Conclusion: Providers are not adequately assessing sexual health for TM, thus potentially missing opportunities to provide important sexual health, HIV/STI prevention information, and access to PrEP and PEP. Gender-affirming sexual health care must include a comprehensive patient-centered model that engages TM in conversation about their body and sexual health. More research is needed to develop of gender affirming sexual history tool for TM.

SEXUAL ORIENTATION COMPARISONS OF CONDOMLESS SEX INTENTION AMONG COLLEGE MALES IN TAIWAN USING THE THEORY OF PLANNED BEHAVIOR

Jiun-Hau Huang, S.M., Sc.D., Chia-Hsien Hsu, B.S.

National Taiwan University College of Public Health, Taipei, Taipei, Taiwan (Republic of China)

Background: Prior studies have found that heterosexual and non-heterosexual males had different patterns of sexual behavior, and non-heterosexual males were at higher risk for HIV infection through sexual risk behavior. However, given the aforementioned differences, little is known about whether and how heterosexual and non-heterosexual male college students differ in their condomless sex intention (CSI) and associated factors. Hence, using the Theory of Planned Behavior (TPB), this study aimed to compare the theory-based factors influencing CSI among heterosexual versus non-heterosexual male college students in Taiwan.

Methods: Anonymous survey responses from 1,640 male college students in Taiwan were included in the multivariate logistic regression analyses, stratified by sexual orientation, to explore the TPB-based factors linked to higher CSI (rated on a 7-point scale and dichotomized by the median). Items derived from the TPB constructs—Attitude Toward the Behavior (ATB), Subjective Norm (SN), and Perceived Behavioral Control (PBC)—were factor-analyzed to form 5 factor-based subscales, whose scores were trichotomized.

Results: Heterosexual and non-heterosexual males perceiving neutral (AOR=2.11 and 6.04) and positive (AOR=4.03 and 6.55) ATB about positive outcomes were more likely to have higher CSI, respectively. Regarding ATB about negative outcomes, only heterosexual males with neutral (AOR=1.85) and positive (AOR=3.18) ATB tended to have higher CSI. Heterosexual and non-heterosexual males perceiving neutral (AOR=1.34 and 5.73) and supportive (AOR=2.70 and 10.51) SN were more likely to have higher CSI, respectively. Under facilitating and constraining conditions, heterosexual males reported higher CSI when perceiving intermediate (AOR=1.42 and 1.92) and high (AOR=1.40 and 2.54) PBC, respectively. Specifically, regarding ATB, heterosexual males cared about sexual excitement, unexpected pregnancy, etc. vis-à-vis non-heterosexual males about psychological pleasure and sexually transmitted infections. As for SN, the support for CSI from lovers was important, especially for non-heterosexual males. About PBC, embarrassment when buying condoms was linked to CSI for all.

Conclusions: All 5 TPB factors were linked to CSI in heterosexual males, compared with ATB about positive outcomes and SN in non-heterosexual males. The specific aspects related to CSI differed between heterosexual and non-heterosexual males and can inform tailored health education programs.

SEXUAL RISK TAKING BEHAVIOR IN YOUNG ADULTS: POOR EXECUTIVE FUNCTION AND EFFORTFUL CONTROL COULD PUT MALES AT RISK

Elisabeth O'Rourke, MA, Joseph Bettcher, MA, Leslie Halpern, PhD
University at Albany, Albany, NY

Introduction. Research points towards temperament, particularly extraversion, as an important factor in predicting risk-taking behavior among adolescents. The associations between extraversion and risk-taking broadly, and sexual risk taking specifically, have not been studied as extensively among young adults. Given the negative health consequences associated with sexual risk-taking, understanding individual differences that contribute to risky behavior could assist in the development of prevention and intervention programs. In addition to extraversion, temperamental effortful control (EC), the ability to inhibit behavior when confronted with something desirable, and executive function (EF; working memory, planning) likely contribute to whether one engages in sexual risk-taking behavior. This study examined whether EF moderated the relation between temperament (extraversion, EC) and sexual risk-taking behavior such that better EF would play a protective role against risky sexual behavior.

Method. The participants were 210 undergraduates at a medium-sized university, [$M(\text{age})=19.11$, $N(\text{males})=130$]. The majority of participants were White (53.3%). Participants completed the following self-report measures: a demographic survey, the Behavior Rating Inventory of Executive Function Adult Self-Report (BRIEF-A), which measures executive dysfunction, the Adult Temperament Questionnaire (ATQ), and the Sexual Risk Survey (SRS).

Results. Males indicated greater EC than females ($M=4.27$, $SD=.74$; $M=4.05$, $SD=.58$; $t(207)=2.34$, $p<.05$). For males and females, higher scores of EF dysfunction were associated with lower EC, $r(130)=-.49$, $p<.001$; $r(79)=-.45$, $p<.001$, respectively. Additionally, for males and not females, lower EC was associated with greater sexual risk taking, $r(130)=-.17$, $p<.05$. Extraversion was not related to any of the other study measures. EF was not associated with sexual risk taking. EF dysfunction moderated the relation between EC and sexual risk taking for males only ($R^2=.07$, $F(3,126)=3.44$, $p<.05$, $b=2.94$, $t=2.27$, $p=.02$) such that individuals with high EC and poor EF were engaging in high levels of sexual risk-taking behavior and individuals with high EC and better EF showed lower risk.

Discussion. Sexual risk-taking is of particular concern in young adults. Because executive function skills are still developing during this time, these skills, along with temperamental EC, likely play a key role in young adults' engaging in sexual risk-taking behavior. The study's findings point towards EC as a significant predictor of sexual risk-taking behavior in males such that individuals with greater EC are less likely to take risks, but that this relationship is impacted by one's level of EF. Unexpectedly, these relations were only found for males. Future research should explore the factors that predict female sexual risk taking.

SEXUAL SHAME: A POSSIBLE MEDIATOR BETWEEN INTERNALIZED HOMOPHOBIA AND SEXUAL COMPULSIVITY IN GAY AND BISEXUAL MEN

Jorge L L. Cienfuegos-Szalay, M.P.H.¹, Raymond L. Moody, MA², H. Jonathon Rendina, PhD, MPH³, Jeffrey T. Parsons, PhD³

¹Graduate Center of the City University of New York, New York, NY; ²Graduate Center, City University of New York, Brooklyn, NY; ³Hunter College of the City University of New York (CUNY), New York, NY

Background: Internalized homophobia has been negatively associated with mental health and psychological wellbeing among gay and bisexual men. Previous research has also found that internalized homophobia is a possible contributor to sexual compulsivity. However, there is little research exploring the possible mechanisms that underlie this relation, thus the possibility of additional variables being involved must be considered. Sexual shame has been previously found to be detrimental to the mental health of sexual minorities, which in turn may lead to poor decision making, risky sexual behavior and adverse physical health outcomes. Limited studies have examined the role of sexual shame and its relation to sexual compulsivity, particularly within gay and bisexual men.

Methods: A national sample of 949 HIV-negative gay and bisexual men aged 18–67 ($M=35.8$) completed at-home surveys, including measures of sociodemographic characteristics, the Internalized Homophobia Scale, the Sexual Shame Scale, and the Sexual Compulsivity Scale.

Results: Adjusting for sociodemographic characteristics, regression analyses indicated significant direct effects for internalized homophobia on sexual shame ($\beta=0.23$, $p<.001$) and sexual compulsivity ($\beta=0.23$, $p<.001$). Modeled simultaneously, the association between sexual shame and sexual compulsivity was significant ($\beta=.37$, $p<.001$) and the association between internalized homophobia and sexual compulsivity weakened ($\beta=-.06$, $p=.050$). Sobel's test indicated the presence of a significant indirect effect of internalized homophobia on sexual compulsivity through sexual shame ($p<.001$).

Conclusions: Findings suggest that internalized homophobia is associated with both sexual compulsivity and sexual shame. Furthermore, the relationship between internalized homophobia and sexual compulsivity was almost completely explained through sexual shame. Addressing these issues at individual and community levels is crucial to reduce the negative effects on the mental and physical health of gay and bisexual men. Efforts should be made to create culturally responsive interventions aiming to reduce sexual compulsivity, especially taking into account the potential effects of internalized homophobia and the role sexual shame has in the relationship between these two.

SHORTER INTERVAL BETWEEN MENARCHE AND FIRST SEXUAL INTERCOURSE ASSOCIATED WITH INCREASED SEXUAL RISK AMONG YOUNG WOMEN

Jordan Thomas, BA¹, Jessica Lewis, LMFT, MPhil¹, Shayna Cunningham, PhD¹, Jonathan Tobin, PhD², Jeannette Ickovics, PhD¹¹Yale School of Public Health, New Haven, CT; ²Clinical Directors Network, New York, NY

RATIONALE: Evidence suggests that age of menarche and age of first sexual intercourse are independently linked to sexual health behaviors, including number and type of sexual partners and incidence of unprotected sex and sexually transmitted infections. Emerging research demonstrates that short intervals between age of menarche and first sexual intercourse are similarly associated with increased risk of cervical disease. Less is known about the relationship between this interval and other sexual health behaviors.

