¹Moffitt Cancer Center & the University of South Florida, Tampa, FL; ²Moffitt Cancer Center, Tampa, FL; ³University of South Florida, Tampa, FL; ⁴Moffitt Cancer Center, Tampa, FL; ⁵National Cancer Institute, Rockville, MD

Background: Fatigue, depression and sleep disturbance (i.e., sickness behavior) often co-occur in cancer patients. Little research has explored whether stress-related variables, such as current life stress (i.e., surgery-related distress) and past life stress (i.e., childhood trauma history) may serve as a risk factor for sickness behavior. The aim of the current analysis was to examine the association between a higher-order latent factor, sickness behavior, and additional latent factors including depressive symptoms, fatigue, sleep disturbance, and current and past stress using structural equation modeling (SEM). It was hypothesized that the stress-related variables would explain additional variance in sickness behavior.

Methods: Eligible women were scheduled to receive surgery at Moffitt Cancer Center for suspected gynecologic cancer. Participants completed a self-report questionnaire packet including demographic, clinical, and psychosocial variables, including those measuring sickness behavior (Center for Epidemiologic Studies Depression Scale, Fatigue Symptom Inventory, and Pittsburgh Sleep Quality Index) and stress-related variables (Childhood Trauma Questionnaire, Impact of Events Scale-Intrusive Thoughts). SEM was conducted using MPlus 7 to examine the associations between latent and observed variables. Nested models with and without associations between stress-related latent factors and the higher-order factor of sickness behavior were tested and evaluated for model fit.

Results: Data from 76 women were included in the current analysis (M age=59.2 years). As hypothesized, latent factors were well delineated in the analysis. Results indicated that the addition of pathways from current and past life stress to the sickness behavior factor added significant explanatory value to the model, as indicated by an improvement in model fit ($\Delta\chi^2=19.7$, $p\chi^2=306.6$, $p=.0001$; RMSEA=.071; SRMR=.087, CFI=.922).

Conclusions: Stress-related variables, including childhood trauma and surgery-related distress are associated with sickness behavior in cancer patients prior to treatment. Future research should examine potential mediators of this relationship (e.g., chronic inflammation, genetic variants). Patients with higher current and past stress may benefit from enhanced screening and early intervention to help mediate the relationship between stress and sickness behavior.

MULTI-LEVEL INFLUENCES ON NOT PERCEIVING FAMILY HEALTH HISTORY-TAKING AS IMPORTANT: THE ROLE OF CANCER RISK

Caitlin G. Allen, MPH¹, Cam Escoffery, PhD, MPH¹, Regine Haardoerfer, PhD², Colleen M. McBride, PhD, MA¹

¹Emory University, Rollins School of Public Health, Atlanta, GA; ²Emory University, Atlanta, GA

Introduction: Family health history assessment (FHHa) provides information about inherited cancer risk that can inform prevention efforts. Perceived importance of FHHa is likely an impetus for collecting information related to family risk. Surprisingly little research has explored levels of the socio-ecological model (SEM) to analyze and identify multi-level characteristics that may contribute to the perceived importance of FHHa in the context of cancer risk.

Methods: Using data from the 2013 Health Information National Trends survey, we tested the association of sociodemographic, family- and personal-history of cancer, and family trust and health communication with not perceiving FHHa to be very important for own health. SEM factors and importance of FHHa were tested using bivariate analyses and hierarchical regression.

Results: Of the 3,185 respondents, 32.7% reported perceiving FHHa as *not* very important for their health. Whites ($p<0.001$), males ($p<0.001$), and those born in the U.S. ($p<0.001$) were more likely to perceive FHHa as not very important. Perceived importance of FHHa did not differ between those with and without a *family* history of cancer, but did differ between those with and without a *personal* history of cancer (38.5% with personal history of cancer perceived FHHa as *not* very important vs. 31.8% without; $p=0.006$). Hierarchical regression showed no model improvement based on family or personal history of cancer adjusting for sociodemographic factors; however, individual's reported trust in family about health information and likelihood to discuss health information contributed significantly to beliefs about the importance of FHHa ($\Delta R=.10$, $p<0.001$).

Conclusion: When accounting for sociodemographic influences, family and personal cancer history were not sufficient contributors to perceiving FHHa to be important. This is concerning as such factors are critical for identifying those who would most benefit from prevention efforts. Social connection variables, however, contributed significantly to the perceived importance of FHHa. Implications of these findings for family-based health communication interventions will be discussed.

MULTIPLE LEVEL PERSPECTIVES REGARDING IMPLEMENTING A PHYSICAL ACTIVITY INTERVENTION TOOLKIT FOR RURAL WOMEN CANCER SURVIVORS

Haiyan Qu, PhD, MSHA¹, Richard Shewchuk, Ph.D¹, Michelle Martin, PhD², Maria Pisu, PhD¹, Danielle Hessong, MPH³, Fatima Iqbal, MPH⁴, Robert A. Oster, PhD¹, Alex Rogers. Minter, MD⁵, Ana Baumann, PhD⁶, Laura Q. Rogers, MD, MPH¹

¹University of Alabama at Birmingham, Birmingham, AL; ²University of Tennessee Health Science Center, Memphis, TN; ³University of Alabama at Birmingham, Denver, CO; ⁴UAB, Madison, AL; ⁵Russell Medical Center, Alexander City, AL; ⁶Washington University in St. Louis, St. Louis, MO

Background: Physical activity can improve quality of life and reduce mortality risk for cancer survivors (CS) yet the prevalence of physical inactivity among CS is unacceptably high (87%). Our study purpose was to obtain multilevel input and priorities to inform a toolkit facilitating implementation of a physical activity intervention for rural women CS by rural organizations.

Methods: We conducted three nominal group technique meetings with rural women CS, three with community stakeholders, and one with potential interventionists. During each session, participants were asked to respond silently to one question asking what would make intervention participation (CS) or implementation (interventionists, stakeholders) doable. Responses were then shared, discussed to clarify meaning, and prioritized by group vote.

Results: The mean age of CS (n=21) was 61.2 ± 11.0 years (range 44 to 83). Most CS reported a history of breast cancer (47.4%) with the remaining reporting bladder, lung, ovarian, uterine, melanoma, or leukemia; 57.9% were early stage; 78.9% were White; 57.9% reported income under \$50,000; and mean education was 15.1 ± 2.75 years. The mean age of community stakeholders (n=16) was 49.5 ± 7.9 years, and interventionists (n=7) was 41.7 ± 15.2 years. CS generated 80 unique items, community stakeholders 96, and interventionists 32. All participants in each group endorsed a prioritized list and felt that it accurately reflected the group's discussion. The most important things for CS were "flexibility" (exercise type, intensity, schedule), "convenient location", "CS commitment", "affordability", and "access to exercise specialist". Community stakeholders prioritized "qualified exercise trainers", "convenient for CS" (time, location), "good tools for interventionists and CS communication", "physician buy-in", and "transportation assistance for CS". Interventionists thought "financial support for the program" and "committed exercise specialists" (e.g., competent, energetic) were most important.

Conclusions: Multilevel input yielded diverse strategies not possible with single level assessment. Recommended strategies reinforce the importance of multilevel implementation strategies for increasing physical activity in an underserved, at-risk population. Physical activity intervention implementation toolkits for rural women cancer survivors should include materials and guidance for implementing these strategies.

PERCEPTIONS OF HPV VACCINE AND PREDICTORS OF VACCINE RECOMMENDATION AND INITIATION AMONG COLLEGE STUDENTS IN GEORGIA

Milkie Vu, MA¹, Robert Bednarczyk, PhD¹, Cam Escoffery, PhD, MPH², Carla Berg, PhD¹

¹Emory University, Atlanta, GA; ²Emory University, Rollins School of Public Health, Atlanta, GA

Background: Human papillomavirus (HPV) vaccine is recommended for prevention against several types of cancers. We assessed predictors of HPV vaccine recommendation and initiation among college students.

Methods: In 2016, 1552 women and 845 men aged 18–25 year old from 7 colleges in Georgia completed surveys. Logistic regressions stratified by sex were used to examine predictors of HPV vaccine recommendation and initiation.

Results: In our sample, 48.32% of women (n=750) and 18.82% of men (n=159) had received a doctor's recommendation for HPV vaccine. Among women, significant predictors of doctor recommendation included older age (OR=1.23), being U.S.-born (OR=2.56), and having a parent with a highest education of a bachelor's degree or above (OR=1.31). Women attending state schools had lower odds of doctor recommendation (OR=0.41). Among men, younger age (OR=0.82) was a predictor of doctor recommendation. Homosexual men had higher odds of doctor recommendation (OR=3.78) while Asian men had lower odds (OR=0.51). Additionally, 43.30% of women (n=672) and 16.69% of men (n=141) had initiated HPV vaccine. Controlling for doctor recommendation, among women, older age (OR=1.13) was a predictor of vaccine initiation. Women attending state schools had lower odds of vaccine initiation (OR=0.63). Moreover, 575 women (85.56% of initiators) and 115 men (81.56% of initiators) completed the three-dose series. Common facilitators of vaccine initiation included doctor recommendation and recommendation by parents, while barriers to vaccine initiation included lack of doctor recommendation and sexual inactivity. Participants reported low perceived susceptibility to HPV (88.49% of the sample), high perceived harmfulness of HPV (78.10%), and high perceived effectiveness of HPV vaccine (77.97%).

Conclusions: Our results highlight key points of intervention and messaging for HPV vaccine. For women, predictors of doctor recommendation were age, socioeconomic status (SES), and nativity; for men, these were age, race, and sexual orientation. When controlled for doctor recommendation, age and SES were predictors of vaccine initiation for women. These associations should be further investigated. Students reported low susceptibility and high harmfulness of HPV and high effectiveness of HPV vaccine. Doctor recommendation strongly predicted vaccine initiation and should be incorporated in interventions. Perception that the vaccine is not needed due to sexual inactivity should also be explored in depth.

POSTMENOPAUSAL WOMEN SURVIVING BREAST CANCER: CAN PHYSICAL ACTIVITY IMPROVE QUALITY OF LIFE?

Kate Dibble, M.A.¹, Keith Bellizzi, PhD, MPH¹, Pamela Taxel, M.D.², Linda Pescatello, PhD, FACS, FAHA¹, Elizabeth J. Siembida, PhD, MPH³, Elizabeth D. Schifano, PhD¹, Samantha Guarneri, B.A.⁴, Susan Tannenbaum, M.D.²

¹University of Connecticut, Storrs, CT; ²UConn Health, Farmington, CT; ³National Cancer Institute, Rockville, MD; ⁴University of Connecticut, Stamford, CT

The role that regular physical activity may have in improving health outcomes in survivors of breast cancer is receiving increased attention. The current study examines the association between physical activity and quality of life (QOL) in postmenopausal survivors of breast cancer. Mailed surveys were administered to 176 postmenopausal breast cancer survivors, and medical record abstraction was completed by the research team. The age mean of the sample was 68.5 yr ($SD=10.3$; Range=50–95 yrs.). Various forms of physical activity (i.e., aerobic, resistance) were assessed via self-reported minutes per week, and the physical, social, function, and emotional well-being QOL dimensions were assessed using the FACIT-B. Physical activity was gauged by asking participants how many minutes per week of each exercise typology they partake in on average. Analyses controlled for covariates (patient age, education, employment status, years in treatment) that were statistically significant with specific subscale(s) of interest. After controlling for these variables, vigorous activity was positively related to physical well-being ($r=.29$, $b=.21$, $p<.01$), functional well-being ($r=.31$, $b=.25$, $p<.01$), and FACT-G ($r=.21$, $b=.21$, $p<.01$), total ($r=.28$, $b=.19$, $p<.01$), and index subscales ($r=.28$, $b=.19$, $p<.01$) which are comprised of physical, functional, and breast cancer subscale scores. The combination of moderate and vigorous activity minutes per week is positively related to functional well-being ($r=.28$, $b=.20$, $p<.01$), FACT-G ($r=.17$, $b=.17$, $p<.05$), total ($r=.26$, $b=.16$, $p<.05$), and index subscales ($r=.26$, $b=.16$, $p<.05$) subscales. No significant findings were found amongst any type of physical activity with social or emotional well-being, and breast cancer subscales. The results of this study suggest that vigorous and vigorous/moderate exercise is positively associated with postmenopausal breast cancer survivors' quality of life. Breast cancer survivors who exercise more regularly are also more likely to perceive better overall functioning (e.g. sleep, work, etc.) related to the disease as well as less symptom burden (e.g. energy, nausea, pain, etc.).

PREVALENCE AND CORRELATES OF PROVIDER RECOMMENDATIONS TO BANK SPERM AMONG ADOLESCENTS NEWLY DIAGNOSED WITH CANCER

Jessica Flynn, MS, CCRP¹, Kathy Russell, Ph.D.², Charlene Sparrow, FNP¹, Theresa Havelka, N/A³, Brigid Lockard⁴, Vicky Lehmann, PhD⁵, James Klosky, PhD, ABPP¹

¹St. Jude Children's Research Hospital, Memphis, TN; ²St. Jude Children's Research Hospital, Memphis, TN; ³St. Jude, Memphis, TN; ⁴St. Jude Children's Research Hospital, Alexandria, VA; ⁵St. Jude Children's Hospital, Memphis, TN

Purpose: Although adolescent males diagnosed with cancer may be at increased risk for infertility due to treatment, sperm cryopreservation remains underutilized. Provider recommendation (PR) to bank sperm may be particularly influential on banking outcomes in this vulnerable group. The present study examines prevalence and correlates of PR for sperm banking among adolescents newly diagnosed with cancer.

Methods: Adolescent males (N=73), parents (N=90), and providers (N=48) across eight pediatric oncology centers completed surveys within two weeks of treatment initiation which queried a variety of potential factors associated with sperm banking outcomes. Males were newly diagnosed, aged 13–21 years, at increased risk for infertility, and \geq Tanner Stage 3. Sociodemographic, medical, and psychological factors were analyzed as potential correlates of PR to bank sperm, as reported by patients. Univariate comparisons for patient and parent factors and generalized estimated equation (GEE) for management of nested provider factors were used in developing the final model which reported variables associated with PR in odds ratios (OR) and 95% confidence intervals (CI).

Results: Over half of at-risk adolescents (57.5%; n=42) reported receiving a PR to bank sperm. Preliminary analyses indicated adolescent diagnosis, parent race and anxiety, and provider confidence in fertility risk assessment, along with conviction in recommendation, significantly differentiated PR to bank sperm (p

Conclusions: Among adolescents at-risk for infertility, 42.5% report not receiving a PR to bank sperm. Compared to those diagnosed with leukemia/lymphoma, those with brain/solid tumor have significantly more time to bank prior to treatment initiation which may influence PR to bank. As banking should take place prior to the start therapy, efforts should be made to provide opportunities for in-patient collection which may increase PR in the leukemia/lymphoma group. Heightened parental anxiety and non-white race also appear to be barriers to PR for banking, suggesting that providers and institutions should have a standardized approach to recommending sperm banking among all developmentally appropriate patients.

PREVALENCE AND PREDICTORS OF LOW SERUM 25(OH)D AMONG FEMALE AFRICAN AMERICAN BREAST CANCER SURVIVORS

Patricia Sheean, PhD, RD¹, Claudia Arroyo, MPH², Jennifer Woo, PhD, CNM, WHNP, RN³, Linda Schiffer, MS, MPH⁴, Melinda Stolley, PhD⁵

¹Loyola University Chicago, Maywood, IL; ²University of Illinois at Chicago, Chicago, IL; ³Baylor University, Dallas, TX; ⁴University of Illinois at Chicago, Oak Park, IL; ⁵Medical College of Wisconsin, Milwaukee, WI

Background: African-American (AA) breast cancer (BC) survivors are prone to low serum 25(OH)D due to decreased cutaneous conversion, high levels of adiposity and BC treatment. However, previous BC investigations have failed to fully address these influential factors and have analyzed AA women in aggregate.

Objective: To determine the prevalence of low serum 25(OH)D in an exclusively AA cohort of female BC survivors with overweight/obesity, taking into account potentially important predictors not previously considered.

Design: Cross-sectional

Participants: Pre- and post-menopausal AA BC survivors (n=244) were recruited from various neighborhoods in the city of Chicago between September, 2011 – September, 2014 for a larger weight loss trial. Demographic, clinical, anthropometric [body mass index (BMI), waist (WC) and hip circumference (HC)], blood biospecimen, dietary intake [Food frequency questionnaire (FFQ)] and sun behavior data were collected by trained study personnel prior to trial participation. Dual energy x-ray absorptiometry (DXA) was used to quantify adiposity (total, %, regional, visceral) and lean mass.

Main outcome: Serum 25(OH)D

Statistical analyses: Mean (\pm standard deviation), frequencies and multivariate linear regression modeling

Results: The average participant was 57.4 (\pm 10.0) y, 6.9 (\pm 5.2) y from initial BC diagnosis with a BMI of 36.2 (\pm 6.2) kg/m². The majority of participants (60%) reported habitual oral vitamin D supplementation with mean intakes of 327 (\pm 169) IUs. Vitamin D deficiency was prevalent in 81% and 43%, applying the cut-points of the Endocrine Society (<30 ng/ml or <75 nmol/L) and the Institute of Medicine (<20 ng/ml or <50 nmol/L), respectively. Linear regression modeling revealed that dietary vitamin D supplementation positively predicted serum 25(OH)D levels, while darker skin pigmentation and WHR negative predicted serum 25(OH)D levels (p<0.01; adjusted R² 0.2877), after controlling for age, BC stage, energy intake and seasonality of blood draw. No significant associations were detected for BMI or any DXA measures of body composition.

Conclusions: Considering the number of women endorsing the use of vitamin D supplementation, the prevalence of vitamin D deficiency among these AA BC survivors was high. Vitamin D supplementation, sun behaviors and WHR may serve as future points of intervention to improve the vitamin D status of this minority survivor population.

QUALITY OF LIFE AND CANCER SURVIVORSHIP CONFIDENCE IN WOMEN ENDING TREATMENT FOR BREAST CANCER

E.L. O'Hea, PhD¹, S. Creamer, BS², C. Crocker, BA², P. Lazar, BS², E. Keating, MS, APRN-BC², K. Edmiston, MD³, S. Feltus, BA⁴, T. Harralson, PhD⁵

¹Stonehill College and UMass Medical School, Easton, MA; ²UMass Medical School, Worcester, MA; ³UMass Medical School and UMass Memorial Medical Center, Worcester, MA; ⁴Stonehill College and UMass Medical School, Fitchburg, MA; ⁵Tridium, Wayne, PA

Within the U.S., the number of cancer survivors will increase by 14.5 million to approximately 19 million by 2024. The Institute of Medicine, the American Cancer Society, along with other cancer care accrediting institutions, encourage oncology care providers to craft Survivorship Care Plans for every patient ending treatment for cancer. These types of requirements echo the increasing awareness that planning for, and addressing, cancer survivorship is an important piece of the puzzle that is cancer treatment. Patients vary in their confidence to handle new cancer-survivor life, along with all the challenges it can bring. As part of an ongoing RCT examining the impact of Breast Cancer (BC) survivorship planning on confidence for survivorship and Quality of Life (QOL), we are presently examining the relationships between confidence and QOL in women ending treatment for BC, prior to receiving any survivorship care planning. Patients were given the Confidence in Survivorship Information (CSI) and the City of Hope QOL scale at the end of their treatment for breast cancer, but prior to receiving cancer survivorship plan. The QOL has four subscales: 1) physical symptoms, 2) psychological well-being, 3) social well-being, and 4) spiritual well-being. Subscales scores range from 0–10, with higher scores indicating better functioning. The CSI provides an overall confidence scale and subscales for confidence in knowledge of 1) treatment, and 2) prevention and late-effects. Scores for the CSI range from 1–3, with higher scores indicating greater confidence. Patients (n=64) were non-metastatic, predominantly White (94%) and married (61%), with a relatively high education level (61% 4-year college degree or beyond) and a mean age of 60 years old. Most patients had been diagnosed within 9 months (94%) and were diagnosed with stage 1 or 2 (77%). Women reported good functioning regarding physical symptoms (x=7.71; SD=1.23), psychological well-being (x=6.58; SD=1.58), social concerns (x=7.00; SD=1.76) and spiritual well-being (x=6.20; SD=2.15). The overall average for the CSI was 2.35 (.43), and the subscales were 2.85 (.24) and 2.17 (.53), respectively. Better overall confidence was significantly correlated with less physical problems (r=.41), better psychological well-being (r=.52) and less social concerns (r=.27). Results will be discussed related to the larger project's goals and baseline status of women who have yet to receive survivorship planning for breast cancer.

RELATIONSHIPS BETWEEN PHYSICAL SYMPTOM MANAGEMENT AND PSYCHOLOGICAL MORBIDITY IN TRANSITIONING CANCER SURVIVORS

Bennett McDonald, MPH¹, Catherine Alfano, PhD², Elizabeth Fallon, MPH, Ph.D.¹, Corinne Leach, PhD MS MPH¹

¹American Cancer Society, Atlanta, GA; ²American Cancer Society, Washington, DC

Introduction: Cancer survivors frequently struggle with physical symptoms that accompany or exacerbate emotional distress when transitioning out of primary cancer treatment. Interventions that build self-efficacy for managing physical symptoms through self-management and cancer rehabilitation referrals may improve distress. This study assessed how self-efficacy in managing physical symptoms relates to psychological wellbeing.

Methods: Data were from the American Cancer Society's Cancer Survivor Transition Study, which surveyed breast, prostate, and colorectal cancer survivors within their first-year post-treatment. A modified Memorial Symptom Assessment Scale was used to assess the presence (past-month) and self-efficacy for managing 8 physical symptoms: pain, fatigue, numbness or tingling, shortness of breath, diarrhea/IBS/problems holding bowels, incontinence or problems with urination, lymphedema, and problems with sexual interest or activity. Mean self-efficacy scores (range 0–4; higher scores=less symptom management self-efficacy) and were regressed on a CES-D scale for depressive symptomatology (yes/no) and a 5-item Fear of Relapse/Recurrence scale (range=0–100; higher scores=more fear). Covariates included demographics, medical characteristics, psychosocial variables and perceived quality of care.

Results: Survivors (N=871) reported experiencing an average of 4.45 physical symptoms (SD=2.07) over the past month; symptom management self-efficacy was high (M=1.10; SD= 0.86). Levels of depressive symptomatology (17%; N=150) and fear of recurrence (M=33.51; SD=21.33) were similar to other studies. Multivariable model results indicated that those who were less confident in managing their physical symptoms were more likely to report higher odds of depressive symptomatology (OR=1.79; 95% CI=1.40, 2.29) and elevated fear of recurrence (B=3.69; 95% CI=2.08, 5.31).

Implications: Few interventions targeting psychosocial distress in cancer survivors involve building physical symptom management skills or physical rehabilitation referrals. Increasing cancer survivors' confidence for symptom management or referring them to rehabilitation may be an avenue for decreasing their psychological comorbidity. Longitudinal studies should be used to further investigate the causal relationship between physical symptom management and emotional distress.

SCREENING AND MELANOMA PREVENTIVE BEHAVIORS AMONG CHILDREN AT ELEVATED RISK FOR MELANOMA

Bridget G. Parsons, MSPH¹, Kelsey K. Zaugg, BS², Angela Zhu, BS candidate³, Lisa G. Aspinwall, PhD⁴, Ryan Mooney, BS³, Stephanie Klein, MD⁵, Yelena P. Wu, PhD⁶

¹Huntsman Cancer Institute, University of Utah, SLC, UT; ²Huntsman Cancer Institute, Provo, UT; ³Huntsman Cancer Institute, Salt Lake City, UT; ⁴University of Utah, Salt Lake City, UT; ⁵University of Utah Department of Dermatology, Salt Lake City, UT; ⁶Huntsman Cancer Institute, University of Utah, Salt Lake City, UT

Melanoma is the most deadly form of skin cancer. Screening through skin self-exams (SSEs) could aid in early detection, when treatment is more effective. Regular SSEs with the help of parents or caregivers could help children establish habits around regular screening and facilitate future early detection of melanoma. There have been few studies examining frequency of SSE among children who have a family history of melanoma, as well as whether SSE implementation is related to other melanoma preventive behaviors, such as sunscreen use. The goal of the current study was to examine the frequency of children's implementation of SSE, and potential relationships between SSE frequency and other melanoma preventive behaviors among children ages 8–17 at elevated risk for melanoma due to family history of the disease. Children ($n=63$) and their parents ($n=69$) were asked to complete a questionnaire that included items on self-reported frequency of engagement in melanoma preventive and screening behaviors. SSE behaviors were dichotomized into one time per month (the recommended SSE frequency) vs. all other frequencies of occurrence. Correlational analyses were conducted to examine potential associations between implementation of melanoma preventive behaviors (wearing sunscreen, protective clothing, hats and sunglasses, and avoiding peak hours of ultraviolet radiation exposure 10 am–4 pm) and child age, gender, and family income. Logistic regression analyses were performed to identify whether performing monthly SSE predicted implementation of melanoma preventive behaviors. The vast majority of parents (90%) and children (86%) reported that children engaged in SSE some amount other than the recommended one time per month. Parents reported that their children engaged in SSE less (74%) or more (16%) than once per month. Children report that they performed SSE less (53%) or more (33%) frequently than one time per month. There were no significant associations between children's SSE frequency and their reported engagement in any melanoma preventive behaviors (p 's = .20-.96). Even among children at elevated risk for melanoma, the majority are not performing monthly SSE. A third of children reported performing SSE more frequently than one time per month, indicating a potential need to understand factors that may lead to overscreening, such as anxiety, or a need to clarify understanding about what constitutes SSE. Future studies could examine potential barriers to SSE implementation in this population (e.g., lack of knowledge, children unwilling to participate in SSEs). Interestingly, SSE implementation was not correlated with engagement in melanoma preventive behaviors. These findings suggest that interventions to promote engagement in melanoma prevention and screening behaviors may require targeted strategies for screening, separate from those for preventive behaviors.

SOCIAL CORRELATES OF MENTAL HEALTH IN ADVANCED GASTROINTESTINAL CANCER PATIENTS AND THEIR FAMILY CAREGIVERS

Ekin Secinti, M.S.¹, Kelly Chinh, M.S.¹, Shelley A. Johns, PsyD, ABPP², Kevin L. Rand, Ph.D.³, Catherine Mosher, Ph.D.¹¹Indiana University-Purdue University Indianapolis, Indianapolis, IN; ²Indiana University School of Medicine, Indianapolis, IN; ³IUPUI, Indianapolis, IN

Few studies have investigated theory-driven factors underlying the impact of social relationship qualities on mental health in cancer patient-caregiver dyads. Guided by social-cognitive processing and loneliness theories, the present study investigated the degree to which loneliness mediated the effects of negative (social constraints) and positive (emotional support) relationship qualities on the global mental health of advanced gastrointestinal (GI) cancer patients and their family caregivers.

Participants ($N=50$ dyads) were recruited from an academic cancer center. Patients and caregivers completed measures assessing social constraints (e.g., avoidance, criticism) from the other dyad member, emotional support from others, loneliness, and global mental health. Patients were predominantly male (62%) and Caucasian (86%), with an average age of 58 years ($SD=11.5$). Common diagnoses were colorectal (38%) and pancreatic (26%) cancer. Caregivers were predominantly female (66%) and spouses of the patients (76%), with an average age of 54 years ($SD=13.7$).

Structural equation modeling was used to examine individual models, and Actor-Partner Interdependence Mediation Modeling was used to test dyadic models. Individual path analyses for patients and caregivers demonstrated that emotional support had an indirect effect on mental health through loneliness ($B=.32$, 95% CI [.11, .52]; $B=.30$, 95% CI [.11, .49] for patients and caregivers, respectively), but no associations were found between social constraints and mental health. Dyadic analyses also indicated that each person's perceptions of emotional support were indirectly associated with their own mental health via loneliness ($B=.33$, 95% CI [.08, .58]; $B=.29$, 95% CI [.14, .47] for patients and caregivers, respectively). However, each person's loneliness and mental health were unrelated to their partner's emotional support and loneliness ($Bs=-.18$ to .15).

Findings suggest that for advanced GI cancer patients and their caregivers, emotional support from others alleviates feelings of loneliness, which may lead to better mental health. However, the benefits of emotional support appear to be primarily intrapersonal rather than interpersonal in nature. Additionally, participants endorsed low levels of social constraints, which may explain their lack of relation to loneliness and mental health. Continued study of interdependence in social processes between cancer patients and caregivers will inform intervention development.

THE ELECTRONIC SOCIAL NETWORK ASSESSMENT PROGRAM: FEASIBILITY AND PRELIMINARY EFFICACY

Maija Reblin, PhD¹, Dana Ketcher, MPH, CPH¹, Peter Forsyth, MD², Lauren Kane, Bachelor of Science in Biology³, Justin R. Pok, BS Multi-Disciplinary Design, Business Minor⁴, Yelena P. Wu, PhD⁵, Jim Agutter, March³¹Moffitt Cancer Center, Tampa, FL; ²H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL; ³University of Utah, Salt Lake City, UT; ⁴University of Utah, Holladay, UT; ⁵Huntsman Cancer Institute, University of Utah, Salt Lake City, UT

Background: Family caregivers of patients with primary malignant brain tumor (CGBT) are at high risk for caregiver burden and distress because of the unique demands associated with the disease. Social support can be a protective factor against burden and anxiety, but barriers prevent CGBTs from seeking support from their networks. Our team developed the electronic Social Network Assessment Program (eSNAP), a visualization tool to help CGBTs catalogue, organize, and prime their social network resources.

Our goal was to test the feasibility of implementing eSNAP in a neuro-oncology clinic and assess the preliminary efficacy of eSNAP in reducing caregiver burden and anxiety and increasing the perceived amount of network support.

Methods: CGBTs were recruited from a neuro-oncology clinic at an NCI-designated comprehensive cancer center. Recruitment rates were assessed. Participants completed baseline questionnaires assessing their demographic characteristics, burden, anxiety, and perceived amount of network support. Participants were then randomly assigned (2:1) to either create a social network visualization using eSNAP or to a usual care (control) condition. Those who used eSNAP provided likeability/usability data and open-ended feedback. All participants were asked to complete follow up questionnaires 3 weeks later on burden, anxiety, and support. Analyses compared difference scores (baseline to 3-week assessment) between groups.

Results: 38 CGBTs were enrolled. Participants were mostly non-Hispanic White (92%), female (77%), spouses of patients (77%), with mean age 57 years ($SD=12$). The recruitment rate was 85% and study retention at 3 week follow-up was 85%. Participants who received eSNAP overwhelmingly reported high likeability and usability. However, 67% wanted/needed more time with eSNAP than available in clinic. Thus, we compared controls ($n=9$) to eSNAP completers ($n=10$) and non-completers ($n=19$). There were no baseline differences. Completers had significantly reduced burden at 3 weeks vs. controls ($p=.02$). Promising trends existed for anxiety and support.

Conclusions: eSNAP was feasible to implement, although limiting use to the clinic prevented engagement and benefit. Preliminary outcome data suggests that for CGBTs who completed use, eSNAP may be effective in reducing caregiver burden and anxiety and increasing the perceived amount of network support. Further research is planned to increase CGBT eSNAP engagement, including continued access at home.

THE ROLE OF COPING AS A MEDIATOR IN THE RELATIONSHIP BETWEEN ILLNESS PERCEPTIONS AND ANXIETY IN CANCER PATIENTS

Crystal Hare, MA, BSc.¹, Lindsey Torbit, MA, BA¹, Cassandra Crangle, PhD, MA, BA¹, Sarah Ferguson, MD, FRCS(C)², Tae Hart, PhD, MA, BA¹¹Ryerson University, Toronto, ON, Canada; ²Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: Anxiety is a common psychological outcome reported by cancer patients (Jensen et al., 2011). Research suggests that the ways in which cancer patients interpret their cancer experience can impact how they cope, which in turn can impact psychological outcomes, including anxiety (Bower et al., 2006; Holzner et al., 2003; Tehekmedyan, Kallich, McDermott, Fayers, & Erder, 2003). One model which allows us to examine the relationship between illness perceptions, coping, and anxiety in cancer patients is Leventhal's Common Sense Model (CSM; Leventhal, Meyer, & Nerenz, 1980). Using Leventhal's CSM, this study examined the indirect effect of positive and negative forms of coping on the relationship between seven illness perceptions (i.e., illness identity, chronicity, cyclicity, consequences, personal and treatment controllability, and coherence) and anxiety in patients with ovarian cancer.

Method: Ovarian cancer patients were recruited from the Princess Margaret Hospital in Toronto ($N=283$), and completed the following questionnaires: Illness Perception Questionnaire-Revised (Moss-Morris et al., 2002); Brief-COPE questionnaire (Carver, Scheier, & Weintraub, 1989); State-Trait Anxiety Inventory-State Subscale (Spielberger, 1983); Brief Pain Inventory (Cleeland & Ryan, 1994); and Functional Assessment of Chronic Illness Therapy Fatigue Scale (Cella et al., 2005). Controlling for three factors associated with anxiety: age, pain and fatigue severity, seven separate multiple mediation analyses were conducted to examine the indirect effect of each illness perception on anxiety severity through the use of positive or negative coping strategies.

Results: Indirect effects analyses revealed that greater negative coping indirectly accounted for greater anxiety in individuals who endorsed greater cyclicity, $\beta = .25$, $SE = .11$, 95% Bca CI [.065, .485], and consequences associated with their cancer, $\beta = .19$, $SE = .09$, 95% Bca CI [.028, .379]. While in contrast, less negative coping indirectly accounted for reduced anxiety in individuals who endorsed greater treatment control, $\beta = -.27$, $SE = .13$, 95% Bca CI [-.558, -.036], and illness coherence, $\beta = -.48$, $SE = .11$, 95% Bca CI [-.736, -.281].

Discussion: This is the first study to examine the full array of Leventhal's illness perceptions in association with anxiety, using coping strategies as mediators. The results from this study indicate that negative coping strategies may be an important mechanism through which illness perceptions impact anxiety outcomes in ovarian cancer patients. These data provide support for the utility of Leventhal's CSM in understanding anxiety in cancer patients, and reveals two modifiable factors that may be addressed through psychosocial therapies to reduce anxiety—illness perceptions and coping strategies.

UNDERSTANDING HCT CAREGIVERS' PREFERENCES FOR A MINDFULNESS-BASED STRESS MANAGEMENT PROGRAM

Christine Vinci, Ph.D., Heather Jim, FL, Maija Reblin, PhD, Joseph Pidala, MD, PhD, Hailey W. Bulls, PhD, Emily C. Cutolo, B.A., B.S.

Moffitt Cancer Center, Tampa, FL

Caregivers of allogeneic hematopoietic cell transplant (HCT) patients have significant responsibilities including 24 hour availability to care for the patient, ability to administer oral and IV medications, strict hygienic precautions and food prep rules, and identification of early infections, over and above the emotional stress associated with caring for someone with a serious illness. This stress can impact caregiver psychological health, which has implications for patient care. Mindfulness-based programs have been shown to decrease stress and increase positive affect among various populations, although no such programs have been tailored for HCT caregivers to date. The goal of this study was to gain insight into caregivers' experiences with mindfulness and evaluate receptiveness to a mindfulness-based stress management program to be implemented during the acute transplant period. Semi-structured phone interviews were audio-recorded and lasted 26–83 minutes. Verbatim transcripts were prepared for thematic content analysis using the constant comparative method. Caregivers ($n=15$; 53% female) were 1–3 years post-patient transplant with a mean age of 61.8 ($SD=8.16$). Forty-seven percent reported hearing of mindfulness before, and when asked “what mindfulness means [to them]” participants commonly offered themes of awareness, focus/paying attention, and how you relate to something (other people, emotions, situations). Despite this, only 21% indicated practicing anything related to mindfulness ever in their lifetime. When a description of a proposed, tailored mindfulness program was provided (e.g., informal mindfulness practices, formal meditation), the majority (80%) indicated that they would have engaged in such a program and believed it would have been useful for them in managing stress. The majority (80%) preferred to receive the program in-person, about once per week, and with sessions lasting no longer than 1 hour. Some participants (53%) indicated interest in a mobile component (e.g., text reminders, meditations on phone, materials available on website). A little more than half of participants (53%) preferred the program to extend from the initial hospitalization period through 90 days post-discharge. Findings suggest HCT caregivers are aware of and open to mindfulness, and that they believe such a program would be beneficial to manage their stress. Additionally, participants provided useful guidance on how to best tailor a mindfulness program to reduce stress in HCT caregivers.

WHAT DO WOMEN WANT? PANEL BASED GENETIC TESTING PREFERENCES IN WOMEN AT INCREASED RISK OF OVARIAN CANCER

Jennifer Shuldiner, MPH¹, Gary Rodin, MD, FRCPC², Julia Knight, Ontario³¹University of Toronto, Toronto, ON, Canada; ²Princess Margaret Cancer Centre, Toronto, ON, Canada; ³Prosserman Centre for Health Research, Toronto, ON, Canada

BACKGROUND: Panel-based genetic testing (PBGT) is becoming increasingly prevalent in clinical practice, but little is understood about information preferences and impact of results. PBGT groups similar genes and involves results of varying significance, including only a small proportion of medically actionable results. A greater understanding is essential to the development of genetic testing guidelines specific to PBGT, along with educational materials and decision support tools for patients and providers. This mixed-methods study explored PBGT preferences of participants with a first-degree relative who has died from ovarian cancer. The specific aims were to understand the patient preferences for PBGT results in this population, the factors that may influence information preferences, and the values, beliefs, and attitudes when receiving PBGT information.

METHODS: We conducted a cross-sectional survey of self-referred unaffected women in Ontario, Canada who have at least one first-degree relative with ovarian cancer and who are undergoing PBGT through a clinical research study. Participants had the option to receive genes (A) BRCA1/2, (B) associated with ovarian and other cancers (C) that are thought to increase the risk of ovarian and other cancers (D) that are known to increase the risks of other cancers (but not ovarian). Quantitative data were collected using a web-based survey platform. Using bivariate analysis and logistic regression, we determined the relationship of sociodemographic and psychological factors (anxiety, depression, decisional conflict) with the genetic information preferences. We also conducted semi-structured telephone interviews with 20 participants who were purposively sampled based on their diverse panel choice selection. Transcripts were analyzed using conventional content analysis.

RESULTS: 350 women participated in pre-genetic counseling and consented to which results they would like to receive. Most women were married (84%), had a post-secondary education (80%), had one relative with ovarian cancer (90%), and chose to receive information from all panels (84%). Those with more decisional conflict did not want to receive genetic information from all panels. Interviews revealed that participants appreciated all forms of “knowledge” regarding their genetic risk, and that many contemplated participation in the program but once committed did not truly consider what information they preferred to receive.

CONCLUSION: In our sample, most women opted to select all panels for PBGT, including panels without actionable results. This preference was associated with a higher level of decisional conflict. Our findings have important implications for the advancement of PBGT in screening for ovarian cancer.