METHODS: Data were collected from a diverse group of pregnant adolescents and young women (14–21 years, N=831) from fourteen community health centers and hospital obstetric outpatient settings in New York City. Logistic and linear regression models adjusted for known predictors of sexual risk and sociodemographic variables were used to test associations between the interval length (in years) between age of menarche and first sexual intercourse and sexual risk behaviors (e.g., number of sexual partners, contraceptive use, exposure to high-risk sexual partners, diagnosis of sexually transmitted infections, engagement in intimate partner violence).

RESULTS: Mean age of menarche was 12.21 ± 1.64 , age of sexual debut 15.23 ± 1.66 and interval 3.02 ± 2.01 years. Short intervals between age of menarche and first intercourse were significantly associated with decreased contraceptive use in the six months prior to pregnancy (OR: 2.126, 95% CI: 1.249, 3.619, $p=.005$) and increased incidence of intimate partner violence (OR: 1.695, 95% CI: 1.014, 2.834, $p=.044$).

IMPLICATIONS: The interval length between menarche and first intercourse is an important marker of risk; shorter windows are associated with lower likelihood of contraceptive use and increased incidence of intimate partner violence. Menarche presents an early window of opportunity to educate young women about sexual and reproductive health. Clinicians and comprehensive sexual and reproductive health education programming should work to identify girls at the age of their first period and subsequently engage them in conversations about their reproductive capacity, contraceptive choice, and dynamics of healthy intimate relationships.

DYNAMIC FEATURES OF PROBLEMATIC DRINKING BEHAVIOR ACROSS AGE

Ashley Linden-Carmichael, Ph.D.¹, John J. Dziak, Ph.D.², Sara A. Vasilenko, Ph.D.³, Stephanie T. Lanza, Ph.D.¹¹The Pennsylvania State University, University Park, PA; ²Penn State, University Park, PA; ³Pennsylvania State University, University Park, PA

Prevalence rates of alcohol use disorder (AUD) peak during young adulthood. There are multiple, diverse criteria that constitute AUD, ranging from drinking longer than intended to continuing to drink despite problems with family. Beyond examining overall prevalence rates of AUD, less is known about the typology of problem drinkers. There may be different profiles of individuals with an AUD based on reported symptoms. Sub-groups also may vary in prevalence by age. Identifying sub-populations of problematic drinkers based on their AUD symptomatology and examining their prevalence across age could highlight aspects of risky drinking that are particularly salient at different ages. We sought to (1) determine the extent to which each symptom of AUD varied by age, (2) identify sub-groups of drinkers with AUD, and (3) examine prevalence rates of sub-groups by age. The current study used data from the National Epidemiologic Survey on Alcohol and Related Conditions (NESARC-III). Current drinkers aged 18–64 who met criteria for a past-year AUD were included ($n = 5,402$). Latent class analysis (LCA) based on 11 AUD criteria revealed 5 classes: Drinkers with Alcohol-Induced Injury (25%), Drinkers with Low Life-Interference (21%), Drinkers Experiencing Adverse Effects (34%), Drinkers with Difficulty Cutting Back (13%), and Highly Problematic Drinkers (7%). Class prevalences were allowed to vary flexibly across age using time-varying effect modeling (TVEM). Drinkers with Alcohol-Induced Injury experienced a linear increase across age. Drinkers with Low Life-Interference were most prevalent in early adulthood, declined with age, and increased around age 52. Drinkers Experiencing Adverse Effects were most prevalent early in adulthood, declining with age. Drinkers with Difficulty Cutting Back remained stable across age, with an increase at age 53 and peak at age 62. Highly Problematic Drinkers remained stable across age, peaking at age 49. The integration of LCA and TVEM provided a novel perspective of sub-groups of problematic drinkers and their variation in risky drinking patterns by age. AUD defined by adverse effects from drinking (e.g., nausea, hallucinating) or highly problematic but low perceptions of interference with life is particularly salient at younger ages; AUD symptoms of difficulty cutting back and experiencing injury are more relevant at later ages. Findings highlight ages and salient symptoms for which prevention and intervention efforts are most needed.

LATENT CLASSES OF DISCRIMINATION AMONG SEXUAL MINORITY ADULTS: ASSOCIATIONS WITH SUBSTANCE USE DISORDERS

Cara E. Rice, PhD, MPH¹, Jessica N. Fish, PhD², Sara Vasilenko, PhD³¹Pennsylvania State University, University Park, PA; ²University of Texas at Austin, Austin, TX; ³The Methodology Center, Pennsylvania State University, University Park, PA

Sexual minorities (SMs) are disproportionately vulnerable to a variety of health outcomes, including substance use (e.g., alcohol, marijuana, and nicotine). The National Institute on Minority Health and Health Disparities recently recognized SMs as a health disparity population, citing discrimination as a key barrier to health equity. Though an emerging body of research demonstrates the effects of discrimination on SM health, there are different types of discrimination experiences, and it is less clear how types or patterns of discrimination may contribute to health disparities.

Using a national sample of SM adults (aged 18–65) from the National Epidemiological Survey of Alcohol and Related Conditions III, we used latent class analysis (LCA) to examine patterns of past-year sexual-orientation-specific discrimination among SM adults and how those patterns are related to substance use. We then examined the association between latent class membership and past year substance use disorders by biological sex, controlling for age.

We identified four latent classes of discrimination: No-Discrimination (87%), Overt Discrimination-Only (7%), All-Types-of-Discrimination (4%), and Healthcare-Discrimination-Only (2%). Among SM males, membership in the All-Types-of-Discrimination class was significantly associated with past-year alcohol use disorder (pyAUD) compared to the No-Discrimination class (odds ratio (OR): 1.89, 95% confidence interval (CI): 1.08, 3.30). Among SM males, membership in the Overt-Discrimination-Only class was associated with pyAUD (OR: 2.70, 95% CI: 1.72, 4.24) and past year drug use disorder (pyDUD) (OR: 1.84, 95% CI: 1.02, 3.30) relative to the No-Discrimination class. Among SM males, there were no significant associations between latent classes and past-year nicotine dependence or past-year marijuana use disorder. Among SM females, the Overt-Discrimination-Only class was significantly associated with pyAUD (OR: 2.00, 95% CI: 1.26, 3.18) relative to the No-Discrimination class. Among SM females, there were no additional statistically significant relationships between latent classes and past-year substance use disorders.

SM adults report varying patterns of discrimination experiences, and their association with substance use disorders vary. These results have the potential to identify critical subgroups of SMs for targeted intervention and prevention programs.

CULTURAL CONSTRUCTS ASSOCIATED WITH SMOKING AND DRINKING IN HISPANIC COLLEGE STUDENTS

Analisse Acosta, Texas, Perla Perez, N/A, Jennifer Kim, Texas, Viridiana Martinez, N/A, Illiana Medina, Texas, Theodore Cooper, Ph.D.

University of Texas at El Paso, El Paso, TX

While drinking and smoking rates within college student samples are notably high, few studies have assessed these addictive behaviors in Hispanic college students. Even fewer have assessed smoking and drinking relative to cultural constructs. The aims of this study were to assess current smoking and weekend drinking, as well as potential cultural construct correlates of use behaviors in a Hispanic college student sample. College students ($N=345$; 72.2% female; Age $M=20.13$, $SD=3.922$) completed an online consent process and battery of surveys which included measures of: smoking status, average number of drinks per weekend, familism, acculturation, Latino/a values, fatalism, and perceived microaggressions. Logistic (current smoking) and linear regression (average weekend drinks) analyses assessed the associations between use and cultural constructs. Any current smoking (39.1%) was statistically significantly associated with (Cox and Snell $R^2=.106$): male gender (OR=1.8), acculturation (OR=.559), and the media microaggression subscale of the Revised Racial and Ethnic Microaggression Scale (OR=.71). Average number of weekend drinks ($M=2.3$, $SD=6.8$) was statistically significantly associated with increased assumptions of inferiority perceived microaggressions (Adjusted $R^2=.076$; $p<.05$). The inverse association between smoking and acculturation is inconsistent with convergence and acculturative stress theories of addictive behaviors, however is consistent with past empirical findings on the border (e.g., Cooper et al., 2011). That smoking was associated with decreased exposure to positive media images of people of color and that weekend drinking was associated with increased perceived assumptions of inferiority by others provides burgeoning evidence that smoking and drinking may be associated with perceived microaggressions. However, cultural constructs accounted for limited variance in both smoking and drinking, suggesting that other psychosocial constructs may be more strongly associated with Hispanic smoking and drinking. Thus, future studies of licit substance use in Hispanic college students may wish to be prospective in nature, utilize more nuanced assessments of substance use behaviors, and include a broader range of psychosocial constructs.