WHEN A HELPING HAND HURTS: NEGATIVE EFFECTS OF SOCIAL RELATIONSHIPS ON PSYCHOLOGICAL ADJUSTMENT IN PARENTS OF AYAS WITH CANCER

Emilia E. Mikrut, N/A¹, Aliza A. Panjwani, MA², Tracey A. Revenson, Ph.D.³¹Hunter College, City University of New York, Maspeth, NY; ²Graduate Center, City University of New York, New York, NY; ³Hunter College & The Graduate Center, City University of New York, New York, NY

Background: Parents of adolescents and young adults (AYAs) diagnosed with cancer are often primary caregivers for their children, requiring social support themselves as they cope with this family stressor. According to Lepore’s social-cognitive processing model, those facing stress need to process their feelings in an interpersonal context in order to adjust to the stressor. However, not all social relationships yield beneficial effects; sometimes network members present constraints on disclosure through negative comments or non-verbal behaviors, which in turn may be related to more distress. Some studies suggest that the negative aspects of social relationships are stronger predictors of distress than positive aspects, while other research suggests that social support and constraints may have both direct and interactive effects.

Aims: 1) To describe levels of psychological distress experienced by parents of AYAs with cancer; 2) To examine the direct effects of social support and social constraints on psychological distress; and 3) To test whether social support moderates the negative effects of social constraints on psychological distress.

Method: Data were collected through an online survey of 71 parents (66 mothers, 5 fathers) of AYAs (aged 15–39) diagnosed with cancer. Psychological distress was assessed using validated measures of depressive symptoms (PHQ-9), anxiety (GAD-7), and post-traumatic stress (IES-R). Social relationship variables were measured with the Contextual Illness-Specific Support Scale (CISS) and Lepore’s Social Constraints Scale (SCS). Multiple regression analyses tested the aims.

Results: Although 14% of parents reported moderate to severe anxiety ($M = 5.8$; $SD = 5.1$), 30% reported moderate to severe PTS ($M = 23.7$; $SD = 19.0$), and 32% reported moderate to severe depressive symptoms ($M = 6.4$; $SD = 6.5$). Social support significantly predicted depressive symptoms ($p = .02$), but not anxiety or PTS, whereas social constraints significantly predicted all three distress outcomes (all $p < .001$). Social support did not moderate the relationship between social constraints and anxiety, PTS, or depressive symptoms.

Conclusion: Among parents whose AYAs have cancer, the negative aspects of social relationships on psychological adjustment may outweigh the positive ones. Future psychosocial interventions for caregivers may benefit from including skills-based work on bettering effective communication in social interactions between network members to minimize social constraints.

ASSESSING UTILITY OF A BEHAVIOR BASED TOOL IN THE CLINICAL SETTING AS A PRIMORDIAL PREVENTION STRATEGY: THE HEALTHY HEART SCORE

Samantha Buls, M.S.¹, Mercedes Sotos-Prieto, PhD², Elizabeth A. Beverly, PhD³, Darlene E. Berryman, PhD, RD, LD⁴¹Ohio University, New Market, MD; ²Ohio University, Athes, OH; ³Ohio University Heritage College Osteopathic Medicine, Athens, OH; ⁴Ohio University, Athens, OH

Created by the Harvard T.H. Chan School of Public Health, the Healthy Heart Score is a previously validated online risk calculator that determines 20-year Cardiovascular Disease (CVD) risk based on nine modifiable lifestyle factors including smoking habits, BMI, physical activity, alcohol consumption, and a diet score. Although previous research has shown that the Healthy Heart Score is associated with development of the clinical risk factors, it remains unknown if the tool can be used as a primordial prevention strategy to stimulate the conversation between patient and healthcare provider about lifestyle modification. Knowing that providers have limited time to assess lifestyle factors, we conducted a qualitative study among health providers and patients to better understand their thoughts about the feasibility and barriers of implementing the Healthy Heart Score in the clinical setting.

A purposive sample of 20 people with no self-reported CVD diagnoses (mean age = 33, 70% female) and 20 health care providers (20% physician/physician assistant, 35% nurse, and 45% dietitian) took the risk assessment and participated in semi-structured interviews. Questions were asked regarding CVD primordial prevention, opinions of the tool, and utility in the clinical setting. Three researchers independently coded the transcribed interviews, discussed codes to resolve discrepancies, and agreed on common themes. Participants suggested ways to best utilize the tool with the most prominent theme being “use in waiting room”. Participants also stated ways to improve the tool, including adding graphics for visual reference of serving size, and removing irrelevant food choices such as “germ”. Most participants said that the overall length was acceptable for use in the clinical setting. Patients showed interest in CVD primordial prevention and expressed willingness to take the Healthy Heart Score prior to seeing a primary care provider. Providers said they would be willing to use the tool in their practice, and all said they would recommend it to their patients. Providers stated few barriers to using the tool with the most common theme being “patient lack of compliance” in follow-through with behavior change. Our findings support the utilization of the Healthy Heart Score as a CVD primordial prevention tool in the clinical setting. Additional research implementing the tool into the clinical setting will provide deeper insight into how the tool can impact behavior change.

ASSOCIATION OF EPICARDIAL FAT WITH PRECLINICAL CARDIOVASCULAR AND METABOLIC FUNCTION

Theresa DiMascio, B.A.¹, Jennifer A. Schmaus, B.A.¹, Gianluca Iacobellis, M.D. Ph.D.², Martin Bilsker, M.D.³, Alex Gonzalez, B.S.¹, Meela Parker, B.A.¹, Neil Schneiderman, PhD⁴, Barry Hurwitz, Ph.D.¹¹University of Miami, Miami, FL; ²University of Miami Department of Endocrinology, Miami, FL; ³University of Miami School of Medicine, Miami, FL; ⁴University of Miami, Coral Gables, FL

Background: Increased levels of visceral and epicardial fat depots are associated independently with increased risk of cardiovascular and diabetic disease pathophysiology. However, little is known about the synergistic relationships of these depots in preclinical cardiometabolic risk in healthy populations. Accordingly, the purpose of the present study was to evaluate whether indices of visceral and epicardial fat are additive or interactive in their relationship with markers of sub-clinical cardiometabolic disease.

Methods: The study assessed 339 adults (48% women) without diagnosed cardiovascular disease, diabetes, or other systemic conditions. Visceral fat was estimated using waist girth (WG). In addition, epicardial adipose tissue (EAT) thickness was measured via 2D-guided M-mode echocardiography. Hierarchical multiple regression was employed, evaluating WG, EAT, and their interaction term in relation to traditional cardiometabolic measures (i.e., blood pressure, left ventricular mass index, lipid profile (total (TC), LDL- and HDL-cholesterol levels, TC/HDL, and triglycerides), fasting glucose and insulin, insulin sensitivity assessed by euglycemic-hyperinsulinemia clamp, and proinflammatory markers (CRP, IL-6).

Results: The analyses showed the expected independent associations of WG and EAT with outcome measures. Notably, only the lipid parameters showed evidence of significant WGx EAT interactions [TC/HDL ratio ($B = -5.61e-5$, $p < .01$), LDL ($B = -.013$, $p < .01$), and triglycerides ($B = -7.21e-5$, $p < .05$)]. Therefore, for each lipid measure, the relationship between WG and lipid levels depended on EAT. Specifically, when EAT was low, increasing WG was linked with increasing dyslipidemia. However, when EAT was high, WG was not associated with dyslipidemia. In this instance, lipid levels were elevated regardless of prevailing WG. Thus, with increasing EAT, EAT was a stronger indicator of dyslipidemia than WG.

Conclusion: The study findings indicate that the relationship of visceral adiposity to dyslipidemia was dependent on EAT. Thus, consideration should be given to the interaction of both of these measures of fat deposition when assessing preclinical alterations in lipid profile. Further, research is needed to elucidate the mechanisms underlying the contribution of epicardial fat accumulation to dyslipidemia.

COGNITIVE FUNCTION IN THE ELDERLY IS ASSOCIATED WITH CELLULAR INFLAMMATION REGULATION AND PHYSICAL FUNCTION.

Jordan Kohn, Ph.D.¹, Laura Redwine, PhD², Nicholas Guay-Ross, B.S.¹, Meredith A. Pung, PhD³, Kathleen Wilson, MS³, Gary Lyasch, B.S.⁴, Amanda Wilson, M.S.R.S.⁵, Chad Spoon, M.R.P.⁵, Chris Pruitt, B.S.⁶, Seong Hong, M.D., Ph.D.¹, Suzi Hong, PhD⁷

¹University of California San Diego, Department of Psychiatry, San Diego, CA; ²University of South Florida, Tampa, FL; ³University of California, San Diego, San Diego, CA; ⁴University of California San Diego, Department of Psychiatry, La Jolla, CA; ⁵University of California San Diego, Department of Family Medicine and Public Health, San Diego, CA; ⁶University of California San Diego, Department of Family Medicine and Public Health, La Jolla, CA; ⁷University of California San Diego, San Diego, CA

Chronic inflammation, even at low grade, is associated with impaired cognitive function in various populations, but the literature remains inconsistent in the relationship between blood levels of inflammatory markers and mild cognitive impairment. Hypertension has also been associated with cognitive impairment, and it is unknown whether dysregulated beta-adrenergic control of inflammatory processes is a mechanism of cognitive impairment in individuals with hypertension. Furthermore, signs of diminished physical functioning and mild cognitive impairment have been linked, especially in aging populations. We aimed to investigate these relationships by examining cognitive and physical functioning in relation to cell-based inflammation regulation in elderly individuals. The current study includes baseline data from older adults with hypertension ($n = 62$; 64.5% female, mean age = 73.5, SD = 8.54) participating in a behavioral intervention study. Cognitive function was assessed via the 30-item Montreal Cognitive Assessment (MoCA), and mobility was assessed using the Timed Up & Go Test (TUG). Beta-adrenergic receptor-mediated inflammation control (BARIC) was quantified by stimulating immune cells *in vitro* with an endotoxin, lipopolysaccharide, while simultaneously administering a dose response to beta-agonist, isoproterenol, for monocyte-produced cytokine (TNF- α) expression. Cognitive function (MoCA: mean = 24.8, SD = 4.12) was considered impaired in 24% of participants ($n = 15$; MoCA ≤ 23) and was associated with age ($\beta_{std} = 0.24$, $t = 2.74$, $p = 0.008$), but not with body mass index (BMI) or gender. According to the CDC guidelines, mobility was within a normal range across the sample (TUG: mean = 9.17 s, SD = 3.15 s), although 22.5% of participants exhibited diminished mobility ($n = 14$, TUG ≥ 12 s). Multivariate linear regression modeling indicated that reduced BARIC and TUG were predictive of diminished cognitive function after controlling for age, gender and BMI (BARIC: $\beta_{std} = 0.21$, $t = 2.57$, $p = 0.013$; TUG: $\beta_{std} = 0.30$, $t = 3.37$, $p = 0.001$). Our findings indicate that impaired inflammation regulation and diminished physical functioning may predict reduced cognitive function among the elderly. The impact of inflammation and physical functioning on cognition in the elderly will be further clarified in future longitudinal analyses of this ongoing investigation.

EFFECTS OF DEVICE-GUIDED BREATHING ON BP ARE RELATED TO REDUCED BREATHING RATE DURING PRACTICE NOT THE BREATHING TARGET RATE

Lynn P. Clemow, PhD, Toya Simmons, MPH, CHES

Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ

Device-guided breathing (DGB) refers to an intervention using a device that generates guiding tones (signals to inhale and exhale) to pace the breathing by gradually prolonging exhalation and slowing the breathing rate. The impact of DGB on blood pressure (BP) has been studied in previous studies, but the mechanisms are not well understood. One explanation proposed is that achieving the target breathing rate of 5–6 breaths per minute (bpm) is the key to BP change, as the Reflex Sinus Arrhythmia (RSA) is maximized and changes blood pressure by resetting the cardiac baroreflex. Others propose that the effect of the breathing practice is a non-specific relaxation response, and other ideas have been advanced.

In a recent randomized controlled trial (RCT), we studied the effects of 8 weeks of DGB (15 min/day) with 2 targets for the respiration rate (RR) (5 bpm – the standard device setting- and 14 bpm – intended as a relaxation control) on ambulatory blood pressure (ABP) in medicated but uncontrolled hypertensives ($n=254$), compared to a usual care (UC) control. Contrary to hypotheses, both DGB groups significantly reduced ABP vs the UC control and were not different from each other. The purpose of the present analyses was to explore data from the RCT stored automatically by the DGB devices (RESPeRate™) to shed light on the elements of the performance of daily practice sessions that led to reductions in systolic ABP.

The device data showed that both DGB groups practiced consistently (mean >70% of daily sessions, 98% did the pre-set 15 min. practice sessions) with good compliance toward the target RR goals. Using multilinear regression models the Change in Systolic BP in the DGB_5 group was found to increase linearly with baseline SBP and the mean change from the beginning respiration period (=60/RR) to the end of the practice sessions ($R = 0.46$, $p=.00005$). In DGB_14 the change in systolic BP increased with age and change in respiration period ($R=.053$, $p=.003$). Interestingly, the initial mean breathing rates were important in the DGB_14 group, in that SBP only decreased in those whose initial breathing rates were >14, who actually reduced their breathing rates during the DGB_14 practice. The degree of synchronization with the guiding tones appears to be the driver of slowing the breathing, as it predicted the increase in the respiration period and the end respiration rate ($R=.93$, $p<.00001$ for DGB_5; and $R=.78$, $p<.0002$ for those in DGB_14 who slowed their breathing). Thus it appears that it is the practice with reducing breathing rate, regardless of the target RR, that predicts the reduction of systolic BP, arguing against the importance of the 5–6 bpm breathing target to BP outcomes.

FEARS OF THE UNKNOWN AND BODILY SENSATIONS PREDICT PATIENT REPORTED CARDIAC SYMPTOMS IN ATRIAL FIBRILLATION PATIENTS

Brian M. Quigley, Ph.D.¹, Anne B. Curtis, M.D.¹, Michael J. Chaskes, M.D.², Rebecca Firth, M.A.¹, Kamila S. White, Ph.D.³, Siva Harsha Yedlapati, M.D.¹, Jeffrey M. Lackner, Psy.D.¹

¹Department of Medicine, Jacobs School of Medicine & Biomedical Sciences, University at Buffalo, Buffalo, NY; ²Department of Medicine, Jacobs School of Medicine & Biomedical Sciences, University at Buffalo, Williamsville, NY; ³Department of Psychology, University of Missouri-St. Louis, Saint Louis, MO

Background: Atrial fibrillation (AF) is the most common sustained cardiac arrhythmia with a one in four lifetime risk in adults over the age of 40. Given the progressive demographic aging of the US population, AF represents a significant public health threat associated with increased morbidity, impaired quality of life (QOL), and significant health care costs. Medical management of AF is complicated by an inconsistent relationship between observed arrhythmias and patient-reported cardiac symptoms. Because symptoms drive QOL and health care use, it is important to understand how psychosocial factors influence patients' illness experience. We examined the impact of two potentially important cognitive processes, intolerance of uncertainty and fear of somatic complaints, on patient reports of AF symptom frequency.

Methods: AF patients (N=101, 46% male, mean age=71) recruited from an outpatient cardiology clinic completed questionnaires on Anxiety Sensitivity, Intolerance of Uncertainty, QOL (SF-12), AF Symptom Frequency (difficulty breathing, racing heart, chest pain, dizziness, dyspnea, exercise intolerance), and health care use. Data were analyzed by 1) correlating AF symptoms with QOL and health care use and 2) regressing AF symptoms on age, gender, anxiety sensitivity, and two reactions to uncertainty (inhibition due to uncertainty and fear of uncertainty). Both main effects and interactions were examined in separate steps.

Results: AF symptom frequency was correlated with lower physical QOL, $r = -.56, p < .001$, mental QOL, $r = -.43, p < .001$, and more physician contacts, $r = .23, p = .023$. Multiple regression analysis showed that AF symptom frequency was related to age, $\beta = -.20, t = -2.56, p = .001$, anxiety sensitivity, $\beta = .36, t = 3.48, p < .001$, and inhibition due to uncertainty, $\beta = .40, t = 3.54, p < .001$, but not gender, $\beta = -.02, t = -0.23, p = .819$. A significant interaction effect indicated that patients reporting both heightened anxiety sensitivity and greater behavioral inhibition due to uncertainty reported more frequent AF symptoms, $\beta = .47, t = 2.46, p = .016$.

Conclusions: AF patients with fear of somatic sensations and uncertainty reported more frequent AF symptoms. While establishing a causal relationship between AF symptoms and these factors is beyond the scope of this study, the findings suggest novel opportunities to improve AF patient care and quality of life by targeting intolerance of uncertainty and fear of somatic complaints in AF patients when cardiac symptoms persist in spite of empiric medical therapies.

LENGTH OF U.S. RESIDENCE AND OBESITY IN THE HISPANIC COMMUNITY HEALTH STUDY/STUDY OF LATINOS

Marisa Perera, MS¹, Diana Chirinos, Ph.D.², Carrie E. Brintz³, Neil Schneiderman, PhD¹, Martha L. Daviglius, MD, PhD⁴, Gregory A. Talavera, MD, MPH⁵, Krista M. Perreira, PhD⁶, Rebeca Espinoza Giacinto, Ph.D., M.P.H.⁷, Qibin Qi⁸, Maria Llabre, PhD¹

¹University of Miami, Coral Gables, FL; ²Feinberg School of Medicine, Northwestern University, Chicago, IL; ³University of North Carolina School of Medicine, Chapel Hill, NC; ⁴University of Illinois at Chicago, Chicago, IL; ⁵San Diego State University, Chula Vista, CA; ⁶UNC School of Medicine, Carrboro, NC; ⁷San Diego State University, San Diego, CA; ⁸Albert Einstein College of Medicine, Bronx, NY

Obesity among immigrant Hispanic/Latino adults in the U.S. increases with greater length of U.S. residence. Exposure to U.S. culture is hypothesized to lead to more obesogenic health behavior, thereby increasing body mass index (BMI) over time. Longer length of residence has been shown to lead to health behavior changes towards unhealthful diet and increased sedentary time. However, the association between obesity and post-immigration diet and sedentary health behaviors in relation to length of residence has not been studied in a representative sample of U.S. Hispanic/Latino immigrants. This study examined length of residence and sex in the relationship between Alternative Healthy Eating Index-2010 (vegetables, whole fruit, whole grains, trans fat, alcohol, etc.) composite-measured diet or accelerometer-measured sedentary health behaviors with BMI in a representative sample of U.S. Hispanic/Latino immigrants and nonimmigrants.

13,962 (80.2% foreign born) participants in the Hispanic Community Health Study/Study of Latinos (HCHS/SOL) aged 18–60 from 4 U.S. cities (Bronx, NY; Chicago, IL; Miami, FL; San Diego, CA) underwent standardized interviews and physical examination. Linear regression analyses, adjusted for nativity, age, income, Hispanic/Latino background, HCHS/SOL site, and tobacco use, were conducted to examine the relationships between diet and BMI, and sedentary time and BMI. Length of U.S. residence and sex were examined as moderators, and three-way interactions (diet length of residence sex; sedentary time length of residence sex) were tested in models that contained main effects and two-way interactions. HCHS/SOL design, stratification, and clustering weights were applied to all models. The diet length of residence sex interaction was significant ($b = .005, 95\% \text{ CI} = .003, .008$). More unhealthful diet was associated with higher BMI among those with longer length of residence, up to 15 years post immigration. Stratification by sex showed that the strongest diet-BMI relation was observed among U.S.-born women, and that the diet-BMI relationship among foreign-born women increased in magnitude and approximated that of U.S.-born women with greater length of residence. Prevention programs aimed at promoting healthy weight and reducing excessive weight gain in Hispanic/Latino immigrants in the U.S. via changes to healthful diet should consider length of residence and sex, and be delivered within the first few years of arrival.

TESTING PSYCHOSOCIAL PATHWAYS OF SOCIAL SUPPORT TO PREDICT 5-YEAR MORTALITY RISK IN CONGESTIVE HEART FAILURE PATIENTS

Lucy Finkelstein-Fox, M.S.¹, Crystal L. Park, PhD², Carolyn M. Aldwin, Ph.D.³¹University of Connecticut, Storrs, CT; ²University of Connecticut, Storrs Mansfield, CT; ³Oregon State University, Corvallis, OR

Congestive heart failure (CHF) impacts more than 5 million people in the U.S., approximately three-quarters of whom are over age 65 (American Heart Association, 2014). Mortality rates in CHF patients are extremely high, and represent a major target of medical and psychosocial interventions. Although considerable research has shown the importance of social support resources for maintaining quality of life with CHF, social support has demonstrated inconsistent effects on mortality (e.g., Murberg & Bru, 2001). However, few studies have compared distinct pathways through which social support resources may be helpful (i.e., instrumental vs. emotional support). Previous research on this sample also showed that spiritual peace promoted longevity (Park et al., 2016), and so we were curious as to whether this might be one possible pathway through which social support impacts mortality. To better understand the ways in which social support influences the mortality of CHF patients, an examination of both direct and indirect effects is needed.

In the present study, we examined relationships between social support resources (ESSI; Vaglio et al., 2002), use of instrumental and emotional support coping (Brief COPE; Carver, 1997), health behaviors (items from Sherbourne et al., 1992), spiritual peace (FACIT-Sp-12; Peterman et al., 2002), and mortality in a sample of 191 CHF outpatients (64% male, mean age= 68.6, 83.2% White). Psychosocial data were collected at two time points, each 6 months apart. Mortality data were collected from medical records at a 5-year follow-up.

Sixty-one participants (32%) were deceased by the 5-year follow-up. Controlling for demographic factors and comorbid conditions, social support at T1 demonstrated only a marginal effect on mortality risk (HR = 0.73, $p = .05$, 95% CI[0.53, 1.00]). Social support was also prospectively associated with instrumental coping ($\beta = 0.32$), emotional support coping ($\beta = 0.60$) and spiritual peace ($\beta = 0.24$) (all $ps < .01$), but not health behaviors ($\beta = 0.11$, $p = .20$) at T2. Further, spiritual peace predicted decreased mortality risk (HR = 0.53, $p < .01$, 95% CI[0.35, 0.80]) and served as an indirect pathway through which social support impacted longevity (40% of total effect mediated, $p < .05$). Health behaviors also predicted decreased risk of mortality (HR = 0.40, $ps > .20$).

These results suggest that social support in CHF patients may be protective through its effects on spiritual peace, but does not impact mortality via coping or health behaviors. This has important implications for interventions to promote perceptions of social support in CHF patients, especially for those experiencing high levels spiritual distress related to their health. Further, given the clear value of practicing health behaviors in addition to maintaining spiritual well-being, programming for CHF caregivers should emphasize strategies for helping patients with daily health-promoting behaviors.

THE RELATIONSHIP BETWEEN SEDENTARY BEHAVIORS AND CARDIOVASCULAR DISEASES: A MULTIPLE MEDIATION MODEL

Sunyoung Jung, PhD, Soohyun Nam, PhD, APRN, ANP-BC

Yale University, School of Nursing, Orange, CT

Sedentary behaviors, physical activity, and fat intake are modifiable lifestyle factors of cardiovascular disease (CVD) risk. Little is known about the relationship among lifestyle behaviors and the mechanism explaining the effects of lifestyle behaviors on CVD risk conditions among the high-risk populations, African Americans (AAs). The purpose of the study is to examine direct and indirect effects of sedentary behaviors on the prevalence of CVD risk conditions through physical activity and fat intake in AAs with overweight or obesity.

Sedentary behaviors and physical activity were measured by the Paffenbarger Physical Activity Questionnaire. Sedentary behaviors included eating, reading, desk work, watching TV, sitting, or using a computer. The physical activity index (PAI) (kcal/week) was calculated by the items on walking, climbing stairs, or leisure activity. Fat intake was measured by % energy from fat intake by the Fat Screener. The CVD risk conditions included hypertension, heart failure, stroke, angina, and myocardial infarction. Multiple mediational analysis with bootstrapping was conducted. Age was included as a covariate in the model.

A total of 225 AAs (mean body mass index = 32.4 ± 6.7 kg/m²; mean age = 53.4 ± 14.0 years; 77.8 % women; mean sedentary behavior time = 46.74 ± 19.7 h/week; 44% with CVD risk conditions) participated in a cross-sectional study. Sedentary behaviors had a direct effect on PAI ($B = -16.75$, $p = .03$) and fat intake ($B = 0.05$, $p = .01$). The PAI ($B = -0.00$, $p = .01$) and fat intake ($B = 0.13$, $p = .00$) also had a direct effect on the prevalence of CVD risk conditions. Sedentary behaviors did not have a direct effect on the prevalence of CVD risk conditions ($B = 0.01$, $p = .29$). However, there was a significant indirect effect of sedentary behaviors on the prevalence of CVD risk conditions through two mediators—physical activity and fat intake ($B = 0.01$, 95% CI = 0.00, 0.02).

The relationship between sedentary behaviors and the prevalence of CVD risk conditions was fully mediated by physical activity and fat intake in AAs. Findings suggest that increasing physical activity and decreasing fat intake may be important particularly for sedentary AAs to improve CVD risk conditions.

TRAIT/TASK FIT: EFFECTS OF AGENCY, COMMUNION & UNMITIGATED COMMUNION ON CARDIOVASCULAR RESPONSE TO AGENTIC & COMMUNAL TASKS

Jill B. Nealey-Moore, PhD, David R. Moore, PhD

University of Puget Sound, Tacoma, WA

Across a number of studies, individuals high in agency, communion, and unmitigated communion (UC) show elevated cardiovascular responses to interpersonal tasks, in contrast to individuals low on these traits. This study examined reactivity to tasks differentially designed to activate agentic and communal concerns, exploring whether stress is activated by orientation match or mismatch. 74 young-adult dating couples watched a film clip, prepared remarks, and discussed their opinions about the film in a verbal interaction task with their partner. Based on random assignment, couples were told their verbal responses would be rated on either individual/agentic dimensions (quality of opinions, depth of thought, word choices) or relational/communal dimensions (active listening, warmth/caring displayed, respect conveyed). Regardless of condition, participants high in trait agency showed larger increases in systolic blood pressure (SBP), $p < .05$ during the discussion task. For those in the agentic condition, there was no effect of agency on physiology, but for those in the communal condition, low agency related to greater increases in SBP, $p < .05$, & heart rate (HR), $p < .01$, showing that the task was more stressful for low (vs. high) agency individuals instructed to behave communally. Individuals who were high (vs. low) in trait communion responded to the task with larger increases in SBP, $p < .005$, diastolic blood pressure (DBP), $p < .05$, & HR, $p < .05$. However, this increase in reactivity was predominantly accounted for by high communion individuals responding in the communal condition, as those individuals showed larger increases in SBP, $p < .001$, DBP, $p < .05$, & HR, $p < .001$, than those lower in trait communion. Trait communion did not affect responses in the agentic condition. Finally, there was no overall relationship between level of UC and task response, nor within the communal condition, despite expectation this trait/situation fit would be activating. For individuals given agentic task directions, people high (vs. low) in UC showed less HR reactivity, $p < .05$, and particularly when listening to their partner speak, they also showed smaller SBP, $p < .05$, & DBP, $p < .05$, responses. This may indicate that people high in UC are using listening time to plan their responses rather than attend to their partners, consistent with task directions and a more agentic orientation. Implications for methodology and understanding the impact of trait/situation fit are discussed.

USING FAITH-BASED HEALTH FAIRS TO EVALUATE CLERGY CARDIOVASCULAR DISEASE RISK FACTORS

Cardella L. Leak, MPH¹, Jessica M. Escareno, MPH², Asos Mahmood, MD, MPH¹, Niels French, MA³, Jonathan C. Lewis, MDiv, BCC⁴, Weiyu Chen, MPH⁵, Chandra Kern, MPH⁵, Obrenka Thompson, MPH⁶, Brook E. Harmon, PhD, RD, FAND¹

¹University of Memphis, Memphis, TN; ²University of Memphis School of Public Health, Memphis, TN; ³Methodist Healthcare, Memphis, TN; ⁴Methodist Le Bonheur Healthcare, Memphis, TN; ⁵University of Memphis, Cordova, TN; ⁶Metro Nashville Public Health Department, Harvest, AL

Background: Obesity is associated with higher rates of cardiovascular disease (CVD) risk factors, including hypertension, diabetes, and high cholesterol. The Southeastern U.S has high rates of these risk factors as well as high rates of religious affiliation and church attendance. Church leaders are influential in their communities and important gatekeepers in the delivery of faith-based health promotion programs. However, clergy have higher rates of chronic disease and obesity than the general population. This study used data collected at United Methodist Church annual conference health fairs to examine the CVD risk factors of church leaders in the Mid-South.

Methods: In 2016, 295 clergy and church laypersons from Memphis, TN, Arkansas (AR) and Mississippi (MS) attended health fairs. Participants self-reported demographics, including medication usage, height and weight, and received screenings for blood pressure, cholesterol, and blood glucose. Logistic regressions were used to examine the likelihood of participants meeting recommendations for blood glucose, blood pressure, and cholesterol.

Results: Participants were on average 62.7 ± 13.7 years old, White (73%), female (53%), and overweight (BMI= 29.5 ± 5.6). Medication was taken for blood pressure, blood sugar, and cholesterol by 22.4%, 1.4%, and 7.8% of participants, respectively, with 30.5% of participants taking 2 or more medications. Males were more likely than females to be overweight ($p = .03$) and have blood glucose values above normal ($p = .02$) while females were more likely to have higher cholesterol values ($p < .001$). Compared to Whites, African Americans were more likely to be classified as overweight or obese ($p < .001$) and have hypertension ($p = .05$). Compared to AR Behavioral Risk Factor Surveillance System (BRFSS) data, AR health fair participants had a higher prevalence of high blood pressure than the general population (52.6% vs. 38.7%). Compared to MS BRFSS data, MS health fair participants had higher prevalence of high blood pressure than the general population (52.8% vs. 40.2%). Older participants (OR: 0.97; 95% CI: 0.95, 0.99), males (OR: 0.56; 95% CI: 0.33, 0.96), and those with a higher BMI (OR: 0.89; 95% CI: 0.85, 0.94) had lower odds of meeting blood glucose recommendations. Older participants (OR: 0.97; 95% CI: 0.95, 0.99) also had lower odds of meeting blood pressure recommendations. However, males (OR: 4.91; 95% CI: 2.52, 9.56) had lower odds of meeting cholesterol recommendations.

Conclusion: Given our findings related to the high prevalence of overweight and obesity as well as high blood pressure among clergy, health fairs should be considered opportunities to monitor clergy health and potentially conduct interventions related to reducing CVD risk factors.

ASSOCIATIONS BETWEEN BEHAVIORAL FACTORS AND METABOLIC SYNDROME AMONG ASIAN AMERICANS

Keith M. A. Ilagan, BA¹, Sugandha Gupta, B.S.², Amanda M. Marin-Cholom, PhD³, Tracey A. Revenson, Ph.D.⁴

¹Hunter College, Staten Island, NY; ²The Graduate Center, CUNY, New York, NY; ³Columbia University, Jersey City, NJ; ⁴Hunter College & The Graduate Center, City University of New York, New York, NY

BACKGROUND: Metabolic Syndrome (MetS) is a term that connects several risk factors for cardiac disease, diabetes, and all-cause mortality in multiple ethnic groups. Little research has examined MetS and its predictors among Asian Americans (AA). Only one study (Palaniappan et al., 2011) examined Asian American subgroups using an adjusted and unadjusted waist circumference and found significantly higher prevalence of MetS for AA at all BMI levels with the adjusted waist circumference. This suggests that lower cutoff values for waist circumference be used for MetS diagnoses for AA, given their smaller bone structure.

AIM: This study examines how psychological (anxiety, depression) and behavioral (sleep duration, physical activity) factors influence MetS scores in a large sample of 3,967 Asian American adults, using both adjusted and unadjusted MetS scores.

METHOD: Data were collected from medical records and self-report questionnaires of AA adults attending a preventive care visit (1864 women, 2103 men; M age=38; SD =10). MetS was assessed using NCEP ATP III criteria, with and without adjustment of waist circumference. Depressive symptoms were assessed with the Patient Health Questionnaire-9, anxiety with the General Anxiety Disorder-7, and physical activity by whether weekly MVPA was the recommended >150 minutes. Multiple regression analyses examined each predictor separately. Prescribed medication for high BP, hyperglycemia, dyslipidemia, depression, and sleep disorder were covaried.

RESULTS: Prevalence of MetS among AAs increased from 5% to 7% in women and 9% to 18% in men using the NCEP ATP III criteria adjusted for a smaller waist circumference. Shorter sleep duration was associated with higher adjusted MetS scores, as well as the individual components of SBP, DBP, waist circumference, and fasting glycemia. Anxiety was associated with higher triglycerides, waist circumference, and fasting glycemia. Participants who reported >150 minutes of weekly MVPA had significantly lower MetS scores (adjusted and unadjusted) than those who did not.

CONCLUSIONS: Adjusting NCEP ATP III MetS criteria using a smaller waist circumference increased prevalence among AA, doubling it for men, suggesting that current guidelines may be underestimating MetS prevalence among AA. Behavioral factors should be considered in designing interventions to reduce MetS among AA. The findings emphasize the need to study MetS and its predictors within specific ethnic and cultural groups.

ATTENTION AND EXECUTIVE FUNCTION, BUT NOT MEMORY, PREDICT MORTALITY IN HEART FAILURE

Emily Gathright, PhD¹, Mary Dolansky, RN, PhD², John Gunstad, PhD³, Richard Josephson, MS, MD, FACC, FAHA⁴, Shirley Moore, PhD², Joel W. Hughes, PhD³

¹Alpert Medical School of Brown University and The Miriam Hospital, Providence, RI; ²Frances Payne Bolton School of Nursing, Case Western Reserve University, Cleveland, OH; ³Kent State University, Kent, OH; ⁴University Hospitals Cleveland Medical Center, Cleveland, OH

Introduction: Heart failure (HF) remains a significant concern for healthcare providers seeking to improve morbidity and mortality. The prevalence and impact of cognitive impairment in HF is increasingly recognized. As cognitive impairment can be detrimental to self-management, it seems likely that cognitive function may also be predictive of outcomes such as mortality. However, little work has tested whether cognitive function is related to mortality risk in HF.

Purpose: To evaluate the effect of cognitive function on mortality risk in HF.

Method: Cognitive function, including the domains of attention, executive function, and memory, were assessed in 325 patients with HF participating in an observational study of self-management behavior. All-cause mortality data were obtained from the National Death Index (median 2.95 years of follow-up). The relationship between each domain of cognitive function and mortality was assessed with Cox proportional hazards regression. Age, gender, New York Heart Association Class (i.e., HF severity), and Patient Health Questionnaire-9 score (i.e., depressive symptoms) were included as covariates.

Results: Participants were 325 patients with systolic HF aged an average of 68.6 ± 9.6 years (59% male, 73% Caucasian). Fifty-seven deaths (17.5%) occurred. Independent predictors of increased mortality risk included older age (HR: 1.05, 95% CI: 1.02 – 1.09), male gender (HR = 1.94, 95% CI: 1.04 – 3.60), and higher depressive symptoms (HR: 1.07, 95% CI: 1.02 – 1.13). Following adjustment for these covariates, better attention was associated with decreased mortality risk (HR = .95; 95% CI: .91 – .99). Similarly, higher executive function was related to decreased mortality risk (HR = .95; 95% CI: .91 – .98). Memory was not related to mortality risk (HR = .99; 95% CI: .96 – 1.04).

Conclusion: Higher attention and executive function, but not memory, were associated with better survival in HF. Medication non-adherence is more strongly associated with memory than attention and executive function, so the current findings may not be explained by medication non-adherence. It is possible that impairment in attention and executive function reduce self-management in other areas, or are markers of more severe disease pathophysiology. Further studies to define the mechanisms of this relationship may ultimately provide insight to mitigate the effects of cognitive impairment on poorer prognosis in HF.

CARDIAC SELF-BLAME, CONTROL APPRAISALS, DEPRESSION, AND HEALTH-RELATED QUALITY OF LIFE IN CARDIAC REHABILITATION PATIENTS

Kadie M. Harry, M.A.¹, Kalon R. Eways, M.A.¹, Elizabeth J. Wilson, B.A.¹, Jillian M. R. Clark, Ph.D.², Marcia Waters, RN³, Dennis Bergland, B.S.³, Andrew J. Smith, PharmD⁴, Kymberley K. Bennett, PhD¹

¹University of Missouri-Kansas City, Kansas City, MO; ²VA Center of Excellence for Stress and Mental Health, VA San Diego Healthcare System/University of California, San Diego, San Diego, CA; ³Truman Medical Center, Kansas City, MO; ⁴Truman Medical Center; University of Missouri-Kansas City, Kansas City, MO

Following a cardiovascular event, most patients engage in a causal search to understand why it occurred. For example, patients tend to attribute their cardiac events to their own behaviors, referred to as behavioral self-blame (BSB), or to stable aspects of their dispositions, referred to as characterological self-blame (CSB). The Cardiac Self-Blame Attribution (CSBA) scale is a valid 12-item scale that assesses both types of attributions, but the scale has not been examined as a predictor of health outcomes. Thus, the present study examined whether each type of self-blame was related to depressive symptoms and health-related quality of life (HRQoL) among underrepresented cardiac rehabilitation (CR) patients, and whether cardiac control appraisals mediated these relationships. CR patients ($N = 69$) recruited from an urban, safety-net hospital completed questionnaires during their CR orientation appointment. Depressive symptoms were assessed using the Patient Health Questionnaire-9, mental and physical HRQoL were assessed with the SF-12 Health Survey, and control appraisals were assessed with the Control Appraisals Scale-Revised. Most of the sample was male (57.8%) with an average age of 55.7 ($SD = 12.2$) years. A plurality were European American (46%) and African American (46%), and 12.5% were uninsured or had a hospital discount. Hayes's PROCESS macro was used to test for mediation. BSB was not significantly related to depressive symptoms or mental HRQoL and neither type of self-blame was significantly related to physical HRQoL. However, CSB was significantly positively related to depressive symptoms ($c' = .19, p < .05$), controlling for age, but control appraisals were not a significant mediator. CSB was significantly negatively related to mental HRQoL ($c' = -.62, p < .05$), controlling for age, but control appraisals did not mediate this relationship. Thus, attributing a cardiac event to one's own character was related to higher depressive symptoms and lower mental HRQoL, but this relationship was not explained by cardiac control appraisals. Results suggest that CR providers should assess CSB and design interventions that target these attributions in order to ameliorate potentially aversive mental health effects in CR patients. In addition, future research should examine other variables that may explain the relationship between self-blame and health outcomes among underserved patients with cardiovascular disease.

CORRELATES OF DECLINE IN HEALTH-RELATED QUALITY OF LIFE AMONG ADOLESCENTS AND YOUNG ADULTS WITH CONGENITAL HEART DISEASE

Jennifer DeSalvo, B.S.¹, Jamie L. Jackson, PhD², Kyle A. Schofield, B.A.³

¹The Ohio State University College of Medicine, Columbus, OH; ²Nationwide Children's Hospital, Columbus, OH; ³Washington State University, Pullman, WA

Introduction: Patient-reported outcomes, such as health-related quality of life (HRQoL), are associated with increased morbidity and mortality among chronically ill populations. Yet, little is known about how HRQoL changes over time among adolescents and young adults with congenital heart disease (AYAConHD), which affects more than 40,000 births per year in the United States alone. Strategies that tailor healthcare to address physical, emotional, and social HRQoL may reduce the burden of CHD morbidity and mortality. This study aims to a) examine change in HRQoL from baseline (T1) to 3-years follow-up (T2) and b) identify demographic and medical predictors of change.

Methods: Participants included 62AYAConHD ($M_{age} = 17.9 \pm 2.2$, range=15–22 years, at T1; 58% female; cardiac lesion severity=27% simple, 50% moderate, 23% complex) recruited from a pediatric and an adult hospital who completed the RAND 36-Item Health Survey of HRQoL at T1 and T2. Paired T-tests analyzed change in HRQoL. Change scores were calculated for HRQoL by subtracting T1 from T2 scores. Pearson correlations examined associations between baseline demographics (age, sex, estimated family income, distance from cardiology clinic) and change scores for HRQoL. An ANOVA examined change in HRQoL across lesion severities.

Results: HRQoL declined in several domains, including role limitations due to emotional concerns ($t=2.17, p=0.03$), emotional well-being ($t=2.64, p=0.01$), social functioning ($t=2.05, p=0.05$), and pain ($t=2.29, p=0.03$). Being older was associated with a steeper decline in role limitations due to physical health ($r=-0.26, p=0.04$), being female was associated with greater decline in role limitations due to emotional problems ($r=-0.30, p=0.02$), and having a lower family income was associated with a greater decline in physical functioning ($r=0.40, p=0.01$).

Conclusions: Significant reductions in multiple domains of HRQoL were identified after only 3 years. Demographic factors were associated with declines in various areas of HRQoL. Given the relationship between HRQoL and health outcomes, pediatric and adult healthcare providers should consider monitoring change in patient-reported outcomes over time, and for those with risk factors for decline, offer psychosocial resources.

DOES LOW CHOLESTEROL LEAD TO HIGHER MORTALITY IN ADULTS WITH HEART FAILURE? IMPLICATIONS FOR CHOLESTEROL-LOWERING IN HF

Nolan Vora, N/A¹, Sundar Natarajan, MD², Binhuan Wang, PhD³¹VA New York Harbor Healthcare System, NY, United States, New York, NY; ²NYU Langone Health, New York, NY; ³NYU School of Medicine, New York, NY**BACKGROUND:** Several studies have shown a linkage between low cholesterol levels and a worse prognosis in patients with HF. The effects of statin on patients with HF remain unclear. Statin and other lipid-lowering agent usage in patients with HF may not be appropriate.**PURPOSE:** This study sought to: a) determine the relationship between intrinsically low cholesterol and mortality in patients with HF, and b) assess if lipid-lowering agent usage provides a benefit in patients with HF.**METHODS:** Data on patients with HF was compiled from the Continuous NHANES database from 1999–2010. These patients were grouped into three total cholesterol categories: Low (200 mg/dL + lipid lowering agent users). Patients were also classed on whether they were taking lipid-lowering agents. These categories were used to examine all-cause mortality via multivariate Cox Models.**RESULTS:** There were 810 patients with HF who were classified into low (n=128), moderate (n=180) and high (n=502) cholesterol categories. Further, 324 were taking lipid-lowering agents, primarily statin. When cholesterol categories were entered into Cox models that excluded patients who died within a year of examination to exclude for frailty (n= 66) and adjusted for age, and CRP, HDL, sodium levels and used high cholesterol as reference, the hazard ratio (HR) for mortality for low cholesterol was 1.915 (95% CI 1.196–3.067, p value 0.0075), and for moderate cholesterol 0.852 (95% CI 0.567–1.280, p value 0.4365). When we compared lipid-lowering agent usage using Cox models that adjusted for age, cholesterol (linear), CRP, HDL, sodium levels, non-users showed a HR of 1.555 (95% CI 1.068–2.265, p value 0.0220).**CONCLUSION:** Inherently low cholesterol patients had significantly worse prognosis compared to high cholesterol patients. This could imply that intrinsically low cholesterol is an indicator of poor prognosis. Lipid-lowering agent users were shown to have significantly better prognosis compared to non-users. These findings support that pharmacologically induced low total cholesterol does not have a negative effect on patients with HF. Continuing statin medication should be advised for patients with HF.**CORRESPONDING AUTHOR:** Nolan Vora, N/A, VA New York Harbor Healthcare System, NY, United States, New York, NY; nnv217@nyu.edu

DOSE EFFECT OF SMARTPHONE BREATHING MEDITATION UPON BLOOD PRESSURE AMONG PRE-HYPERTENSIVE ADULTS

Jessica Chandler, Ph.D.¹, Zack Adams, PhD², Vanessa Diaz, MD¹, John Sieverdes, PhD¹, Mercedes Cain, HS¹, Bradley Perlitz, HS¹, Candie Mendez, HS¹, Brenda Brunner-Jackson, MPH¹, Sachin Patel, MSc¹, Frank Treiber, Ph.D.¹¹Medical University of South Carolina, Charleston, SC; ²Indiana University, Indianapolis, IN**Background:** Pre-hypertension (HTN), a primary risk factor for HTN affects ~33% of adults. Chronic stress is a risk factor for HTN and cardiovascular disease. Breathing awareness meditation (BAM) reduces stress levels and blood pressure (BP), but optimal dosage level has not been determined. An iOS and Android smartphone BAM app (Tension Tamer, TT) uses text/audio instructions with proprietary embedded, validated reflective photoplethysmography software that captures real-time heart rate (HR) from a user's fingertip placed over video camera lens during BAM sessions. Users receive feedback graphs after each session showing their HR changes. TT timestamps all HR data, which provides an index of adherence to completing sessions. Three dosages of TT were tested over a 6-month trial.**Methods:** Sixty-four adults with pre-HTN (mean age: 34.9 yrs; 35 males; 33 White; 31 Black) (mean SBP over 3 consecutive screenings: 128.3 mmHg; 95% recruitment rate) were randomly assigned to 5, 10 or 15 minute (min) sessions, twice daily.**Results:** Mixed modeling results showed a significant time effect for systolic BP (SBP) with a dose-response effect at months 3 (5 min= -6.8;10 min= -6.1;15 min= -12.1 mmHg, p<.02) and 6 (5 min=-5.1;10 min= -8.3;15 min= -12.4 mmHg, p<.02). Adherence declined over time and was lowest in the 15 min dose group, though SBP reductions were maintained. Generally, adherence was negatively associated with dose as the study progressed. Average % adherence declined from month 1 through month 6 across dosage groups (ps<.001); 5 min (mth 1: 76% to mth 6: 78%), 10 min (mth1: 76% to mth 6: 73%) and 15 min (mth 1: 73% to mth 6: 48%).**Conclusion:** The TT app is acceptable and useful in tracking adherence and shows promise in reducing SBP in adults with pre-HTN. A 12-month two arm (TT vs enhanced attention control) efficacy RCT is underway.**CORRESPONDING AUTHOR:** Jessica Chandler, Ph.D., Medical University of South Carolina, Charleston, SC; chandlje@musc.edu

6:15 PM-7:15 PM

EXERCISE TRAINING TO IMPROVE PHYSICAL FUNCTION AND QUALITY OF LIFE IN HEART FAILURE PATIENTS: A META-ANALYSIS

Alexander Beekman, N/A¹, Binhuan Wang, PhD², Sundar Natarajan, MD³¹New York University, Teaneck, NJ; ²VA New York Healthcare System, New York, NY; ³NYU Langone Health, New York, NY

Background: Heart Failure (HF) is a leading cause of morbidity and mortality. More than half of HF cases have Heart Failure with Preserved Ejection Fraction (HFpEF). No good treatment currently exists for HFpEF. Small clinical trials indicate that exercise training may be an effective treatment for HFpEF. A few meta-analyses of these trials have been conducted but these only include approximately half of the available data and there were methodological problems. Our goal was to use all currently available data to quantitatively evaluate the effectiveness of exercise as treatment for HFpEF.

Methods: Our search of PubMed, Web of Science, and Embase for ((HFpEF OR Heart Failure) AND (Exercise Training OR Exercise OR ET)) resulted in 1134 studies. Of these, 68 papers were selected for abstract review. After all papers were reviewed, 8 fit the inclusion criteria for the meta-analysis. Biographic data, indicators of physical function such as the 6 Minute Walk Test (6MWT), the Minnesota Living with Heart Failure Questionnaire and the Short Form 36 were extracted from the included studies. After excluding pre-post studies, 7 randomized studies were included for the 6MWT outcome, 7 for the MLWHFQ and 6 for the SF-36 physical function QOL for the random effects meta-analysis.

Results: We analyzed 6–7 studies. Mean difference for the 6MWT for HFpEF patients was 44.34 (95%-CI 22.77, 65.92), showing a clear improvement in physical function. For the MLWHFQ outcome, mean difference was -7.07 (95%-CI -13.71, -0.42). Lower scores indicate better quality of life, therefore HFpEF patients placed on an exercise regimen experienced a better HF-specific quality of life after participating in the trial. Finally, when we assessed studies that evaluated SF-36 physical function as an outcome, mean difference was 6.73 (95%-CI 1.45, 12.01). Even when we included studies that did not include a control group (n=6) or tested alternate forms of exercise (n=2) in sensitivity analyses, the results were robust and the results did not change.

Conclusion: Exercise is a promising treatment for HFpEF. There is a clear relation between exercise training and both improved physical function and increased quality of life. Further large scale randomized clinical trials need to be carried out to definitively show the benefits of exercise on patients with HFpEF.

HIGHER ANXIETY AND WILL TO LIVE ARE ASSOCIATED WITH POORER ADHERENCE TO CARDIAC REHABILITATION

Kristie Harris, M.S.¹, Derek R. Anderson, Ph.D.², Jacob Landers, M.A.³, Charles F. Emery, Ph.D.⁴¹Warren Alpert Medical School of Brown University, Providence, RI; ²VA Puget Sound Healthcare System, Steilacoom, WA; ³The Ohio State University, Dublin, OH; ⁴Ohio State University, Columbus, OH

Background: Despite the documented benefits of cardiac rehabilitation (CR), adherence remains suboptimal. Greater distress (e.g. depression and anxiety) has been associated with both better and poorer adherence. Will to live (i.e. desire, determination, and effort to survive) has been associated with survival among cardiac patients, thus it also may be relevant to CR adherence. In particular, will to live may exacerbate the influence of depression and anxiety on CR adherence. It was hypothesized that depression and anxiety would be negatively associated with adherence, and that will to live would moderate these relationships.

Methods: Sixty patients (mean age = 56.9 ± 10.8 years; 38 males) completed self-report measures within a week of starting outpatient CR. The 14-item Hospital Anxiety and Depression Scale (HADS) was used to measure symptoms of depression and anxiety, with higher scores reflecting greater distress. The 5-item Wish to Prolong Life questionnaire was used to assess will to live. Patients rated their desire to continue living across varied conditions (e.g. "Even if I could not get out of bed, I would want to live rather than die") on a 5-point Likert scale, with higher scores indicating greater desire to live, regardless of potential consequences. Hierarchical regression analyses were performed to predict CR adherence, measured as session attendance (%) and program completion (yes/no) from depression and anxiety, as well as the interaction of those variables with will to live.

Results: Neither depression nor anxiety was significantly associated with CR adherence ($p > .33$). However, there was a significant interaction of will to live with anxiety in predicting attendance ($\beta = -0.31, p = .03, \text{Model } R^2 = 0.19, p = .01$), reflecting that anxiety predicted lower CR attendance only among patients reporting greater endorsement of will to live.

Conclusions: These data help clarify the complex relationship between distress and CR adherence. Findings suggest that higher anxiety is associated with poorer adherence, but only in combination with greater motivation for living. Patients reporting higher anxiety and greater will to live at the start of CR may benefit from additional guidance regarding strategies to make actionable behavioral change in the context of CR.

INTERNAL HEALTH LOCUS OF CONTROL AND ANXIETY IN PATIENTS WITH LEFT VENTRICULAR ASSIST DEVICES

Connor Tripp, MS, CRC¹, Shaina Gulin, PhD², Cait Chizmar, BA², Eileen Burkner, PhD, CRC²¹East Carolina University, Greenville, NC; ²University of North Carolina Chapel Hill, Chapel Hill, NC

Six million Americans are living with heart failure and this number is expected to increase by 46% within the next 15 years. Surgically implanted mechanical pumps, Left Ventricular Assist Devices (LVAD), are becoming a more common treatment for end stage heart failure. However, there is limited research on the patient experience of living with an LVAD. This study, consisting of 28 patients with LVADs recruited from the heart failure clinic of a large academic medical center, examined relationships between stressors specific to living with an LVAD, levels of generalized anxiety, and health locus of control (HLOC). Bivariate correlations were calculated for a researcher-developed questionnaire of LVAD stressors, the Generalized Anxiety Disorder-7 item scale (GAD-7), and the Multidimensional Health Locus of Control Scale. Eighteen percent of patients endorsed clinically significant levels of anxiety on the GAD-7. Higher scores on the GAD-7 were significantly positively correlated with several LVAD stressors including stress related to the driveline ($r = .72, p < .01$), LVAD-related pain or discomfort ($r = .88, p < .01$), and fear of LVAD-related infection ($r = .76, p < .01$). Participants with a higher internal health locus of control reported lower levels of anxiety on the GAD-7 ($r = .48, p < .05$). A series of regression analyses showed that among all LOC types (Internal HLOC, Powerful Others HLOC, Chance HLOC), greater Internal HLOC significantly predicted lower stress related to the driveline, $\beta = -.62, t(21) = -3.62, p < .01$; possibility of having to change over to the backup controller, $\beta = -.50, t(22) = -2.79, p < .05$; dressing changes, $\beta = -.53, t(21) = -3.08, p < .01$; LVAD-related pain or discomfort, $\beta = -.51, t(22) = -2.98, p < .01$, and showering with the LVAD, $\beta = -.49, t(22) = -2.61, p < .01$. Results indicate a relationship between an internal health locus of control and decreased levels of anxiety and LVAD-related stress. Further research is needed to determine whether interventions that promote an internal health locus of control may improve quality of life for LVAD patients.

LOWER ESTIMATED GLOMERULAR FILTRATION RATE IS ASSOCIATED WITH POORER VISUAL MEMORY PERFORMANCE AMONG OLDER ADULTS

Regina Wright, PhD¹, Desiree C. Bygrave, PhD¹, Denee T. Mwendwa, PhD²¹University of Delaware, Newark, DE; ²Howard University, Washington, DC

Neurocognitive decline and decline in renal function are significant public health issues that strongly impact older adults. Often exacerbated by age-related vascular and metabolic co-morbidities, prior evidence suggests that poor renal function is linked to neurocognitive decrements and cognitive decline. Given the documented link between these age-related factors, it is vital to understand the subclinical changes that precede the onset of renal disease and neurocognitive decline and/or dementia among healthy older adults; however, the role of renal function in neurocognitive performance among older adults without frank renal disease (i.e., chronic kidney disease, end stage renal disease) is not well understood. Therefore, the aim of the current study was to examine relations of eGFR to cognitive function among a racially diverse sample of community-based older adults, absent of renal disease, using data from the Healthy Heart and Mind (HHM) Study. The HHM Study is a cross-sectional examination of relations of subclinical cardiovascular disease to brain pathology and neurocognitive function among community-dwelling older adults. Sixty participants (26.3% male; 29% African American) with a mean age of 68.63 years (SD=6.04) completed an eligibility screening, neuropsychological test battery, vascular testing, a blood draw, and structural MRI. The domains of neurocognitive function assessed included attention and cognitive flexibility, verbal fluency, verbal memory, visuospatial memory, working memory, and perceptuo-motor speed. Multiple regressions were used to analyze relations among eGFR and performance on specific neuropsychological tests, adjusting for age, gender, education, body mass index, and systolic blood pressure. Results showed that eGFR was significantly and positively associated with short delay ($p < .05$) and long delay ($p < .01$). That is, lower eGFR was associated with poorer performance. Results suggest that renal function may play an important role in visuospatial memory among older adults even prior to the potential onset of renal disease. Future studies might examine whether volume loss in specific brain areas may mediate this association. In addition, future research should assess whether pharmaceutical and lifestyle interventions aimed at promoting renal health may help to delay visuospatial memory decline among older adults; however longitudinal studies are needed to test these hypotheses.

PERCEIVED CONTROL, PSYCHOLOGICAL DISTRESS, AND ADHERENCE TO HEALTH BEHAVIORS IN PATIENTS IN CARDIAC REHABILITATION

Kalon R. Eways, M.A.¹, Kadie M. Harry, M.A.¹, Jillian M. R. Clark, Ph.D.², Elizabeth J. Wilson, B.A.¹, Alisha Howarter, MA¹, Kymberley K. Bennett, PhD¹¹University of Missouri-Kansas City, Kansas City, MO; ²VA Center of Excellence for Stress and Mental Health, VA San Diego Healthcare System/University of California, San Diego, San Diego, CA

Evidence supports a relationship between psychological distress and health outcomes in patients with cardiovascular disease (CVD). For example, anxiety and depression have been shown to negatively affect health behavior adherence. Less is known, however, about the cognitive and emotional precursors to distress within the context of CVD. This project assessed relationships between perceived control (PC), psychological distress, and health behavior adherence in patients in cardiac rehabilitation (CR). It was hypothesized that symptoms of anxiety and depression would mediate the relationship between PC and adherence.

Patients in CR ($N = 146$) completed questionnaires at the beginning of CR (Time 1) and 12 weeks later at the end of CR (Time 2). The mean age of participants was 64 years, and most were male (69%) and European-American (94%). Two forms of PC (prevention and recovery), anxiety symptoms (using the Beck Anxiety Inventory), and depressive symptoms (using the Beck Depression Inventory-II) were measured at Time 1. Health behaviors were measured at Times 1 and 2 using an adapted version of a validated health behavior scale. Adherence was calculated by coding whether participants' behaviors met current recommendations.

Hayes' PROCESS macro was used to test for mediation. First, anxiety and depressive symptoms failed to mediate the relationship between prevention-focused PC and adherence. However, prevention control was negatively related to depressive symptoms ($a_2 = -2.19, p < .01$), and had a significant direct effect on adherence ($c' = .371, p = .01$), after controlling for covariates. Prevention control was unrelated to anxiety symptoms, and neither anxiety nor depressive symptoms predicted adherence. Second, anxiety and depressive symptoms were nonsignificant mediators of the relationship between recovery-focused PC and adherence. Recovery control had significant direct effects on anxiety symptoms ($a_1 = -2.92, p < .01$), depressive symptoms ($a_2 = -3.80, p < .001$), and adherence ($c' = .591, p = .001$), after controlling for covariates. Neither anxiety nor depressive symptoms were related to adherence.

Findings did not support mediation. However, significant associations were found between PC and immediate and long-term physical and mental health outcomes, suggesting that PC should be assessed upon entrance to CR. If patients endorse low levels, further assessment and intervention may be warranted to prevent aversive outcomes and facilitate recovery.

PERCEIVED HEALTH COMPETENCY PREDICTS EMOTIONAL DISTRESS AMONG YOUNG ADULT SURVIVORS OF CONGENITAL HEART DISEASE

Carine Leslie, B.S., Kathryn Vannatta, PhD, Jamie L. Jackson, PhD

Nationwide Children's Hospital, Columbus, OH

Objective: Congenital heart disease (ConHD) places survivors at increased risk for health complications as they age and requires long-term medical management. Perceived health competency, or how capable individuals feel in managing their health, is linked to emotional adjustment in various disease populations, but has not been investigated among ConHD survivors. The present longitudinal study examined perceived health competency at baseline (T1) as a predictor of emotional distress at three-year follow up (T2). Lower T1 PHC was hypothesized to predict higher T2 emotional distress, independent of T1 emotional distress and T1 functional impairment.

Methods: ConHD survivors ($n=125$; $M_{age}=27, SD=7.26$; range=15–39; 58.6% female; 25% simple, 44% moderate, 31% complex) were recruited from a pediatric and an adult hospital as part of a larger study. Participants completed measures of general perceived health competency (PHC; e.g., "I handle myself well with respect to my health") and emotional distress (Youth or Adult Self-Report) at T1. At T2, participants completed the Hospital Anxiety and Depression Scale. New York Heart Association functional class, a measure of functional impairment, was abstracted from medical charts at T2. Pearson correlations were performed to establish relationships between study variables. Stepwise linear regression was conducted to determine whether T1 PHC predicted significant variance in T2 depression and anxiety symptoms above and beyond T1 emotional distress and T2 functional impairment.

Results: Lower T1 PHC was significantly associated with greater T1 emotional distress ($r=.50$) and T2 emotional distress, (depression: $r=-.46$; anxiety: $r=-.46$) as well as T2 functional impairment ($r=-.36$). T1 PHC predicted T2 depression ($\beta=-.43, 95\% CI: -.31$ to $-.12$) and anxiety symptoms ($\beta=.38, 95\% CI: -.33$ to $-.11$), and accounted for a significant amount of variance in T2 symptoms of depression ($FD_{depression}=22.06, p.01$) and anxiety ($FD_{anxiety}=18.02, p<0.01$) above and beyond T1 emotional distress. Functional impairment did not account for any additional variance in T2 emotional distress.

Conclusion: Findings suggest that ConHD survivors who feel more competent in managing their health may be less likely to experience future emotional distress. Future research should consider including enhancing patients' confidence in their disease self-management as a component of psychosocial interventions to promote emotional wellbeing among ConHD survivors.

SISTERTALK II: A RANDOMIZED CONTROLLED TRIAL TO IMPROVE ADHERENCE TO WEIGHT LOSS FOR HYPERTENSION CONTROL AMONG BLACK WOMEN

Patricia M. Risica, DrPH¹, Augustine W. Kang, MSc, MA²¹Brown School of Public Health, Providence, RI; ²Brown University School of Public Health, Providence, RI

Introduction: Weight loss, physical activity (PA) and improved nutrition are important behavioral recommendations for hypertension. However, adherence to these health behavior recommendations are poor, especially among Black American women. The present study assessed two mechanisms to deliver a culturally tailored video program for weight loss, PA and nutrition among hypertensive Black women.

Methods: *SisterTalk II* is a Randomized Controlled Trial with two 3-month intervention groups (clinic-delivery (CD) versus home-delivery (HD) channel) and a control group. Participants, recruited from clinical sites in southeastern New England, completed measurements at baseline, and 4 months (4M) and 12 months (12M) after the intervention. The CD group met weekly over 12 weeks and were led by a trained lay-facilitator, while the HD group received intervention materials via mail. Primary outcomes are dietary changes and PA behavior as measured by the food frequency questionnaire (FFQ) and total leisure activity score (TLAS). Secondary outcomes include intervention food-related behaviors, and psychosocial measures (e.g. self-efficacy, social support). Exploratory outcomes include BMI, WC and BP. Analyses of study variables include chi-square and paired-samples t-test. 2-way repeated measures ANOVA assessed group differences. Missing follow-up data were imputed using the last observation carried forward.

Results: The CD group reported the highest increase in consumption of fruits and vegetables (FV) ($p < .001$) at 4M compared to HD and control. HD reported significantly greater decrease at 12M compared to CD ($p = .01$). Both CD and HD reported significantly greater decreases in % Cal Fat at 4M and 12M compared to CTRL (both $p < .001$). The CD group reported the highest increase in PA compared to HD and control at 4M and 12M (both $p < .001$). The CD group reported significantly greater increases in use of goal setting, self-rewards, grocery list and recognizing triggers to unhealthy eating (all $p < .05$) compared to controls. Also, compared with the control group, the CD group reported significantly greater increases in motivation to increase FV intake and to eat less, and confidence in reading food labels (all $p < .05$).

Conclusion: The CD group in *SisterTalk II* reported most of the greatest improvements in FV intake, PA, following intervention-recommended food behaviors, motivation and confidence for several healthy diet behaviors relative to the controls and in some cases, the HD group.

SOCIAL DETERMINANTS OF HYPERTENSION AND TYPE-2 DIABETES IN KENYA: A LATENT CLASS ANALYSIS OF A NATIONALLY REPRESENTATIVE SAMPLE

Rahma Mkuu, MPH¹, Tamika D. Gilreath, Ph.D.², Gabriela Reyes, MPH Student³, Idethia Shevon. Harvey, DrPH⁴¹Texas A&M University, College Station, TX; ²Texas A&M University, Houston, TX; ³CU Denver-Anschutz Medical Campus, Denver, CO; ⁴Texas A & M University, College Station, TX

Objective: Cardiovascular disease is among the leading causes of death in Kenya and type II diabetes (T2D) is a growing chronic health concern in the country. A gap exists in examining how demographic characteristics coalesce to identify individuals at high risk for hypertension and/or T2D in Kenya. The current study examined demographic typologies associated with self-report diagnoses.

Methods: We examined 43,898 individuals between the ages of 15 and 49 from the 2014 Kenya Demographic and Health Survey (KDHS). Descriptive analyses were conducted using STATA 14. Latent class analysis (LCA) was conducted on Mplus 7.4., and explored the social determinants of T2D and hypertension among Kenyan adults. To determine the number of classes, a series of models was conducted starting with a 1-class model followed by specifying an increased number of classes (e.g., 2-class, 3-class, etc.). Optimal model selection was based upon recommended indices including low adjusted Bayesian Information Criterion (BIC) relative to other models, significant Lo-Mendell-Rubin Likelihood Ratio Test (LMR-LRT), and entropy (quality of classification).

Results: Findings from the KDHS revealed that 5% of the population were diagnosed with hypertension and 1% of the population was diagnosed with T2D. Latent class analysis identified four latent class: 1) Single, never married, young adults (11%), who were nonsmokers, has a low likelihood of being diagnosed with hypertension or T2D. 2) Married men, who were over the age of 35 years 2 (17%), were more likely to be smokers and diagnosed with hypertension or T2D. 3) Married women over the age of 30 years (53%), who were typically nonsmokers, had a 10.3% chance of being diagnosed with hypertension. 4) Single, never married individuals, who were under the age of 20 years, had a zero risk of being diagnosed with hypertension or T2D.

Conclusions: The results suggest that Kenyan women over 30 years may be at increased risk of hypertension. Future studies should include additional socio-demographic characteristics. Increasing knowledge of correlates should be used for targeted and tailored health promotion-interventions in this group.

THE EFFECT OF PATIENT DEPRESSION ON CARE PARTNERS' HELPING AND PERCEIVED STRAIN AMONG PATIENTS WITH CONGESTIVE HEART FAILURE

Aaron A. Lee, Ph.D.¹, James E. Aikens, Ph.D.², Ann-Marie Rosland, MD MS³, John Piette, PhD⁴

¹VA Center for Chronic Disease Management, Ann Arbor, MI; ²University of Michigan, Ann Arbor, MI; ³University of Pittsburgh, Pittsburgh, PA; ⁴University of Michigan School of Public Health, Ann Arbor, MI

Background: Patients with congestive heart failure (CHF) frequently receive support for self-care from important family members and friends (i.e., “Care Partners”). Over 20% of CHF patients experience clinical depression, which is associated with higher rates of mortality, morbidity, and hospitalization. Support from Care Partners (CP) can lower the risk of these poor outcomes. The interpersonal theory of depression predicts that individuals with depression will receive less social support than non-depressed individuals. However, some evidence suggests that CPs provide more support to patients they identify as having depression. It is not known whether CPs’ support correspond to patients’ self-reported depressive symptoms. Accordingly, we examined the association between CHF patients reported depressive symptoms and CP reported time spent providing assistance and strain.

Methods: We analyzed baseline survey data from 323 CHF patient-CP dyads participating in a randomized trial. Patients’ CESD-10 scores were dichotomized (10) to create an indicator of probable depression status. Outcome variables were CP reported hours per week helping their patient-partner in person and via telephone, and CP strain (assessed using the Caregiver Strain Index). Negative binomial regression was used to examine over-dispersed count variables. Multiple linear regression was used to examine continuous outcomes. Models controlled for patients’ total cardiovascular comorbidities.

Results: CPs provided more hours of in-person help per week to CHF patients with depression ($M = 3.42$, $SE = .36$) compared to those without depression ($M = 2.46$, $SE = .26$; $IRR = 1.40$, 95%CI: [1.04, 1.87], $p = .025$). CPs also provided more hours of telephone support to patients with depression ($M = 2.94$, $SE = .22$) compared to those without depression ($M = 2.01$, $SE = .16$, $IRR = 1.46$, 95%CI: [1.19, 1.81], $p < .001$). CP strain did not differ between depressed and non-depressed CHF patients ($B = .13$, $SE = .32$, $p = .691$).

Conclusion: Patients with depression received approximately one additional hour of CP reported assistance and telephonic support per week – suggesting that CPs recognize and respond to patients’ depression. Yet, CP reported strain did not differ between depressed and non-depressed patients. These findings provide an important counterpoint to conventional wisdom regarding the impact of depression on patients’ social support.

THE EFFECTS OF GENETIC RISK AND NEIGHBORHOOD SOCIAL FACTORS ON BLOOD PRESSURE IN AFRICAN AMERICANS ADULTS

Raines M. Waggett, Student¹, Tyler McDaniel, M.S.¹, Dawn K. Wilson, Ph.D., FSBM¹, Cody M. King, Student², Sandra Coulon, Ph.D.³

¹University of South Carolina, Columbia, SC; ²Clemson University, Clemson, SC; ³Medical University of South Carolina, Charleston, SC

African-American adults have a long-standing disparity in cardiovascular health in the United States, and disproportionately experience greater rates of elevated blood pressure (BP) as compared to other ethnic minorities and Caucasians. Gene environmental interaction frameworks offer insight into how neighborhood social factors may moderate genetic susceptibility in understanding blood pressure outcomes. The purpose of the current study was to examine the effects of genetic risk (HPA axis index) and neighborhood factors (social control- likelihood of neighbors intervening in negative events-; and social life- positive interactions with neighbors) on BP (systolic BP [SBP], diastolic BP [DBP]) in underserved African-American adults from the Positive Action for Today’s Health (PATH) trial. To evaluate genetic risk, two single nucleotide polymorphisms (SNPs) were genotyped related to the HPA axis (HPA-axis SNP; *Bcl1* [rs41423247], *FKBP5* [rs1360780]). Blood pressure data was assessed for each participant by averaging three assessments using a standard research protocol. Regression analyses were conducted to assess the effects of genetic risk and neighborhood social factors on SBP and DBP outcomes. The sample size included 165 participants (59% female; BMI $M=30.94$, $SD=7.46$; age $M=52.10$, $SD=14.64$). The regression model for SBP was significant ($F [14,149] = 2.66$, $p < .01$), accounting for over 12% of variance, indicating that age and BP medications were both significant predictors of SBP. The regression model for DBP was also significant ($F [14,149] = 2.23$, $p < .01$), accounting for 10% of variance. In the regression model for DBP, neighborhood social control ($B = -1.37$; $SE = 0.70$; $p=0.05$) and social life ($B = 0.35$; $SE = 0.15$, $p<0.03$) both significantly predicted DBP. DBP was negatively associated with neighborhood social control, suggesting that higher neighborhood social control was associated with lower levels of DBP. Unexpectedly, DBP was positively associated with neighborhood social life, suggesting that greater social life was associated with higher levels DBP. While we did not find any significant gene-by-environment interactions for SBP or DBP, we did identify neighborhood social life and social control as potentially important predictors of DBP. Further research is warranted as this study clearly identifies the neighborhood environment as a potentially important factor in BP regulation, particularly in Africa-American communities.

THE RELATION BETWEEN HEART HEALTHY BEHAVIORS IN COLLEGE-AGED UNIVERSITY STUDENTS

Tyler Kuhn, B.S.¹, Fawn A. Walter, M.S.², David Ede, Jr., B.S.³, Joel W. Hughes, PhD³¹Kent State University, Pittsburgh, PA; ²Kent State University, Stow, OH; ³Kent State University, Kent, OH

Introduction: Behavioral risk factors (BRFs) for cardiovascular disease (CVD) are well established: tobacco use, alcohol abuse, physical inactivity, and poor diet^{1,2}. Sleep quality is emerging as an additional BRF². Together, these BRFs are responsible for considerable modifiable and preventable risk for CVD¹. Addressing multiple BRFs may improve other health variables related to CVD, such as depression, oxidative stress, and cognitive ability^{3,4,5}. We previously suggested that emerging adulthood is a crucial stage of life for addressing BRFs for CVD¹. Intervention during this stage could have a profound effect on future health behaviors and CVD risk. A clustering effect between BRFs has been suggested^{2,6}, but little research has examined how BRFs are related during emerging adulthood. This study examined the relation between smoking behavior, sleep, physical activity, and diet in college-aged university students.

Methods: The sample (N = 89) was aged 19.38 ± 1.43 , 75.3% female, and 78.7% Caucasian. Participants were asked their weekly cigarette smoking frequency. Participants completed self-report inventories of physical activity (Global Physical Activity Questionnaire: GPAQ), dietary intake (Starting the Conversation Questionnaire: STC), and sleep quality (Pittsburgh Sleep Quality Index: PSQI). Correlation analyses were performed to determine the relation between smoking behavior, physical activity, diet, and sleep.

Results: Total PSQI score was positively associated with GPAQ total score, $r = .23$, $p = .03$. GPAQ total score was negatively related to STC score $r = -.244$, $p = .021$. There were no other significant correlations between BRF measures (see Table 1).

Discussion: Besides a negative relation between diet and total physical activity, BRFs were not related. Thus, our data does not support a clustering effect of BRFs in college-aged students. In other words, participants who showed healthy scores on one measure did not necessarily show healthy scores on another, except for diet and physical activity. If true, future efforts may need to target individual BRFs separately during emerging adulthood, as opposed to general BRF interventions. One notable limitation was that alcohol data was not collected, as our sample was under 21. Future research should explore why BRFs related to cardiovascular risk are largely unrelated during emerging adulthood.

MATERNAL EDUCATION IS RELATED TO UNHEALTHY EATING HABITS IN MIDDLE SCHOOL GIRLS

Daniella Carucci, M.S., Mary Kate Clennan, M.S., Patrice G. Saab, Ph.D.

University of Miami, Coral Gables, FL

Introduction: Poor eating patterns are one of the factors that contribute to obesity and chronic disease, particularly among ethnic minority groups. Parents have an important influence on their child's eating habits, as they usually determine which food is available at home and they model dietary behaviors. Maternal education can influence lifestyle habits and support positive health behaviors in families. The purpose of the current study was to investigate whether maternal education is related to their daughters' eating habits.

Methods: The relationship between maternal education (M = 14.95 years, SD = 4.18) and dietary habits was investigated in 338 middle school age girls (M = 11.8 years; 76.3% minority status) enrolled in a 3-week summer program that emphasized the importance of a healthy lifestyle. Maternal education was reported by parents prior to program onset. At baseline, participants were administered an eating behavior survey to assess dietary habits, which included an 8-item healthy eating (0–24) and a 13-item unhealthy eating (0–39) subscale.

Results: Multiple regression analysis indicated that maternal education, age, BMI, and ethnicity are not significantly related to healthy eating habits. However, in a separate multiple regression analysis, years of maternal education, age, BMI, and ethnicity accounted for significant variability in baseline unhealthy eating habits (M = 8.86, SD = 8.18), adjusted $R^2 = .075$, $F(6, 331) = 5.55$, $p < .001$. Results indicate that, controlling for age, ethnicity, and BMI, for every one-year increase in maternal education, unhealthy eating at baseline decreased by .24 points, $t(337) = -2.30$, $p < .05$, 95% CI [-.451, -.035]. Ethnic differences were also found, with Black girls engaging in more unhealthy eating habits, compared to Hispanic girls, controlling for the remaining predictors ($b = 4.17$).

Conclusion: The results of the present study show that maternal education influenced unhealthy eating habits but did not influence healthy eating habits. These findings underscore the role that maternal education plays in children's health outcomes. There are several pathways through which maternal education can influence children's dietary habits, including health knowledge acquisition, food provided at home, and modeled health behavior. Given the importance of maternal education, it may be important to develop interventions aimed to improve health knowledge in parents with low education backgrounds to help reduce chronic disease risk in children.

EXAMINING THE ROLE OF INTUITIVE BELIEFS ABOUT RISK IN THE RISK PERCEPTION-HEALTH BEHAVIOR RELATIONSHIP

Kristen E. Riley, Ph.D.¹, Jennifer L. Hay, Ph.D.¹, Erika Waters, PhD, MPH², Marc T. Kiviniemi, PhD³, Elizabeth Schofield, MPH¹, Caitlin Biddle, Ph.D.¹, Yuelin Li, PhD.¹, Heather Orom, PhD³

¹Memorial Sloan Kettering Cancer Center, New York, NY; ²Washington University in St. Louis, St Louis, MO; ³University at Buffalo, Buffalo, NY; ⁴CCNY Inc, Buffalo, NY

Purpose: Individuals' conceptualization of their disease risk affects their health behavior engagement. Studies have focused primarily on deliberative (cognitive; quantitative) risk perceptions, but these effects on health behaviors are modest. Individuals may also determine risk using more intuitive (gut-level; automatic) risk beliefs. We examine whether deliberative risk perceptions are related to intuitive risk beliefs, compare their relative contributions to health behavior engagement, and describe their relationships with demographic variables and worry.

Methods: 1002 participants from a nationally-representative panel (82% white, 51.8% female, age 49.8) completed a cross-sectional survey assessing demographics, health behaviors (smoking, red meat consumption, and physical activity), and deliberative risk perceptions (absolute and comparative risk), intuitive risk beliefs (cognitive causation and unknowability), and worry regarding diabetes and colorectal cancer. Cognitive causation is believing that thinking about disease risk tempts fate and increases the chances of developing the disease. Unknowability is believing there is no way of knowing who will contract the disease. Data were analyzed using hierarchical linear regressions and ANOVAs controlling for demographics.

Results: Intuitive risk beliefs and deliberative risk perceptions are positively related. Controlling for demographic variables, intuitive risk beliefs are related to health behaviors above and beyond deliberative risk perceptions. Diabetes risk unknowability was related to smoking ($F=0.08$; p

Conclusions: Intuitive risk beliefs seem to account for more variance in health behaviors than traditional cognitive deliberative risk perceptions. Intuitive risk beliefs also seem to be a better predictor than an affect-only construct such as worry. It is important to consider intuitive risk beliefs in future health behavior interventions.