INTEGRATED PSYCHOTHERAPY FOR CO-OCCURRING SUBSTANCE USE AND PSYCHOLOGICAL DISORDERS: A SYSTEMATIC REVIEW OF OUTCOMES

Jennifer L. Brown, PhD¹, Nicole Gause, M.A.²¹University of Cincinnati College of Medicine, Cincinnati, OH; ²University of Cincinnati, Cincinnati, OH

Opioid use is an epidemic, and co-occurring psychiatric disorders (COD) are prevalent among individuals with Opioid Use Disorder (OUD). COD are associated with worse treatment outcomes among individuals with OUD and treatment approaches that do not address the relationship between substance use and psychological distress lack empirical support. This systematic review examined the efficacy of integrated psychotherapy, defined as a stand-alone intervention to concurrently treat a Substance Use Disorder (SUD) and COD by addressing the reciprocation between symptomologies. Studies were retrieved from electronic databases (Google Scholar, Academic Search Complete, PsycINFO, MEDLINE, ERIC, Health Source: Nursing/Academic Edition, Psychology and Behavioral Sciences Collection) and existing reviews and meta-analyses, and were included if at least one participant had a documented OUD diagnosis or reported opioids as his/her primary substance. Across studies, integrated psychotherapies were generally effective in reducing self-reported SUD and COD severity. Regarding COD outcomes, integrated psychotherapy for SUD & PTSD was superior to SUD-only treatment controls; however, findings for integrated psychotherapy for SUD & other COD were inconclusive. Evidence of the superiority of integrated psychotherapy compared to SUD-only treatment on SUD outcomes is lacking. However, there were promising implications for individuals with OUD indicating that integrated psychotherapy combined with medication assisted treatment (MAT) may be more effective than SUD-only treatment combined with MAT in reducing opioid use across follow-up. Limitations of current research and gaps in the literature are discussed, and future directions are suggested.

MENTAL CONTRASTING WITH IMPLEMENTATION INTENTIONS (MCII): AN ONLINE SELF-REGULATION INTERVENTION TO REDUCE DRINKING

Sandra Wittleder, PhD¹, Andreas Kappes, Ph.D.², Gabriele Oettingen, Ph.D.³, Peter Gollwitzer, Ph.D.³, Melanie Jay, MD, MS⁴, Jon Morgenstern, Ph.D.⁵¹New York University School of Medicine, New York, NY; ²City University of London, London, England, United Kingdom; ³New York University, New York, NY; ⁴New York University School of Medicine, Brooklyn, NY; ⁵Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY

Background: Drinking has detrimental health consequences, which cost the United States billions of dollars each year. Effective interventions to reduce hazardous drinking are needed. Online interventions could save costs while increasing dissemination. Although they have promise as alternative treatments, the evidence for the effects of online interventions is still mixed, and the most efficient framework for delivering online alcohol reduction intervention remains unknown. For other health behaviors, the self-regulation intervention of mental contrasting with implementation intentions (MCII) has been successful. We explored whether MCII qualifies as a new online intervention framework to help people who were worried about their drinking to reduce it.

Method: Participants ($N = 200$, female = 107) were recruited online. They either learned MCII or solved simple math problems (control). During mental contrasting, people juxtapose their mental images about a desired and feasible future (e.g., drink less alcohol) with an inner obstacle (e.g., feeling pressured by friends). This helps people understand how to overcome their obstacle (e.g., saying no when pressured to drink). Implementation intentions complement mental contrasting. Implementation intentions frame the obstacle as an if/then statement “If situation x arises, then I will show goal-directed behavior y .” Implementation intentions increase the accessibility of the situational cue specified in the “if”-part and foster an automatic goal-directed response specified in the “then”-part, once this critical cue is encountered.

Results: Immediately after the intervention, participants in the MCII condition (vs. control) reported increased commitment to reduce drinking. After one month, they reported having taken action measured by the Readiness to Change drinking scale (RTC). Importantly, when drinking was hazardous (AUDIT ≥ 8 , $n = 85$), participants in the MCII condition indicated a decreased number of drinking days ($OR = .47$) and drinks per week ($OR = .57$) compared to the control condition.

Conclusion: These first findings indicate that a brief, self-administered online MCII intervention ($Mdn = 28$ minutes) might reduce drinking in people who worry about their drinking, especially for people at-risk for hazardous drinking. MCII is scalable, and future studies should test the cost-effectiveness of the intervention in real-world settings.

MORE INVESTMENT IN EXPLICIT DRINKING IDENTITIES IS ASSOCIATED WITH MORE ALCOHOL CONSUMPTION AND HAZARDOUS DRINKING

Andrew Hertel, PhD¹, Kirsten P. Peterson², Kristen Lindgren, PhD³¹Knox College, Galesburg, IL; ²University of Washington, Lake Stevens, WA; ³University of Washington, Seattle, WA

Research has demonstrated that alcohol consumption and its negative outcomes are elevated among those who identify with drinking. We extended prior research on drinking identity by considering multiple dimensions of investment in it, including perceptions of how important it is and how frequently one thinks of being a drinker/drinking. We also investigated these dimensions of investment in absolute terms as well as in terms relative to other life domains (education, well-being, personal relationships). Our central aim was to evaluate whether these dimensions of investment were positively associated with alcohol consumption and hazardous drinking (i.e., greater risk of alcohol use disorders) either in interaction with or in addition to identification with drinking. The aim was evaluated with a sample of college student hazardous drinkers. College students who were screened for hazardous drinking ($N = 521$; AUDIT ≥ 8 ; age $M = 21.46$, 57.4% female, 58.2% White) completed self-report measures of alcohol consumption (# drinks/week), hazardous drinking (AUDIT: alcohol use disorder identification test), identification with drinking (ASCS: alcohol self-concept scale), and investment in drinking identity (absolute and relative drinking identity importance as well as absolute and relative frequency of thought about being a drinker/drinking) at a single time point. Controlling for gender, and in addition to a main effect of identification with drinking, we observed main effects of thought frequency. Specifically, alcohol consumption and hazardous drinking were both independently and positively associated with identification with drinking ($b = .25$, $z = 3.28$, $p = .001$; $b = .18$, $z = 2.23$, $p = .026$), absolute frequency of thought about being a drinker ($b = .10$, $z = 4.51$, $p < .001$; $b = .10$, $z = 4.94$, $p < .001$), and relative frequency of thought about drinking ($b = .13$, $z = 4.11$, $p < .001$; $b = .11$, $z = 3.84$, $p < .001$). There were neither effects of drinking identity importance, perhaps because they were accounted for by thought frequency effects, nor interaction effects between identification with drinking and drinking identity investment. In sum, drinking identity investment is associated with alcohol consumption and hazardous drinking beyond identification with drinking. Absolute and relative frequency of thought about being a drinker/drinking may be an additional risk factor and/or clinical target for alcohol consumption and hazardous drinking.

PERCEPTION OF HARM RELATED TO OPIOIDS IS ASSOCIATED WITH SUBSTANCE USE FREQUENCY IN COLLEGE UNDERGRADUATES

Karlyn A. Edwards, B.A., Kevin Vowles, PhD

University of New Mexico, Albuquerque, NM

Previous research has shown that perceptions of harm related to substances are associated with less frequent use. For example, more harmful perceptions of cocaine, marijuana, and alcohol have been associated with less use of multiple substances. Recent health campaigns have utilized this research to increase the perception of harm of opioid use, however few studies have examined the relationship between perceptions of harm of opioid use and substance use frequency. Therefore, the present study sought to understand the association between the perception of harm related to opioids and substance use frequency among college undergraduates. Participants ($N=981$; Mean age = 20.52 ± 4.68) were mostly Hispanic (47%) or White (37%), and female (72%). Each completed on-line assessments regarding frequency of recreational drug use in the past 30 days (i.e., alcohol, marijuana, opioids, sedatives, stimulants, and psychedelics) and an assessment of perceived harm of opioids in comparison to other substances. Participants were categorized into one of three groups, those who endorsed that opioids were: more harmful than illicit drugs ($N=215$), equally as harmful ($N=568$), and less harmful ($N=198$). Cross-sectional negative binomial regression analyses that controlled for age revealed that those who perceived opioids to be less harmful than illicit drugs reported the lowest number of days using marijuana, opioids, sedatives, stimulants, and psychedelics. In addition, those who perceived opioids to be more harmful reported the highest number of days using marijuana, sedatives, and psychedelics. The more harmful and equally harmful groups were similar in stimulant and opioid use, but reported significantly higher use than the less harmful group. Lastly, the less harmful and more harmful group reported similar alcohol use, which was significantly less than the equally harmful group, and there were no significant differences in binge drinking among the three groups ($IRR = .01 - .91, p < .05$). These findings suggest that harmful perceptions of opioids may not be strongly associated with decreased substance use within the past 30 days, but rather may be associated with more frequent use. Moreover, health campaigns aimed at increasing perceptions of harm of opioids to reduce substance use frequency among college students may not be strongly supported.

PSYCHIATRIC COMORBIDITIES AND TREATMENT ADHERENCE IN WOMEN RECEIVING PRENATAL MEDICATION ASSISTED TREATMENT FOR OPIOID USE

Avery Meyer, B.S. Student¹, Meghan Sharp, M.A.², Mona Prasad, D.O., MPH¹, W. Thomas Whitlow, B.S.¹, Courtney Lynch, PhD, MPH¹, Kristen Carpenter, Ph.D.¹¹The Ohio State University Wexner Medical Center, Columbus, OH; ²East Carolina University, Greenville, NC

Introduction: A reported 25–33% of pregnant women with an opioid use disorder (OUD) have a comorbid psychiatric disorder. These comorbidities may contribute to poorer treatment adherence in medication assisted treatment (MAT) programs. The purpose of this study is to characterize psychiatric diagnoses and treatment and explore relationships among comorbidities and program adherence in women seeking prenatal care combined with MAT for OUD.

Method: Retrospective medical chart review was conducted for patients undergoing prenatal care at a multifaceted substance abuse treatment clinic that includes MAT, high-risk obstetric care, group counseling, and newborn planning. Preliminary analysis was conducted on 134 patients. Sample: majority Caucasian (86.6%), non-Hispanic (99.3%), Single (77.2%), Medicaid insurance (83.2%); $M_{\text{maternal age}} = 27.04$ ($SD = 4.08$), $M_{\text{gestational age at birth}} = 38.01$ weeks ($SD = 2.20$); 46.1% being treated with buprenorphine/naloxone, and 53.9% being treated with methadone at the time of delivery.