A BRIEF INTERVIEW PROMOTES AUTONOMOUS MOTIVATION TO DONATE BLOOD

Kristen R. Fox, M.S.¹, Shraddha Selani¹, Holly L. Hays¹, Emily C. Kunkler¹, Caroline D. Martin¹, Jacob Dickman, Christopher R. France, Ph.D.²

¹Ohio University, Athens, OH; ²Department of Psychology, Ohio University, Athens, OH

BACKGROUND: Autonomous motivation is associated with enhanced behavioral intent and engagement. Thus, interventions fostering autonomous motivation to donate blood may bolster the safety and security of the national blood supply. Indeed, interventions informed by the principles of Motivational Interviewing (MI) have been associated with increased donor motivation and behavior, but little is known concerning the specific mechanisms that make these interventions effective. The purpose of the present study was to compare the effects of two distinct, MI-informed interventions on autonomous motivation to donate blood and to evaluate the treatment integrity of both interventions.

METHODS: Participants ($N = 130$) were randomly assigned to participate in one of two brief interventions: 1) a change talk interview, or 2) a decisional balance interview. The change talk interview elicited motivation to donate blood by asking evocative questions, exploring personal goals and values, using importance, confidence, and likelihood rulers, and querying extremes. Alternatively, the decisional balance interview explored perceived benefits and drawbacks of both giving and not giving blood. Both interviews incorporated MI-consistent techniques, such as reflections, summaries, and asking for permission before providing information. Participants completed a measure of autonomous motivation immediately before and after the interview. Interviews were audio recorded, and a random 50% of the interviews were assessed for MI integrity by two independent raters.

RESULTS: With respect to autonomous motivation, a repeated measures ANOVA revealed a significant time by group interaction ($p < 0.01$), which reflected significantly greater increases in autonomous motivation from pre- to post-interview among participants in the change talk group compared to the decisional balance group. MI integrity ratings indicated high levels of empathy and partnership across both interview groups; however, t -tests indicated that the change talk interview was associated with significantly higher scores on the domains of cultivating change talk ($p < 0.01$) and softening sustain talk ($p < 0.01$) relative to the decisional balance group.

CONCLUSIONS: Evocation of change talk is associated with increased autonomous motivation to donate blood. Future work should examine the relationship between MI integrity ratings and blood donation behavior.

A MULTIMODAL EXAMINATION OF IMPULSIVITY AS A PREDICTOR OF OUTCOME FROM TREATMENT FOR BULIMIA NERVOSA

Stephanie Manasse, PhD¹, Rowan Hunt, B.A.², Adrienne Juarascio, PhD¹¹Drexel University, Philadelphia, PA; ²Drexel University, Philadelphia, PA

Outcomes from treatment for bulimia nervosa (BN) are suboptimal, with up to 40–60% symptomatic at post-treatment. To improve outcomes, it is imperative to identify predictors and moderators of outcome. Impulsivity, i.e., the tendency to act rashly without forethought, is an established predictor of BN. Yet, only one study has examined impulsivity as a predictor of outcome from treatment for BN, and no studies have utilized behavioral measurements in doing so. We examined whether baseline levels of delay discounting (i.e., the tendency to prioritize short-term over long term reward) and inhibitory control (i.e., the ability to withhold an automatic response) predicted outcomes from treatment. Individuals with BN (current $n=23$; data collection ongoing) were administered a food-specific and neutral Stop Signal Task and a monetary delay discounting task at baseline of a behavioral treatment for BN. Given evidence that “rapid” (i.e., in four weeks) response is a robust indicator of later outcomes, outcomes were assessed at four weeks and post-treatment (20 weeks) using the Eating Disorders Examination Questionnaire. Poorer food-specific ($r=.47$, $p=.02$) and neutral ($r=.50$, $p=.02$) inhibitory control, but not delay discounting ($r=-.10$, $p=.63$), predicted fewer decreases in binge episodes at week 4. No indices of impulsivity appeared to be strongly associated with changes in self-induced vomiting at week 4 ($r=.05-.27$, $ps=.23-.84$). Only 15 participants (projected $n=25$) have completed treatment, and as such, we rely on effect sizes for interpretation of 20-week data. Prioritizing long-term reward was associated with greater decreases in binge eating at 20 weeks ($r=.48$, $p=.07$). Additionally, poorer food specific ($r=.41$) and neutral inhibitory ($r=.41$) control were associated with fewer decreases in vomiting at 20 weeks ($ps=.11-.13$). Although samples sizes are small, results suggest that several facets of impulsivity predict treatment outcomes for BN. The ability to withhold automatic responses may be especially crucial for early success in treatment, which requires individuals to set and follow a structured eating plan. On the other hand, the ability to long-term reward may be more important for adhering to this eating plan over the course of treatment. Interestingly, inhibitory control may be important for refraining from self-induced vomiting. With replication, results could indicate that the development of impulsivity-focused treatment components are warranted.

AFFECTIVE ASSOCIATIONS WITH THE HPV VACCINE RELATE TO PAST VACCINE BEHAVIOR AND FUTURE INTENTIONS

Lynne B. Klasko, N/A¹, Marc T. Kiviniemi, PhD²¹University at Buffalo, SUNY, Buffalo, NY; ²University at Buffalo, Buffalo, NY

Introduction: HPV is the most commonly sexually transmitted pathogen in the world, with strains 16 and 18 responsible for cervical, anal, and oropharyngeal cancers. As such, routine vaccination is advised for males and females starting at age 11 to prevent future HPV-associated cancers. As policies have recently shifted to cover early adolescents, young adult ages 19–26 are still eligible for the HPV vaccine but are less likely intervention targets and coverage is low with 41.6% of women and 10.1% of men receiving at least one dose in 2015. While HPV vaccine decision making research has traditionally focused on health beliefs, emotions, and stigma related to the virus, this work examines how affective associations with the HPV vaccine relate to past vaccine behavior in young adults and, for those not already vaccinated, future vaccination intentions.

Methods: Participants ages 18–26 ($n=151$) received an emailed flyer disseminated through student organizations at a state university. Interested participants completed an online survey assessing positive and negative affective associations with the HPV vaccine, their own HPV vaccination behavior, and for those unvaccinated, intentions to vaccinate.

Results: More positive affective associations with the vaccine were associated with a greater likelihood of having been vaccinated ($OR=1.73$, $p<0.01$). Negative affective associations were somewhat associated with decreased likelihood of receiving the HPV vaccine, but this relation was only marginally significant ($OR=0.57$, $p=0.05$). Looking at negative affect items individually; however, embarrassment and shame associated with the vaccine predicted decreased likelihood of vaccination ($ORs=0.52$, $ps<0.05$). Only positive affective associations were related to future intentions to get the HPV vaccine ($b=0.41$, $p<0.01$).

Discussion: For young adults, positive affective associations with the HPV vaccine were related to both past vaccine behavior and future intentions. Such affective associations may play a role in whether young adults choose to get vaccinated against HPV. Interventions targeted to this population should include messages that associate getting vaccinated with positive feelings, such as feeling relaxed to have reduced one’s personal risk of getting HPV-related cancer.

AWARENESS OF DNA TESTING FOR HEALTH ISSUES IN A NATIONALLY REPRESENTATIVE SAMPLE

Jennifer M. Bowers, M.A.¹, Jada G. Hamilton, Ph.D., M.P.H.², Brittany C. Miller, M.A.³, Jennifer L. Hay, Ph.D.²¹Stony Brook University, Port Jefferson, NY; ²Memorial Sloan Kettering Cancer Center, New York, NY; ³Stony Brook University, Stony Brook, NY

Background: DNA testing awareness is changing quickly, dictating a need for understanding current patterns of awareness across psychosocial and demographic factors. This study examined levels and correlates of Americans' DNA testing awareness.

Method: Data were obtained from the nationally representative 2017 NCI Health Information National Trends Survey (HINTS). Data from 3,285 adult participants were used (mean age = 49, 51% female, 66% Non-Hispanic White, 16% Hispanic, 10% Non-Hispanic Black, 6% Non-Hispanic Asian) to examine whether participants had heard or read about DNA testing for health reasons (i.e., DNA testing awareness) as the primary outcome; awareness of specific tests was a secondary outcome. Multivariable logistic regression was used to determine correlates of DNA testing awareness. Potential correlates included Internet use (yes/no), seeking health information (yes/no), cancer fatalism (categorical), perceived cancer risk (continuous), family cancer history (yes/no), and demographics (health insurance status, age, general health status, gender, education, income, and combined race/ethnicity).

Results: Over half the sample (57%) endorsed DNA testing awareness. Higher income ($p < .01$), better self-reported general health ($p < .05$), and race/ethnicity ($p < .05$) were significantly associated with DNA testing awareness. In the multivariable model, Asians had lower odds of being aware of DNA testing ($OR = .42$, $p < .01$) than Whites; no differences were observed for other racial/ethnic groups. Significant psychosocial correlates were also identified; those reporting DNA testing awareness were more likely to use the Internet, seek health information, have lower cancer fatalism, and higher perceived cancer risk ($ps < .01$; adjusted model $R^2 = .16$).

Of those aware of DNA testing, most had heard or read about tests determining risk or likelihood of getting a particular disease (88%), or passing on inherited disease to children (87%). Few were aware of tests determining how a disease should be treated (41%), or which drug(s) may or may not work for an individual (43%).

Conclusions: Results demonstrate the strong contribution of psychosocial and demographic factors to DNA testing awareness. Odds of awareness were lower in Asians, demonstrating the need for outreach. Awareness of predictive uses of genetic testing was doubled compared to awareness of precision medicine uses. While more research is needed, this study provides a current snapshot of Americans' DNA testing awareness.

HEALTH LITERACY, SOCIOECONOMIC STATUS, AND ENGAGEMENT IN SHARED DECISION-MAKING IN CANCER

Brittany D. Cullen, MA, Laura M. Perry, BS, Michael Hoerger, PhD, MSCR

Tulane University, New Orleans, LA

Objective: Engaging patient, caregiver, and clinician stakeholders in shared decision-making is a national priority. This study aimed to evaluate whether health literacy explained increased engagement in shared decision-making while accounting for variation in socioeconomic status.

Method: Participants with a history of cancer ($n = 413$) completed a survey battery between July and December 2017 that included validated measures of health literacy, financial strain, and decisional engagement. First, we examined zero-order correlations among health literacy, level of engagement in shared decision-making, five indicators of socioeconomic status, demographics, and health history. Then, a hierarchical multiple regression analysis was conducted to examine whether health literacy explained increased engagement in shared decision-making, over and above the effects of socioeconomic status and other key demographic and health covariates included in the model.

Results: Increased health literacy was significantly associated with increased engagement in shared decision-making ($r = .35$, $p < .001$). Across three indicators, higher socioeconomic status was also associated with increased engagement in shared decision-making ($rs = .11-.12$, $ps = .02-.03$). Health literacy continued to explain increased engagement in shared decision-making ($\Delta R^2 = .10$, $\beta = .33$, $p < .001$) over and above the contribution of socioeconomic status and other covariates.

Conclusion: Findings demonstrate the importance of health literacy in shared decision-making, even when accounting for multiple indicators of socioeconomic status. To better engage patients in the shared decision-making process, clinicians and other stakeholders should examine interventions to improve health literacy for key decisions.

HYPOTHETICAL CASH BENEFIT PARTICIPATION AND TIME OF THE MONTH EFFECTS ON DELAY DISCOUNTING

Kelseanna Hollis-Hansen, MPH¹, Leonard H. Epstein, PhD²¹State University of New York at Buffalo, Buffalo, NY; ²University at Buffalo, Buffalo, NY

People tend to discount the future in favor of immediate rewards. This process of delay discounting is robustly related to income, as people with less income are more likely to focus on immediate needs rather than allocate time or expenses for future use. People on public assistance often rely on limited funds to satisfy basic needs, and in most instances, these funds are provided on a monthly basis. Research suggests that these funds are spent unevenly throughout the month, with the heaviest spending in the beginning of the month and fewer resources available as people get near to their next allotment. It is possible that delay discounting may be an important driver of this phenomenon for people with low income. This hypothesis was tested in a crowdsourced sample of 425 18-55 year-old adults. Delay discounting was measured for participants randomized to hypothetical conditions that varied in whether they were on assistance or had a stable job crossed with whether they had just received their benefits/paycheck or were in the last week of the month. Results showed that people discounted the future more if they were on assistance than if they had a steady job, and discounted the future more if they were in the last week of the month than after they had received their last benefit transfer/paycheck. These results suggest that delay discounting may be an important mechanism that helps understand the challenges that low income people face as they attempt to allocate resources in a constrained environment. The ability to modify discounting of the future and shift priorities from immediate needs to important long-term goals or the ability to implement policy change regarding benefit disbursement could have a great impact on decisions made by people on public assistance.

PROSPECTIVE ASSOCIATION BETWEEN PARENTAL MOTIVATION AND ADOLESCENT HPV VACCINATION

Deanna C. Denman, MA¹, Austin S. Baldwin, PhD², Emily G. Marks, MS³, Jasmin A. Tiro, PhD⁴¹Southern Methodist University, Nashville, TN; ²Southern Methodist University, Dallas, TX; ³UT Southwestern Medical Center, Dallas, TX; ⁴University of Texas Southwestern Medical Center, Dallas, TX

Objectives: Self-Determination Theory (SDT) posits three types of motivation influence behavior: external motivation (based on maximizing rewards or demands), introjected motivation (based on avoiding guilt/shame about others' views of oneself), and autonomous motivation (based on personal values). Parental decisions about the human papillomavirus (HPV) vaccine could be influenced by all three types—to please their child's doctor (external motivation), to avoid feeling guilty (introjected motivation), or because it aligns with one's own values (autonomous motivation). We examined patterns of association between motivation types and HPV vaccination.

Methods: As part of a larger project developing an intervention to promote HPV vaccination, parents (N=183) of unvaccinated adolescents with upcoming appointments during 2015–2016 at safety-net clinics in Dallas, TX completed a telephone-administered survey including an 8-item measure of parental motivation for adolescent vaccination. After 12 months, we reviewed electronic medical records to obtain HPV vaccination coverage data. Multinomial regression models were examined to determine which motivation types were associated with 1-dose coverage (0 doses vs. 1 dose), 3-dose coverage (0 doses vs. 3 doses), and differences among those who initiate but fail to complete the series (1 dose vs. 3 doses).

Results: Results indicate autonomous motivation was a marginally significant predictor of 1-dose coverage (OR = 2.49; 95%CI: [.93, 6.67], $p = .069$) and a significant predictor of 3-dose coverage (OR = 3.57; 95%CI: [1.25, 10.22], $p = .018$). Autonomous motivation, however, did not distinguish vaccine series completers from those who only initiated the series (1 dose vs. 3 doses; $p = .566$). There were no significant effects of introjected or external motivation on any of the HPV vaccination outcomes—1-dose- or 3-dose coverage ($ps > .110$), or among those who initiated but did not complete the vaccine series ($ps > .084$).

Conclusion: Findings support the utility of distinguishing underlying motivation for adolescent HPV vaccination. Autonomous, rather than introjected and external, motivation was positively associated with receipt of the 3-dose series. Thus, intervening on parents' perceptions about the ways in which the HPV vaccine is important and beneficial to their child's health may be an effective mechanism for increasing completion of the vaccine series.

THE VALUE OF SHARED DECISION MAKING AIDS FOR PATIENTS ELIGIBLE FOR TRIAL OF LABOR AFTER CESAREAN SECTION

Erin LePoire, BA,BS, MPHc¹, Deborah Bowen, PhD², Alia Memon³¹University of Washington, Seattle, IL; ²University of Washington, Seattle, WA; ³University of Washington, Bellevue, WA

Background: Shared decision-making (SDM), where providers and patients come to a dyadic decision about a medical test or procedure, is an emerging practice in medicine, with emphasis on decisions that lack a clear medical recommendation. One such decision occurs among pregnant women who have previously had a cesarean section, and who must decide whether to have a second cesarean-section (C-section) or trial labor. The Health Care Authority of Washington state recently certified tools for trial of labor after cesarean section (TOLAC)/vaginal birth after cesarean section (VBAC)/C-Section SDM study. This study is part of an evaluation of the implementation of shared decision-making tools (booklet/pamphlet) used at three pilot sites in Washington State.

Methods: Qualitative semi-structured interviews were conducted with X providers and X patients involved in this study at baseline and 6 months after implementation. Interviews were audio-recorded and transcribed. Transcriptions were coded by two research assistants using a codebook developed before interviews were conducted.

Results: While providers consistently reported they would have preferred online tools that could be sent through electronic medical records, patients reported that they valued having a paper copy in their hands to look at. Both patients and providers valued the tool and reported high levels of satisfaction. Most providers and patients indicated that the tools used were balanced, not leaning one way or another. Providers expressed hope in expanding shared decision making statewide, however, there was also caution, specifically that resources (funds for electronic medical record upkeep, provider buy-in) are low.

Discussion: When discussing medical decisions that do not have one clearly superior option, SDM between patient and provider can work in clinical practice. It is important to understand the coverage and intent of shared decision making, both on the provider and patient side. Providers, especially OBGYNs, are often overworked, yet the value of SDM for providers is in time-savings in clinical practice. Meanwhile, there is a movement among the patient population to take increasing interest and accountability for their own health, and SDM is one way to really advance patient roles in the process. SDM allows providers to educate patients at a level not formerly possible while enabling patients the opportunity to really think about, and digest information, allowing for a thoughtful, confident decision, and increased satisfaction with medical care.

A PILOT STUDY TO DESIGN AND TEST HPV VACCINE EDUCATION AND DECISION SUPPORT TOOLS FOR AFRICAN AMERICAN PARENTS

Rachel Shelton, ScD, MPH¹, Hayley S. Thompson, Ph.D.², Todd Lucas, Ph.D.³, Laura Brotzman, MPH¹, Yang Kim, BS⁴, Rabbie Hanna, MD⁵, Rabbie Hanna, MD⁶

¹Columbia University Mailman School of Public Health, New York, NY; ²Wayne State University -Karmanos Cancer Institute, Detroit, MI; ³Wayne State University, Detroit, MI; ⁴Wayne State University School of Medicine, Detroit, MI; ⁵Henry Ford Health System and Wayne State University School of Medicine, Detroit, MI; ⁶Henry Ford Health System, Detroit, MI

Objective: This pilot study was designed to develop a lay health worker (LHW)-led HPV vaccine education session and an HPV vaccine parental decision support tool (DST) for African Americans, and to test the impact of both on HPV vaccine decision making and discussions with a healthcare provider (HCP) through a randomized controlled trial (RCT).

Methods: Participants were recruited in community settings in metro Detroit and 70 women were screened for eligibility, which included having at least one unvaccinated child and no previous in-depth vaccine discussion with an HCP. Of these, 27 (39%) were eligible, consented, completed baseline assessments, and were randomized to the education alone group (ED) or education plus DST group (ED+DST). Education and DST distribution took place in community-based sites. Participants completed a Time 2 (T2) survey at one week assessing knowledge and decision-related variables, and a Time 3 (T3) survey at two months assessing initiation and quality of parent-HCP discussions. Qualitative (QUAL) components were included at T2 and T3 to assess responses to the interventions.

Results: At baseline, 75% of participants reported hearing “a little/nothing/almost nothing” about HPV or the vaccine. Only 30% reported HCP recommendation of the vaccine. Compared to baseline, there were statistically significant improvements in HPV knowledge in both ED (BL μ = 0.53, T2 μ = 0.83, p=.008) and ED+DST (BL μ = 0.39, T2 μ = 0.83, p=.002) groups. Both groups responded positively to the education session based on QUAL data but ED participants reported wanting more information on vaccine risks and side effects and 70% reported the DST was as or more useful than the education session. At T2, 40% of the ED+DST group had decided to vaccinate their child, compared to 54.5% of ED participants, increasing at T3 to 75% and 87.5%, respectively. Across both groups of participants, those who were undecided at T2 but decided to vaccinate by T3 (30%), STD protection was the most commonly cited reason. All participants who remained undecided at T3 across both groups (25%) wanted to talk to a provider before making a final decision. At T3, 47% of all participants had not discussed the vaccine with an HCP yes, but intended to do so in the next 2 months.

Conclusions: Findings suggest that the degree of information received about the HPV vaccine, including its benefits and risks, and HCP recommendation play key roles in the decision making process. Additional research examining parent-focused interventions in promoting HPV vaccination is needed.

COST EFFECTIVENESS OF A COMMUNITY-BASED CARDIOVASCULAR DISEASE PREVENTION INTERVENTION IN MEDICALLY UNDERSERVED RURAL AREAS

Rebecca A. Seguin, PhD, CSCS¹, Hua Wang, PhD¹, Meredith L. Graham, MS¹, Sara C. Folta, PhD², David Strogatz, PhD³, Galen Eldridge, MS⁴

¹Cornell University, Ithaca, NY; ²Tufts University, Boston, MA; ³Bassett Research Institute, Cooperstown, NY; ⁴Montana State University, Boston, MT

Background. Community-based programs aimed at reducing the risk of cardiovascular and other chronic diseases in rural communities are an important strategy to address rural health disparities. A rigorous understanding of the costs associated with running these programs and the value of the health outcomes realized by program participants can provide decision makers with important information about adoption and implementation.

Intervention. Sixteen medically underserved rural towns in Montana and New York were randomized to one of two six-month intervention programs: a twice-weekly experiential learning health behavior change program focused predominantly on diet and physical activity (aerobic and strength training) related behaviors, *Strong Hearts, Healthy Communities (SHHC)* (n=101) or a monthly healthy lifestyle education-only, minimal intervention control program (n=93). Females who were sedentary, overweight or obese, and aged 40 years or over were recruited to the study.

Objective. The objective of this study was to conduct cost-effectiveness analyses of the SHHC program compared to the control program in terms of change in Simple 7, a gold-standard composite cardiovascular disease risk score, as well as body weight.

Analysis. The estimated incremental cost-effectiveness ratio (ICER) was calculated with respect to changes in Simple 7 and body weight by dividing the incremental costs (average cost of resources – e.g. labor, space, food, equipment, curriculum printing – minus average resource cost for the education only comparison program) by incremental effectiveness (Simple 7 score improvement and weight loss).

Results. SHHC cost \$536 per participant, with an average improvement of Simple 7 score of 0.93 points and an average weight loss of 4.6 pounds (2.08 kg). The ICER was \$577 per Simple 7 point increase and \$117 per pound [\$258 per kilogram].

Conclusion. The cost of the SHHC intervention was comparable to similar lifestyle behavior change programs. The ICER for SHHC in terms of weight loss tended to be similar or slightly higher than for other weight management programs; a comparison couldn't be found for Simple 7 ICER. These data, and similar types of analyses for community programs, are critical for program implementation and dissemination considerations.

DECISION-MAKING PRACTICES SURROUNDING CHOOSING A VAGINAL BIRTH AFTER PRIOR CESAREAN DELIVERY

Laura Hooberman, BA¹, Frances Howell, BA², Margaux Genoff Garzon, M.A.³, Lisa R. Rubin, Ph.D.⁴, Rachel Keegan, Ph.D.²

¹The New School for Social Research, Brooklyn, NY; ²The New School for Social Research, New York, NY; ³Memorial Sloan Kettering Cancer Center, New York, NY; ⁴New School for Social Research, New York, NY

Background: The choice to have a vaginal birth after cesarean section (VBAC) is a contested healthcare decision. While research indicates that VBAC is a safe and advantageous option for most persons, rates of this procedure have decreased nationwide. There is limited research exploring the lived experiences of individuals who choose VBAC and critically examining the contexts in which these decisions are made.

Methods: In this prospective study, a sample of sixteen participants who previously underwent a C-section were interviewed pre- and postpartum. Semi-structured interviews were used to inquire about their experience with their previous C-section, their decision-making process regarding their current birth plan with a VBAC, and their satisfaction with their birth experience postpartum. Data were analyzed using thematic analysis.

Results: The majority of participants described their previous C-section as a negative experience, with seven participants saying the experience left them traumatized. Participants discussed the following factors that influenced their decision to have a VBAC: 1) strong desire for a vaginal birth, 2) vaginal birth seen as “healthier” for both mother and child, 3) quicker recovery, and 4) desire to maintain control during birth. While all participants chose to have a VBAC before the interview, nearly all participants maintained a flexible attitude towards birth outcomes. Nine (56%) participants had successful VBACs and the majority of women (81%) described their birth experience as satisfactory.

Conclusions: Main factors in deciding to attempt a VBAC included negative experience with previous C-section, and belief that vaginal birth is optimal for both mother and child. Women were able to maintain a sense of control before and during childbirth through a stance of planned flexibility, which allowed women to find their birth experience positive even when women were not able to have a VBAC. Future studies should explore how attitudes towards birth choice, including attitudes toward medicalization and natural childbirth, influence decision-making and birth satisfaction.

DIFFERENCES BETWEEN DECISIONAL CONFLICT IN MEN WITH EARLY STAGE PROSTATE CANCER AND THEIR PARTNERS

Emma Straus, BA¹, Lauren Gelfarb, BS¹, Kara Buda, MA¹, Michael Diefenbach, PhD², Christian Nelson, PhD¹

¹Memorial Sloan Kettering Cancer Center, New York, NY; ²Northwell Health, New York, NY

Background: Advancements in understanding the natural progression of low grade prostate cancer have led to “active surveillance” protocols where patients can delay active treatment. Given that this may be a difficult decision for patients and their partners, it is important to understand the factors that contribute to a patient’s treatment decision.

Purpose: This study aims to collect information on how patients who are eligible for active surveillance and their partners make treatment decisions.

Methods: Patients and their partners were recruited from the clinic at the Urology Service at Memorial Sloan Kettering Cancer Center (MSK). Recruitment is ongoing. Eligible patients must have early stage prostate cancer, eligible for active surveillance, and have not made a treatment decision. The patient may identify a partner to participate in the study. Enrolled participants completed assessments prior to treatment decision, after treatment decision and every 6 months for 2 years. Outcome data explored factors such as decisional conflict, illness perception, and patient assessment of their doctor’s treatment suggestion.

Results: 114 patients and 50 partners have completed the baseline and six month follow-up questionnaire. Preliminary results showed that 26% of patients chose active treatment over active surveillance. Patient total anxiety and prostate cancer related anxiety was more likely to decrease if treatment decision was more strongly aligned with the patient perception of the doctor’s treatment suggestion than if not. After a treatment decision was made, patients’ decisional conflict decreased significantly ($p < 0.001$), while partners’ decisional conflict increased significantly ($p = .025$).

Conclusion: Preliminary results suggest that although patients’ decisional conflict may decrease after a treatment decision is made, partners’ decisional conflict increases. Further research must be conducted to explore the cognitive and affective treatment decision making processes among prostate cancer patients eligible for active surveillance and their partners. Final analysis will occur once all data has been collected.

EXPLORING STRATEGIES TO ENGAGE HISPANIC PATIENTS IN SCREENING FOR A DIABETES PREVENTION PROGRAM AT A COMMUNITY HEALTH CENTER

Blanca S. Noriega Esquivas, MD¹, Kiarabet Quintana Ramos, MPH Candidate², Sara M. St. George, PhD³, Mark Stoutenberg, PhD, MSPH⁴

¹University of Miami - Miller School of Medicine, Miami, FL; ²University of Miami, Coral Gables, FL; ³University of Miami - Miller School of Medicine, West Miami, FL; ⁴University of Miami, Miami Beach, FL

Background: Increasing early identification and engagement of prediabetic Hispanic individuals in diabetes prevention programs is a public health priority as this ethnic minority population is disproportionately affected by diabetes and obesity.

Objective: To explore factors influencing patients' willingness to attend screening for a diabetes prevention program being offered at a federally qualified community health center (FQHC).

Methods: Semi-structured phone interviews, based on the Health Belief Model, were conducted with patients who had been invited to attend a free screening at the FQHC. Purposeful random sampling was used to recruit patients who: 1) declined to attend a screening (n=13), 2) agreed, but did not attend (n=12), and 3) attended (n=11). A general inductive approach was used to identify key themes and group them into categories.

Results: A total of 36 Hispanic adults (21 women) were interviewed. *Perceived Susceptibility:* Individuals who declined to attend a screening considered themselves to be healthy and not at risk of chronic diseases, which was reinforced by a recent check-up. Those who agreed but did not attend a screening also considered themselves healthy, but at risk for chronic diseases. Attendees perceived themselves as unhealthy and at risk for chronic diseases. *Perceived Severity and Benefits:* Lack of awareness of health status was considered a major consequence of not participating in the screening and being aware of potential problems with their health as the main benefit. *Perceived Barriers and Cues to Action:* Individuals perceived the schedule offered by the FQHC as the biggest barrier to participating in health screenings. Thus, providing more convenient appointments was perceived as a key motivator to increasing participation. *Self-Efficacy:* Individuals who declined to attend a screening reported feeling confident in their ability to prevent diabetes or other cardio-metabolic diseases and not needing help in making lifestyle changes as compared to those in the other groups.

Conclusions: Patients that attend health screenings, versus those that do not, exhibit different beliefs and attitudes regarding their health status and their risk for chronic diseases. Future screening efforts should consider these different viewpoints, offer flexible appointment times, and emphasize the benefits of early detection of diabetes to enhance the participation of Hispanic patients in diabetes screening.

FACTORS AFFECTING SURGICAL DECISIONS IN NEWLY-DIAGNOSED YOUNG WOMEN WITH EARLY-STAGE BREAST CANCER

Shoshana M. Rosenberg, ScD, MPH¹, Mary L. Greaney, PhD, MPH², Andrea F. Patenaude, PhD¹, Ann Partridge, MD, MPH¹

¹Dana-Farber Cancer Institute, Boston, MA; ²University of Rhode Island, Kingston, RI

Background: Young women with breast cancer often have concerns and priorities (e.g., fertility, impact on young family, starting a career) attributable to their life stage. Consequently, young women may consider their surgical options differently than older women. Using a series of key informant interviews, we sought to gain an in-depth understanding of how newly-diagnosed young women approached decisions about breast cancer surgery.

Methods: We screened institutional clinic lists and approached newly-diagnosed women with non-metastatic (Stage 0-III) breast cancer diagnosed at age ≤40 who had not yet undergone surgery and invited them to participate in a one-time interview study. Interested women who were eligible were interviewed (in person or via phone) using a semi-structured interview guide between February and October 2016. Interviews were recorded and transcribed with identifiers removed. Emergent themes were identified by thematic content analysis using NVivo 11.

Results: Among 20 participants, 20% (4/20) identified as Hispanic or non-White; almost all (18/20) were partnered; median age at interview was 37. Women spoke of how a desire to breastfeed, concerns about how an extended recovery would affect caring for young children and returning to work factored into their surgical decision and in some cases, contributed to decisional conflict. In weighing the pros and cons of different types of surgery, one participant spoke of wanting to "choose the easiest, less invasive...that would be the fastest for me to be able to be back to my children" while also acknowledging that a lumpectomy "doesn't feel like... sufficient surgery." Another described how she "worried initially...about the recovery time with the double mastectomy because I do have young kids so that was...daunting." Several women also spoke of their worry of leaving cancer cells behind while others cited the need for continued surveillance, including anxiety surrounding frequent mammograms and lack of trust in imaging, as a consideration during the decision process.

Conclusions: Surgical decisions can be complex for young women with breast cancer due to factors specific to their life stage affecting decision-making. Developing novel, targeted interventions that deliver relevant information and address these issues may reduce decisional conflict, ensuring decisions are made in a supportive and patient-centered setting.

FACTORS INFLUENCING U.S. PHYSICIANS' DECISION TO PROVIDE BEHAVIORAL COUNSELING

Daniel Goldberg, MEd¹, Beom-young Cho, PhD¹, Hsien-Chang Lin, PhD²¹Indiana University, Bloomington, IN; ²Indiana University Bloomington, Bloomington, IN

Objective: Prevention and treatment of non-communicable diseases is critical due to high costs of healthcare and increasing prevalence. Historical trends suggest physicians underperform in behavioral counseling (exercise, diet/nutrition, or weight loss). This study looked at physicians' decision-making process by examining sociological factors that influence provision of behavioral counseling.

Method: Using the Eisenberg model of physician-decision making, we analyzed data from the 2001–2011 National Ambulatory Medical Care Surveys to obtain national estimates of provided behavioral counseling in physician offices. The Eisenberg model posits physician characteristics, patient characteristics, physician-healthcare system interactions, and the physician-patient relationship impact physician decision-making to provide treatment. Weighted, multiple logistic regressions were utilized to determine the likelihood of a physician delivering behavioral counseling.

Results: Sociologic factors significantly influenced physicians' decision to provide behavioral counseling. Diet/nutrition counseling was provided at 13.43% of visits, exercise counseling was provided at 9.29% of visits, and weight loss counseling was provided at 3.66% of visits. Exercise and diet/nutrition counseling was not as likely to be provided in ensuing years despite increasing rates of non-communicable disease. Weight loss counseling was more likely to be provided compared to previous years. Highlighted findings of factors linked to a higher likelihood of providing behavioral counseling include: seeing a primary care physician, patients with visits for chronic problems, and patients with visits for preventive care. Patients who had been seen before by a doctor were less likely to receive diet/nutrition or weight loss counseling.

Conclusion: Behavioral counseling continues to be underutilized, and specific sociologic factors influence physicians' provision of counseling. Physicians should consider factors that may influence their decision to provide behavioral counseling. Future research should focus on finding the most effective behavioral counseling training and provision, while also considering methods to improve physician rates of counseling.

LONGITUDINAL DETERMINANTS OF SEDENTARY BEHAVIOR AMONG COLORECTAL SURVIVORS

Madison M. DeMello, Ph.D.¹, Bernardine M. Pinto, Ph.D.¹, Shira Dunsiger, PhD²¹University of South Carolina, Columbia, SC; ²The Miriam Hospital/Brown University, Portsmouth, RI

Introduction: Colorectal survivors spend approximately 9 hours per day in sedentary behavior (SED), even though recommendations to reduce sitting time have been released. While there is extensive research into the health detriments of SED, less is known about the determinants of SED, specifically among cancer patients. In this longitudinal study, we examined determinants of SED among colorectal survivors who participated in a 12-month randomized controlled trial for physical activity promotion.

Methods: Male and female colorectal survivors (Stage 0–3) within 5 years of diagnosis were randomized. SED was objectively measured using the Computer Science and Applications, Inc. monitor (CSA model 7164) at baseline and 3, 6 and 12 month follow-ups. Additionally, fitness (Treadmill walk test), mood (Profile of Mood States, POMS), body fat (Bioelectrical Impedance Analysis) and cognitive and behavioral processes of change for physical activity (Marcus et al., 1992) were assessed at baseline and follow-ups. Using Latent Class Analysis (LCA), we identified 4 distinct subgroups of the sample with respect to SED over one-year. Classes were compared using Analysis of Variance with respect to baseline data including demographics, fitness and psychosocial constructs (i.e., mood and processes of change). Finally, class was used as a predictor of change in psychosocial outcomes over 12-months using a series of generalized linear models controlling for group assignment.

Results: 46 colorectal survivors (mean age = 57 years old, 57% female, 70% Stage 0–2, 30% Stage 3 disease) were randomized. Data supported a 4 class model: 22% who had high and sustained min/week of SED over 12 months (Class 1), 24% who had low and sustained SED (Class 2), 33% who had increasing SED over time (Class 3) and 22% who had high SED through 6 months followed by a marked decreased through 12 months (Class 4). There were significant between-class differences with respect to gender, baseline mood, fitness (time to complete 1-mile treadmill walk), body fat, and cognitive processes (p 's<0.05). Females were less likely to be in Class 1; Total Mood Disturbance (POMS) was significantly lower at baseline in Class 2; and baseline cognitive processes were highest and fitness and body fat were significantly worse at baseline for Class 3. Finally, class was a significant predictor of changes in fitness, mood and moderate-to-vigorous physical activity (p 's<.05) over 12 months.

Conclusions: Characteristics such as gender, fitness, body fat and psychosocial constructs may be useful variables to help guide researchers and practitioners in their efforts reduce SED among survivors.

PATIENT ACTIVATION AS A MEDIATOR FOR TREATMENT SATISFACTION & DECISIONAL CONFLICT AMONG PATIENTS APPROACHING ESRD

Miriam Velez-Bermudez, Master of Science¹, Ellen Kinner, Master of Arts², Anne Roche, Master of Arts¹, Mony Fraer, MD³, Alan Christensen, PhD¹

¹University of Iowa, Iowa City, IA; ²University of Iowa, Iowa City, IA; ³University of Iowa Hospitals and Clinics, Iowa City, IA

Decisional conflict is the state of uncertainty regarding treatment choices and lack of patient confidence in making treatment decisions. Patients with chronic kidney disease (CKD) approaching end-stage renal disease (ESRD) experience a high level of decisional conflict. They are tasked with selecting a form of renal replacement therapy that is right for them, but are often not provided with sufficient support and information regarding the different treatment options prior to renal failure. It is necessary to identify ways to better support patients making such a life-altering medical decision. Treatment satisfaction is an important predictor of decisional conflict, as it is associated with disease- and treatment-related knowledge that can inform decision-making. The present study explored additional psychosocial and health-related factors that mediated the relationship between treatment satisfaction and decisional conflict in 64 patients approaching ESRD. It was predicted that patient activation mediated this relationship. Measures included a Kidney Disease Treatment Questionnaire (KDTQ) developed by the authors to measure patients' understanding of CKD and their satisfaction with their CKD-related care, the Decisional Conflict Scale (DCS), and the Patient Activation Measure Short Form (PAM-SF). There was a high level of decisional conflict in this sample, with 62.5% of the patients ($n = 40$) having "decision-making difficulty" ($DCS \geq 25$) and 40.6% of the patients ($n = 26$) having decision delays and/or negative perceptions about the decision ($DCS > 37.5$). Initial linear regression analyses were performed with DCS as the outcome variable, and demographic and clinical variables, KDTQ, and PAM-SF, as predictors. No significant results involving demographic and clinical variables were observed; however, there were significant relationships between the KDTQ, PAM-SF, and DCS. Following these analyses, the model was entered into PROCESS to test for a significant mediational relationship. A bootstrapping procedure based on 5,000 samples was used to estimate the standard error of the indirect effect of KDTQ on DCS with PAM as the mediator. The results confirmed the indirect effect was statistically significant ($B = -.88$, $SE = .39$, bias corrected 95% $CI = -1.94, -.23$). While the link between treatment satisfaction and decisional conflict is well established, these results indicate this relationship can be explained by patient activation, a potentially modifiable process. Interventions to reduce decisional conflict among patients approaching ESRD should be focused on encouraging patients to become actively involved in their care.