Results: Nearly half of the patients (46.3%) had at least one psychiatric diagnosis noted during pregnancy in their medical documentation. A high percentage of those patients (91.9%) had a historical psychiatric diagnosis, and 11.9% had a history of suicide attempt. Half had documented illicit substance use during pregnancy other than opiates. One-third were prescribed psychiatric medication during pregnancy (33.6%), but only 6.7% were in the care of a psychiatrist. Less than one-fifth (18.7%) were seeing a counselor outside of the MAT program. Additional analyses will explore relationships between substance use, program adherence, and psychiatric diagnoses.

Conclusions: The rate of comorbid psychiatric diagnoses during pregnancy reported here is higher than expected based on reported rates in the literature. This clinic is unique in its offering of multi-disciplinary prenatal support that includes regular social work and group counseling sessions, which may contribute to greater attention to psychiatric care among clinic providers. These results highlight the importance of including psychiatry in prenatal MAT. Information gathered from additional analyses will evaluate the potential influence that psychiatric problems may have on program adherence.

RELIGIOSITY AND HEALTH RISK BEHAVIORS AMONG LATINO SEXUAL MINORITY MEN

Kalina M. Lamb, BA¹, John P. Brady, MS², Manuel Gonzales, IV, N/A³, Aaron Blashill, Ph.D.¹¹San Diego State University, San Diego, CA; ²San Diego State University, La Jolla, CA; ³San Diego State University, Palmdale, CA

Objective: Sexual minority men (SMM) are at risk for a number of negative health behaviors, including substance abuse and condomless anal sex (CAS). Mixed findings are noted when examining religiosity and health outcomes in SM samples. Thus, the current study aimed to explore the association of three subcomponents of religiosity: organizational religious activity (ORA; i.e., public religious activity), non-organizational religious activity (NORA; i.e., private religious activity), and intrinsic religiosity (IR; i.e., degree of personal commitment to one's religion) in predicting illicit substance abuse and HIV sexual risk.

Methods: Participants were 151 Latino SMM recruited from the San Diego County area ($M = 24.18$ years of age, $SD = 3.19$), who completed online self-report questionnaires in either English or Spanish, which included items assessing frequency of various forms of illicit substance abuse and CAS with an HIV-positive or unknown partner. Binary variables were created representing use of illicit substances in the past month vs. no use, and a count variable of number of CAS partners. Religiosity was assessed using the three subscales (ORA, NORA, and IR) of the Duke University Religion Index (DUREL).

Results: Logistic regression models were conducted separately with each binary substance abuse variable entered as the criterion, and a negative binomial regression was conducted with CAS partners as the criterion. ORA, NORA, and IR were simultaneously entered as the predictor variables. ORA was associated with opiates ($OR = 1.47, p = .03$). NORA was associated with cocaine ($OR = 2.03, p < .001$), heroin ($OR = 1.84, p = .001$), opiates ($OR = 1.81, p = .002$), amphetamines ($OR = 1.82, p = .002$), sedatives ($OR = 2.36, p < .001$), and increased CAS partners ($B = .633, p = .01$). IR was associated with amphetamines ($OR = 1.22, p = .04$) and decreased CAS partners ($B = -.355, p = .03$).

Conclusions: Results indicate NORA is generally positively associated with the use of a number of health risk behaviors, whereas ORA and IR generally did not display significant associations with criterion variables. NORA may represent greater internalization of anti-gay religious doctrines compared to other components of religiosity. Clinicians may wish to recognize the unique ways religiosity may be associated with health behaviors of Latino SMM and address the potential perceived dissonance between identities these individuals may experience.

SCREENING AND BRIEF INTERVENTION FOR ALCOHOL MISUSE IN SCHOOL-BASED HEALTH CENTERS: A RANDOMIZED TRIAL OF CHECK YOURSELF

McCarty McCarty, PhD¹, Elon Gersh, PhD², Katherine Katzman, MPH³, Gina Sucato, MD, MPH⁴, Christine Lee, PhD¹, Laura P. Richardson, MD, MPH¹¹University of Washington, Seattle, WA; ²Seattle Children's Research Institute, Windsor, Victoria, Australia; ³Seattle Children's Research Institute, Seattle, WA; ⁴Washington Permanente Medical Group, Bellevue, WA

Purpose: School-based settings are a promising venue for delivery of substance use screening and brief intervention due to their accessibility. We developed the *Check Yourself* tool to automate multi-risk screening, give real-time motivational feedback on substance use and other health behaviors, and summarize results for providers prior to a visit at the school-based health center (SBHC). In this study, we compare care delivery and substance use outcomes for moderate to high risk adolescent alcohol users who received a visit at their SBHC with and without the *Check Yourself* tool.

Methods: We conducted a randomized controlled trial with 148 adolescents aged 13–18 who met criteria for moderate to high risk alcohol use, recruited from urban SBHCs. Participants were randomized to receive their SBHC visit with ($n=73$) or without ($n=75$) the *Check Yourself* tool. All SBHC providers received a brief training on the use of motivational interviewing to address substance misuse.

Results: Adolescents who received the *Check Yourself* tool + SBHC visit reported higher levels of alcohol (67%) and marijuana counseling (73%) from the provider during their visit, compared to those who received a SBHC visit without the tool (40% and 45% respectively, $ps=.02$). Relative to baseline, adolescents in both groups reduced their typical drinks of alcohol, maximum drinks of alcohol and hours high on marijuana over time ($ps < .02$). Adolescents who received *Check Yourself* reported perceiving that fewer of their peers use alcohol ($p=.001$) compared to those who did not.

Conclusions: SBHCs are an excellent venue for delivery of brief substance use interventions, as adolescents across groups who had a visit with a trained provider decreased the amount of alcohol use. Using an electronic screening and brief intervention tool can prompt providers to increase counseling of adolescents at risk for substance use. Additionally, the provision of personalized feedback with normative comparisons may impact adolescents' views about the extent to which other teens their age use substances.

TRAUMA, POSTTRAUMATIC STRESS, AND NON-MEDICAL USE OF PRESCRIPTION DRUGS IN YOUNG ADULTS IN KOSOVO

Eric G. Benotsch, MA, Ph.D.¹, Dafina Muçaj, M.S.², Cheuk Chi Tam, M.S.¹¹Virginia Commonwealth University, Richmond, VA; ²UNICEF Kosovo, Richmond, VA

Prior research has documented substantial non-medical use of prescription drugs (NMUPD; i.e., without a physician's prescription) among young adults. Most previous studies have collected data from the United States, Western Europe, or Australia. The present study collected data from an anonymous sample of young adults (N = 300) referring for drug treatment in Kosovo, an independent state formed in the aftermath of the dissolution of Yugoslavia. Participants responded to questions assessing use of alcohol and illicit drugs, NMUPD, demographic information, traumatic experiences, and PTSD symptoms. Primary substances of use were: alcohol (75%), marijuana (50%), cocaine (24%), and heroin (16%). Overall, 49% of participants also reported NMUPD with sedatives the class of medications most commonly used without a prescription (42%), followed by analgesics (37%) and anxiolytics (13%). In some cases, participants reported combining the non-medical use of prescription medications with alcohol (29%) or illicit drugs (20%). Individuals who reported an interpersonal traumatic event (e.g., assault) were significantly more likely to report NMUPD (55%) than those who did not (33%); $\chi^2(1, N = 264) = 7.23, p < .001$. In a hierarchical logistic regression, PTSD symptoms significantly predicted NMUPD after controlling for gender, age, income, and education, OR = 1.07 (95% CI = 1.04, 1.09), $p < .001$. Findings suggest that NMUPD is a concern among young adults referring for drug treatment in Kosovo, some of whom report health-jeopardizing behavior such as combining the non-medical use of prescription medications with the use of alcohol or illicit drugs. Trauma history and PTSD symptoms were significant predictors of NMUPD. Clinicians working with young adults referring for substance use treatment should assess the non-medical use of prescription drugs, trauma history, and PTSD symptoms.

ADVERSE LIFE EXPERIENCES AND NICOTINE USE AMONG SEXUAL MINORITY WOMEN

Vanessa Schick, PhD¹, Laura Witte, MPH², J. Michael Wilkerson, PhD²¹University of Texas School of Public Health, Houston, TX; ²UTHealth School of Public Health, Houston, TX

Introduction: Sexual minority women (SMW) have unique stressors that place them at increased risk for nicotine use relative to their heterosexual counterparts. Less attention has been paid to the diversity of life experiences among SMW and how those experiences contribute to differential risk within SMW.

Methods: *Study 1.* We partnered with an LGBTQ+ service organization to recruit sexual and gender minorities in Texas. To reach individuals disconnected from the community, additional participants were recruited through a social marketing campaign. Participants reported how many days out of the past 30 they smoked tobacco, chewed tobacco or smoked e-cigarettes. A total of 543 cis women completed the web-based survey with an average age of 21.88 (SD=10.66). A third of the sample was Hispanic with 54.5% (N=278) identifying as White, Non-Hispanic. Most identified as a lesbian (39.6%, N=211) or bisexual (41.1%, N=219). *Study 2.* To explore whether smoking among SMW with adverse life experiences was a function of those experiences or whether there was something unique about being a SMW with those lived experiences; data from an interviewer-administered survey with those unstably housed was explored. A time-location sampling approach was used.

Results: *Study 1:* Approximately 1/3 of the sample reported that they had smoked in the past 30 days with just under 10% (N=53) reporting daily smoking. Age, race, ethnicity and sexual orientation were not significantly related to smoking. Experiences of sexuality-related discrimination (OR=1.37, $p < .001$) were significantly related to smoking in the bivariate model. In the multivariate model, education, substance use (AOR=1.59, $p < .001$), housing insecurity (AOR=3.52, $p < .001$), intimate partner violence-IPV (AOR=2.10, $p < .001$) and sex work (AOR=3.90, $p < .05$) were related to smoking. Among SMW participants, 20.3% (N=110) reported past year experiences of housing insecurity, IPV or sex work; those who reported these experiences accounted for 37.4% (N=68) of recent smokers and 66% (N=35) of daily smokers. Of those who reported 2+ life experiences, 91.89% (N=34) smoked in the past 30 days. Of those who reported all three life experiences (N=15), all reported smoking in the past 30 days and 88.2% reported smoking every day. *Study 2:* Homeless sexual minority women were almost twice as likely to report smoking relative to their heterosexual counterparts ($p < .05$).

Conclusions: Smoking was related to adverse life experiences among SMW. Although encouraging someone with multiple competing immediate needs to prioritize smoking cessation may be challenging, behavior change experts working with homeless individuals have started to prioritize smoking cessation programs given the long-term health benefits. The present study suggests the importance of tailoring these interventions to SMW since it is women at these intersections who may be at greatest risk.

ASSOCIATION BETWEEN SYNDemic FACTORS AND CIGARETTE SMOKING AMONG TRANSGENDER WOMEN RESIDING IN NEW YORK CITY

Sitaji Gurung, MD, MPH¹, Brett M. Millar, PhD², H. Jonathon Rendina, PhD, MPH³, Jeffrey T. Parsons, PhD³¹CUNY Graduate School of Public Health and Health Policy, Flushing, NY; ²Graduate Center CUNY, New York, NY; ³Hunter College of the City University of New York (CUNY), New York, NY

Background: Smoking presents a greater risk of harm for HIV-positive individuals both from the cardiovascular standpoint and increased risk of various cancers and emphysema. Transgender women (TGW) experience higher rates of cigarette smoking compared to other groups. Despite these disparities, TGW are not included in smoking prevention interventions and pose a significant challenge to HIV-positive TGW and their providers. We considered the syndemics framework – assessing the presence of depression, childhood sexual abuse (CSA), intimate partner violence (IPV), and polydrug use – to help explain the greater prevalence of current smoking among TGW. The current study sought to address smoking prevention challenges by focusing on an understudied population.

Methods: The sample included 213 TGW in NYC recruited for a group-based intervention study targeting substance use and sexual risk. Logistic regression was used to assess the association between syndemic factors (individually, and as a summed score or count) and current smoking at the baseline assessment (i.e., pre-intervention).

Results: The sample was predominantly TGW of color – Black (31.9%) and Latina (28.2%); mean age was 34 and 34.7% were HIV-positive. Overall, nearly half of the participants (42.7%) reported as current smokers. In bivariate analyses, being Black, HIV-positive, unemployed, identifying as straight, and having lower income were positively associated with greater odds of current smoking, as were three of the four syndemic factors: CSA, IPV, and polydrug use. Age, education, and relationship status were not. In the multivariable model, adjusting for each of these covariates, having a greater number of syndemic factors was associated with increased odds of current smoking (AOR=1.4, *pp*

Conclusions: Having a greater number of syndemic factors was a significant predictor of current smoking. Our findings highlight the need for smoking-reduction interventions to also address syndemic factors among TGW, particularly among HIV-positive TGW. This has implications to increased training of healthcare providers in promoting smoking cessation interventions during regular visits. Health care providers have a unique opportunity to engage this population in a discussion of their personal strength, lifestyles, barriers and medication adherence and provide support to quit smoking successfully for those who are at high risk for cardiovascular disease.

ADDRESSING TOBACCO USE AMONG ASIAN AMERICAN PATIENTS WITH CHRONIC HEALTH CONDITIONS IN PRIMARY CARE

Khanh Hoa T. Nguyen, BA¹, Isabel Nguyen, BS², Emily Sa Nan Park, BS¹, Tung Nguyen, MD², George Lee, MD¹, Thu Quach, PhD¹, Janice Y. Tsoh, PhD³¹Asian Health Services, Oakland, CA; ²University of California - San Francisco, San Francisco, CA; ³University of California San Francisco, San Francisco, CA

Background: Smoking causes and worsens many health conditions, but tobacco use might not get addressed in many clinical visits due to time, competing clinical demands or other factors. Asian American male immigrants have high rates of smoking. This study examined documentation of the 5As (Ask, Advise, Assess, Assist, Arrange) among Asian American male patients who are smokers at a federally qualified health center.

Methods: We utilized electronic Health Record (EHR) data of 106 Asian American male daily smokers who participated in one of the two smoking cessation intervention trials. De-identified EHR progress notes, limited to one primary care visit immediately prior to trial enrollment, were coded for presence or absence of the documentation of the 5As. We used generalized estimating equations to adjust for provider clusters and examined the associations between selected health conditions and the occurrence of EHR-documented 5As.

Results: The participants' mean age was 56 (range: 28–73), with 62% Vietnamese, 24% Korean, and 14% Chinese. The mean cigarettes smoked daily was 9.4. Most (90%) had at least one chronic conditions: hyperlipidemia (68%), hypertension (59%), diabetes (30%), respiratory (20%), cancer (9%), cardiovascular (8%), or behavioral health (31%). The proportions of patients who had a 5A action documented in their progress notes of the selected visit were: 77% Ask, 25% Advise, 30% Assess, 14% Assist, and 8% Arrange. Tobacco-related discussion (Advise, Access or Assist) was documented in 46.2% of the patients, with diabetic patients less likely to have discussion documented (OR=0.4; *p*=0.04) than those who did not have diabetes. Patients with a behavioral health diagnosis were more likely to have "Advise" documented than those without such diagnosis (OR=3.1; *p*=0.02). Overall, 17% had no smoking related information noted, with cardiovascular patients more likely to have no smoking related documentation (OR: 5.5; *p*=0.02) than those who did not have cardiovascular disease.

Conclusions: While tobacco use related information was frequently documented, tobacco-related discussion was documented among slightly <50% of the patients including many with chronic conditions. Investigations are needed to identify and address barriers for providing tobacco intervention such as lack of time during a visit, provider training and patients' readiness for quitting.

BODY IMAGE AND CIGARETTE SMOKING AMONG YOUNG SEXUAL MINORITY LATINO MEN

Kaitlin N. Rozzell, BS, Kelsey A. Nogg, BA, Adoril A. Oshana, Aaron Blashill, Ph.D.

San Diego State University, San Diego, CA

Background: Sexual minority Latino men, an understudied population, engage in high rates of cigarette smoking. For example, the prevalence of smoking within the past 30 days among sexual minority Latino men in California was 41.8%, compared to 20.1% of their heterosexual counterparts. To date, no known studies have examined predictors of smoking specific to sexual minority Latino men. Body image variables have previously been explored as a predictor of cigarette smoking among women and college students; however, findings have generally been mixed. One explanation for these findings is the lack of testing interaction effects. Being preoccupied with one's weight, for instance, may only be associated with increased smoking under certain conditions. One such condition to explore is appearance orientation—cognitively and behaviorally investing in the importance of one's appearance. Thus, the current study explored the association between overweight preoccupation and smoking in addition to the moderating effects of appearance orientation on this association among a highly vulnerable group—young sexual minority Latino men.

Methods: Participants were 151 sexual minority Latino men living in the San Diego area ($M=24.18$ years old, $SD=3.19$) who completed an online study. The Multidimensional Body-Self Relations Questionnaire (MBSRQ-AS) was used to assess appearance orientation (AO), and overweight preoccupation (OWPRE). In addition, participants indicated the number of cigarettes they smoked per day. A binary variable was created: 10+ cigarettes/day vs. less than 10 cigarettes/day. A logistic regression model was conducted, using OWPRE as the focal predictor and AO as the moderator.

Results: A significant interaction between AO and OWPRE was revealed (OR: 0.08; 95% CI: 0.02, 0.38; $z = -3.2$; $p = .002$). Probing AO at low and high levels through simple slope analysis revealed that OWPRE predicted lower odds of smoking 10+ cigarettes/day only at high levels of AO (OR: 0.18; 95% CI: 0.06, 0.56; $z = -2.9$; $p = .003$).

Conclusion: Possessing high investment in one's appearance may serve as a protective factor against smoking behavior among sexual minority Latino men. Preoccupation with one's weight in combination with low levels of appearance orientation is indicative of higher rates of smoking. Interventions pertaining to the harmful effects of smoking on appearance may be effective in reducing smoking and its associated risks within this vulnerable population.