PATTERNS OF CHANGE OVER TIME FOR PSYCHOSOCIAL CONSTRUCTS IN RESPONSE TO A CULTURALLY TARGETED COLONOSCOPY INTERVENTION

Lynne B. Klasko, N/A¹, Deborah Erwin, PhD², Lina Jandorf, MA³, Marc T. Kiviniemi, PhD⁴

¹University at Buffalo, SUNY, Buffalo, NY; ²Roswell Park Cancer Institute, Buffalo, NY; ³Icahn School of Medicine at Mount Sinai, New York, NY; ⁴University at Buffalo, Buffalo, NY

Introduction: Colonoscopy can reduce mortality from colorectal cancer (CRC), yet uptake remains low, especially for African Americans. Educational interventions to improve screening may target both cognitive beliefs (e.g. benefits, efficacy) and affective associations (e.g. disgust, fear). The assumption is that appropriate interventions change a person's beliefs and feelings in ways leading to behavior change. However, the patterns and time course of change in these constructs are not well understood. We examined patterns of change in cognitive and affective decision making constructs following a culturally targeted educational intervention.

Methods: Participants eligible for colonoscopy and self-identifying as African American ($n=516$) received an educational video intervention. At three time points, immediately before (pre), immediately following (post), and 6 months after the intervention (6mo), participants reported perceived benefits of and barriers to colonoscopy, positive and negative affective associations with colonoscopy, screening self-efficacy, CRC knowledge, colonoscopy fear, cancer fear, cancer worry, and screening intentions. Paired t-tests tested changes in each construct across timepoints.

Results: With the exception of cancer worry, all constructs changed in response to the intervention. However, the patterns and timecourse of changes differed across constructs. Screening intentions continued to increase and positive affective associations with colonoscopy steadily decreased. Perceived barriers decreased at post-test and curved back to baseline levels at 6 months, while perceived benefits did not change significantly from pre-test to post-test, but increased at 6 months. Fear of colonoscopy, fear of having cancer, and negative affective associations decreased initially and plateaued.

Discussion: The ability to understand how determinants change over time supports intervention development by providing appropriate timecourse information for specific constructs to make the most impact on behavior. As such, future research should investigate change in constructs over a longer timespan. These results suggest that intervention components addressing each construct may need to occur at different timepoints to make best influence behavior change for populations less likely to be CRC screening adherent.

PSYCHOSOCIAL SUBJECTIVITY BY SPORTS MEDICINE CLINICIANS IN POST-CONCUSSION RECOMMENDATIONS

Emily Kroshus, ScD¹, Christine M. Baugh, MPH², K. Vish Viswanath, PhD³¹University of Washington, Seattle, WA; ²Harvard University, Cambridge, MA; ³Harvard T.H. School of Public Health, Boston, MA

Background: Repeated brain trauma from sport can have lasting neurologic consequences. At present, there is no clinical consensus about the number of concussions after which athletes should stop participating in contact sport. Thus, sport cessation is a preference-sensitive decision where the injured athlete must balance future health risks against current and future financial, psychological, physical, and social benefits of continued participation. Sports medicine clinicians often make clinically subjective recommendations about whether an athlete should retire post-concussion. Guided by the risk-return framework of behavioral decision theory, the present study evaluated how psychosocial factors and risk perceptions relate to clinician recommendations about sport cessation post-concussion.

Method: 677 sports medicine clinicians completed an online survey (35% response rate). Ordered logistic regression was used to assess the association between perceived risk, benefit and demographic variables with the number of concussions after which sport cessation would be recommended. Clinicians also indicated the extent to which psychosocial factors would influence their recommendations about sport cessation.

Results: On average, clinicians indicated they would discuss sport retirement after 3.2 concussions (SD=1.2). In a multivariate regression model, this number was lower when clinicians more strongly prioritized athletic achievement in their clinical decision-making ($p=0.027$), among older clinicians ($p=0.047$), and in the most athletically competitive schools ($p=0.049$). Psychosocial factors that were most likely to influence clinician recommendations about sport retirement included the coach wanting the athlete to continue football (96.6%) and the athlete being a star player on the team (90.6%).

Conclusion: There is substantial clinician subjectivity in when post-concussion sport cessation is recommended, and this study finds that clinician recommendations incorporate psychosocial considerations. This may be consistent with prioritizing the athlete's wellbeing, as athletes likely weigh a range of risks and benefits of continued sport participation. Patient-centered decision aids must be developed to help provide structure to this subjective process and to engage the injured athlete in clarifying and communicating their goals, preferences, and values. Such aids could also ensure that clinicians and athletes are working from the same set of facts about concussion.

REAL-TIME DECISION MAKING OF WIC PARTICIPANTS AT THE GROCERY STORE: USE OF THINK ALOUD METHODOLOGY

Shannon Robson, PhD, MPH, RD¹, Rosemary DeLuccia, MS, RD², Sandra Baker, EdD, RD, LDN¹, Barry Bodt, PhD¹, Jillian Trabulsi, PhD, RD¹¹University of Delaware, Newark, DE; ²University of Delaware, Newark, DE

The foods and beverages brought into the home environment are the foods and beverages typically consumed by children at home. Due to this relationship, understanding decisions that influence parent food and beverage purchasing is important particularly among at risk populations. Environmental-level factors are often associated with grocery shopping behaviors and little work has investigated decision making processes while in the store. A qualitative study of 35 parents (30.1 ± 6.5 years; 41.9% African American; 32.3% Hispanic or Latino) with a young child (38.4 ± 11.7 months; 43.3% African American; 33.3% Hispanic or Latino) enrolled in the Special Supplemental Program for Women, Infants and Children (WIC) was undertaken; parents were audio recorded while thinking-aloud about their thoughts and decision-making while grocery shopping. Audio recordings were transcribed and independently coded using a codebook with codes determined *a priori*. Three individuals coded independently, analyzed for emerging themes and then met and reached consensus on the themes. Descriptive statistics were used to characterize parent and child demographics, food security status and food shopping behaviors. *Child's preference* emerged as a primary theme impacting a parent's decision in a food purchase. A parent's decision was also based on *value* particularly related to cost, *need* of an item for preparation or to stock the pantry, and/or the parent choice for a product based on *taste*, *perception of health or nutrition and past experience* with the product. In addition, several unique themes related to their shopping behavior including the influence of participation in WIC on food and beverage purchases, multiple trips to the store, and a frequent focus on purchasing bottled water and juice emerged. Low food security was common (46.7%), with low or very low accounting for 70%. The average duration of the shopping trip was 31.5 ± 15.7 minutes. The average total cost of goods purchased was $\$60.10 \pm \61.30 (median $\$38.61$) and was most commonly paid for through WIC and the Supplementation Nutrition Assistant Program (SNAP). Understanding the thinking processes influencing decisions in food purchases could be helpful in designing interventions to improve the home food environment.

WHY DO SOME PEOPLE NOT KNOW THEIR RISK FOR DIABETES AND COLORECTAL CANCER?

Heather Orom, PhD¹, Elizabeth Schofield, MPH², Marc T. Kiviniemi, PhD¹, Erika Waters, PhD, MPH³, Caitlin Biddle, Ph.D.⁴, Yuelin Li, PhD.², Jennifer L. Hay, Ph.D.²

¹University at Buffalo, Buffalo, NY; ²Memorial Sloan Kettering Cancer Center, New York, NY; ³Washington University in St. Louis, St Louis, MO; ⁴CCNY Inc, Buffalo, NY

Background: People who say they don't know their risk for a disease have been shown to be less likely to engage in protective behavior. The purpose of this study was to identify possible pathways that lead to not knowing one's risk for common diseases. While it has been common to attribute don't know responding to satisficing or "lazy responding," we hypothesized that rather than satisficing, lower health literacy and higher health information avoidance would be associated with not knowing one's risk for colorectal cancer and diabetes due to being less informed about risk factors for the diseases.

Methods: Participants were a nationally representative sample of 1005 GfK panel members. Comparative and absolute perceived risk were assessed for diabetes and colorectal cancer; for each question, participants had the option to answer "don't know". Health literacy was assessed with the Newest Vital Sign and avoidance was assessed with Shepperd et al.'s health information avoidance questionnaire adapted to the colorectal cancer and diabetes contexts. The tendency to satisfice was assessed with a count of well-accepted indicators of lazy or inattentive responding behaviors (straightlining, missing attention checks, speeding). We compared model fit for hypothetical models including avoidance and literacy/knowledge pathways to don't know responding, with and without pathways for satisficing (MPlus). We bootstrapped estimates for indirect effects.

Results: Overall, the best fitting model contained indirect effects of health literacy and avoidance through risk factor knowledge, a direct effect of avoidance, and no effect for satisficing (all p for RMSEA >0.18 ; all CFI >0.91 , all TFI >0.81). Adding the direct effect for satisficing did not improve fit (RMSEA all $p < .001$). Indirect effects for health literacy (-0.03 to -0.06 , all $p < .02$) and avoidance (0.05 to 0.14 , all $p < .01$) through knowledge were significant. Additional direct effects for avoidance (0.19 to 0.25 , all $p < .02$) were significant for all risk outcomes, but the direct effect for literacy was only significant for diabetes comparative risk (-0.07 , $p = 0.03$).

Discussion: Satisficing was not associated with don't know responding to disease risk perception questions, but low health literacy and health information avoidance were. The latter may be related to don't know responding because they are barriers to forming a knowledge base for making risk appraisals. While don't know responders may need more health information, they do not need the 'same old health information'. Intervention might include targeting messages for low health literacy audiences and interrupting defensive processing of threatening health information with strategies shown to be effective such as self-affirmation.

COMORBIDITY AMONG WHITE AND AFRICAN AMERICAN PATIENTS WITH TYPE 2 DIABETES

Julienne K. Kirk, PharmD¹, Jaimie C. Hunter, MPH, PhD¹, Beverly Levine, PhD¹, Debbie Pleasants, MEd², Suzanne Danhauer, PhD¹, Shannon L. Mihalko, PhD³, Heather Black, PhD⁴, Sally A. Shumaker, PhD¹

¹Wake Forest School of Medicine, Winston Salem, NC; ²Wake Forest School of Medicine, Winston Saelm, NC; ³Wake Forest University, Winston Salem, NC; ⁴Merck and Co., Inc., Kenilworth, NJ

Patients with type 2 diabetes commonly have multiple comorbid conditions that can influence and complicate self-care but little is known regarding whether African Americans (AA) and whites conceptualize these comorbidities differently. Through in-depth qualitative interviews, we assessed patients' beliefs about managing their diabetes. Experiences with comorbidities while living with diabetes were captured. Data on patient demographics, comorbidities, and A1c were derived from participants' medical records. We examined the association between number of comorbid conditions and A1c level [low ($\leq 7\%$) versus high ($>7\%$)], age, gender, race, and socioeconomic status (ability to pay for basic needs). Following a mixed methods approach, data were analyzed using ANOVA and content analysis. Comorbid conditions included cardiovascular disease, chronic obstructive pulmonary disease, mental health conditions, chronic kidney disease, pain, and cancer. Mean age (SD) was 57.33 (± 10.48) years for AA ($n=42$) and 55.63 (10.75) years for white ($n=46$) participants. There were no significant differences in number of diagnosed comorbidities based on age, ethnicity, gender, A1c status, or ability to pay for basic needs. After cardiovascular disease (90% diagnosed), pain was the most common comorbidity found via chart review (65% diagnosed). During interviews, approximately 40% of patients reported that pain interfered with their lives. Neuropathy (nerve pain) was the most common cause of pain reported and was often described as "needles and pins." Many patients also had chronic pain that interfered with daily functioning while others talked about pain causing their body to feel uncomfortable and stressed. White women recounted their experiences with pain expressively and with detail, while AA men were the least descriptive, usually mentioning that they had pain but not providing any detail about their experiences with pain. Identifying the ways in which pain is expressed across ethnicities can provide an understanding of the impact of pain on diabetes daily management. Future analyses will further explore the relationship of pain to A1c control and other factors.

DIABETES KNOWLEDGE, FATALISM, AND PREVENTIVE HEALTH BEHAVIORS IN YOUNG ADULTS WITHOUT DIABETES

Emily Rose N. San Diego, BA, Erin L. Merz, PhD, MPH

California State University, Dominguez Hills, Carson, CA

Type 2 Diabetes (T2D) prevalence has increased among young adults. Greater T2D knowledge has been linked with preventive behavior such as diet and exercise. However, other studies suggest that knowledge and health behavior may not be related. One potential interfering factor called *fatalism*, a belief that health outcomes are outside one's control, may help clarify the relationship between health knowledge and behavior in the context of T2D prevention. Cross-sectional data were collected on 345 ethnically diverse (68.1% Latino, 13.0% Black, 7.0% Asian, 4.9% White, 1.7% Pacific Islander, 5.2% Multiracial) young adults without diabetes. Validated self-report measures were used to assess T2D knowledge, fatalism, and six T2D-related health behaviors. Results revealed that T2D knowledge, fatalism, and their interaction were not related to physical activity, sedentary behavior, sleep, or smoking. There was a significant main effect suggesting that greater fatalism was associated with lower alcohol use ($b = -.02$, $p = .02$); the main effect for T2D knowledge and the T2D knowledge X fatalism interaction were not significant. There was not a main effect for T2D knowledge on diet, but the main effect for fatalism ($b = -.08$, $p = .001$) and the T2D knowledge X fatalism interaction ($b = .00$, $p = .01$) were both significant. Inspection of simple slopes suggests that for individuals with low fatalism, greater T2D knowledge was associated with healthier diet ($b = .05$, $p = .03$), and for individuals with medium ($b = -.08$, $p = .001$) and high ($b = -.14$, $p = .001$) T2D knowledge, greater fatalism was associated with poorer diet. In sum, T2D knowledge and fatalism were not related to many health behaviors in this study. Paradoxically, greater fatalism predicted slightly lower alcohol use, but it is worth noting that alcohol use was extremely low in the sample and this small effect does not translate to clinically significant drinking behavior. Greater T2D knowledge was associated with healthier diet among individuals with low fatalism while greater fatalism was related to poorer diet among individuals with moderate or high knowledge. This suggests that T2D knowledge should be considered within the context of fatalism, as this appears to be a modifying risk factor for diet. Future research should utilize more comprehensive measures of dietary quality (e.g., food recalls) and evaluate potential predictors of fatalism such as family history of T2D or ethnicity.

FAMILY HISTORY, ILLNESS PERCEPTIONS AND HEALTH OUTCOMES AMONG AT RISK LATINO STUDENTS

Karina R. Aguilar, B.A.¹, Griselda Bernabe, B.A.², Silvia J. Santos, Ph.D.³, Maria T. Hurtado-Ortiz, Ph.D.³

¹California State University, Dominguez Hills, Wilmington, CA; ²California State University, Dominguez Hills, South Gate, CA; ³California State University, Dominguez Hills, Carson, CA

This study is part of a larger NIH funded investigation that seeks to examine the influence of family illness-history on beliefs, regarding disease-threat and health-related outcomes among Latino college students who are at risk for future diabetes acquisition due to genetic predisposition. The sample included 156 Latino college students (44% male; 66% female) ages 18 to 60. Based on the NIH Diabetes Risk Test, 30.7% of the sample was classified to be at low-risk for diabetes, 44% at moderate-risk, and 25.3% at high-risk. The mean BMI score for the total sample was 26.7 (considered overweight) with 57.7% of participants classified as being overweight and/or obese and 38.5% at a healthy weight. Participants completed a comprehensive survey that assessed constructs identified in the Health Belief Model and Common Sense Illness Model of disease. The results presented center on the relationship between family history of diabetes (degree of genetic risk and illness severity of afflicted relative) on perceptions of disease threat to self if acquired, self-rated risk for disease acquisition in the future, and perceived seriousness of the disease on participants' self-rated perception of health, health importance and actual health as indicated by BMI indices and Diabetes Risk scores. The findings of the path analysis using linear regression revealed an indirect positive effect between a family member's illness severity to self-rated threat for future disease acquisition which in turn impacted participants' perception of their health status negatively. Interestingly, illness severity of the afflicted relative also had an indirect effect on how threatening the disease would be to self if acquired which in turn positively impacted their overall view on health importance. Family genetic risk (1st, 2nd or 3rd degree relative afflicted) had a positive indirect effect on health outcomes such as having a higher BMI and diabetes risk score when mediated by perceived risk. However, a negative indirect effect was seen when it came to their health perception and its mediation by the aforementioned variable. The results suggest that the influence of family illness-history on objective and psychological health-outcomes are mediated by disease-threat indicators and will be discussed within the context of the HBM and CSIM of disease.

LINKS OF COMMUNAL COPING TO RELATIONSHIPS AND HEALTH: A LATENT VARIABLE APPROACH

Melissa Zajdel, M.S.¹, Vicki Helgeson, Ph.D.¹, Howard Seltman, M.D., Ph.D.¹, Mary Korytkowski, M.D.², Leslie R. M. Hausmann, Ph.D.³¹Carnegie Mellon University, Pittsburgh, PA; ²University of Pittsburgh Medical Center, Pittsburgh, PA; ³Veterans Affairs Pittsburgh Healthcare System and University of Pittsburgh, School of Medicine, Pittsburgh, PA

Communal coping was originally defined by Lyons and colleagues (1997) as the perception of a problem as shared (i.e. “our problem” as opposed to “my” or “your” problem) and collaborative action to address the problem. However, there is currently no consensus as to how best to measure communal coping. Therefore, we explored 5 distinct measures of communal coping in a study of 123 couples in which one person was recently diagnosed with type 2 diabetes (age of 54 years. Communal coping was measured through 1) a series of self-report questions 2) the proportion of first person plural pronouns (“we”) used during a brief coping interview, 3) behaviors coded from a videotaped discussion of a diabetes problem 4) a diabetes-adapted measure of the Inclusion of Other in Self scale (Aron, 1992) which consists of pairs of circles signifying the self and other with varying degrees of overlap, and 5) an aggregate measure of self-report questions that were tracked over 14 consecutive days during a daily diary assessment. Our first goal was to determine if we could create latent variables to reflect the shared appraisal and collaborative components of communal coping from these measures. Our second goal was to determine if the two components of communal coping were related to better self-care, lower psychological distress, and higher relationship satisfaction. A confirmatory factor analysis revealed that two latent variables, one reflecting shared appraisal and one reflecting collaboration, fit the data well ($\chi^2_{(11)} = 9.24, p = .60$; RMSEA = .00; CFI = 1.00; TLI = 1.02; SRMR = .04). One structural equation model (SEM) showed that the shared appraisal was related to lower psychological distress ($\beta = -.26, p = .06$), higher relationship satisfaction ($\beta = .38, p < .001$), and better self-care behavior ($\beta = .34, p < .01$) ($\chi^2_{(16)} = 27.88, p = .03$; RMSEA = .08; CFI = .94; TLI = .90; SRMR = .06). A second structural model showed that collaboration was linked to lower psychological distress ($\beta = -.27, p = .02$), higher relationship satisfaction ($\beta = .59, p < .001$), and better self-care behavior ($\beta = .40, p < .001$) ($\chi^2_{(10)} = 20.98, p = .02$; RMSEA = .09; CFI = .95; TLI = .90; SRMR = .04). SEM enabled us to identify two distinct aspects of communal coping, each of which was related to positive relationship, psychological, and behavioral outcomes in the case of chronic illness.

I have been PI on numerous intervention studies involving adolescents with diabetes and conducted research examining cognitive and behavioral factors impacting regimen adherence; [#]I was a Co-I on the NHLBI/NICHHD project from which this work originated and have been studying stress and disease for the past decade; ¹Merrill Palmer Skillman Institute, Royal Oak, MI; ²Wayne State University School of Medicine, Detroit, MI; ³Florida State University, Royal Oak, MI; ⁴Johns Hopkins School of Medicine, Baltimore, MD; ⁵The University of Wisconsin, Milwaukee, WI; ⁶Wayne State University, Detroit, MI

Background: Psychological stress is linked with impaired diabetes management and glycemic control in persons with type 1 Diabetes (T1D). Cognitive-behavioral interventions (CBT) have been shown to reduce self-reported stress, but do not serve as an effective means for improving diabetes management (DM) and/or glycemic control in adolescents and adults with T1D. Despite the large body of data suggesting the importance of improving skills to cope with stress, those stress management interventions developed to date have been ineffective in improving important health outcomes for adolescents and adults with T1D. Mindfulness-Based Stress Reduction (MBSR) is an intervention shown to reduce stress-related symptoms in various patient populations, but its efficacy in older adolescents and young adults (OAYA) with T1D has not been previously evaluated.

Objective: To examine the effect of two stress management interventions (CBT and MBSR) and a diabetes support and education control group (DSE) on stress, diabetes management, and glycemic control, among an urban sample of OAYA.

Methods: Forty-eight (48) OAYA with type 1 diabetes and poor metabolic control were randomly assigned to one of the three intervention groups. A pre-post design was used to evaluate treatment outcomes after treatment.

Results: OAYA receiving DSE showed marginally significant improvement in self-reported stress ($t(15) = -1.48, p = .08$) and significant improvement in glycemic control ($t(15) = -2.49, p = .0125$). OAYA receiving MBSR showed a significant improvement on self-reported stress only ($t(15) = -1.96, p = .0345$). All outcomes for CBT were not significant.

Conclusion: While MBSR effectively reduced stress, diabetes support and education improved both stress and diabetes-specific outcomes. OAYA with T1D may benefit from opportunities for group social support specific to their medical condition.

SEX AND RACE DIFFERENCES IN THE RELATIONSHIPS AND HEALTH OF ADULTS WITH TYPE 2 DIABETES

Jeanean Naqvi, B.A.¹, Vicki Helgeson, Ph.D.¹, Leslie R. M. Hausmann, Ph.D.², Mary Korytkowski, M.D.³, Howard Seltman, M.D., Ph.D.¹

¹Carnegie Mellon University, Pittsburgh, PA; ²Veterans Affairs Pittsburgh Healthcare System and University of Pittsburgh, School of Medicine, Pittsburgh, PA; ³University of Pittsburgh Medical Center, Pittsburgh, PA

The positive impact of close relationships on the physical health of people with chronic diseases, including Type 2 diabetes, has been well-established. In particular, relationship quality has been associated with better diabetes self-management and less diabetes distress. Sex differences have been observed such that marital quality results in more health benefits for men than for women. However, few studies have examined racial differences in the association between relationship quality and health. In the current study, we examined 1) race and sex differences in relationship and health outcomes among persons with Type 2 diabetes, and 2) whether race and sex moderate the association between relationship quality and health outcomes. Participants were in a committed relationship and were recently diagnosed with Type 2 diabetes ($n=200$; average age 53; 54% White, 47% African American; 55% male, 45% female). Males experienced marginally better relationship quality than females, and White participants experienced marginally better relationship quality than African American participants (all p 's $< .10$). African-American participants reported higher psychological distress, worse diabetes self-care, and worse medication adherence than White participants (all p 's $< .01$). Males reported receiving more emotional support ($p < .05$) and more instrumental support ($p < .001$) as well as experiencing more overprotectiveness ($p < .01$) and more unsupportive interactions ($p < .007$) from their partners. Interestingly, there were no race differences in support received from partners, but African-American participants reported experiencing more negative social interactions than White patients (avoidance, $p < .001$; unsupportive interactions, $p < .01$) from their partners. Relationship quality was related to greater medication adherence, but this effect was moderated by both sex and race ($p < .001$). The strongest relation was observed for African-American females: those with low relationship quality had the lowest medication adherence, and those with high relationship quality had the highest medication adherence of all groups. Similar trends were noted for general distress and diabetes self-care. These results indicate that there are sex and race differences in the challenges people with diabetes encounter as well as the types of partner involvement they experience. Relationships appear to be an important resource for people with diabetes, especially for African-American women.

A DIABETES SELF MANAGEMENT E-HEALTH INTERVENTION: PERCEPTIONS AND RATINGS OF ADULTS WITH TYPE 2 DIABETES MELLITUS

Joanne Duncan-Carnesciali, EdD, MSc, MS

New York University School of Medicine, New York, NY

The Centers for Disease Control and Prevention (CDC) statistics for 2017 indicated that over 30 million people have been diagnosed with type 2 diabetes mellitus (T2DM) in the United States. The populations most affected by T2DM are groups of low socioeconomic status and who represent group of ethnic minority populations. Healthy People 2020 has set as a national objective the goal of increasing the proportion of persons who receive formal diabetes education. This disparity between diabetes self-management providers and type 2 diabetes mellitus prevalence complicates achieving that goal, particularly among the populations of low socioeconomic status and minority ethnic groups. In order to address this challenge and work towards reaching the national objective of increasing access to diabetes self-management education (DSME), this study evaluated adults with T2DM perceptions of a culturally-appropriate, avatar-based e-health-intervention that delivered diabetes self-management education (DSME). This study investigated the potential the e-health intervention, grounded in health behavior theories, had in facilitating adoption of the seven self-care behaviors associated with successful management of type 2 diabetes, known as the AADE7 (healthy eating, being active, monitoring, taking medications, problem solving, reducing risks and healthy coping). Additionally, participants' stage of change and self-efficacy were measured pre and post viewing of the avatar video.

METHODS: Cross-sectional, survey-based design utilizing quantitative and qualitative paradigms. A logic-model framed the study which centered on the broad and general concepts leading to study outcomes of a positive perception of the e-health intervention and increases in participants' stage of change and self-efficacy. $N = 46$ participated in the evaluation. Participants were mostly female and represented an age range of 21–70 years. The majority of the participants were employed full-time.

ANALYSIS: The data were analyzed using independent and paired t -tests, Pearson product moment correlation and content/thematic analysis.

RESULTS: The data revealed statistically significant increases in the participants' stage of change and self-efficacy. The qualitative data revealed that the participants' overall impression of the e-health intervention was positive.

CONCLUSIONS: An e-health intervention grounded in evidenced-based health behavior theories has potential to increase access to DSME as well as facilitate behavior change as is evidenced in the increases in the participants' stage of change, self-efficacy and perceptions of the video.

ACCEPTABILITY OF A PHYSICAL ACTIVITY AND SELF-MANAGEMENT SUPPORT PROGRAM FOR ADOLESCENTS WITH TYPE 1 DIABETES AND THEIR PARENTS

Kevin Joiner, PhD, RN, ANP-BC¹, Garrett Ash, PhD², Mary Savoye, RD, CDE³, Julien Baker, Ph.D, D.Sc, FRSM, FHBA, FIBiol, FICR, C.Biol, C.sci⁴, Stuart A. Weinzimer, MD⁵, Lois S. Sadler, PhD, PNP-BC, FAAN⁶, Margaret Grey, DrPH, RN, FAAN⁶

¹University of Michigan School of Nursing, Ann Arbor, MI; ²Yale, New Haven, CT; ³Yale School of Medicine, New Haven, CT; ⁴University of the West of Scotland, Hamilton, Scotland, United Kingdom; ⁵Yale University, New Haven, CT; ⁶Yale University, West Haven, CT

Adolescents with type 1 diabetes (T1D) and their parents sometimes struggle with the time-consuming and complex behaviors that are needed to manage T1D and maintain a healthy lifestyle. Few interventions have addressed the problem of physical activity (PA) promotion for this population. The purpose of this qualitative analysis was to evaluate the feedback from participants following a pilot 12-week peer group intervention for sedentary overweight adolescents with T1D and their parents in which we combined a PA component modeled after *Bright Bodies*, a weight management program, and a self-management support component modeled after the program *Teens-Connect*.

Telephone interviews (mean 27 ± 8 min) were conducted post-intervention with 16 adolescents (age 14.2 ± 2.4yr, 69% female, 63% African-American/Latino) and their parents (42.4 ± 6.8yr, 88% female). Two authors reviewed a subset of the transcribed interviews (6) using Atlas.ti 7 and identified emerging patterns guided by Thorne's Interpretive Description approach and based on Sekhon's theoretical framework of acceptability as a multidimensional construct.

One pattern identified was the expressed desire on the part of several parent-child dyads to connect with others living with T1D and the feeling of community they experienced in the program. For several, this was their first opportunity to interact with peers with T1D. For adolescents, the two most popular aspects of the program were the non-competitive games and the group discussions and role-playing. Some parents cited travel time to the program as burdensome. Many spoke about how much they value messages focused on good health through PA and other lifestyle behaviors and their appreciation for that emphasis in the program. Parents gave up the time they typically spent doing housework to participate, while adolescents reported missing birthday parties and sacrificing sleeping time. Parents reported that the adolescents had increased interest in participating in PA after the program. Others reported that through participating in the program their adolescents changed their perception about using an insulin pump and that they had either started using one or were going to discuss it at their next appointment.

As analysis of the remaining transcripts continues, we aim to confirm and describe these preliminary patterns more richly. Key patterns contributing to acceptability were the peer group approach, non-competitive games, and demonstration of self-efficacy for healthy behaviors. Key barriers were logistical (travel, time) suggesting a more pragmatic delivery approach is needed. Compared with previous programs for sedentary adolescents with T1D using a more individual approach, these preliminary results suggest that our peer group approach to PA promotion for this population holds promise and warrants further investigation.

ACHIEVING RECRUITMENT GOALS IN A PRIMARY PREVENTION STUDY OF ADULTS WITH DIABETES: THE PATRIOT RANDOMIZED CLINICAL TRIAL (RCT)

Madison McCarthy, Bachelor of Arts¹, Sushmita Banerjee, BS¹, Elora Basu, BA¹, Bernardo Da Silva, BA², Noah Hellermann, BA³, Stephanie Rettig, MPH⁴, Sundar Natarajan, MD., MSc.⁵

¹VA NY Harbor Healthcare System, New York, NY; ²VA New York Health Harbor System, New York, NY; ³VA NY Health Harbor System, Brooklyn, NY; ⁴NYU School of Medicine, New York, NY; ⁵Dept. of Veterans Affairs New York Harbor Healthcare System, New York, NY

Objectives: Diabetic neuropathy is the antecedent to diabetic foot ulcer (DFU), a major risk factor for lower extremity amputations. We report on the success in enrolling participants with diabetic neuropathy in the PATRIOT RCT, which tests a personalized intervention to lower the risks of developing DFU.

Methods: In order to prevent DFU, the VA instituted screening for foot risk using the PAVE (Prevention of Amputation for Veterans Everywhere) score. We identified Veterans at risk for a DFU by searching electronic medical records for the ICD-10 codes associated with increased risk, i.e. PAVE scores 1,2 or 3. Veterans at risk of developing a DFU were sent an invitation letter about the program. Veterans who did not opt out were then approached by a team member who obtained informed consent and then screened the patient for eligibility. After enrollment, participants had a 1-month run-in period before coming in for the baseline visit and being randomized. A modest \$40 was provided for time and travel. Participants were kept engaged through ongoing phone and mail contact before and after enrollment.

Results: From August 2015 to September 2017, we identified 1,817 patients from electronic search and medical record review. Of the 1,817 PATRIOT patients, 808 (44.5%) were not eligible for the trial because they did not meet eligibility criteria. Of the 1,009 patients who were eligible for the program, 184 (18.24%) are currently enrolled in the study and 109 (10.80%) have completed the 12-month trial (total enrolled = 293). Of the eligible participants, 287 (28.44%) were not interested after being contacted about the program and 106 (10.5%) were interested in joining the study, but had not yet been enrolled. Various reasons lead participants to cancel their enrollment in the program (n=36, 3.57%) during the run-in, or drop out of the program (n=8, 0.79%) following randomization. Furthermore, from the pool of 1,009 patients, there are 254 (13.98%) patients who have not yet been approached for the study and new eligible patients are being identified in an ongoing basis.

Conclusion: A major challenge to RCT execution is recruitment. Recruitment for the PATRIOT RCT is on pace to reach the goal of 404 subjects. If recruitment lags, we have a list of interested eligible Veterans (n=106), Veterans who have not been approached yet (n=254) as well as a stream of ongoing newly identified eligible Veterans. This provides reassurance that the recruitment goals will be met.

BRIGHT 1 BODIES: EXTENDING THE BRIGHT BODIES FAMILY-BASED INTENSIVE LIFESTYLES THERAPY TO ADOLESCENTS WITH TYPE 1 DIABETES

Garrett Ash, PhD¹, Kevin Joiner, PhD, RN, ANP-BC², Mary Savoye, RD, CDE³, Julien Baker, Ph.D, D.Sc, FRSM, FHBA, FIBiol, FICR, C.Biol, C.sci⁴, James Gerosa, MS⁵, Emma Kleck, BS, RN⁶, Neha Patel, DO⁷, Matthew Stults-Kolehmainen, PhD⁸, Stuart A. Weinzimer, MD⁹, Margaret Grey, DrPH, RN, FAAN⁶

¹Yale, New Haven, CT; ²University of Michigan School of Nursing, Ann Arbor, MI; ³Yale School of Medicine, New Haven, CT; ⁴University of the West of Scotland, Hamilton, Scotland, United Kingdom; ⁵Southern Connecticut State University, New Haven, CT; ⁶Yale University, West Haven, CT; ⁷Penn State Health Milton S. Hershey Medical Center, Hummelstown, CT; ⁸Yale - New Haven Hospital, New Haven, CT; ⁹Yale University, New Haven, CT

Background: Over two-thirds of adolescents with type 1 diabetes (T1D) are sedentary. The Bright 1 Bodies Intensive Lifestyles Program aimed to promote their physical activity (PA) by group exercise classes from the Bright Bodies Weight Management Program, combined with T1D self-management education, coping skills discussions, and parent classes. This pilot study aimed to: 1) evaluate intervention feasibility and acceptability; and 2) examine changes in PA, nutrition, BMI, and T1D self-management behaviors.

Methods: Bright 1 Bodies offered 12 sessions per week to sedentary adolescents with T1D (n=18; age 13.7 ± 2.3yrs; 67% female; 67% African-American/Latino; A1c 9.5 ± 2.3%; BMI 88 ± 12%ile). At baseline and 12wk we assessed: a) feasibility by % enrolled of eligible candidates approached and # of sessions attended; b) acceptability by a 28-item exit survey graded on a 5-point Likert scale; c) PA apart from intervention sessions by number and duration of moderate to vigorous bouts (≥10min, ≥3 METs) registered by a hip accelerometer over 7 days' wear; d) nutrition by # of fruit and vegetable servings (80g) recorded on 3-day food logs; e) glycemic control by HbA1c, mean glucose, glycemic profiles (% readings <70, 70–180, and >180 mg·dL⁻¹), and insulin daily dose; and f) self-management variables by # of weekly glucose tests, the Hypoglycemia Fear Survey Worry Subscale (HFS-W), diabetes Self-Care Inventory (SCI), and Quality of Life Diabetes Module (QOL-D). Repeated measures ANCOVA (covariates gender & age, significance p<0.05) and Becker's effect size (d≥0.20 small, ≥0.50 moderate, ≥0.80 large) analyzed the data.

Results: Among the 105 eligible candidates approached, n=18 enrolled (16%) and attended median 8 of 12 sessions (range 3–12) while 78% of parents (n=14) attended median 6 sessions (range 1–10). Acceptability scores on all subscales were high (program components/strategies X±SD 4.5 ± 0.4, participant comfort 4.3 ± 0.5, instructor-related factors 4.3 ± 0.6). At both baseline and 12wk, PA (2.6 ± 3.4vs4.3 ± 7.1 * 10-min bouts/week, p=0.52, d=0.22) was low, screen time high (3.6 ± 2.8vs4.1 ± 2.9hrs/day, d<0.20), BMI overweight (24.8 ± 3.1vs24.9 ± 3.3kg·m⁻², p=0.35, d<0.20), and glycemic control poor (A1c 9.5 ± 2.3vs9.4 ± 2.1%, p=0.72, d<0.20). Self-management behaviors were also unchanged (p>0.05, d<0.20).

Conclusion: The intervention was feasible and acceptable but did not improve poor PA and nutrition among sedentary adolescents with T1D, suggesting this at-risk population needs more intensive interventions.

DEPRESSIVE SYMPTOMS ASSOCIATED WITH COPING AND SELF-CARE IN TEENS WITH POORLY CONTROLLED TYPE 1 DIABETES

Emily R. Hamburger, MEd, Sarah S. Jaser, PhD

Vanderbilt University Medical Center, Nashville, TN

Background: Type 1 diabetes (T1D) is one of the most common chronic conditions affecting teens. T1D requires a rigorous treatment regimen, and teens experience high levels of diabetes-related stress. Previous studies have shown that teens with T1D exhibit increased rates of depression. However, the relationship between depressive symptoms, coping strategies, and self-care in adolescents with poor glycemic control has not been previously investigated.

Methods: Teens with T1D (n=120, age 13–17, 52.5% female, 86.8% White non-Hispanic, mean A1c=9.2%) and their caregivers completed the Self Care Inventory (SCI), a measure of diabetes management behaviors. Teens also completed the Patient Health Questionnaire (PHQ9), a measure of depressive symptoms, and the Responses to Stress Questionnaire (RSQ), which assesses coping strategies and involuntary stress responses (e.g., intrusive thoughts, physiological arousal). Clinical data (i.e., A1c) were collected from medical charts.

Results: 60% of teens in this sample reported minimal depressive symptoms, 30% reported mild symptoms, and 8.6% reported moderate/severe symptoms. There were no significant differences in depressive symptoms between genders or between those using insulin pumps vs. injections. Age was significantly associated with increased depressive symptoms (r=.28, p=.002); however, disease duration and A1c were not. Comparisons between those scoring 0–4 on the PHQ9 (little or no depression) and those scoring 5 or higher (at least mild depression) revealed differences on several measures. Parents of depressed teens reported significantly worse self-care than parents of non-depressed teens (t(118)=2.20, p=.03). Likewise, depressed teens also reported worse self-care (t(118)=3.87, p<.001). Responses to stress also differed. Depressed teens reported lower levels of primary control coping strategies, such as problem solving, than non-depressed teens (t(118)=2.36, p=.02), as well as less frequent use of secondary control coping strategies, such as acceptance and distraction (t(118)=3.62, p<.001). Additionally, depressed teens reported higher levels of stress reactivity (t(118)=3.40, p=.001).

Discussion: In our sample with of teens with poor glycemic control, we found more than twice as many teens reporting mild depression as described in a nationally representative sample of teens with T1D (in which 14% reported mild symptoms). Further, teens reporting clinically significant depressive symptoms exhibited worse self-care (as reported by both teens and parents), and also indicated less frequent use of primary and secondary control coping strategies and higher levels of stress reactivity. Greater use of adaptive coping strategies may be targeted in future interventions as a way to prevent depression and promote adherence in this high-risk population.

DIABETES COMMUNITY PARTNERS: A CASE STUDY OF A DIABETES COMMUNITY COALITION IN RURAL APPALACHIAN OHIO

Elizabeth A. Beverly, PhD¹, Karie Cook, BSN², Kristin Kerwin, BSN³¹Ohio University Heritage College Osteopathic Medicine, Athens, OH; ²Ohio University Diabetes Institute, Athens, OH; ³Ohio University Heritage College of Osteopathic Medicine, Athens, OH

In the Appalachian region of rural southeastern Ohio, diabetes rates are more than double the national average (19.9% versus 9.3%). Here, diabetes patients are more likely to have microvascular complications, limited access to health care, lower health literacy, food insecurity, and depression. To address rising rates of diabetes in the region, we formed the Diabetes Consumer Coalition to mobilize community members with diabetes along with key healthcare personnel to make southeastern Ohio more diabetes friendly. On average, six community members and two group leaders attend the monthly coalition meetings. Coalition members put forth a new group name, Diabetes Community Partners (DCP), articulated a clear vision and mission statement, and selected peer-to-peer diabetes mentoring as their programmatic initiative for rural southeastern Ohio. Five of the six coalition members also completed six two-hour training sessions in peer-to-peer diabetes mentoring. To assess members' experiences with DCP, we conducted a qualitative process evaluation. Process evaluations allow researchers to gain insight into the best practices of a program. All eight coalition members (mean age=62.0 ± 16.2 years, 75% female, 87.5% white, 85.7% type 2 diabetes, 21.6 ± 17.5 diabetes duration) participated in in-depth individual interviews. Three themes emerged from the analysis: 1) A Helping Spirit: When asked why they became involved in DCP, leaders and members explained that they saw themselves as helpers, supporters, and peers to individuals living with diabetes in the community. Participants agreed that DCP was necessary to give support to diabetes patients who might not have support at home. 2) The Value of Emotional Support: Participants readily acknowledged the importance of emotional support and talking to others about how diabetes makes you feel. For many of these participants, DCP gave them hope because they were helping others and helping themselves at the same time. 3) The Power of Mentorship: Leaders and members enjoyed learning more about diabetes while supporting each other through the six-week program. Participants recognized that if an individual was receptive, mentorship could be very powerful. Importantly, they also noted the significance of being non-judgmental when mentoring and being honest with mentees that they did not have all the answers. Next steps will focus on the development of strategic plans for sustainability of the coalition.

DO VETERANS WITH A PREVIOUS DIABETIC FOOT ULCER HAVE LOWER HEALTH STATUS COMPARED TO DIABETIC VETERANS WITHOUT A PREVIOUS ULCER?

Bernardo Da Silva, BA¹, Sushmita Banerjee, BS², Noah Hellermann, BA³, Elora Basu, BA², Sundar Natarajan, MD⁴¹VA New York Health Harbor System, New York, NY; ²VA NY Harbor Healthcare System, New York, NY; ³VA NY Health Harbor System, Brooklyn, NY; ⁴NYU Langone Health, New York, NY

Objective: A diabetic foot ulcer (DFU) is a serious complication of diabetes mellitus with more than 90% of non-traumatic lower extremity amputations being preceded by a DFU. Previous studies have described impaired health-related quality of life in patients with previous DFU. This study aims to compare the cognitive, emotional, and physical health states between diabetic veterans with neuropathy (without a previous DFU) and those with a history of a DFU.

Methods: A cross-sectional study was designed with diabetic veterans with history of DFU and diabetic veterans with neuropathy but without DFU. All veterans completed the Mini Mental State Exam (MMSE), Personal Health Questionnaire Depression Scale (PHQ-8), Euro-Qol-5D (EQ-5D), and Foot and Ankle Ability Measure (FAAM) questionnaires. MMSE scores served as measurements of cognitive impairment between the two groups. Data regarding the emotional and physical health state of patients were obtained from PHQ-8 scores and from the VR-12, EQ-5D, and FAAM assessments.

Results: Our analysis included 102 diabetic veterans with previous DFU and 274 diabetic veterans with neuropathy but without DFU. Patients with and without history of DFU had an average age of 67.92 years and 69.06 years, respectively ($p = .14$). Both groups were overwhelmingly male (>98%) and had similar racial demographics with a large proportion of African Americans. Veterans with history of DFU demonstrated higher MMSE scores than those without (27.66 vs. 27.02, $p = .04$). Furthermore, veterans with history of DFU averaged similar general health scores on the EQ-5D compared to those without (70.32 vs 68.13, $p = .23$). Patients with a history of DFU reported similar scores on the PHQ-8 (7.05 vs. 6.11, $p = .24$) and on the FAAM scale (66.33 vs 67.27, $p = .82$) than those without a previous DFU.

Conclusions: Although Veterans with a history of DFU performed better on the MMSE than those without history of DFU, the small difference may not have clinical significance. No other statistically significant differences were observed between these two groups suggesting that these two subgroups are similar to one another. While both groups had similar health status, it is important to note that their health status is quite low. Comprehensive efforts should continue to be made to focus on such complex diabetes patients to optimize their care and to retard further deterioration in health.

FEASIBILITY OF USING A FITBIT-BASED INTERVENTION FOR INCREASING PHYSICAL ACTIVITY IN PATIENTS AT RISK FOR A DIABETIC FOOT ULCER

Kristin Schneider, Ph.D.¹, Ryan T. Crews, MS², Vasanth Subramanian, MS³, Elizabeth A. Moxley, PhD, RN⁴, Julie Hwang, PhD⁵, Frank E. DiLiberto, PT, PhD¹, Laura Aylward, M.S.⁶, Jermaine Bean, M.S.⁶, Sai V. Yalla, PhD³

¹Rosalind Franklin University of Medicine & Science, North Chicago, IL; ²CLEAR at Rosalind Franklin University, NORTH CHICAGO, IL; ³Rosalind Franklin University of Medicine and Science, North Chicago, IL; ⁴DePaul University, North Chicago, IL; ⁵DePaul University, Chicago, IL; ⁶Rosalind Franklin University of Medicine and Science, Chicago, IL

In one year, US adults with diabetic foot ulcers (DFUs) incur \$9–13 billion in healthcare costs, in excess of the costs associated with treating diabetes itself. Since 25% of adults with diabetes will develop a DFU, prevention of DFUs is critical to curbing amputations and decreasing costs. Regular physical activity may prevent DFUs, if increased gradually. While supervised physical activity programs increased physical activity in adults at risk for DFUs, these programs are unlikely to be disseminated widely since physical activity sessions are rarely covered by insurance and can be burdensome. In this mixed-methods study, we examined the feasibility of a low intensity, Fitbit-based behavioral intervention to increase physical activity in adults at risk for a DFU. Participants at risk for a DFU ($n=12$, 66% female, $M_{age}=59.9$ years) received 4 in-person physical activity and behavioral counseling sessions over 2 weeks, supplemented with the use of a Fitbit (to track steps) and text messages (to reinforce behavioral strategies) for an added 8 weeks. Gradual increases in activity goals, as little as 50 steps/day, were used to increase activity without increasing DFU risk. Pre- and post-intervention assessments of accelerometer measured activity (PAMsys) and glycemic control (A1c) were completed by all but one participant. Treatment acceptability was assessed by questionnaire and via key informant interview at the post-intervention assessment. Results suggest that the program was feasible such that all but 1 participant attended all 4 sessions, all used the Fitbit and all responded to text messages. One participant developed a DFU, which resolved, and she returned to being physically active. Treatment acceptability (scale: 1=very dissatisfied, 5=extremely satisfied) was high; average item ratings ranged from $M=4.2$ ($SD=1.14$) for satisfaction with the length and location of sessions, to $M=5.0$ ($SD=0$) for satisfaction with the session safety precautions, provision of interesting information and discussions of monitoring physical activity. Participants increased their steps by an average of 761 steps/day ($d=0.55$) and A1c decreased on average by 0.32% ($d=0.23$). Interview results suggest that participants found the sessions, Fitbit and text messaging useful. Individuals at risk for a DFU might benefit from a low-cost, less intensive intervention to increase their physical activity, with little risk. Future research comparing the intervention to usual care is warranted.

LINKS OF DISPOSITIONAL PLAYFULNESS IN ADULTS WITH TYPE 1 DIABETES AND THEIR PARTNERS TO WELL-BEING

Meredith Van Vleet, Ph.D.¹, Vicki Helgeson, Ph.D.¹, Cynthia Berg, Ph.D.²

¹Carnegie Mellon University, Pittsburgh, PA; ²University of Utah, Salt Lake City, UT

Chronic illness research has traditionally focused on stressful contexts of the illness and their impact on health and well-being, while overlooking the role of positive characteristics and contexts. One positive dispositional characteristic that is likely to affect well-being and self-care is playfulness, defined as a tendency to pursue activities with the goal of amusement or fun, and with an enthusiastic and in-the-moment attitude. Playfulness is likely to generate positive affect, reduce stress, improve problem-solving (by taking a positive approach to handling illness-related problems), and bring partners closer together. We hypothesized that playfulness would be linked to greater life satisfaction, less stress, less depression, greater perceived problem resolution during a diabetes stressor discussion, and greater relationship quality in individuals with type 1 diabetes and their spouses ($n = 199$ couples, 52% female, M age = 47 years). We also expected that playfulness would be linked to better self-efficacy, less diabetes stress and better self-care, due to improvements in diabetes problem-solving and mood. Findings indicated patient playfulness was linked to greater life satisfaction, less stress, less depression, greater perceived problem resolution and better mood during the discussion, and marginally less diabetes distress, but no other diabetes outcomes (significant p 's < .05, marginal p 's < .10). When controlling for extraversion and agreeableness, links from playfulness to perceived problem resolution and better mood during the discussion remained and the link to depression became marginal, but playfulness was also linked to worse self-efficacy and marginally worse self-care. For spouses, playfulness was linked to less depression, higher relationship quality, greater perceived problem resolution and better mood during the discussion. When controlling for personality constructs, the link to perceived problem resolution became marginal, all other links remained significant. Findings suggest that playful individuals have positive views of how they handle diabetes care, but these perceptions may not translate into self-care behavior. Implications will be discussed.

NOCTURNAL CAREGIVING OF ADOLESCENTS WITH TYPE 1 DIABETES: INTERVIEWS WITH CAREGIVERS ON SLEEP AND DIABETES MANAGEMENT

Erin M. Bergner, MPH, MA¹, Emily R. Hamburger, MEd¹, Rodayne Williams, BA¹, Morgan Lyttle, BA², Sarah S. Jaser, PhD¹

¹Vanderbilt University Medical Center, Nashville, TN; ²Vanderbilt University Medical Center, Mt. Juliet, TN

Nocturnal caregiving has been identified as a barrier to sleep and a source of parenting stress in caregivers of younger children with type 1 diabetes (T1D), but it has not been explored in parents of teens with type 1 diabetes. We conducted semi-structured interviews with 25 caregivers (92% parents; 88% female) of teens with T1D (mean age = 15.6 years; 52% female; mean HbA1c = 8.9%; 56% using insulin pumps, 20% using continuous glucose monitors (CGMs)) exploring caregivers' role in diabetes management at night and its effect on teens' and caregivers' sleep. Interviews were transcribed, and each interview was coded by two raters in Atlas.ti. Inter-rater reliability was 82%, and consensus was reached for any remaining coding discrepancies. Nocturnal caregiving behaviors were reported by 60% (n=15) of caregivers, of which 40% (n=6) reported that they regularly check their child's blood sugar at least once during the night. Caregivers described feelings of anxiety related to their child's diabetes management, reporting a heightened sense of worry and increased overnight monitoring when their child has low blood sugar before bed, is sick, or after a change to their teen's insulin regimen (in these situations, medical providers generally recommend overnight checks). In these instances, caregivers postponed their own bedtime or set personal alarms in order to monitor their child's blood sugar. Others were woken and alerted to diabetes-related concerns by their teen or their teen's CGM. Notably, of the 5 caregivers whose teen used CGM, 3 reported that they still checked their teen's blood glucose at night. Caregivers reported the effects of T1D on their teens' sleep as well as their own, describing difficulty falling asleep, interrupted sleep, and feeling tired and cranky the following day. Findings from these interviews suggest that nocturnal caregiving is common among caregivers of teens with T1D, even when it may not be medically necessary, and these behaviors may have a negative impact on both teens' and caregivers' sleep and wellbeing. Results will inform interventions to improve sleep in teens with T1D and reduce caregivers' distress.

PARTNER PERCEPTION OF DIABETES AS SHARED BENEFITS PA- TIENTS WITH LOW SELF-EFFICACY

Melissa Zajdel, M.S.¹, Vicki Helgeson, Ph.D.¹, Caitlin S. Kelly, MA², Eunjin Lee, Ph.D.³, Michelle L. Litchman, PhD, FNP-BC, FAANP⁴, Cynthia Berg, Ph.D.²

¹Carnegie Mellon University, Pittsburgh, PA; ²University of Utah, Salt Lake City, UT; ³University of Utah, salt lake city, UT; ⁴University of Utah College of Nursing, Salt Lake City, UT

Traditionally coping has been viewed as an individual process, but it has increasingly been recognized that patients' disease adjustment may be influenced by their social network. One type of interpersonal coping is communal coping, which is defined by Lyons and colleagues (1998) as the appraisal of a problem as "our problem" (compared to "my problem"), and subsequent collaboration to solve it. Past research has indicated that shared illness appraisals are particularly beneficial to patients, especially when those appraisals are held by partners. We studied illness appraisals among couples in which one partner was diagnosed with type 1 diabetes (N = 199; patients 91% white, 52% female, average age 47[range 26–75]; partners 94% white, 47% female, average age 46[range 24–77]). We examined whether shared illness appraisals were especially beneficial when patients felt less confident about their abilities to take care of their diabetes. We assessed illness appraisal by asking patients and partners whether they viewed diabetes as the patient's issue, the patient's issue with effects on the partner, or a shared issue. The interaction between patient shared illness appraisal and patient self-efficacy was not significant in predicting any outcomes. However, multiple regression analyses showed that partner appraisal interacted with patient self-efficacy to predict depressive symptoms ($p < .05$), life satisfaction ($p < .001$), stress ($p < .01$), self-care behaviors ($p < .05$), diabetes distress ($p < .10$), mental functioning ($p < .10$), and sleep quality ($p < .10$). In all cases, partner report of the problem as shared was associated with better patient outcomes when patients reported low diabetes self-efficacy. By contrast, when patients reported high diabetes self-efficacy, partner appraisal of the problem as shared was unrelated or related to slightly worse outcomes. These findings indicate that partner appraisal of diabetes as shared is particularly adaptive for patients when they feel less capable of managing the illness.

PHYSICAL ACTIVITY AND PRO-HEALTH BEHAVIOR PROFILES IN DIABETES RISK AMONG BLACKS AND WHITES: A NOVEL MA- CHINE LEARNING ANALYSIS

Azizi Seixas, PhD, MS, MA¹, Dwayne Henclewood, PhD², Aisha T. Langford, PhD, MPH³, Samy McFarlane, PhD⁴, Girardin Jean-Louis, PhD⁵

¹NYU Langone Health, New York, NY; ²Booz Allen Hamilton Inc, Boston, MA; ³NYU School of Medicine, New York, NY; ⁴NYU school of Medicine, Rockaway park, NY; ⁵New York University, New York City, NY

The goal of the current study is to assess the prevalence of diabetes across four physical activity profiles/phenotypes (sedentary, moderate, active and very active) and infer through machine learning which combinations of physical activity, sleep, stress and body mass index yield the lowest prevalence of diabetes in Blacks and Whites. Data were extracted from the National Health Interview Survey (NHIS) dataset from 2004–2013 containing demographics, chronic diseases, and sleep duration (N=288,888). Of the total sample, 9.34% reported diabetes (where the prevalence of diabetes in Blacks/African Americans being 12.92% and 8.68% in Whites). Over half of the sample reported sedentary lifestyles (Blacks were more sedentary than Whites); approximately 20% reported moderately active lifestyles (Whites more than Blacks); approximately 15% reported active lifestyles (Whites more than Blacks), and approximately 6% reported very active lifestyles (Whites more than Blacks). Across four different physical activity lifestyles, Blacks consistently had a higher diabetes prevalence compared to their White counterparts. Physical activity combined with healthy sleep, low stress, and average body weight reduced the prevalence of diabetes, especially in Blacks. Our study highlights the need to provide alternative and personalized behavioral/lifestyle recommendations to one-size-fits-all national physical activity recommendations, specifically among Blacks, to reduce diabetes and narrow diabetes disparities between Blacks and Whites. Therefore, we highly recommend diabetes counselling take a personalized and "bundled approach" where a variety of pro-health behaviors are recommended but personalized to the individual's profile. Moving forward, ubiquitous sensing wearables may be a solution to more accurately assess multiple behaviors without unduly burdening individuals with self-tracking.

REVISITING THE FACTOR STRUCTURE OF THE CES-DC FOR DEPRESSIVE SYMPTOMS IN CHILDREN AND ADOLESCENTS WITH TYPE 1 DIABETES

Arwen M. Marker, BA¹, Mark A. Clements, MD, PhD, CPI, FAAP², Ryan J. McDonough, DO, FAAP³, Anna M. Egan, PhD, ABPP³, Susana R. Patton, PhD, CDE⁴

¹University of Kansas, Lawrence, KS; ²Children's Mercy Hospitals & Clinics, Kansas City, MO; ³Children's Mercy Hospital Kansas City, Kansas City, MO; ⁴University of Kansas Medical Center, Kansas City, MO

Introduction: Up to 30% of youth with type 1 diabetes (T1D) will develop depressive symptoms, which are linked to impaired T1D management (Buchberger et al., 2016). Cost-effective, reliable screeners are needed to assess these youth to facilitate early treatment. The Centers for Epidemiological Studies - Depression Scale for children (CES-DC) is a measure that is free, easy to use, reliable, and valid (Weissman et al., 1980; Stockings et al., 2014; Roy et al., 2011; Fountoulakis et al., 2007). However, the CES-DC has been criticized for its biased items and inconsistent factor structures (Carleton et al., 2013). Here, we test the stability of empirically derived factor structures of the CES-DC in youth with T1D, to measure its acceptability as a screening measure.

Methods: 499 youth (Mean age = 15.5 ± 2.1 years; Mean time since diagnosis = 6.1 ± 3.9 years; 49.9% male; 82.9% white) completed the CES-DC during a routine clinic visit. We also collected hemoglobin A1c (A1c) and demographic information at the visit. We tested the 3- and 4-factor structures with the most empirical support (Radloff, 1977; Carleton et al., 2013) using maximum likelihood estimation in Mplus. We tested the stability of the factor structure across age groups (≤ 14 years or ≥ 15 years) after controlling for A1c using weighted least squares means and variance adjusted for categorical measurement invariance.

Results: In this sample, only 18.2% of youth had good glycemic control (A1c ≤ 7.5%), while 43.8% had poor control (A1c ≥ 9.0%). On the CES-DC, 27.1% of youth scored ≥ 15, indicating a concerning level of depressive symptoms. Our factor analysis confirmed better model fit for the 3-factor versus the 4-factor model, providing support to remove six potentially biased items. Remaining items assessed negative affect, anhedonia, and somatic symptoms. Controlling for A1c, the 3-factor structure showed configural and weak invariance across age groups.

Conclusion: Our results support using the 3-factor structure to interpret the CES-DC in youth with T1D. Stability across age groups and glycemic control suggests the CES-DC provides a reliable measure of depressive symptoms. However, additional research is needed to determine whether depression ratings on the CES-DC are impacted by cognitive or somatic symptoms of diabetes (Stewart et al., 2011; Shemesh et al., 2005; Ohayon & Schatzberg, 2003).

STEREOTYPES AND BARRIERS: THE ROLE OF THE STEREOTYPE CONTENT MODEL AND DIABETES DISTRESS IN BLIND ADULTS WITH DIABETES

Nazanin Heydarian, M.A., Allyson Hughes, M.A., Osvaldo Morera, PhD.

The university of Texas at El paso, El Paso, TX

The current project examined the perspectives of blind adults with diabetes through the theoretical framework of the Stereotype Content Model impacting Diabetes Distress. Comorbidities, experiencing two or more chronic conditions concurrently, are linked to poor health outcomes, and difficulty managing self-care. The experiences of persons living concurrently with blindness and diabetes are understudied. According to the Stereotype Content Model, healthcare providers (HCPs) may view minority patients, such as blind adults, with pity or contempt and, as a result, the quality of their interactions with their blind patients may be diminished. Minority patients perceive this pity or contempt and, as a result, may become disheartened, distressed, and mistrustful of medical authorities. Diabetes Distress is diabetes-related emotional hardship and Diabetes Burnout is apathy and depression symptoms that affect diabetes self-management. These stereotypes may lead some HCPs to patronize patients, over-emphasize impairments, and construct barriers, be it incidental or otherwise, for blind patients with diabetes. As a result of these barriers, individuals in this population may feel a heightened level of distress. We predicted that this distress would be evident in the qualitative responses of this sample. Eleven blind adults with diabetes participated in focus group interviews. Thematic analyses revealed that participants perceived being regarded as incompetent by many of their HCPs. In addition to this, participants often reported feeling as if their HCP could not communicate with them. Participants discussed unique barriers they faced such as inaccessible medical equipment and problematic hospital policies. Participants reported that such experiences often led to distress and mistrust in healthcare advice from HCPs, although they did not mention instances when this distress affected their disease management. Conversely, participants reported feeling respected by some HCPs and, as a result, they felt content with healthcare and trusted healthcare information. These results shed light on the role of stereotypes in shaping the healthcare experience of patients who live the unique experience of blindness and diabetes.

THE DETRIMENTAL ASSOCIATION BETWEEN STRESS AND DIABETES MANAGEMENT IN A SAMPLE OF HIGH-RISK, LOW-INCOME LATINAS

Vivianna M. Goh, Undergraduate¹, Kelly Biegler, PhD², Emily Dow, MD³, David Kilgore, MD³, Karen Rook, PhD², Dara H. Sorkin, PhD²

¹California State University, Long Beach, Garden Grove, CA; ²University of California, Irvine, Irvine, CA; ³University of California, Irvine, Orange, CA

Background: Hispanic-Americans are one of the fastest growing ethnic groups in America. This group is at a disproportionate risk of suffering from diabetes. Hispanic women are of particular risk; in 2014, their lifetime risk of being diagnosed with diabetes exceeded 50%, almost twice the risk for non-Hispanic white women. Latinas also report higher levels of stress, which may impede their ability to manage diabetes. Previous research suggests that stress negatively affects health behaviors such as eating and exercise.

Purpose: This study aims to investigate the associations between perceived stress and: (1) indicators of diabetes control; (2) behaviors related to diabetes management (e.g., medication adherence, testing blood sugar); and (3) general health behaviors.

Methods: Data was derived from 89 women who identified as Latina and were diagnosed with diabetes. Participants were recruited to enroll in *Unidas por la Vida*, a lifestyle diet and exercise intervention for Latina mothers with diabetes and their overweight adult daughters. Participants completed a baseline questionnaire to assess perceived stress (nine-item Perceived Stress Scale), frequency of hypoglycemia, behaviors related to diabetes management, and diet and physical activity. Women's glycated hemoglobin (HbA1c; average blood sugar levels over 3 months) was also measured. Bivariate analyses were conducted to examine correlations between stress and the primary outcomes.

Results: On average, participants evidenced high levels of stress ($M = 15.1$, $SD = 6.5$). Stress was positively correlated with experiencing a major hypoglycemic episode ($r = 0.28$, $p < 0.05$); however, stress was not associated with HbA1C level ($p = 0.47$). Stress was also associated with fewer diabetes self-management behaviors (e.g. remembering to test blood sugar, $r = -0.24$, $p < 0.05$), but not with medication adherence ($p = 0.93$). Finally, stress was associated with greater reports of exercise barriers ($r = 0.42$, $p < 0.01$) and lower reports of exercising daily ($r = -.029$, $p < 0.05$).

Conclusions: Findings from this study suggest that stress may influence certain health behaviors in diabetic Latinas. Assessment of stress may predict effective management of diabetes. In addition to promoting exercise and a healthy diet, health care providers should also provide resources for stress management and coping techniques.

Key words: stress, diabetes, Latina, health behaviors, control

THE ROLE OF SES IN HEALTH DISPARITIES AMONG LATINO AND NON-LATINO WHITE YOUTH WITH DIABETES: A SYSTEMATIC REVIEW

Daniel Mello, Doctoral Candidate¹, Deborah Wiebe, PhD, MPH²

¹University of California - Merced, Merced, CA; ²University of California, Merced, Merced, CA

Latino youth are the fastest growing minority population in the US, and may have higher risk for adverse diabetes-related health than non-Latino Whites (NLW). However, the extant literature on the presence of ethnic disparities in diabetes (e.g., prevalence, BMI, glycemic control) among NLW youth is inconsistent, possibly due to methodological decisions regarding socioeconomic status (SES). Low SES is a known risk factor for poor diabetes health, and Latinos are often of lower SES than NLWs, but research has not consistently evaluated whether ethnic disparities exist independent of SES. SES, rather than more cultural aspects of ethnicity, may account for disparities, and SES may moderate ethnic health disparities (consistent with the Hispanic paradox). The current study systematically reviewed the literature to elucidate the presence of disparities in diabetes health among Latino and NLW youth, and to understand the role of SES in explaining such disparities. The MEDLINE and PSYCINFO databases were searched for peer-reviewed literature that compared Latino and NLW children, adolescents, and emerging adults (ages 0 to 22) on illness-related characteristics for type 1 and type 2 diabetes. After excluding 497 studies, a total of 45 articles were sourced: 26 examined type 1 diabetes, 9 examined type 2 diabetes, and 10 examined both type 1 and type 2. In 51.1% of studies, Latino youth were reported to have poorer diabetes-related characteristics (e.g., higher BMI, higher prevalence, poorer metabolic control) than NLWs. Only two-thirds (66.6%) of all studies reported any measure of SES, and of these, only 63.3% included SES in analyses to determine whether ethnic disparities exist independent of SES. In the 24.4% of studies which reported analyses with and without covarying SES, 41.6% found that controlling for SES eliminated the Latino disparity. Only 15.5% examined if SES moderated ethnic disparities, with most finding no interaction, and two finding opposite results. The rapid growth of the Latino youth population, and their increasing prevalence of diabetes, has led to concerns of ethnic disparities in diabetes health in youth. The extant literature is inconsistent as to the presence of Latino disparities, and raises questions about whether disparities exist independent of SES. Future research that systematically evaluates the role of cultural and SES-related processes is necessary to guide effective approaches to minimize disparities in this vulnerable population.

TRAJECTORIES OF GLYCEMIC CONTROL AMONG DIVERSE
YOUTH FROM THE TYPE 1 DIABETES EXCHANGE CLINIC
REGISTRY

Daniel Mello, Doctoral Candidate¹, Deborah Wiebe, PhD, MPH²

¹University of California - Merced, Merced, CA; ²University of California, Merced, Merced, CA

Adolescence is a time of known risk to glycemic control among youth with type 1 diabetes (T1D). Despite evidence suggesting that minority youth may be at higher risk for poorer glycemic control, deterioration in glycemic control across adolescence has been typically studied among non-Latino Whites (NLW). Examining race/ethnic differences in control trajectories across adolescence may illuminate developmental periods when disparities appear. Further, minority youth often have reduced socioeconomic resources, a risk factor for poor T1D management, but the role of socioeconomic status (SES) in ethnic disparities has rarely been studied. The present study examined whether race/ethnicity and SES worked independently or interactively to predict longitudinal trajectories in glycemic control across adolescence (ages 10 to 18). Adolescent data from the national Type 1 Diabetes Exchange Clinic Registry ($N = 5,963$; 48.6% female; 83.2% non-Latino White, 11.3% Latino, 5.5% Black) was used. Glycemic control was indexed via HbA1c in clinic records obtained across time from ages 10 to 18; an average of 25.7 HbA1c assays were available per participant across time. Annual household income indexed SES. Hierarchical linear modeling estimated HbA1c trajectories across adolescence, and examined whether ethnicity and SES were related to HbA1c at age 10, and rate of deterioration across time. Analyses without SES revealed that Blacks had poorer HbA1c at age 10, and deteriorated more rapidly across adolescence than NLWs. Latino youth had similar HbA1c at age 10, but deteriorated more rapidly across adolescence than NLW. Statistically controlling SES did not alter these findings, and SES did not moderate race/ethnicity effects. Independent of race/ethnicity, lower SES was associated with poorer HbA1c at age 10, and with more rapid deterioration across age. Results highlight that race/ethnic minority status and lower SES may independently contribute to risks for poor glycemic control, and identifies adolescence as a developmental period of time when these risks are exacerbated. Future research to understand the developmental and socio-cultural processes that contribute to such risks will be necessary to guide effective interventions and support diabetes management in these at risk populations.

UNIDAS POR LA VIDA: EXAMINING DIABETES MANAGEMENT
AND WEIGHT LOSS IN AN INTERVENTION DESIGNED FOR LATI-
NAS WITH TYPE 2 DIABETES

Kelly Biegler, PhD¹, Karen Rook, PhD¹, Emily Dow, MD², David Kilgore, MD², Dara H. Sorkin, PhD¹

¹University of California, Irvine, Irvine, CA; ²University of California, Irvine, Orange, CA

Mexican-American women have one of the highest lifetime risks of developing diabetes, and compared to non-Hispanic whites, are more likely to suffer from diabetes-related sequela. Diligent self-management is a key factor in controlling diabetes and preventing complications; however, low physical activity and a high fat, high carbohydrate Americanized Mexican diet serve as commonly reported barriers toward sufficiently managing diabetes in Latinas. As such, it is essential that lifestyle interventions be culturally tailored and evidence-based to overcome common diabetes-related obstacles in order initiate and sustain health behavior change.

Purpose: We conducted a pilot randomized controlled trial testing the effectiveness of a dyadic lifestyle intervention (Unidas por la Vida) among Latina mothers with diabetes and their overweight/obese, at-risk adult daughters. This study examined whether a culturally tailored lifestyle intervention, modeled after the Diabetes Prevention Program, was associated with fewer hassles/barriers around diabetes management (e.g., planning meals, testing blood sugar), greater diabetes control, greater weight loss, and glycemic control in Latinas with type 2 diabetes relative to usual care.

Method: Data were derived from 89 Latinas (mothers) who were overweight/obese, had a clinical diagnosis of type 2 diabetes, and were randomized to either the intervention or usual care. Self-reported measures of diabetes-related hassles and diabetes control, and clinical markers of weight (lbs) and glycemic control (HbA1c) were collected at baseline and 16 weeks.

Results: Demographic results were reported previously (Sorkin et al. 2014). Latinas in the intervention group reported having significantly fewer diabetes-related hassles ($\beta = -0.21$, $p = 0.04$) and had greater weight loss ($\beta = -.05$, $p = 0.004$) at study completion, relative to Latinas in usual care. However, no significant intervention effects were observed in self-reported diabetes control and in actual glycemic control.

Discussion: The findings demonstrate that the Unidas pilot intervention was effective in promoting weight loss and reducing self-reported hassles and obstacles around diabetes management. Perhaps the 16 week interval was too brief to capture modulations in HbA1c levels, and by extension, self-reported diabetes control. Implications for tailoring weight loss interventions to Latinas with diabetes will be discussed.

USE AND BENEFITS OF A STUDY HELPLINE IN A BEHAVIORAL RANDOMIZED CONTROLLED TRIAL

Sarah E. Williamson, MA¹, Erin M. Bergner, MPH, MA², Chad Gentry, PharmD³, Lyndsay A. Nelson, PhD², Lindsay S. Mayberry, PhD²

¹Center for Health Behavior and Health Education, Vanderbilt University Medical Center, Nashville, TN; ²Vanderbilt University Medical Center, Nashville, TN; ³Lipscomb University College of Pharmacy and Health Sciences, Nashville, TN

Helplines are widely used to offer convenient and prompt access to information and support; however, their use in research studies for study-related questions/concerns is uncommon. We developed and implemented a Helpline for the REACH study, a 15-month randomized controlled trial evaluating mobile phone-based support for improving self-care and glycemic control among adults with type 2 diabetes. The purpose of the Helpline is for potential participants to express interest in the study, and currently enrolled participants to report technical problems with the mobile phone program, and ask study- and diabetes medication-related questions. The Helpline is listed as the point of contact on recruitment materials. At study enrollment, we tell participants about the other uses of the Helpline and assist with programming the number in their cell phone. Helpline callers are instructed to leave a voicemail after which study staff receive an e-mail notification, log on to a HIPAA-compliant website to access the voicemail, and return participants' call within one business day. All medication-related calls are returned by a clinical pharmacist, who can offer medication advice and communicate with participants' healthcare provider. Many participants express enthusiasm about the option to talk to a clinical pharmacist by calling the Helpline. Currently, 391 participants are enrolled in the study (52% female; 48% non-white; 58% income \leq \$35K). We have received a total of 248 calls on the Helpline since the beginning of the study in May 2016; 106 calls were from people who were not yet study participants (62% expressing interest in the study or scheduling enrollment appointments) and 142 were from enrolled study participants. Of the 85 unique participants who called the Helpline, 42% were in the control condition and 58% were in the intervention. The most common reasons for participant calls include: to learn their study A1c result (23%), to schedule/confirm study appointments (18%), to update contact and study-related information (11%), and to report technical problems (e.g., did not receive text messages as scheduled; 11%). Only 2 calls have been made to ask a question of the clinical pharmacist. In conclusion, a study Helpline has been a powerful tool for study recruitment and retention. The Helpline also provides an additional intervention component (i.e., option to talk to a clinical pharmacist), which study participants express excitement about but rarely use.

A 'SNAP'SHOT OF THE RELATIONS BETWEEN SOCIAL MEDIA USE AND HEALTH BEHAVIORS IN COLLEGE

Kristen Pasko, Bachelor of Science¹, Sabrina DiBisceglie², Danielle Arigo, Ph.D. in Clinical Psychology³

¹University of Scranton, Dunmore, PA; ²University of Scranton, Scranton, PA; ³The University of Scranton, Scranton, PA

Background: Information shared via social media is known to influence college students' health perceptions and behaviors. In particular, *fitspiration* posts on social media (i.e., images of healthy food or people exercising, fitness quotes) have been associated with both positive and negative outcomes for eating behavior and physical activity. Although information from posted images (vs. posted text) may have different effects, there has been little research on this distinction with respect to students' health behaviors. This study examined relations between students' health behaviors and (1) use of image-based (IB: Instagram, Snapchat) compared to text-based (TB: Twitter, blog sites) social media, and (2) exposure to fitspiration posts.

Methods: Participants were 336 college students (70% women, $M_{Age} = 19$, $M_{BMI} = 24 \text{ kg/m}^2$) who completed self-report measures of their social media use (hours per day), exposure to fitspiration posts, and health behaviors (alcohol consumption, sexual activity, eating behavior, physical activity). Participants also identified 3 healthy and 3 unhealthy behaviors they engage in regularly (free response).

Results: Snapchat, a newer platform that allows users to post images that disappear quickly, was the most popular type of IB media (85% reported use more than once per day). Twitter was the most popular type of TB media, though only 28% reported use more than once per day. Time spent on IB media was significantly longer than time spent on TB media ($p < 0.001, d = 0.79$). Greater time spent on IB media was associated with fewer days per week spent exercising ($r = -0.21, p < 0.001$). In contrast, greater time spent on TB media was associated with increased risky sexual activity ($r = 0.17$) and alcohol consumption ($r = 0.12; ps < 0.05$). Intentional exposure to fitspiration posts was positively associated with exercise, fruit consumption, vegetable consumption and junk food consumption ($ps < 0.03, \eta^2 = 0.04-0.14$). Unintentional exposure to fitspiration posts was positively associated only with exercise and fruit consumption ($ps < 0.05, \eta^2 = 0.05-0.07$). Time spent viewing IB and TB media was not associated with open-ended health behavior responses.

Conclusion: College students engage with image-based social media more frequently than with text-based social media; although their engagement with each type is differentially associated with their health behaviors, greater engagement is associated with worse health behaviors overall. Frequent viewing of fitspiration posts (both intentionally and unintentionally) was associated with better health behaviors, though intentional viewing was more strongly associated with eating behavior. Understanding relations between social media use and health behaviors in college could inform future interventions that incorporate these platforms to target specific health behaviors among students.

A MODEL FOR DEFINING AND MEASURING USER ENGAGEMENT IN DIGITAL BEHAVIOR CHANGE INTERVENTIONS

Heather Cole-Lewis, PhD, MPH¹, Nnamdi Ezeanochie, MD, PhD², Chun Wang, MS¹, Shawn Mason, PhD, LP³, Jennifer Turgiss, DrPH¹¹Johnson & Johnson, New Brunswick, NJ; ²Johnson and Johnson, New Brunswick, NJ; ³Johnson & Johnson, West Bloomfield, MI

Researchers and practitioners of Digital Behavior Change Interventions (DBCIs) use varying and oftentimes incongruent definitions of the term engagement; thus, leading to lack of precision in DBCI measurement and evaluation. The objective of this project was to propose nuanced definitions for various types of user engagement and explain why precision in the measurement of these engagement types is integral to ensuring intervention effectiveness. Additionally, we developed a framework and practical steps for how engagement can be measured in practice and used to inform DBCI design and evaluation. In this presentation, we present an example of how the framework has been successfully applied to an actual DBCI.

Using available literature and practice-based knowledge of DBCIs, the framework conceptualizes two main categories of engagement that must be measured in DBCIs. The categories are *health behavior engagement*, referred to as “Big E” and *digital behavior change intervention (DBCI) engagement*, referred to as “Little e.” *DBCI engagement* is further bifurcated into two subclasses to represent engagement with discrete components of the intervention (i.e., user interface, user experience, content) and engagement with behavior change intervention components (i.e., behavior change techniques) compiled to influence determinants of health behavior and subsequently result in behavior change.

The key purpose of a DBCI is to influence change in a target health behavior of a user, which may ultimately improve a health outcome. Achievement of Big E, *health behavior engagement*, in an intervention delivered via digital means, is contingent upon Little e, *DBCI engagement*. If users do not interact with DBCI features and enjoy the user experience, the exposure to the behavior change intervention components is unlikely to influence behavioral determinants and lead to Big E, *health behavior engagement*. Big E, *health behavior engagement*, is also dependent upon the quality and relevance of the behavior change intervention components within the solution. Therefore, the combination of user interactions and behavior change intervention components create Little e, *DBCI engagement*, which in turn produces Big E, *health behavior engagement*.

The framework includes a logic model to support measurement of DBCIs that describes categories of engagement, details how components of Little e produce Big E, and provides suggestions for factors that should be measured in each engagement category.

The framework was applied to a real-world implementation of a DBCI with success, as measured by the ability to differentiate components of engagement for evaluation efforts. Examples of actual measurement metrics are provided. This framework can be applied to DBCIs supporting various health behaviors and outcomes and can be utilized to identify gaps in program efficacy and effectiveness.

ARE NUMBER OF HEALTH COACH VISITS, WEARABLE USE ASSOCIATED WITH CHANGES IN CARDIOVASCULAR RISK IN AN EMPLOYEE WELLNESS PROGRAM?