6:15 PM-7:15 PM

DO CHANGES IN FOOD INSECURITY AFFECT SMOKING STATUS? ANALYSIS OF THE 2003 AND 2015 PANEL STUDY OF INCOME DYNAMICS

Jin E. Kim-Mozeleski, PhD¹, Hilary K. Seligman, MD, MAS², Irene H. Yen, PhD³, Susan J. Shaw, PhD¹, David R. Buchanan, DrPH¹, Janice Y. Tsoh, PhD²¹University of Massachusetts Amherst, Amherst, MA; ²University of California San Francisco, San Francisco, CA; ³University of California Merced, Merced, CA

Smoking is disproportionately high among individuals who are socioeconomically disadvantaged. Food insecurity arises from lack of money or adequate access to enough food and is a stressor. Cross-sectional studies have reported that food insecurity is independently associated with higher smoking prevalence. We examined whether experiences of food insecurity over time were associated with changes in smoking status in a national longitudinal sample.

We analyzed data from the Panel Study of Income Dynamics, following 4,563 adult respondents from 2003 (current study baseline) to 2015. The outcome variable was smoking status change (continued smoking, stopped smoking, started smoking, and remained non-smoking). The primary independent variable was food insecurity status change (stayed food secure, stayed food insecure, became food insecure, and became food secure). We conducted logistic regression analyses using survey weights. Model 1 examined the likelihood of stopping vs. continuing smoking by 2015 among smokers at baseline, covarying average number of cigarettes per day at baseline. Model 2 examined the likelihood of starting smoking vs. remaining non-smoking by 2015 among non-smokers at baseline, covarying whether one ever smoked regularly. Both models controlled for socio-demographics, psychological distress, and receipt of food assistance.

The sample consisted of 75% men with a mean age of 47 years at baseline (2003), and were 13% African American and 75% White. From 2003 to 2015, 13% continued smoking, 10% stopped smoking, 2% started smoking, and 75% continued non-smoking; 84% stayed food secure, 5% stayed food insecure, 8% became food insecure, and 4% became food secure. In Model 1, becoming food insecure (vs. staying food secure) was independently associated with lower likelihood of stopping smoking (AOR=0.52, 95% CI 0.30, 0.88) among smokers at baseline. In Model 2, becoming food insecure (vs. staying food secure) was independently associated with higher likelihood of starting smoking (AOR=4.00, 95% CI 2.03, 7.86) among non-smokers at baseline.

Experiences of food insecurity were associated with smoking status over time for both smokers and non-smokers. In particular, those who became food insecure were less likely to stop smoking and more likely to start smoking. These results underscore the importance of considering the role of food insecurity in reducing socioeconomic disparities in cigarette smoking.

MOTIVATIONS FOR TOBACCO USE AND BARRIERS TO CESSATION AMONG URBAN YOUNG ADULTS IN BALTIMORE: FINDINGS FROM A QUALITATIVE STUDY

Daisy Le, PhD, MPH/MA¹, Gypsyamber D'Souza, PhD, MPH/MS², Meghan Bridgid. Moran, PhD, MA²¹Johns Hopkins Bloomberg School of Public Health, Washington, DC; ²Johns Hopkins Bloomberg School of Public Health, Baltimore, MD

Background: The landscape of tobacco use is rapidly changing. Evidence suggests that place of residence may be associated with smoking whether independently of, or in conjunction with, variables such as education, income, and socioeconomic status. In 2007, the prevalence of current smoking in Baltimore City surpassed Maryland's statewide prevalence by more than 10%. Moreover, poly-use of tobacco is increasing, with 12% of current adult tobacco users in 2014 reporting the use of more than one type of tobacco product during the past 30 days. While there is considerable research on cessation generally, there is less in-depth data on this population. Mobile-based programs are a potentially useful cessation tool for this population. This type of data is needed to inform effective cessation programs.

Objective: We sought to understand young adults' motivations for tobacco use, their perceived barriers to cessation, and their thoughts on mobile cessation programs (e.g., apps, text-based programs).

Methods: We engaged 97 tobacco users between the ages of 18 and 26 from Baltimore County, Maryland across 17 focus group discussions. Qualitative data were analyzed using framework analysis.

Findings: 85% (n=82) of our participants reported using more than one type of tobacco product during the past 30 days. Across tobacco products, the common theme for motivation of initiation, continued use, and poly-use included: boredom due to inactivity, the need for stress relief, the influences from family members and friends, and easy access to the variety of tobacco products. With regards to barriers to cessation, sub-themes that surfaced included the idea of self-control, belief that one was not actually addicted, and the influence of those within their social networks. Finally, mobile-based cessation programs were viewed favorably by our participants, with everyone indicating that these programs would substantially be more appealing than other paper- or phone-based cessation tools. Discussions suggested that the ideal program would provide tailored/customized prompts along the way, delivering cues to action such as relatable messages that would assist its' users along their own tobacco cessation journey. Existing social media platforms should also be leveraged for use to promote or deliver the cessation program.

Significance: Cessation programs for this population must address/account for poly-use. Use of other substances concurrently with tobacco must be addressed. Mobile technology and social media allow youth to manage cessation in their own time, and it fits into their existing patterns of media use and lifestyle, serving as a cue to action. But, this is not enough. Cessation programs (e.g., quit lines) may not be enough and are not addressing the built environment. Policies to address tobacco use could be better enforced (smoke-free homes, no sale of "loosies").

SMOKING DIFFUSION AMONG DIVERSE, URBAN AMERICAN ADOLESCENTS DURING HIGH SCHOOL

Kayla de la Haye, PhD, Heesung Shin, PhD, George Vega Yon, MA M.Sc., Thomas Valente, PhD

University of Southern California, Los Angeles, CA

Background: Influence from peers and friends is a consistent and important predictor of smoking initiation and regular cigarette use among adolescents, and youth rarely initiating smoking without exposure to smoking friends. Social network analysis has been applied to examine smoking diffusion through adolescent social networks, and the underlying social selection and social influence processes, however common limitations of this work include: a focus on 'case studies' of one or two networks; data collected before the year 2000; longitudinal data that span one year or less; and samples that lack diversity.

Aims: This study investigates the diffusion of smoking initiation among 1,425 diverse high school students (76% Hispanic) nested in four U.S. high schools from one urban neighborhood, and tracks changes in their friendship networks and smoking behaviors over four time points from 2010 to 2014, over their full 3-year high school period.

Methods: Regression models and longitudinal social network models (stochastic actor-based models; SABMs) were applied to test if high school friendship networks predict smoking initiation and diffusion. SABMs teased apart social selection and social influence effects related to smoking.

Findings: At the start of the 10th grade, about 1 in 4 students had initiated smoking, and by the end of the 12th grade, between one third and one half of students had initiated smoking, with rates varying by school. We found strong evidence of smoking initiation diffusing through friendship networks over the high school period, in 3 of the 4 schools. In these three schools, exposure to friends who had tried smoking predicted smoking initiation among non-smokers. In these schools, smoking was also closely linked to popularity in the friendship network: students who had initiated smoking gained popularity during high school.

In the one school where smoking initiation was not influenced by the friendship network, having friends who had tried smoking, or who smoked in the past month, did not predict smoking initiation. This school context was notably different on several dimensions: it had higher smoking rates and pro-smoking norms, and students who had initiated smoking became less popular during high school. We discuss the potential impact of school contextual factors, such as smoking norms and smoking popularity, on the diffusion of smoking initiation in adolescent friendship networks.

EVALUATION OF EMPOWERING PROMOTORES TO BE COMMUNITY-BASED TOBACCO CONTROL SPECIALISTS

Joe Tomaka, Ph.D., Ernesto A. Morales, PH.D., Michele Banner, PhD, Christine Spurny, MPH

New Mexico State University, Las Cruces, NM

The Empowering Promotores Program (EPP) trains and supervises Community Health Workers/Promotores de Salud (CHW/PdS) to work as tobacco control specialists in their local communities. The program also assists CHW/PdS with the development of Community Action Plans, tailored to the unique needs, resources, and contexts of their communities. Finally, the program provides ongoing supervision and support of community-based education and cessation activities.

In this first implementation, the EPP recruited 9 CHW/PdS and trained them to lead community-based educational activities, use brief intervention strategies (including motivational interviewing) to encourage cessation, and advocate for social justice surrounding tobacco. Training also facilitated the development of Community Action Plans that included cessation, education, and sustainability components. Following training, program supervisors monitored and assisted the CHW/PdS as they implemented their plans over seven months.

Evaluation data was collected during training and program implementation. During the 3-day training, CHW/PdS completed knowledge checks before and after each content module and also reported their perceived confidence regarding mastery of the material and ability to teach the content to others. After, they provided their overall rating of the training and rated how well the program met their training goals. During program implementation, outcome data was extracted from standard data collection logs that CHW/PdS completed at monthly intervals.

Analysis revealed that the training course improved knowledge by over 24% across all training modules from pre-test ($M=43.65\%$, $SD=17.50$) to post-test ($M=68.36\%$, $SD=18.36$); $t(35)=-6.53$, $p<.001$. Training also significantly improved perceived mastery of the material from pre-test ($M=3.36$, $SD=0.88$) to post-test ($M=6.76$, $SD=0.35$) on a 7-point scale; $t(6)=-9.17$, $p<.001$. Confidence to teach the material also significantly increased from pre-test ($M=3.10$, $SD=1.17$) to post-test ($M=6.74$, $SD=0.40$); $t(6)=-7.90$, $p<.001$. Furthermore, CHW/PdS rated the training positively ($M=6.90$) and felt it met their training goals ($M=6.52$).