Bryan Gibson, DPT, PhD¹, Leah Yingling, BS¹, Kelly McLeod, BA², Robin Marcus, PT, PhD³¹University of Utah, Salt Lake City, UT; ²University of Utah, Salt lake city, UT; ³University of Utah, salt lake city, UT

Background: Prior work has shown that health coaching in an employee wellness setting can improve behavior change and health outcomes. However, it is currently unknown what the dose response relationship association is between the number of health coaching visits and change in health outcomes. In addition, wellness programs increasingly use wearable sensors to collect data on participants health and behaviors. However, the effect of using wearables on the efficacy of health coaching is unknown.

Methods: We conducted a secondary analysis of data from the University of Utah’s wellness program. We began by creating a subset of individuals who had complete data from biometric screening in both 2016 and 2017. For each participant we counted the number of coaching visits from the number of unique visit notes written and determined whether they had wearable sensors connected to the programs electronic platform.

To determine what the average effect of health coaching visits and wearable sensors on health risk, we used a linear model that accounted for baseline ASCVD (Atherosclerotic Cardiovascular Disease) 10-year risk score and any differences in the demographics of participants who did or did not receive health coaching.

Results: 736 individuals had complete biometric screening data from both years, 282 of these individuals had at least one coaching session. 207 had at least one wearable sensor connected to the platform. Individuals who received coaching were likely to be older and female than individuals who did not receive coaching.

Results from the linear model suggest that for each coaching meeting there was a small but significant decrease in ASCVD risk (beta=-0.05, T=-2.34, p= 0.02), however the decrease in risk score for having a connected wearable sensor was not significant (beta= -0.11, T=-0.92, p=0.36). As expected, risk score decreased more for individual with higher baseline risk (beta=-0.17, t=-8.2, p < 0.0001), increased slightly with age (beta= 0.05, T= 8.6, p < 0.0001) and increased more for males than females (beta= 0.36, T=2.98, p= 0.003).

Conclusion: Health coaching visits were associated with decreases in objectively measured health risk, however, the use of connected wearable devices was not. In presenting this work we will discuss specific risk factors that changed with coaching and planned work to ascertain which behavior change techniques successful health coaches use with their clients.

BASELINE SAMPLE CHARACTERISTICS AND 6-MONTH EVALUATION OF AN MHEALTH PROGRAM FOR PEOPLE WITH TYPE 2 DIABETES - MY DIABETES COACH

Shaira Baptista, Bsc, GradDip (Psych)¹, Jillian Zemanek¹, Suman Shetty¹, Dominique Bird², Brian Oldenburg¹

¹The University of Melbourne, Melbourne, Victoria, Australia; ²University of Queensland, Woolloongabba, Queensland, Australia

Background and Aims: Type 2 diabetes (T2D) involves complex self-management which most healthcare systems are not able to support. My Diabetes Coach is an mHealth program using an interactive relational agent, 'Laura', supporting blood glucose monitoring and providing personalized feedback and advice. The aim of this presentation is to describe the baseline characteristics of study participants and 6-month data on program use.

Methods: MDC is a real world RCT undertaken in Australia. Participants were recruited through the National Diabetes Services Scheme, consumer diabetes organisations and Facebook. Participants completed clinical tests, demographics and self-report measures at baseline and 6-months. There were also extensive analytics for evaluating program use.

Results: 187 participants were randomized to a waitlist control (n=94) or intervention (n=93) condition. Participants were aged 56 ± 10 years, 45% (n=83) were women. At baseline, they had an HbA1c (average blood glucose) of $7.32 \pm 1.58\%$.

Sample characteristics: Almost half of the study participants were employed full-time (47%); most were between 50 and 69 years old (69%); and the majority had completed at least 12 years of education (53%).

Program use: Of the 93 participants randomly assigned to the intervention group, 56% used a smartphone, 14% used a tablet, and 30% used both to access the MDC app. At 6 months, n=79 (85%) were still using the MDC app to complete chats with Laura, self-monitor their glucose levels, access the program website, and/or participate in the MDC online community discussions. Of these, 50% were weekly chats, 15% fortnightly, 18% monthly and 17% were less than once a month. Over the 6 months, participants had responded to a total of 57,265 statements and questions asked by Laura; and an average of 622 statements per participant.

Conclusions: We have recruited a diverse sample of people with diabetes from around Australia. Smartphones were preferred for program access. Program uptake and use was excellent when compared with other similar technology interventions delivered by phone. Program delivery resulted in on-going, weekly use for most MDC participants. The level and frequency of program use suggests a high degree of program engagement.

DEVELOPMENT AND USABILITY OF A MHEALTH INTERVENTION TO REDUCE SEDENTARY BEHAVIOR BEFORE AND AFTER CANCER SURGERY

Carissa A. Low, PhD¹, John M. Jakicic, PhD¹, Krina Durica, MA¹, Lillian Smith, BA¹, Blessy Bellamy, BA¹, Raghu Mulukutla, MS², David L. Bartlett, MD¹, Dana H. Bovbjerg, PhD¹, Anind K. Dey, PhD³

¹University of Pittsburgh, Pittsburgh, PA; ²Carnegie Mellon University, Pittsburgh, PA; ³University of Washington, Seattle, WA

Background: Sedentary behavior is common after cancer surgery and can negatively affect health and quality of life. Here we report on the first phase of development and testing of a mHealth intervention to address this issue. A smartwatch app was developed to detect prolonged sedentary behavior bouts and prompt patients to take brief walking breaks, with timing of prompts based on symptom severity monitored with a companion smartphone app.

Methods: Eight patients who underwent abdominal cancer surgery in the past year (M age = 52, 63% female, M = 127 days since surgery) participated in individual qualitative interviews and usability testing. The semi-structured interview included questions about activity patterns and barriers to and facilitators of activity before and after surgery. Transcripts were reviewed for common themes. Participants were guided through interactions with the smartphone and smartwatch apps and were instructed to "think aloud" about their experiences and rate the system's ease of use and pleasantness of the interface from 0 (worst) to 100 (best).

Results: Evolving barriers to and facilitators of activity over the perioperative course were described by patients. Prior to surgery, symptoms related to cancer/treatment (e.g., fatigue, nausea) as well as work and caregiving responsibilities made it difficult to be active, while family activities, owning a dog, and having an established exercise routine helped. During inpatient recovery, symptoms such as dizziness and lack of sleep were described as key barriers to activity, along with IVs/monitors and lack of pleasant environment in which to walk. Adequate pain management and encouragement from family and providers emerged as facilitators of inpatient activity. After discharge, depression and persistent physical symptoms interfered with activity, while personal goals and time off from other responsibilities motivated activity. Patients rated both the smartphone and smartwatch apps as easy to use (M = 88 and 80, respectively) and both interfaces as pleasant (M = 87 and 83).

Conclusion: Preliminary results suggest that our mHealth intervention to reduce sedentary behavior has good usability. Patients reported that symptoms were a consistent barrier to activity, with additional evolving barriers over the perioperative course that could be considered in further refinement of the app. The intervention will be evaluated in a randomized clinical trial later this year (NCT03211806).

DIGITAL HEALTH TOOLS FOR CHRONIC ILLNESS AND DEMENTIA RISK ASSESSMENT IN OLDER ADULTS

Sofia Laghouila, Vlad Manea, Veronica Estrada, Katarzyna Wac

University of Copenhagen/ Quality of Life Lab, Copenhagen, Hovedstaden, Denmark

The current state we live in is that populations are growing and the average human lifespan is longer. Seniors may be especially vulnerable to experience poor lifestyle choices as they are out of work, do not exercise, live alone without most opportunity to socialize, may be smoking and having poor diet. Poor lifestyle choices may be developing over a longer period, resulting in chronic illness or dementia later in life. While chronic illness like cardiovascular disease, diabetes influences the physical body, individuals with dementia are losing their memory and experience decline in their cognitive functions. Getting chronic illness or dementia can affect their everyday life to such an extent that they depend on others to function. To our knowledge, curing chronic illness or dementia with pharmaceutical treatments is not possible.

As ever-sophisticated wearable activity trackers and mobile applications enable to assess individual's daily life patterns and risk factors influencing their long-term health state, we have attempted to operationalize the major risk factors for the prevalence of poor lifestyle choices in older adults - including physical factors (e.g., exercise, alcohol), psychological factors (e.g., stress, depression), social factors (e.g., loneliness) and environmental factors (e.g., risk of a country at large). We have thoroughly examined these factors to identify which of those can be operationalized via ICT-based tools and quantified by leveraging unobtrusive sensors, including sensors embedded in personal smartphones and wearables. Such an operationalization will enable to provide reliable assessment and prediction of risk exposure, which, in turns, will permit early recognition and preventive interventions.

To support our research claims we have conducted an explorative pilot study with twenty older adults (>65 years old) in Hungary and Spain wearing Fitbit Charge 2 activity and sleep tracker for a minimum of three months each, as well as providing a set of self-reported measures like blood pressure, diet or alcohol. We provide the risk assessment for their cardiovascular disease as well as dementia, as supported by the latest evidence from the medical literature.

Additionally, we discuss the implications for further research in this domain, where the wearable device's features like interaction design, battery lifetime and fashion-ability; influence the quality of the data collected. Given the results and existing research so far, we discuss design implications for monitoring and assessment of multi-dimensional lifestyle factors and behavioral variables in the natural daily settings of the older adults, ideally leveraged towards their behavior change and prevention of chronic illness like cardiovascular disease as well as dementia in a long term.

FEASIBILITY OF A MOBILE HEALTH-INFUSED DANCE PROGRAM FOR MIDDLE-AGED AND OLDER LATINOS

Isabela G. Marques, BS¹, David X. Marquez, PhD²¹University of Illinois at Chicago/CAPES Foundation, Chicago, IL; ²University of Illinois at Chicago, Chicago, IL

More than 21 million Latinos 55 years and older live in the U.S. Older Latinos have low levels of physical activity and high risk of chronic diseases. Dance is a culturally appropriate form of physical activity to address these risks. Also, technology ownership is increasing among older Latinos; therefore, mobile health could be an appropriate strategy to promote physical activity among this population. The purpose of this study was to assess the feasibility of a mobile health-infused dance program for middle-aged and older Latinos. A single group pre- post feasibility trial was conducted for 16 weeks. Mobile health components (wearable, mobile application, and text messages) were added to the BAILAMOS© dance program. Classes were held twice a week for two hours each session. The first 30 minutes were devoted to a technology class, followed by one hour of the BAILAMOS© Latin dance program, and an extra 30 minutes of technology practice. Participants wore a wearable fitness tracker for 18 weeks (16 weeks of the program + baseline and post testing weeks) and received text messages for 12 weeks (last 12 weeks because many participants needed training in reading messages). Feasibility was assessed by recruitment capability (e.g., recruitment strategies); acceptability and suitability (e.g., enjoyment); and resources (e.g., monetary costs). Recruitment was conducted for eight weeks. The main recruitment strategies were announcements at the host senior center, and having the study announcement printed in Catholic churches' weekly bulletins. Fifty-eight middle-aged and older Latinos who owned a smartphone were assessed for eligibility, and 20 participants (34%) started the intervention (female n=15, M age = 67). Twenty participants (100%) wore the wearable for the 18 weeks, and 17 participants (85%) completed the dance program. In debriefing sessions, participants reported great enjoyment of the program and stated that it was too short. The most valuable components of the intervention were the dance and technology classes, and the support provided by the instructors that taught the technology classes. Costs for the intervention was \$8140 (i.e., dance instructor, wearables, text messages, participant compensation, data collector). Thus, a mobile health-infused dance program appears feasible for middle-aged and older Latinos. Funding provided by the UIC Department of Kinesiology and Nutrition.

GENDER, RACIAL, AND ETHNIC DISPARITIES IN YOUNG ADULTS' MOBILE TECHNOLOGY USE AND MHEALTH TEXT MESSAGE PREFERENCES

Kelly A. Romano, MS, EdS, Kristin Heron, Ph.D., Abby Braitman, Ph.D.

Old Dominion University, Norfolk, VA

Risky health behaviors (e.g., substance use, unhealthy eating behaviors), inadequate health promoting behaviors (e.g., sedentary lifestyle), and mental health concerns (e.g., depression, anxiety) are common in young adults, and can adversely impact health and well-being. To address these behaviors and concerns and to promote holistic health, mobile health (mHealth) interventions have been created. Yet, little is known about how to aptly design these treatments for use with young adults. To enhance mHealth intervention design and delivery, this study surveyed a large, racially diverse sample of 1,371 college students ($Mage=20.54$) who answered an online survey designed to meet two aims: 1) examine mobile technology ownership and use; 2) assess preferences in text message content, tone, and style. Descriptive statistics and chi-square tests examined gender (337 male, 1,027 female), racial (563 Black, 640 White), and ethnic (109 Latino, 1,262 non-Latino) differences. Addressing Aim 1, 99.5% of participants owned smartphones and $\geq 92.0\%$ used various mobile phone features daily (e.g., text, email, internet, apps). Compared to their gender and racial counterparts, more females owned Apple smartphones and had unlimited data, more female and Black respondents had unlimited texting, more males owned Android smartphones, and more White respondents had long-term contracts ($ps < .05$). Also, more females than males texted and used email on mobile devices daily, and more Black than White participants used the internet on mobile devices daily ($ps < .01$). Addressing Aim 2, young adults preferred texts that were grammatically correct, polite, nondirective, had a statement and emphatic linguistic features. Notably, more females preferred a long message and emoji use, and more female and White individuals preferred a polite message than male and Black respondents ($ps < .04$). This study is first to concurrently assess technology use and mHealth text message preferences relative to young adults' gender, racial, and ethnic identities. These results can increase the acceptability, usability, and efficacy of mHealth interventions, with the goal of improving the health and well-being of diverse young adult subsets. By understanding technology use and text preferences, researchers can tailor mHealth treatments to these populations, increase engagement, and improve treatment outcomes. This line of work ultimately aims to create feasible and effective mHealth interventions for young adults.

INTERVENTION INC, A TECHNOLOGY-ENHANCED CHILDHOOD OBESITY INTERVENTION: CHILD AND PARENT BASELINE CHARACTERISTICS

May May Leung, PhD, RDN¹, Laura Harrison, BA², Katrina F. Mateo, MPH³, Eman Abbas, BS⁴

¹Hunter College, City University of New York, New York, NY; ²Hunter College/CUNY School of Public Health, New York, NY; ³CUNY Hunter College / CUNY School of Public Health, New York, NY; ⁴Primary: Hunter College, City University of New York, Woodside, NY

Introduction: Childhood obesity is a public health crisis in the United States, particularly in low-income, minority populations. Technology-based tools may be an engaging approach to reach at-risk youth and their parents to reduce childhood obesity risk.

Methods: Latino/Black children 9–12 years, and their parent/guardian were recruited to participate in *Intervention INC*, an innovative technology-enhanced health promotion tool. It comprises a web-based 6-chapter (6-week) interactive nutrition comic optimized for use on tablets. Recruitment strategies consisted of community flyering and event tabling, letters to clinic patients, and local organization and study participant referrals. From August to November 2017, parent-child dyads were randomized to the experimental (E) (web-based intervention) or control (C) (online newsletters) group. Intervention content was tailored to a targeted behavior (fruit/vegetable (F/V) or water) based on initial screening questions. Baseline surveys were completed for demographic variables, technology use, child dietary behaviors, home food environment, and parental feeding practices. Descriptive analyses were conducted for demographic and technology characteristics using chi-square tests for categorical variables and 95% confidence intervals for numerical variables to assess differences.

Results: Most successful recruitment strategies included community flyering and event tabling. Of 153 dyads screened, 131 (85.5%) were eligible to participate. Primary reasons for ineligibility included child reading difficulties (11.5%), child age (7.2%) and inability to attend all study sessions (6.6%). A total of 89 dyads (E: n=45, C: n=44) were enrolled. Parent demographics included: mean age=30.8 \pm 8.9 years; 94.4% female; 55.1% Black, 44.9% Hispanic; and 82% English-speaking. One-third had an annual household income of $< \$20,000$ and 60.2% received SNAP benefits. Regarding technology, 56.2% reported using an Android phone and 20.2% shared their smartphone, most often with their child/ren (18.0%). Child demographics included: mean age=10.4 \pm 1.0 years; mean BMI percentile=73.9 \pm 26.9; 60.7% female; 61.8% Black, and 41.6% Hispanic. Nearly 60% received content tailored to F/V behavior. Regarding technology, 46.1% used an Android phone and 30.3% reported sharing a smartphone, most often with their mother (13.5%). No significant differences were found between E and C for demographic and technology characteristics, except for parent smartphone type ($p=0.015$).

Discussion: Key community recruitment strategies led to successful enrollment of low-income minority preadolescents at-risk for childhood obesity and their parent/guardian. This study will test the feasibility and potential impact of an innovative interactive health promotion tool designed and individually tailored to this population.

MOTIVATION OR SELF-EFFICACY? EXAMINING WHICH CONSTRUCT BETTER EXPLAINS THE ASSOCIATION OF BODY DISSATISFACTION WITH EXERCISE

Miriam H. Eisenberg Colman

Fors Marsh Group, Arlington, VA

Regular physical activity (PA) is critical for maintaining a healthy body weight and preventing disease, but it declines in young adulthood. Body dissatisfaction (BS), which increases during young adulthood, may inhibit rather than motivate physical activity. Evidence suggests that components of Social Cognitive Theory (SCT) and Self-Determination Theory (SDT), self-efficacy and autonomous motivation respectively, may explain this counterintuitive association – self-efficacy likely as a moderator and motivation as a mediator or moderator. However, research is needed that directly compares each of these hypothesized models using prospective, objective data to determine which are strongest and most useful for interventions aiming to mitigate the adverse effect of BS on PA.

Participants ($n = 121$, 73% White, $m = 25y$, $BMI = 24kg/m^2$, 75% female) reported their body dissatisfaction, motivation for PA, and self-efficacy for PA. Fitbits recorded each participant's PA over the following two weeks. Bootstrapping Process Macro's six and two were used to test the extent to which autonomous motivation and self-efficacy mediated and moderated the association of BS with PA respectively, adjusting for gender, BMI, and age. Bootstrapping allowed for more reliable results than regression analyses while also directly comparing various mediation and moderation models.

Mediation results revealed that the association of BS with PA was driven primarily by autonomous motivation and not by self-efficacy. Bootstrapping results showed a strong indirect effect of BS on PA through autonomous motivation (indirect effect = 3.05, $SE = 1.56$, 95% CI: .38, 6.5) but no significant indirect effect of BS on PA through self-efficacy (indirect effect = -1.56, $SE = 1.53$, 95% CI: -5.36, 1.42). Moderation results using bootstrapping showed that neither autonomous motivation (interaction coefficient = 1.57, $SE = .91$, $p = .09$) nor self-efficacy (interaction coefficient = 2.14, $SE = 6.89$, $p = .76$) significantly moderated the association of BS with PA, although the coefficient for the BS*autonomous motivation interaction did approach significance.

Findings support and extend previous literature by using objective and prospective data to directly compare two constructs believed to help explain the association of BS with PA. Findings clearly show that autonomous motivation, not self-efficacy, explains the association of BS with PA. Further, findings suggest that a mediation rather than moderation model is most appropriate for understanding these associations, as is suggested by Self-Determination Theory. These findings inform future interventions and suggest that using resources to improve autonomous motivation rather than self-efficacy for PA may be a more effective and efficient approach to mitigating the adverse effect of body dissatisfaction on PA in young adults.

OPPORTUNITIES FOR VIDEO-ENABLED TABLETS TO ENHANCE ACCESS FOR VETERANS WITH BARRIERS TO IN-PERSON CARE

Cindie Slightam, MPH¹, Amy Gregory, BS¹, Leonie Heyworth, MD², Josephine Jacobs, PhD¹, Emily Wong, MPH¹, Isabella Romero, BS¹, Daniel Blonigen, PhD¹, Rachel Kimerling, PhD¹, Donna Zulman, MD, MS¹¹VA Palo Alto Health Care System, Menlo Park, CA; ²VA San Diego Health Care System, San Diego, CA

Background: Rural and low-income Veterans encounter multiple barriers to receiving in-person care at Veterans Health Administration (VHA) facilities. In 2016, the VHA launched an initiative to issue video-enabled tablets to Veterans with geographic, clinical, or social barriers to accessing in-person care. The objective of this study is to understand these Veterans' current use of technology and self-reported barriers to care.

Methods: We mailed a survey to 2,200 Veterans who received a tablet from VHA to facilitate remote video visits in their homes. Survey respondents were queried about their current technology use, barriers to health care access, transportation-related costs to accessing clinical care, social support, and current financial stability. Patient demographics and clinical characteristics were confirmed using administrative data.

Results: Among the 1,283 survey respondents (response rate 59%), characteristics resembled the broader VA population: they were predominately males (83%), Caucasian (75.6%), married (58%), and mean (SD) age was 57(16) years. Survey respondents reported using the VHA for most of their primary (78%) and mental health care (78%). 87% of respondents reported at least one barrier to accessing VA care, the most common barriers included travel time (67%), cost of travel (55%), current health conditions (54%), and poor weather (57%). Common socioeconomic barriers included financial strain and limited social support: Over two-thirds reported at least some difficulty "making ends meet" (69%); and approximately one third reported insufficient social support for their health and daily living needs. Participants reported high rates of health-related technology use: 75% have used the VHA's electronic personal health record system to manage their health care (including to check their records, refill a prescription, communicate with their provider, or monitor their health conditions), and 58% reported using technology to search for health information. Overall, 74% reported that video visits could help them access their VHA providers.

Conclusions: Video-enabled tablets have the potential to enhance access for patients in broadband accessible locations with barriers to in-person care. An ongoing evaluation of the program is investigating how this technology influences patients' experiences with and engagement in their care.

RELATIONAL AGENT

Molly Sawdy, BA¹, Kate Yeksigian, MPH², Shuo Zhou, MA³, Timothy Bickmore, PhD³, Steven Simon, MD, MPH¹, Amy Rubin, PhD¹

¹VA Boston Healthcare System, Boston, MA; ²VA Boston Healthcare Specialist, Boston, MA; ³Northeastern University, Boston, MA

Background: Healthcare systems have adopted Screening, Brief Intervention, and Referral to Treatment (SBIRT) as an effective method for addressing unhealthy alcohol use. In VA primary care, providers are required to screen patients annually and provide brief intervention (BI) and referral to specialty care if needed. Research demonstrates this requirement is implemented unevenly at best. We hypothesized that a computer character (Relational Agent; RA) designed to build rapport with patients could improve the rate of BI and referral, as well as decreasing drinking.

Methods: Participants are referred from primary care staff, or by invitations sent to veterans at VA Boston Healthcare System who scored positive on the Alcohol Use Disorders Identification Test-Consumption (AUD-C). Participants are randomized into one of two groups: Relational Agent plus Treatment as Usual (RA+TAU) or Treatment as Usual (TAU). In contrast to prior research that focused only on risky drinkers, anyone who scores positive on the AUD-C is eligible, replicating real world clinic conditions. Participants are then stratified based on severity of alcohol use (Risky Drinking vs. Alcohol Use Disorders) and gender. Those randomized into RA+TAU receive 2 “sessions” with the RA, which is customized to the veterans at this facility. The RA delivers a BI and offers referral as appropriate. Participants provide open-ended feedback after completing each RA session.

Results: Recruitment is ongoing: 43 of 180 participants have completed to date. The majority of participants who provided feedback on the RA program felt the RA was polite, empathetic, and similar to a therapist. Participants also liked that the RA used their name and remembered information about the participant from Session 1 during Session 2. For both conditions, it appears drinking decreased from baseline to 3-month follow-up in Drinks per Drinking Day (DDD) and Average Weekly Drinks (AWD). Although RA+TAU appeared to show greater decreases in drinking, there is not enough power in this preliminary sample to determine significance. The RA has successfully referred 12 participants to treatment whereas primary care only referred one participant.

Discussion: SBIRT can be expanded to include all patients with unhealthy alcohol use, not just risky drinkers, if the goals are different (referral to treatment vs. decrease in drinking). Patients like talking with RAs, and they can be used effectively to provide BI and offer referral.

TOWARD #FITSPARATION AS A TOOL FOR HEALTH PROMOTION: EXAMINING THE PERCEPTIONS OF FITSTAGRAMERS AND FOLLOWERS

Sabrina DiBisceglie, Kristen Pasko, B.S., Danielle Arigo, Ph.D. in Clinical Psychology

The University of Scranton, Scranton, PA

Background: Young adulthood is a critical period of risk for weight gain and sedentary behavior, which may persist into later adulthood. Trends on social media are known to influence young adults' health behaviors; for example, the #fitspiration trend allows users to view fitness and nutrition posts on Instagram. Due to its popularity among young adults, fitspiration may be useful for health promotion in this population, though little is known about (1) young adults' preferences for and responses to various types of fitspiration posts, and (2) how their preferences and responses align with posters' intentions. The goal of this study was to examine the perceptions and experiences of both people who follow fitspiration accounts (followers) and those who post fitspiration content (fitstagramers).

Method: Participants ($N=120$) were 63 college students who actively follow fitspiration accounts on Instagram (92% women, $M_{Age}=21.7$ years) and 57 fitstagramers (68% women, $M_{Age}=29.9$ years). Participants answered questions about their fitspiration experiences: reasons for posting/following, frequency of posting/viewing fitspiration posts, and their common reactions to fitspiration posts, and were asked to select one of six fitspiration images they found most motivating.

Results: Young adult followers reported the most common reasons for following fitspiration were to learn exercises and tips that they could use for themselves (84%) and to be inspired to exercise (88%). Among fitstagramers, the most common reasons for posting fitspiration were to inspire others (81%) and to keep themselves motivated and accountable (74%). Some fitstagramers and followers reported feeling mostly positive (e.g. inspired, confident) when viewing fitspiration posts (followers 11%, fitstagramers 42%). However, much larger subsets reported feeling negative (e.g. frustrated, ashamed) at least sometimes (followers 64%, fitstagramers 50%). Both followers (25%) and fitstagramers (31%) selected an image with the underlying message of ‘fitness is earned and not given’ as the one they found most inspiring.

Conclusion: The recent #fitspiration trend provides an opportunity to understand how Instagram users share and respond to health content on social media. Followers use this hashtag for both inspiration and information, whereas fitstagramers use it as an opportunity to inspire and to keep themselves accountable. Both fitstagramers and followers prefer the fitspiration image that conveyed the importance of hard work to other types of posts. However, given that large groups of both followers and fitstagramers sometimes have negative responses to fitspiration posts (perhaps due to negative social comparisons), there is need for further investigation into the potential for this trend to promote health.

U-HEALTHCARE SERVICE FOR THE MANAGEMENT OF METABOLIC SYNDROME: A PILOT STUDY CONDUCTED IN A KOREAN PUBLIC HEALTH CENTER

Ji-Young An, PhD, MPH¹, Hyunjung Moon, PhD, MPH², Sunkyung Cha, PhD³
¹Rutgers University, Camden, NJ; ²Far East University, Eumseong, Ch'ungch'ongbukto, Republic of Korea; ³Sunmoon university, Asan, Ch'ungch'ongnamdo, Republic of Korea

Background: u-Healthcare service (UHS) uses the wired/wireless communication network infrastructure to prevent disease and provide personalized healthcare services regardless of place and time. The 2011 National Health and Nutrition Examination Survey conducted in Korea reported that 50% of Koreans have one or two metabolic syndrome risk factors and 23.3% have three to five risk factors. Therefore, the Ministry of Health and Welfare provided a public health center-based pilot UHS for metabolic syndrome (MS) management.

Purpose: This pilot study aimed to describe the use of UHS and identify the relationships between health literacy (HL), service quality (SQ), service value (SV), communication (C), service satisfaction (SS), and intention to reuse (IR) for the management of MS in a Korean public health center.

Methods: A cross-sectional survey using convenience sampling of elders (n=41; 65.2 ± 9.4) was utilized. Data were analyzed by SPSS 20.0. Measurements used were: HL ($\alpha = .933$), SQ ($\alpha = .890$), SV ($\alpha = .841$), C ($\alpha = .971$), SS ($\alpha = .976$) and IR ($\alpha = .933$). All except IR (7-Likert scale) are 5-Likert scale.

Results: The majority were women (68.3%), married (81.6%), house wives (47.5%), unemployed (27.5%), middle school graduates (48.6%); had monthly income less than \$1,000 (48.5%); used u-Healthcare service less than 6 months (68.6%). Respondents reported: SS (4.2 ± 1.0), SV (4.0 ± 0.8), SQ (3.8 ± 0.8), C (3.8 ± 0.9), IR (5.8 ± 1.6), HL (3.0 ± 0.1). Users who earn less than \$1,000 reported SQ, SV, C and IR higher; who used UHS more than six months reported SV, SS and C higher. SQ was positively related to SV ($r = .576, p < .001$), C ($r = .484, p = .001$), SS ($r = .495, p = .001$), IR ($r = .570, p < .001$); SV was positively related to C ($r = .723, p < .001$), SS ($r = .640, p < .001$), IR ($r = .644, p < .001$); HL was positively related to IR ($r = .378, p < .015$); C was positively related to SV ($r = .723, p < .001$), SS ($r = .815, p < .001$), IR ($r = .727, p < .001$); SS was positively related to IR ($r = .771, p < .001$).

Conclusion: UHS for MS management is valuable as a public health service for people with low income. To increase IR, it is necessary to improve HL of its users. Strategies for good communication with healthcare providers, which us based on individual attention, increase SS.

CONTENT FOR A COGNITIVE BEHAVIORAL THERAPY APP IDENTIFIED BY VETERANS OF THE IRAQ AND AFGHANISTAN CONFLICTS AND VA THERAPISTS

Judith A. Callan, PhD, RN¹, Gretchen Haas, PhD², John W. Kasckow, MD, PhD³, Lisa K. Tamres, MS¹

¹University of Pittsburgh School of Nursing, Pittsburgh, PA; ²MIRECC/Department of Veterans Affairs, Pittsburgh, PA; ³Beckley VA Health Care System, Beckley, WV

Psychiatric and adjustment sequelae are common among Operation Enduring Freedom (OEF), Operation Iraqi Freedom (OIF), and Operation New Dawn (OND) Veterans. Although cognitive behavioral therapy (CBT) is the leading evidence-based treatment for Veterans, the clinical response to CBT is variable. A smartphone app, tailored for OEF/OIF/OND Veterans, may improve CBT outcomes by improving CBT practice.

To tailor an existing CBT phone app (CBT MobileWork) for Veterans, we conducted semi-structured interviews with 15 OEF/OIF/OND Veterans and five Veterans Administration (VA) CBT therapists. The interviews addressed psychiatric symptoms, adjustment difficulties, treatment barriers, and participant evaluation of CBT MobileWork. Participants rated 13 components of the app on a 1–10-point scale (10 most favorable) and identified areas for improvement.

Participants comprised 15 primarily married/cohabiting (50%), Caucasian (93%), male (60%) OEF/OIF/OND Veterans, with a mean age of 38 years, 15 years of education, and 1.5 combat deployments. Participants met the following DSM criteria: major depression 66.7%; panic disorder 80%; agoraphobia 53.3%; post-traumatic stress disorder (PTSD) 53.3%; generalized anxiety disorder 53.3%. The five VA CBT therapists were primarily female (80%) and doctorally trained.

Ratings of the app components among Veteran participants averaged 8.83 (range 8.42–9.15). The therapist rating averaged 8.23 (range 7.00–9.60). Content analysis of interview transcripts yielded the following themes for improvement: *topical* (normalization of reintegration experience; inspirational Veteran quotes and humor; military model of decision making); *features* (coping card; lifeline for suicidal symptoms); *CBT exercise additions* (dealing with panic attacks, PTSD, anger, and irritability; improving assertiveness; enhancing reintegration and stabilization); *additional links* (VA websites and resources); *functionality* (expand mood lists and multiple graphs; link with educational components; low mood ratings connect to crisis numbers); *approaches* (reinforcement; corrective experiences; clear semantics).

CBT MobileWork was rated favorably by OEF/OIF/OND Veterans and VA CBT therapists. In the next stage of our research, information about vital mental health concerns will be addressed in the modified app (CBT MobileWork-V) and we will engage Veterans and VA clinicians in evaluation of the adequacy of the modifications to CBT MobileWork-V (software and clinical content).

EFFECT OF A WEB-BASED INTERACTIVE SIMULATION ON CLINICIAN'S INTENTIONS TO PROVIDE PA COUNSELING TO ADULTS WITH TYPE-2 DIABETES

Leah Yingling, BS¹, ashwini Janamatti, M.S, B.E.², Ingrid Oakley-Girvan, PhD MPH BS³, Bryan Gibson, DPT, PhD¹, Nancy A. Allen, PhD¹¹University of Utah, Salt Lake City, UT; ²Larry H Miller Sports and Entertainment, salt lake city, UT; ³Cancer Prevention Institute of California (CPIC), Fremont, CA**Background:** Counseling about the benefits of physical activity (PA) is known to facilitate behavior change among patients with Type-2 Diabetes (T2DM). Unfortunately, healthcare providers do not provide PA counseling to patients with T2DM as frequently as recommended.**Objective:** We conducted a within-subjects study to determine whether an interactive simulation showing the immediate effects of PA on blood glucose (BG) would alter healthcare providers' beliefs about PA and increase their intentions to provide PA counseling to patients with T2DM.**Methods:** A link to the web-based simulation was distributed to participants via e-mail. After participants consented, they completed a questionnaire capturing demographic information, PA and T2DM-related knowledge, and intentions to counsel patients. Participants were then shown a simulated diurnal BG curve and asked to draw the expected difference in the curve if the simulated patient had walked for 30 minutes (i.e., outcome expectancy). Participants then used an interactive simulation to explore the expected effect of PA (e.g., walking) on the glucose curve. After the simulation, participants completed a second drawing of their outcome expectancy and finally a questionnaire that captured PA and T2DM-related knowledge and intentions to counsel patients.

A paired t-test was used to compare the difference of differences between the change in area under the curve in the simulation and the participants' two drawings. Paired t-tests were also used to test if participants' perceived knowledge of the benefits of walking on BG and intentions to counsel patients increased. Quantitative and qualitative data on participants' perceptions of the drawing tasks and simulation were also collected.

Results: A total of 243 healthcare providers (n=135) and trainees (n=108) visited the simulation website and provided complete data. Participants varied in age (22–78 years, mean= 38.3 ± 12.7) and were primarily white (80%, n=195) and female (74%, n=181). Provider type (i.e., MD/DO, NP/PA, RN/LPN, etc.) varied among participants, with MD/DOs comprising the largest percentage (28%, n=69).

Participants' outcome expectancies shifted toward the outcome presented by the simulation (mean change in differences= 2588.8 mg/dl*min, t=5.11, p<0.001). Additionally, providers' intentions to counsel patients increased (mean change= 0.49/5.0, t=6.64, p<0.001), as did PA and T2DM-related knowledge (mean change= 0.31, t=4.30, p<0.001). Qualitative feedback from 36 participants suggested improvements for future work.

Conclusion: A novel web-based simulation is effective for changing providers' beliefs and increasing intentions to counsel patients with T2DM on the benefits of PA. We will discuss applications of our results to the design of a clinically integrated mHealth intervention.

6:15 PM-7:15 PM

A REVIEW TO IDENTIFY THE USE OF BEHAVIOR CHANGE TECHNIQUES IN TECHNOLOGY-BASED HEALTH INTERVENTIONS FOR PHYSICAL ACTIVITY

Carmina G. Valle, PhD, MPH¹, Sarah Mye, MPH², Lara Balian, MPH², Deborah F. Tate, Ph.D.¹¹University of North Carolina at Chapel Hill, Chapel Hill, NC; ²UNC - Chapel Hill, Carrboro, NC**Introduction:** eHealth interventions have been shown to have positive effects on physical activity, but less is known about what technology-delivered behavior change techniques (BCTs) drive behavior change. This systematic review evaluates BCTs used in technology-delivered physical activity interventions to identify the additive effects of BCTs on outcome(s) and to isolate BCTs that may contribute to greater intervention efficacy.**Methods:** Multiple databases were searched to identify RCTs that compared at least two technology-based interventions or evaluated the additive effects of technology components on physical activity outcomes. Of 1934 abstracts reviewed, 38 studies (n=91 arms) met eligibility criteria. Two of four independent coders used the 93-item BCT Taxonomy to code all study arms (intercoder reliability ≥0.8) for BCT presence and mode of delivery.**Results:** Across 38 studies, fewer than half of the available BCTs (n=42 of 93; 45.1%) were used. Technology-based intervention arms (n=52) used 12.7 (range: 2–25) unique BCTs on average, while technology-based control arms (n=26) used 6.6 (range: 1–19). The average number of unique BCTs delivered by mode was highest for internet (7.8), followed by mobile (7.0), phone (6.6), human (5.7), email (5.6), wearables (5.4), print (4.5), and social media (3.4). Among all technology arms (n=78; 1248 total BCTs represented), the largest proportion of BCTs delivered were in domain 2 (feedback and monitoring; n=322, 25.8%), domain 1 (goals and planning; n=308, 24.7%), and domain 3 (social support; n=109, 8.7%). Within domains, the proportion of BCTs used varied by mode (domain 1: 45.5% of BCTs delivered by internet, 18.8% email, 14.3% human; domain 2: 34.2% internet, 29.8% wearables, 11.8% email; domain 3: 23.9% social media, 22.0% internet, 21.1% human, 21.1% email). Of 24 studies that compared a single technology-based intervention with a technology-based control group, 10 had positive between-group effects on physical activity. Efficacious interventions used between 2 to 11 (M=6.8) more BCTs than controls; some provided greater doses and/or different delivery modes for the same BCT also represented in control groups.**Conclusions:** The BCT taxonomy is useful for identifying technology-based intervention components that may underlie mechanisms of behavior change. Additional efforts to evaluate BCTs by dose and mode of delivery can further elucidate effective approaches for eHealth interventions.

DEFINING ADHERENCE TO MOBILE DIETARY SELF-MONITORING AND ASSESSING TRACKING OVER TIME

Gabrielle Turner-McGrievy, PhD, MS, RD¹, Caroline G. Dunn, MS, RD², Alycia Boutte, MPH¹, Brent Hutto, MSPH¹, Eric Muth, PhD³, Adam Hoover, PhD⁴, Sara Wilcox, PhD¹

¹University of South Carolina, Columbia, SC; ²USC, Columbia, SC; ³Clemson, Clemson, SC; ⁴Clemson University, Clemson, SC

Background: Dietary self-monitoring (DSM) methods via mobile devices allow for objective assessment of adherence to DSM and examination of how DSM changes over time; however, the best way to define DSM adherence is not known. The purpose of this study was to use objective mobile DSM data from 2 mobile weight loss studies that used 3 different types of DSM methods to determine the best way to define DSM adherence.

Methods: Overweight adults (n=125; mean BMI 34.6 ± 5.6 kg/m²) with smartphones were enrolled in 1 of 2 remotely-delivered 6-month randomized weight loss interventions: DIETm [n=42 standard app (App) or n=39 wearable Bite Counter device (Bite)] and 2SMART [n=20 App or n=24 photo meal app (Photo)]. All participants received the same behavioral weight loss information via twice weekly podcasts. Participants were assigned to a specific DSM method and were asked to use their assigned method throughout the study. The goal of this study was to identify the best criteria to use for defining adherence to DSM (e.g., number of days tracked, number of meals tracked, the day at which monitoring after that day dropped below 25% and 50% of days monitored, etc.) when predicting weight loss and to examine patterns of DSM usage over the course of two 24-week studies.

Results: Adherence defined as the overall number of days ≥2 meals were logged explained the most variance in weight loss at 6 months (R² = 0.21, F=25, P<0.001) for all study completers combined (n=96). For the App group, the number of days at least 800 kcals were logged explained the most variance (R² = 0.29, F=18.6, P<0.001). For the Bite group, the day at which monitoring after that day dropped below 50% of upcoming days monitored was the best predictor (R² = 0.16, F=5.2, P=0.03). For the Photo group, the total number of meals tracked was the best predictor (R² = 0.26, F=5.9, P<0.001). Overall, regardless of DSM device or method to quantify adherence, DSM declined over time with all methods having fewer than half the sample still tracking after week 10.

Conclusions: With various tracking methods combined, using an adherence measure of the total number of days ≥2 meals were tracked may be the best method to determine adherence to DSM in weight loss studies using mobile tracking methodology. This study shows that DSM rates decline quickly and elucidates potential times for early interventions to stop the reductions in DSM.

DEVELOPMENT AND PILOT EVALUATION OF AN APP-BASED REFERRAL SERVICE TO SUPPORT ADULT CANCER SURVIVORS INCREASE PHYSICAL ACTIVITY

Camille Short, PhD¹, Amy Finlay, B Psychological Science, Public health (hons)¹, Ilea Sanders, Bachelor Degree², Carol Maher, PhD³

¹University of Adelaide, Adelaide, South Australia, Australia; ²School of Health Sciences, University of South Australia, Adelaide, South Australia, Australia; ³University of South Australia, Adelaide, South Australia, Australia

Background: Cancer survivors are interested in using technology to help them adopt and maintain healthy lifestyles. However, there are hundreds of apps and websites available and finding a good one can be difficult. This is especially true for mobile phone applications, where recent audits have shown that the most popular apps in app stores lack evidence-based strategies. This study aimed to develop and pilot test a smartphone app referral service designed to assist cancer survivors to increase their physical activity by matching them with high quality existing apps based on their individual characteristics (behavioral goals, phone type, fitness tracker preference, and personality). In particular, the study sought to examine feasibility and acceptability of the service and explore preliminary efficacy for physical activity behaviour change.

Methods: A systematic search was used to identify potentially appropriate iOS and Android smartphone apps. The apps were audited to examine the type of physical activity encouraged and evidence-based behavioural strategies and other characteristics, which could be used to match apps to users' preferences and characteristics. A structured service was also devised to deliver the apps and counselling, comprising two face-to-face appointments with a mid-week phone or email check-up. The app referral service was piloted using a pre-post design among twelve cancer survivors. Participants' feedback regarding the service's feasibility and acceptability was sought via purpose-designed questionnaire, which was analysed using inductive thematic analysis and descriptive statistics. Changes in physical activity was assessed using a valid and reliable self-report tool and analysed using paired t-tests. In line with recommendations for pilot studies, confidence intervals and effect sizes were reported to aid interpretation of clinical significance.

Results: Of 374 apps identified during the systematic search, 54 progressed to the audit (iOS = 27, Android = 27), and 30 were used in the service. The apps consistently scored well for aesthetics, engagement and functionality, and inconsistently for gamification, social and behaviour change features and relevance to survivors. Ten participants completed the pilot evaluation and provided positive feedback regarding the service's acceptability and feasibility. On average, participants increased their moderate-vigorous physical activity by 236 minutes per week (d = 0.73; 95% CI = -49 to 522; p = 0.09).

Conclusion: This study offered initial evidence that a smartphone app referral service for cancer survivors is feasible and acceptable and may increase physical activity levels. Further research is warranted on a larger scale to investigate generalisability, long-term compliance and application in clinical settings.

DEVELOPMENT OF A THEORY-BASED APP TO PROMOTE GUT HEALTH FOR CELIAC DISEASE: MYHEALTHYGUT

A. Justine Dowd, PhD¹, Desiree Nielsen, RD², Darlene Higbee Clarkin, Founder of MyHealthyGut³, Colleen Jackson, MSc¹, Karen T-Y. Tang, Bachelor of Arts Student¹, Nicole Culos-Reed, PhD⁴

¹University of Calgary, Calgary, AB, Canada; ²Desiree Nielsen, RD, Calgary, AB, Canada; ³WholeLife HealthTech Inc., Delta, BC, Canada; ⁴Faculty of Kinesiology, University of Calgary, Calgary, AB, Canada

Aim: The overall goal of this study was to design and pilot test a smartphone app (MyHealthyGut), which was created to promote effective self-management of celiac disease and gut health. The purpose of Part 1 of the study was to gather feedback from end-users (adults with celiac disease) regarding the desired functions and content of an app to manage celiac disease. The purpose of Part 2 of the study was to pilot test the MyHealthyGut app with end-users and health care providers.

Method: One-hundred and eighteen adults diagnosed with celiac disease participated in the initial survey (Part 1). Seven adults with celiac disease engaged in focus groups to provide feedback after testing the MyHealthyGut app for a 1-week period; 7 health care providers (dietitians and physicians) provided online feedback about the app after using it for a 1-week period (Part 2).

Results: Part 1) Cost, ease of use and available functions were the most important perceived factors determining use of an app to manage celiac disease. Over 90% of participants indicated they felt there was a need for an app for celiac disease. End-users wanted content to be supportive and indicated it was important to have the ability to track diet and symptoms, access nutritious gluten-free recipes and foods, cooking tips, evidence-based supplements and safe restaurants. Part 2) Focus group participants suggested revisions to the app pertaining to app content (integrate functions of the app for improved organization and usage), functionality and ease of use (clearly marked way-finding buttons), and to improve several features (symptom journaling, cooking tips). The majority of health care providers reported positive perceptions of the app (5 of 7) and reported similar revisions as the end-users pertaining to content, functionality and ease of use.

Conclusion: Health-related mobile applications make smartphones useful tools in providing point of care to the user. Participants reported a need for the MyHealthyGut app (Part 1) and provided feedback to revise the content, features and functions of the app (Part 2). MyHealthyGut is the first evidence-based user-centred app that may be helpful in empowering users to effectively self-manage celiac disease.

6:15 PM-7:15 PM

DEVICE OWNERSHIP, HEALTH APP USE, AND INTEREST IN EHEALTH TECHNOLOGY: AN ANALYSIS OF U.S. ADULTS IN HINTS WITH HIGH BLOOD PRESSURE

Aisha T. Langford, PhD, MPH¹, Craig Solid, PhD, MS², Azizi Seixas, PhD, MS, MA³

¹NYU School of Medicine, New York, NY; ²Solid Research Group, LLC, Saint Paul, MN; ³NYU Langone Health, New York, NY

Background: mHealth and eHealth interventions have been used to help people manage chronic conditions like hypertension (HTN), but challenges in access and willingness to use these interventions can be barriers.

Objectives: (1) Describe prevalence of device ownership, health app use, and interest in sharing medical information electronically with providers by sociodemographic status; and (2) evaluate predictors of accessing personal health information online via a secure website or app among people with HTN.

Methods: Data from the 2014 Health Information National Trends Survey (HINTS) 4 Cycle 4 were evaluated (N=3677), of which 1602 people had HTN. This analysis only includes those with HTN. People were asked if they: (1) had a tablet computer, smartphone, or basic cell phone technology only; (2) if they had health-related apps on their smartphone or tablet and if so, did the apps help them: (a) achieve a health-related goal, (b) make a decision about how to treat an illness, or (c) ask a doctor new questions. Interest in exchanging medical information electronically and the number of times they accessed their health information online was also assessed. Chi-square tests assessed differences in observed proportions and multivariate linear regression evaluated predictors of accessing personal health information, controlling for sociodemographic factors, self-rated health, and confidence in data security.

Results: Basic cell phone technology was the most commonly used option for all participants; however, there were significant differences in device ownership by age (P<0.001), gender (P=0.037), and education (P<0.001). Smartphone users were younger and more educated, while tablet users were older. Men were more likely than women to own smartphones and tablets; this trend held true for those with more education. Regarding general health app use, significant differences were observed by age (P=0.023) and race (P=0.045), with those aged 18–34 and 35–49 more likely than adults 50+ to use apps and Blacks (47%) reporting more app use than Whites (38%) and Hispanics (19%). There were no differences in use of health apps designed to help people achieve a goal, make a decision, or ask doctors news questions. Interest in sharing medical information electronically with providers was significant by age (P<0.001) and education (P=0.001), with younger adults and those with a college education showing the most interest. Lastly, people were significantly more likely to access their personal health information online if they were younger, White, more educated, interested in sharing medical information electronically, and confident of data security.

Conclusion: mhealth interventions that use basic cell phone technology can potentially reach a wide cross-section of people with HTN. Apps may be one strategy to provide health information that can be used to increase better management of HTN in Blacks.

FEASIBILITY OF EVALUATING DIGITAL TOOLS TO PROMOTE FLUID INTAKE IN PATIENTS WITH A HISTORY OF KIDNEY STONES

David E. Conroy, Ph.D.¹, Lacy Alexander, Pennsylvania², Necole Streeper, MD³¹The Pennsylvania State University, University Park, PA; ²Penn State University, University Park, PA; ³Penn State Health Milton S. Hershey Medical Center, Hershey, PA

The prevalence of kidney stones is rising and stones are associated with an estimated economic burden of \$4 billion annually. Clinical guidelines for preventing recurrence emphasize increasing fluid intake but less than 50% of patients adhere to those guidelines. Emerging digital tools, such as mobile applications (apps), incorporate a number of evidence-based behavior change techniques but the efficacy of these tools is unknown. Using single-group pre-post (AB) design, this study examined the feasibility of using an app to support patients seeking to increase their fluid intake. For 14 days, adults (n=10) who previously experienced a kidney stone provided a first morning urine sample to evaluate electrolyte content, osmolality, and urine specific gravity at the beginning of each day and completed an online survey at the end of each day. On days 6 and 13, participants completed a 24-hr urine collection to evaluate total volume and sodium excretion. On day 7, participants set a goal for fluid intake (1.9 L/day), installed a commercial hydration app on their smartphone, and received training on how to use the app. Measurement completion rates were excellent for end-of-day surveys (94%), beginning-of-day urine samples (99%), and 24-hr urine collections (100%). App use had minimal impact on concentrations of urinary sodium and potassium, osmolality, urine specific gravity, color, or 24-hr collection volume. The most common end-of-day reasons for not drinking enough involved not being thirsty (48%), interference from other tasks (46%), not having water at hand (38%), and not being motivated to drink (30%). Participants reported that the app was easy to use ($M=93/100$) and enjoyable ($M=79/100$). Most reported that the app was likely to help them achieve their goal (60%) and that they would use the app again (60%). Participants reported interest in using connected devices to measure/monitor fluid intake (70%), scheduled prompts/reminders (70%), and self-monitoring tools to track their fluid consumption (70%). None owned a connected water bottle but 90% believed it would help them to achieve their goal. One month later, half of the participants still had the app installed on their smart phone but few continued to use it (20%). Overall, this study demonstrated the feasibility of evaluating digital tools for promoting fluid intake in patients with a history of kidney stones but suggested that a multi-component intervention may be needed to modify clinical outcomes.

FINANCIAL INCENTIVES FOR PHYSICAL ACTIVITY IN ADULTS: AN UPDATED SYSTEMATIC REVIEW AND META-ANALYSIS

Marc Mitchell, PhD¹, Stephanie L. Orstad, PhD², Avi Biswas, PhD³, Guy Faulkner, PhD⁴, Marc A. Adams, PhD, MPH⁵, Melanie Jay, MD, MS⁶¹Western University, London, ON, Canada; ²New York University School of Medicine, New York, NY; ³Institute for Work & Health, Toronto, ON, Canada; ⁴University of British Columbia, Vancouver, BC, Canada; ⁵Arizona State University, Phoenix, AZ; ⁶New York University School of Medicine, Brooklyn, NY

Background: Financial health incentives have grown in popularity due in part to technological advances that have made it easier to track and reward physical activity (e.g., Apple Inc. introduced the Health Kit app in 2014). The purpose of this study was to update the evidence on the effects of financial incentives on physical activity in light of recent transformative technologies.

Methods: A systematic review and meta-analysis was conducted among studies published since the last known review in 2012. Seven databases were searched for randomized controlled trials (RCTs) published in English-language peer-reviewed journals from January 2012 to April 2017. RCTs to increase physical activity in adults with incentives contingent on specific physical activity behaviors (e.g., steps per day) or fitness outcomes (e.g., VO₂max) were included. Two reviewers independently screened titles and abstracts. Included studies were appraised using a standardized data extraction and quality assessment tool. A descriptive analysis of intervention design characteristics was conducted and a random-effects meta-analysis was undertaken for studies reporting average weekly steps per day for intervention and post-intervention periods.

Results: Fourteen studies met the inclusion criteria involving 2,962 participants. Eight of 14 studies incorporated wireless activity trackers and smartphone technology to track and reward physical activity. Compared to controls, incentives exhibited significant, positive effects on physical activity in 10 of 13 studies during the intervention, and 1 of 10 studies at follow-up. Nine studies were included in the meta-analyses involving 1,263 participants. The majority (7 of 9 studies) were of moderate methodological quality, short in duration (8 of 9; 12–16 weeks) and included a follow-up period (8 of 9; 8–24 weeks). The pooled meta-analysis results favored the incentive condition during the intervention period (mean difference (MD): 1,143 steps per day; CI 95%: 777–1510) and at follow-up (MD: 987 steps per day; CI 95%: 246–1727). Statistical variation between studies was low to moderate.

Conclusions: This updated systematic review and meta-analysis found that incentives increased physical activity for interventions of short durations (≤16 weeks) and after incentives were removed. Contrary to what has been previously suggested, a short-term incentive ‘dose’ may promote sustained physical activity post-intervention.

HEALTH BEHAVIORS AMONG YOUNG ADULTS IN THE AGE OF SOCIAL MEDIA

Melissa A. Napolitano, PhD¹, Meghan Mavredes, MPH², Jessica Whiteley, PhD³, Loretta DiPietro, PhD, MPH²

¹The George Washington University, Washington, DC, DC; ²The George Washington University, Washington, DC; ³UMass Boston, Boston, MA

Purpose: With the growth of peer-to-peer social media, understanding the role of these social networks in relation to health behaviors is important, particularly among young adults who are developing lifelong health behaviors and may be more susceptible to peer influences, role models or negative self-comparisons. We sought to answer who is more affiliated with social networking and how high affiliation relates to health behaviors and self-evaluations.

Methods: Young adults (18-35yo) enrolled in a healthy body weight clinical trial at two urban universities (n=316; %female=81.3%; %Caucasian=57.0%; M age=22.1 ± 3.9; M BMI=31.3 ± 4.6) completed surveys: Social Media Affiliation (SMA; e.g. “Facebook is part of my daily routine, “I would be sorry if Facebook shut down”); enrollment status (undergraduate vs. graduate student); the International Physical Activity Questionnaire (IPAQ); the Population Assessment on Tobacco and Health (PATH) questions; the Body Image Quality of Life Inventory; Perceived Stress Scale; and MOS Sleep Scale.

Results: There were differences in SMA by demographics: undergraduate ($p < .05$) and white ($p < .01$) students were more likely to report high affiliation. No differences in SMA were found by sex nor age. Among the full sample, 37.4% met criteria for MVPA, 62.3% reported never smoking cigarettes, 83.2% reported never using e-cigarettes, and 26.2% reported at least 8 hours of sleep per night. In terms of self-evaluation, 52.4% reported high levels of stress and 73% reported low body image. Level of SMA (high vs. low) was not associated with the health behaviors or self-evaluation measures.

Conclusions: Despite differences in SMA by enrollment status and race, there were no differences in health behaviors nor negative self-evaluation by SMA. Given the lack of association between SMA and negative health behaviors/self evaluations, these data provide preliminary evidence to mitigate concerns regarding use of these intervention channels for improving health. Implications of these findings will be discussed, such as: 1) social norms and the role of social networking by life stage and/or peer group; and 2) how future interventions can leverage information on SMA, demographics, and/or type of social networking platform to optimize success.

HEALTH TECHNOLOGY USE AMONG UNDERGRADUATE STUDENTS: A PILOT INVESTIGATION

Emily Brooks, M.A.¹, Paige Hildreth, B.A.², Jessie Schulman, MA¹, Afiah Hasnie, MA³, Madison Tompkins, M.A.⁴, Nataliya Zelikovsky, Ph.D.²

¹LaSalle University, Philadelphia, PA; ²La Salle University, Philadelphia, PA; ³La Salle University, Conshohocken, PA; ⁴La Salle University Psy.D. Program, Philadelphia, PA

Due to the many environmental changes, undergraduate education has been acknowledged as a critical period for promoting healthy behaviors and preventing unhealthy behaviors. The transition to independence and adopting more responsibility can make undergraduate students (UGS) vulnerable to developing unhealthy habits such as poor diet, lack of sleep, and reduced physical activity (PA). Many UGS do not meet health behavior guidelines. However, the use of mobile apps may assist in monitoring daily lifestyle choices and can provide informed recommendations that promote better health. Research has found that 65.8% of UGS owned a smart phone and 17% reported downloading a health application. The aim of the present study is to explore the relation between health behaviors (i.e. sleep, eating, and PA) and the use of health technology (HT) among UGS.

Demographic information, health behaviors and use of HT were assessed using an online survey. Forty-five UGS participated in this pilot study. Frequency distributions and descriptive statistics revealed that 100% of the sample own a smart phone. Forty-six percent of UGS (N=21) use health devices (e.g. Fitbit) and 71% (N=32) use health apps. Among UGS who use health devices, 43% use Fitbit and 24% use Apple Watch. The type of health app that UGS reported using most was MyFitnessPal (31%), Fitbit App (31%), Nike+ Training Club (25%) and the iPhone Health App (19%). Females (85%) were more likely than males (61%) to use health apps; whereas, males (38%) were more likely than females (24%) to use health devices. UGS reported PA, diet/calorie-counting, weight loss and sleep to be the most common reasons for using health technology. On average, 48% of UGS using devices spent over \$100 on HT and 69% of app users obtained them for free. Fifty percent of UGS who use health apps engage in purposeful PA; whereas, 87% of UGS using health devices engage in purposeful PA. Further data collection can reveal additional patterns in health behaviors and HT use. By understanding the extent to which HT promotes healthy behaviors in UGS like sleep, PA and eating, interventions can be created or adapted to include effective apps or devices.

HEALTHY MOM2B: BASELINE FEATURES OF PREGNANT WOMEN PARTICIPATING IN A MOBILE HEALTH STUDY TARGETING GESTATIONAL WEIGHT GAIN

Alicia A. Dahl, MS, PhD (abd), Gabrielle Turner-McGrievy, PhD, MS, RD, Sara Wilcox, PhD, Jihong Liu, ScD, Rachel E. Davis, MPH, PhD

University of South Carolina, Columbia, SC

INTRODUCTION: Almost one-half of all pregnant women in the U.S. exceed the Institute of Medicine's (IOM) gestational weight gain (GWG) guidelines. The Healthy Motivations for Moms-to-Be (HM2B) Study is a randomized mobile health intervention for pregnant women living in the U.S. The intervention condition received targeted GWG goals and evidence-based behavioral strategies to encourage healthy GWG, while the comparison condition received content related to stress management techniques to reduce overall stress levels during pregnancy. The purpose of this study was to examine the baseline demographic, anthropometric, weight-related behaviors, and perceived stress of women enrolled in HM2B.

METHODS: Using Facebook and Twitter social media sites for recruitment, women who were in early pregnancy (less than 20 weeks), living in the U.S., and owned a smartphone and bathroom scale were recruited to participate in HM2B. Participants (n=142) completed an online self-report baseline survey that included adapted questions from the Rapid Eating Assessment for Participants (REAP), Godin Leisure Time Exercise Questionnaire, and the Perceived Stress Scale (PSS). Descriptive statistics were used to summarize the data.

RESULTS: The HM2B sample was predominately White (80.3%, n=114), followed by African American (10.5%, n=15) and Asian (9.2%, n=13). The mean age of participants was 29.7 ± 3.5 years. Pre-pregnancy Body Mass Index (BMI) was calculated from self-reported height and weight. Results indicated that 44.3% (n=63) were normal weight and 55.7% (n=79) were overweight or obese. Mean gestational age at enrollment was 13.9 ± 4.1 weeks. Of the 142 pregnant women, 56.3% (n=80) of participants were primigravida, 84.5% (n=120) were married, 75.4% (n=107) had at least a Bachelor's degree, and 61.3% (n=87) were employed for wages full time. Eating behaviors varied, but most participants reported eating less than 2 servings of fruits (52.8%, n=75) and 2 serving of vegetables (53.5%, n=76) a day. Regarding exercise behaviors, 47.9% (n=68) reported use of a physical activity (PA) tracker. On average, participants reported engaging in moderate PA 2 days per week and an average of 6.41 ± 0.52 hours of sedentary activity per day. Perceived stress levels were low among all participants (mean PSS score= 4.8 ± 2.7 points out of 16). There were no significant differences in baseline measures by intervention conditions (P 's>0.05).

DISCUSSION: Overall, dietary and PA behaviors were below recommendations, and perceived stress levels were low at baseline, indicating that among this sample, targeting healthy eating and PA may be more important than stress reduction. The HM2B Study provided participants with group-based health behavior goals and tracking features related to healthy eating, exercise, weight, and stress management. Future analyses will examine the role of HM2B on GWG.

MI SALUD, MI VIDA: A SELF-DISCOVERY TOOL FOR BREAST CANCER SURVIVORS

Valerie Alaimo, BA¹, Daniela Macias, N/A¹, Dara H. Sorkin, PhD², Yunan Chen, PhD¹, Alfred Kobsa, PhD¹, Alice Police, MD¹, Dana Mukamel, PhD¹, Sadeeka Al-Majid, PhD, RN³, Kelly Biegler, PhD²

¹U.C. Irvine, Irvine, CA; ²University of California, Irvine, Irvine, CA; ³California State University, Fullerton, Fullerton, CA

Breast cancer survivors are at risk for weight gain, obesity, and diabetes. Relative to non-Hispanic whites (NHW), Latinas have a higher risk of developing these sequelae. Self-management strategies leading to weight loss have been associated with reduced risk of morbidity and mortality. Although a broad selection of health and cancer-related mobile applications (apps) designed to promote a healthy lifestyle exist, few are evidence based, and none are designed to promote self-discovery.

Purpose: To assess the feasibility and acceptability of *Mi Salud, Mi Vida*, a mobile phone application that extends self-monitoring to provide personalized information to promote self-discovery. That is, it prompts women to realize their own personal preferences and to discover health behaviors that work best for them in order to maximize the potential for women to lose weight and incorporate a healthy lifestyle into their daily life.

Methods: Thirty-seven breast cancer survivors (19 Latinas and 18 NHW) participated in the 12-week intervention. Women were randomized to receive either a self-monitoring only app or the app with both self-monitoring and personalized feedback for self-discovery. BMI, self-report measures of diet and physical activity, and mood were collected at baseline, 6-week, and 12-weeks.

Results: The mean age of participants was 51.2. Overall, 14% of women reported being a very sophisticated technology user; NHW participants were more likely to report being a very sophisticated technology user than Latinas (22% v. 5%), although this difference reached trend level significance $p = 0.10$. In addition, there was a trend showing that NHW had a higher percentage of days with app usage than Latinas (57% v. 40%, $p = 0.10$). Common participant discoveries were related to connections between mood, a healthy lifestyle, and the social environment. For example, women reported: "I feel like when I am happy that I eat like a healthy woman...And when I am sad I keep on eating more." "I think I tend to eat less when I eat by myself, and with others I eat a lot more." Positive feedback on the app included user-friendliness and the large variety of food and exercise choices.

Discussion: Findings suggest that Latina and NHW breast cancer survivors are interested in using mobile apps to gain insight into their own health behaviors around weight loss. Implications for tailoring health behavior change apps to breast cancer survivors, particularly Latinas, will be discussed.

PATIENT PORTAL USE AMONG OLDER ADULTS: WHAT IS REALLY HAPPENING NATIONWIDE?

Eun-Shim Nahm, PhD, RN, FAAN¹, Shijun Zhu, PhD¹, Michele Bellantoni, MD², Linda Keldsen, MS, MBA-HC³, Vince Russomanno, BS⁴, Matt Rietschel, MS¹, Hyojin Son, MS¹, Leslie M. Smith, N/A⁵

¹University of Maryland School of Nursing, Baltimore, MD; ²Johns Hopkins School of Medicine, Baltimore, MD; ³VA Maryland Health Care System, Baltimore, MD; ⁴University of Maryland Medical System, Linthicum, MD; ⁵SeniorNet, Cape Coral, FL

Patient portals (PPs), secure websites that allow patients to access their electronic health records (EHRs) and other health tools such as eMessages and prescription refills, can be beneficial to older adults managing multiple chronic conditions (MCCs) and their caregivers. With their high prevalence of MCCs, older adults could be a major PP user group. However, prior studies have highlighted a lack of PP use in older adults and usability issues. Little is known about how older adults in the community are using PPs and what specific challenges they encounter. The aim of this study was to examine the current state of PP use in older adults, using selected baseline data from an ongoing nationwide online trial. The dataset includes quantitative and qualitative data from 272 older adults (mean age, 70.0 ± 8.5 years) with chronic conditions. The majority of participants ($n=194$, 71.3%) had at least one PP account, and 51.5% ($n=100$) had two or more PP accounts (range, 1–6). Many participants expressed frustration with juggling multiple PPs. The types of PPs varied widely, including at least 38 different PPs from hospitals, outpatient clinics, insurance payors, Medicare, pharmacies, and labs. Half of participants ($n=96$, 49.5%) learned to use PPs via information on PP websites, and 35.1% ($n=68$) learned via brochures. A total of 170 participants provided written comments about their experiences with PP education, including “no training/self-taught” ($n=55$) and “minimal information” ($n=23$). Overall, the level of perceived PP usability was low (mean, 28.7; range: 6–42). Regarding barriers to PP use, log-in problems generated the highest number ($n=26$) of comments. About half of participants ranked the ability to view lab results ($n=63$, 32%) and communicate with healthcare team members ($n=41$, 21.1%) as the most frequently used PP functions. Overall, the study findings suggest that many older adults have multiple PP accounts and are using them. PP usage, however, is limited due to several challenges associated with PP technology combined with a lack of training support. There has been a rapid growth in the number of older adult online, and PPs can be a robust tool to engage these individuals in their own care. To do so, PPs must be easily manageable by older adults and sufficient training must be provided. Further studies with different groups of older adults will provide additional information to develop more usable PPs for older adults.

PINPOINT: GAMING TECHNOLOGY TO ENGAGE ADOLESCENT SICKLE CELL PATIENTS IN PRECISION PAIN MANAGEMENT

Valerie H. Myers, PhD¹, Hilton M. Hudson, Jr., MD², Tiffany Jerrod, MPH³, Sophia Strickfaden, MA³, Mary K. Buller, MA¹, Megan Lippert, MBA²

¹Klein Buendel, Inc., Golden, CO; ²Hilton Publishing Company, Munster, IN; ³Klein Buendel, Golden, CO

Sickle cell disease (SCD) is the most common inherited blood disorder in the U.S., and affects primarily African Americans and Hispanics. Approximately, 1,000 U.S. children are born with SCD annually. SCD complications can be serious and have a significant impact upon well-being and quality of life. Pain is the hallmark symptom associated with SCD, and is the primary cause of SCD-related hospital admissions. Accurate assessment of pain specifiers (type, frequency, and intensity of pain) can help with ameliorating pain quickly and effectively. Reducing barriers to collection and promoting the value of accurate SCD pain assessment is a need in pediatric medicine. The interactive games for health literature among youths has shown video games can improve self-efficacy; stimulate health discussions with friends, family and clinical team; encourage seeking support and advice; and can emphasize behavior acquisition via experiential learning. Interactive games can provide information about causes, treatments, and self-care options, and can improve self-care and reduced emergency clinical utilization. Pinpoint: Gaming technology to engage adolescent sickle cell patients in precision pain management was a Small Business Innovation Research (SBIR) Phase I project that examined the feasibility and acceptability of a gamified tablet application intended to encourage teens (aged 13–17) to assess and talk about their SCD pain. The prototype consisted of a Pain Assessment Tool, vocabulary game, body scanner reflection, educational self-disclosure activity, and excerpts from the *Hope and Destiny Jr.* book by Hsu, Rodrigues, and Brandalise (2013). Healthcare providers were interviewed on the app's acceptability and potential function within the clinical practice ($n=4$). Teens participated in cognitive interviews, focus groups, and usability testing ($n=16$). Of these participants, the average age was 14.5 + 1.3 years, 33.75% were female, and 50% were diagnosed with Hemoglobin SS (Hb SS), the most common form of SCD. The System Usability Scale (SUS), a validated tool for assessing the usability and acceptability of technological products, served as the primary outcome. The preliminary SUS score ($n=5$) was 82.5 (68 is “above average”), suggesting a high level of acceptability and usability among users; usability testing is ongoing. Final project outcomes and the development of the full Pinpoint app will be discussed.

SYSTEMATIC REVIEW OF SOCIAL MEDIA AS A RESEARCH TOOL FOR DIET AND WEIGHT LOSS

Jessica R. Hawks, MPH, MSW¹, Eric Buhi, MPH, PhD², Hala Madanat, PhD³¹University of California, San Diego & San Diego State University, San Diego, CA; ²Graduate School of Public Health, San Diego State University, San Diego, CA; ³San Diego State University, San Diego, CA

Social media use has become widespread over the past several years and may be a rich data source and intervention tool for diet and weight loss research. Despite increasing interest in social media research, no systematic review has synthesized the literature on how social media is used as a research tool for diet and weight loss. This systematic review examined the following research questions: 1) How is social media being used as a research tool for diet and weight loss? 2) What methodologies are used in diet for weight loss studies that use social media as a research tool? 3) What research gaps exist among diet for weight loss studies that use social media as a research tool? To answer these questions, we conducted a systematic review of studies related to diet, weight loss, and social media. Articles were included if they used at least one of the specified social media platforms (Instagram, Twitter, Pinterest, Tumblr, Vine, Flickr, Myspace, Facebook, or blogs); had empirical, original research; were written in English; and published after 2003. After duplicates were removed, 2202 unique articles were screened for inclusion, and 39 met inclusion criteria. Most articles focused exclusively on Twitter (33%, n=13) and Facebook (33%, n=13). The next most studied platform was Instagram (15%, n=6), followed by blogs (8%, n=3), Pinterest (3%, n=1), and YouTube (3%, n=1). Two studies (5%) focused on multiple social media platforms. Most studies were descriptive (62%, n=24) and the rest were intervention studies (38%, n=15). Of the 19 studies that analyzed content from social media posts, 74% analyzed text (n=14) and 16% (n=5) analyzed images. Intervention studies most often used social media platforms to enhance social support for individuals trying to lose weight, to study engagement with study content and how engagement is related to weight loss, and as a tool to deliver educational materials and facilitate weight loss-related behavior change. Descriptive studies used social media (particularly Twitter and Instagram) for surveillance of things like prevalence of obesity and presence of food deserts and swamps. These findings suggest the need for more studies that analyze photo-based social media platforms such as Pinterest and Instagram. In addition, since many of the experimental studies were feasibility studies with small sample sizes, larger social media-based diet/weight loss intervention studies should be conducted.

USING DUAL PROCESS THEORY TO DETERMINE EFFECTIVE MESSAGING TO SUPPORT ADHERENCE TO A TIME RESTRICTED DIET

Angela F. Pfammatter, PhD¹, Elyse Daly, BA², H. Gene McFadden, N/A³, Bonnie Spring, PhD³¹Northwestern University Feinberg School of Medicine, Chicago, IL; ²Feinberg School of Medicine, Chicago, IL; ³Northwestern University, Chicago, IL

Self-monitoring is one of the most beneficial intervention strategies to support adherence to a diet. Typically, self-monitoring during a dietary intervention involves searching a food database, selecting a portion size, and sometimes the time or meal for which food was consumed. This action is considered to be burdensome and biased. While using smartphone applications has eased the burden, issues persist, leading researchers to develop strategies to improve completeness and accuracy of dietary self-monitoring. Self-monitoring, in its typical form engages an effortful cognitive process that is vulnerable to disruption. We proposed two competing strategies to improve adherence to the diet by considering both “type 1” and “type 2” processes of the dual process model. To engage a type 1, automatic process, we proposed an intervention designed to trigger a behavior via a cue or stimulus. To engage a type 2, cognitive process, we proposed an intervention designed to positively reinforce the desired behavior by showing performance feedback. We conducted a 2x2 experiment that randomized 40 female participants in a time-restricted diet trial for 6 months. Participants were all asked to adhere to a 10 hour window of eating and randomized to receive cue messages, reinforcing feedback, both, or neither on a smartwatch. Participants receiving cues were sent a message indicating when it was time to eat and when it was within one hour of the time to stop eating. Participants receiving reinforcing feedback were shown their overall adherence percentage to the time window when they indicated an eating episode had occurred. We hypothesized that participants receiving both types of support would show greatest adherence to the time restricted diet. 42 healthy women with a BMI between 25 and 40 (M=32.68, SD= 4.43) and between 18 and 65 years of age (M=48.04, SD=11.10) were recruited. A two way ANOVA with 2 levels of cues (yes, no) and 2 levels of reinforcement (yes, no) predicting adherence to the diet was conducted. The main effect of reinforcement demonstrated a significant effect, $F(1, 34) = 5.442$, $p=0.026$, such that adherence was higher in those receiving reinforcement. The main effect of cues and the interaction effect were non-significant. These results did not confirm that supporting dietary adherence using both cues and reinforcing feedback was necessary. It seems reasonable that participants were most supported by reinforcement, or a type 2 process, while the individual was making a significant behavioral change. It is possible that once the new behavior becomes more habitual that a type 1 message could be most helpful. Future work will investigate whether matching the type of support provided is best delivered dependent on whether the behavior is newly initiated or established. Wearable sensors that provide data on the dynamic nature of behavior change could further inform this work.

USING MOBILE APPS TO PROMOTE PRESCHOOLERS' PHYSICAL ACTIVITY: PERSPECTIVES OF PARENTS AND CHILDCARE CENTER DIRECTORS

Elizabeth D. Joseph, N/A¹, Jessica B. St. Romain, BS¹, Andrew T. Allen, MBA², Corby K. Martin, PhD¹, Amanda E. Staiano, PhD³

¹Pennington Biomedical Research Center, Baton Rouge, LA; ²InHealth Strategies, Baton Rouge, LA; ³Pennington Biomedical Research Center, Baton Rouge, LA

Background: The American Academy of Pediatrics recommends limiting preschoolers' daily screen-time to 1 hour of educational material, given the association of screen-time with risk for obesity and lower levels of physical activity. Considering the high prevalence of screen-time among both parents and children, mobile applications (apps) may be a useful way to disseminate educational information and support for healthy behaviors. The purpose of this study was to identify parents' and childcare center directors' perspectives on using mobile apps to promote preschoolers' physical activity.

Methods: Four focus groups of 28 participants, including 20 parents of preschoolers and 8 childcare center directors, were facilitated to identify familiarity and usage of mobile apps, ways an app may help preschool children become more physically active, desired features related to content/look/usability, desired frequency of prompts/reminders, and ways to tailor the app to the user. Conversations were recorded and transcribed, and NVivo was used to identify themes.

Results: Participants reported currently using mobile apps as a tool for both educating and entertaining preschool-aged children. While most focus group members voiced concern over children's amount of screen-time, both parents and directors expressed a sense of responsibility to put quality content in front of young children and use technology to teach healthy habits. Respondents in all focus groups stated that they want to learn more about how to help children be more physically active including local community resources, indoor play areas, and play groups. Most, but not all, participants were open to a smartphone app delivering this education. Parents expressed interest in receiving educational content through videos and reminder notifications including motivational messages, which would aid them in delivering better and more consistent physical activity education to their children.

Conclusion: Parents and childcare center directors were concerned about children's screen-time but were receptive to using an educational mobile app designed to help parents teach their preschoolers about physical activity.

USING THE COMPUTERIZED HEALTH SURVEY TO IMPROVE BEHAVIORAL HEALTH SERVICES IN THE ED

Colette Houssan, MPH¹, Rachel Davis-Martin, PhD², Edwin D. Boudreaux, PhD²

¹University of Massachusetts Medical School - Department of Emergency Medicine, Worcester, MA; ²University of Massachusetts Medical School, Worcester, MA

The Computerized Health Survey (CHS) is a patient-administered electronic survey designed to screen for mental health (MH) and substance use disorders (SUD) and provide referral resources based on appropriate level of care needed by the patient and their readiness to change. Patients take the CHS on tablet PCs installed in treatment rooms. The CHS was created to reduce clinician burden of screening patients for common behavioral health problems and improve patient care. The CHS uses well-known, brief validated screeners to identify MH (ie, PHQ-2, GAD-2, PC-PTSD) and SUD (eg, US AUDIT 1–3) within an average of 4 minutes. The assessment portion with the remaining validated items will open for each screener section a patient is positive. The entire survey takes roughly 15 minutes to complete if a patient has multiple MH and SUD behaviors. If the patient screens positive, an email alert is sent to hospital behavioral health staff (BHS). BHS then administers a brief intervention and provides referral to treatment and resources if needed. When appropriate, BHS conduct follow-up calls within the week after ED discharge.

Since May 2017, 932 patients have been prompted by hospital staff to take the CHS. Three hundred eighty-six patients (41.4%) did not complete for reasons expected in an ED setting including: disinterest, too ill/medical interventions, language barriers, visual, and auditory impairments/disabilities, technological deficits, illiteracy, and discharged during interaction. Of the 546 (58.6%) patients who completed the CHS, 198 (36.3%) screened positive and had an alert sent to BHS. BHS approached 135 (68.2%) of these patients, with 98 (72.6%) receiving brief intervention, 85 (86.7%) receiving referral to treatment and/or resources, and 20 (23.6%) receiving follow-up calls.

Integrating CHS into the ED improved BHS workflow. It reduced time spent screening and increased time spent on intervention and referral. Since implementing CHS, the typical BHS 30–45 minute screening, brief intervention and referral to treatment has become 20–25 minutes of brief intervention and referral to treatment. This more focused approach led to BHS seeing more patients per shift. CHS eliminates the BHS time spent screening a patient with no target behavior, while validating the patient has little to no risky behavior. The CHS continues to screen more patients daily and will continue to improve BHS workflow and assist in providing better care for patients.