Outcome data indicated that the program met or surpassed objectives related to program reach and impact. Some examples: CHW/PdS engaged 3,683 individuals in over 85 locations across southern NM, educated 467 class attendees, and counseled 120 tobacco users with a quit plan. These results provide support for the EPP.

HETEROGENEITY IN TOBACCO USE BEHAVIOR AMONG US BLACKS PER WORLD REGION OF BIRTH

Launick Saint-Fort, B.S., Kelvin Choi, PhD, MPH

National Institutes of Health, Bethesda, MD

Background: Smoking-related illnesses are the number one causes of death in the US Black community. US Blacks are a heterogeneous population by country of origin, but few previous studies investigated the prevalence of smoking among US Blacks by country of origin and age of immigration. We aim to examine the differences in tobacco-use behaviors among US Blacks by world region of birth and age of immigration.

Methods: Data from the 2006–2015 waves of the Current Population Survey–Tobacco Use Supplement was analyzed. We included participants who self-identified as Black race only ($n=48,912$). Based on participant self-reported country of origin, countries were classified into world regions (US, Africa, Europe, West-Indies). Age of immigration was calculated based on age, survey year, and self-reported year entering the US, dichotomized into before 13 vs. at or after 13 years of age. Participants reported their tobacco use behaviors (e.g., current cigarette and cigar smoking). Covariates included survey year, age, education, income, and U.S. census region. Data were weighted to be representative of the US Black population. Multiple logistic regression models adjusted for covariates were used to examine the associations between world region of birth, age of immigration, and tobacco use behaviors.

Results: Prevalence of current cigarette smoking among US Blacks varied significantly by world region of birth (US-born=17%, European-born=18%, African-born=5%, West Indian-born=5%; $p<0.01$). Compared to US-born Blacks, African-born Blacks were less likely to be current cigar smokers (AOR=0.06, 95% CI=0.01, 0.35). Among current smokers, African-born Blacks were less likely than US-born Blacks to start smoking regularly before 18 years of age (AOR=0.35, 95% CI=0.12, 0.99). Foreign-born Blacks are also less likely than US-born Blacks to smoke menthol flavored cigarettes ($p<0.05$). Furthermore, African-born Blacks are less likely than US-born Blacks (AOR=0.31, 95% CI=0.11, 0.86) to have their first cigarette within 30 minutes after waking up.

Conclusion: Tobacco use behaviors somewhat varied by world region of birth and age of immigration among US Black population. Interventions for smoking prevention and cessation need to recognize these differences. Further research is needed to examine the heterogeneity in perceptions and beliefs on tobacco-use behaviors within the US Black to inform tailored interventions.

INITIATION, CONTINUATION OF USE, AND CESSATION OF ALTERNATIVE TOBACCO PRODUCTS AMONG YOUNG ADULTS: A QUALITATIVE STUDY

Milkie Vu, MA¹, Betelihem Getachew, MPH¹, Jackelyn Payne, MPH¹, Thomas Kirchner, PhD², Carla Berg, PhD¹

¹Emory University, Atlanta, GA; ²New York University, New York, NY

Background: Diverse non-cigarette alternative tobacco products are increasingly popular in the United States, particularly among young adults. This study investigates reasons young adults initiate and continue use, potential motivations to quit, and strategies or approaches for cessation of alternative tobacco products. Products assessed included cigarettes, little cigars/cigarillos (LCCs), smokeless tobacco, e-cigarettes, and hookahs.

Methods: As part of a larger research study, we conducted 60 in-depth telephone interviews with tobacco users aged 18–24 years enrolled in college in the state of Georgia. Qualitative analytical techniques were used to code line-by-line and identify themes emerging from the data.

Results: Reasons for initiation, continued use, and (potential) cessation show both similarities and differences across tobacco products. Most commonly cited reasons for initiation include peer influence (all products), flavors and tastes (all products except for cigarettes), and ease of environmental access and/or low costs (LCCs, smokeless tobacco, and e-cigarettes). Participants discussed several influences on continued use such as peer influence (cigarettes, LCCs, and hookahs), stress management (all products except for hookahs), and co-use with other substances (cigarettes, LCCs, and hookahs). Primary motivations for cessation mentioned by participants were family responsibilities (cigarettes, e-cigarettes, and hookahs) and concern about current and future health (all products except for e-cigarettes). Frequently used strategies for cessation include avoidance of other tobacco users (cigarettes, LCCs, and hookahs) and reduction of nicotine intake (cigarettes and e-cigarettes).

Conclusions: Our findings suggest that researchers and health professionals should consider the differences in reasons for use and discontinued use of the range of tobacco products in order to develop targeted messaging strategies, particularly noting the differential impact of interpersonal influences and health concerns. We also point to a need for regulatory action that limits diversification and accessibility of different tobacco products.

LIVING WITH OTHER SMOKERS: DOES IT HELP—OR HURT—CANCER PATIENTS WHO SMOKE?

Robyn A. Pennella, N/A¹, Amy S. Farrell, M.A., M.P.H.², Leslie A. Robinson, Ph.D.², Margaret Fahey, Master of Arts¹

¹University of Memphis, Memphis, TN; ²The University of Memphis, Memphis, TN

Significance. Living with smokers might affect how oncology patients perceive the harms of smoking. Understanding these differences might improve cessation programs for oncology patients.

Methods. The sample consisted of 829 adult smoking oncology patients in the Mid-South surveyed about the effects of smoking on a cancer diagnosis. Participants responded to statements about the potential harms of smoking. Such statements involved beliefs about whether smoking causes cancer; whether smoking can lead to a second cancer; whether smoking interferes with the benefits of cancer treatment; whether smoking exacerbates the side effects of treatment; and whether quitting smoking improves one's health even though advanced cancer is present. Each statement was rated as *Very True* (0), *Somewhat True* (1), *Somewhat Untrue* (2), and *Very Untrue* (3).

Analysis. In this report, we explored differences between those living with no smokers (n=478), one smoker (n=251), vs. two or more smokers (n=100) on items measuring perceptions of potential harms of smoking. ANOVA revealed significant differences in perceptions between groups on two of our five questions about smoking-related harm, ps < .02. Follow-up tests revealed that those living with two or more smokers (M=2.16) were more likely than those living with no smokers (M=2.47) to report that people with cancer who smoke are at a higher risk of developing a second cancer. Similarly, those living with two or more smokers (M=2.05) were more likely than those living with no smokers (M=2.37) to believe that cigarette smoking can worsen the side effects of cancer treatment.

Conclusion. Results indicate that cancer patients living with two or more smokers are more likely to acknowledge smoking-related harms. It appears that cancer patients who live alone are more likely to deny the damage tobacco use can have on their treatment and possible recovery. Cessation programs in an oncology setting should consider targeting smokers who are the only smokers in their home for special intervention.

PREDICTORS OF SMOKING INITIATION AND PROGRESSION IN LOW INCOME YOUNG ADULTS

Daniel Rodriguez, 1914¹, Tiffanie Goulazian, BA², Heather A. Carlos, N/A³, Anna M. Adachi-Mejia, PhD³¹La Salle University, Philadelphia, PA; ²Children's Hospital of Philadelphia, Yardley, PA; ³Geisel School of Medicine at Dartmouth, Lebanon, NH

Background: Despite vast regulations limiting access to cigarettes, and environmental restrictions on where one can smoke, cigarette smoking remains the leading preventable cause of morbidity and mortality worldwide. Adolescence is a critical period for initiation and progression to a regular smoking habit, with the majority of adult regular smokers initiating smoking before age 18. Yet, less is known about smoking progression post high school in young adulthood, especially among low socioeconomic status (SES) youth, the population most likely to progress to a regular habit. We sought to better understand what factors predict cigarette smoking initiation and progression in low-SES young adults.

Methods: We obtained a nationally representative sample of data from the Panel Study of Income Dynamics (PSID), Transition to Adulthood (TA) supplement. Participants were (n=1,510) young adults who turned 18, completed or left high school, had families continuing to participate in PSID, and who had participated in a federal lunch program; our indicator of low SES (71.4% of the available sample). Using Latent Growth Curve Modeling (LGCM) to model individual trajectories of cigarette smoking (across four waves, 2007–2013), we assessed which low SES and smoking-related factors (i.e., sex, ethnicity, maternal smoking, peer smoking, family fighting/conflict, emotional disturbance, and adolescent sense of belonging) predicted smoking behavior at baseline as well as over time.

Results: Peer smoking (OR=1.398, 95%CI = 1.204, 1.622) and having a high school education or less (OR=2.109, 95%CI = 2.106, 3.686) were associated with higher odds of smoking at baseline. By contrast, being Black (OR=0.745, 95%CI = 0.579, 0.745), and living with a family that does not fight often/low family conflict (OR=0.833, 95%CI=0.716, 0.968) were associated with a decrease in the odds of baseline smoking. Having a high school education or less predicted continued smoking progression beyond baseline (OR=1.084, 95%CI=1.009, 1.166).

Discussion: Efforts aimed at reducing smoking in young adults warrants a unique perspective in conceptualizing how family factors influence smoking progression. These findings support development of targeted programs to address how smoking among low-SES youth develops, and provide insight into possible intervention points to address how family difficulties may affect smoking behaviors during this developmental period.

PREVALENCE AND CHARACTERISTICS OF SECONDHAND SMOKE AND SECONDHAND VAPOR EXPOSURE AMONG YOUTH IN FLORIDA

Jennifer Bayly, B.S.¹, Debra Bernat, PhD², Kelvin Choi, PhD, MPH³¹National Institute on Minority Health and Health Disparities and National Institutes of Health Clinical Center, Bethesda, MD; ²George Washington University, Washington, DC; ³National Institute on Minority Health and Health Disparities Division of Intramural Research, Bethesda, MD

Background: Secondhand smoke (SHS) exposure causes significant health issues. While less is known about the health effects of secondhand vapor (SHV) from electronic vapor products (EVP), recent evidence suggests it is not benign. We aim to describe the characteristics associated with past 30-day SHS and SHV exposure among a representative sample of youth in Florida.

Methods: Data from youth in middle school (MS, ages 11–13) and high school (HS, ages 14–17) who completed the 2016 Florida Youth Tobacco Survey were analyzed (n= 58,616). SHS and SHV were independently assessed by self-report of being in a car and/or room with someone using cigarettes or EVP, respectively. Demographics, environmental factors, cigarette and EVP use status, and SHS and SHV related beliefs were assessed. Descriptive statistics and weighted multivariable logistic regressions were performed.

Results: Overall, 42% of the sample reported SHS exposure and 29% reported SHV exposure during the past 30-days. The prevalence for each was higher in HS than MS youth. SHS and SHV exposure was most common among non-Hispanic white youth (48% and 37%, respectively), followed by non-Hispanic American Indian/Alaskan Native youth (43% and 36%, respectively). Housing type was associated with SHS exposure, with prevalence rates higher among those living in trailers/mobile homes than those in stand-alone houses (AOR 1.59, 95% CI 1.46-1.73). Nonmetropolitan youth were more likely to be exposed to SHS than metropolitan youth (AOR 1.11, 95% CI 1.03-1.20) but less likely to be exposed to SHV (AOR 0.86, 95% CI 0.81-0.87). Beliefs on the harms of SHS and SHV had differing associations with exposure to SHS and SHV. Prevalence of SHS (AOR 1.71, 95% CI 1.53-1.91) and SHV (AOR 1.95, 95% CI 1.74-2.19) was higher among youth who believed SHS was harmful compared to youth that did not. Conversely, belief that SHV is harmful had a negative association with SHS exposure (AOR 0.86, 95% CI 0.81-0.92) and SHV exposure (AOR 0.55, 95% CI 0.52-0.59).

Conclusions: Factors associated with SHS and SHV exposure are similar but not identical. Interventions targeted at reducing SHS will likely have an impact on SHV as well if smoke free education and policies are expanded to be tobacco free initiatives. More research is needed to understand in what settings youth are being exposed to both SHS and SHV. Further, the sources that inform youth's beliefs regarding SHS and SHV should be investigated.

PROGRAM UTILIZATION AND QUIT OUTCOMES BY MODE OF ENTRY AMONG CLIENTS ENROLLED IN A QUITLINE

Uma Nair, PhD¹, Ryan C. Reikowsky, MA, MPH¹, Betsy C. Wertheim, MS², Cynthia Thomson, PhD, RD¹, Judith S. Gordon, PhD¹¹University of Arizona, Tucson, AZ; ²University of Arizona Cancer Center, Tucson, AZ

Tobacco cessation quitlines are an integral part of comprehensive tobacco treatment nationally. Clients enter quitline services through direct referrals from a health care provider (provider referral), or proactively call the quitline on either advice from their health care provider (passive referral) or through other sources like media or family and friends (self-referral). While provider referral systems are a cost-efficient model to expand quitline reach, research evaluating differential change in clients' smoking behavior based on mode of entry is limited. The purpose of this study was to examine how mode of entry may influence program utilization and quit outcomes in clients enrolled in the Arizona Smokers' Helpline. Clients who completed a 7-month follow-up phone visit between January 2011 and June 2016 ($N=18,650$) were categorized by mode of entry as provider proactively referrals (27%), passive referrals (9%), or self-referrals (63%). Logistic regression was used to measure the association between mode of entry and use of tobacco cessation medication and quit outcomes (30-day tobacco abstinence) at 7 months. Multinomial logistic regression was used to measure the association between mode of entry and number of coaching sessions. After controlling for potential confounders, compared to self-referred clients, provider referred clients were least likely (OR, 0.88; 95% CI, 0.81–0.97), while passively referred clients were most likely (OR, 1.14; 95% CI, 1.00–1.30), to report tobacco abstinence. Proactively referred (OR, 0.79; 95% CI, 0.70–0.88), but not passively referred, clients were 21% less likely to report tobacco cessation medication use than self-referred clients. There was no significant association between mode of entry and number of coaching sessions. Unlike many previous studies, we found that proactive referrals were associated with lower utilization of tobacco cessation medication and less successful quit outcomes. We also found that passively-referred smokers are a unique group. In addition to optimizing use of cessation medication, there is a need to examine potential barriers among both providers and provider-referred clients enrolling into quitline services.

TESTING THE MECHANISMS OF ACTION OF INTEGRATED TELEMEDICINE FOR SMOKING CESSATION USING SELF-DETERMINATION THEORY

Edward Liebmann, MA¹, Kristopher Preacher, PhD², Kimber P. Richter, PhD³, A. Paula Cupertino, PhD⁴, Delwyn Catley, PhD⁵¹University of Kansas, Kansas City, MO; ²Vanderbilt University, Nashville, TN; ³Department of Preventive Medicine and Public Health, University of Kansas School of Medicine, Kansas City, KS; ⁴University of Kansas Medical Center, Kansas City, KS; ⁵Children's Mercy Hospital, Kansas City, MO

A recent randomized controlled clinical trial for rural smokers—Connect2Quit—compared the effectiveness of telemedicine counseling that was integrated into smokers' primary care clinics (Integrated Telemedicine—ITM) versus quitline-like telephone counseling (QL), delivered to smokers in their homes. The interventions delivered in this trial were based on Self-Determination Theory (SDT). Mediation analysis of theoretically-based behavioral RCTs can advance understanding of behavior change theory as well as specific intervention mechanisms. The aim of this study was to evaluate our SDT-based conceptual model using mediation analysis to evaluate the effects of telemedicine and phone counseling on smoking cessation. The sample included 560 smokers from rural Kansas. The counseling format and content were designed to be the same across both conditions (ITM vs QL), and took place in four sessions between study baseline and month 3. Follow-up assessments were conducted at months 3, 6 and 12. The analysis used structural equation modeling (SEM) with latent change scores for the SDT constructs, which were measured at baseline and 3-months. The outcome measure was biochemically verified 7-day point prevalence at 12-months. Mediating paths were estimated using maximum likelihood and their confidence intervals were estimated using Monte Carlo simulation. Participants in ITM reported significantly greater perceived health care provider autonomy support compared to participants in QL ($b = .347, p < .05$). At 3-months, therapeutic alliance ($b = .508, p < .05$) and change in perceived support provided by health-care providers ($b = .164, p < .01$) predicted gains in perceived competence to quit smoking (PC). Change in PC was associated with greater odds of cessation at 12 months ($OR = 1.50, p < .01$). The mediation analysis showed that compared to quitline, ITM was indirectly associated with quitting smoking by increasing perceived autonomy support and perceived competence to quit smoking (indirect effect = .029, 95% CI [.004, .053]). Integrated telemedicine influences the likelihood of smoking cessation by enhancing perceived support from the healthcare team, rather than enhancing perceived interpersonal support through telemedicine. These results provide theoretically informed support for the integration of smoking cessation services—even those delivered from a distance—into primary care settings.

TOBACCO CONSUMPTION PATTERN AMONG AUTO RICKSHAW DRIVERS IN CHENNAI CITY, TAMIL NADU, INDIA

Delfin Lovelina Francis, MDS

Dr MGR Medical University, Chennai, Tamil Nadu, India

Background: Tobacco use is a major preventable cause of premature death and diseases, currently leading to five million deaths worldwide which are expected to raise over eight million deaths worldwide by 2030. India is the second largest consumer of tobacco in the world. Cigarettes and Other Tobacco Products Act (COTPA) is a powerful Indian national law on tobacco control. The prevalence of tobacco use among adults (15 years and above) is 35% and the prevalence of overall tobacco use is 48% among males. This study is contemplated with an aim to assess the prevalence of tobacco consumption and the associated factors involved in its consumption, as this group of the population is under constant pressure and account for the workforce of the country. So through this study we could be able to know

* The reasons of consumption. * Amount of consumption * Awareness of ill effect of tobacco consumption * Out of Pocket expenditure.

MATERIALS AND METHODS: A cross sectional descriptive study was conducted among 400 Auto Rickshaw Drivers in Chennai City. Auto drivers who were working for more than two years and present on the day of examination and who were willing to participate in the study were included. Cluster random sampling technique was used. Data was collected using a Survey Proforma which comprised of a Questionnaire which can assess the frequency of consumption, age of initiation, the amount of consumption, mental stress, economic factors, any past history of disease and most importantly the awareness towards oral cancer. Age, tobacco consumption pattern, reasons of consumption, amount of consumption, harmful effects of tobacco are the variables. Chi-square test was used to test the significance between groups.

RESULTS: Prevalence among auto rickshaw drivers for consumption of tobacco products was very high (87%). Auto rickshaw drivers were mostly used tobacco in the form of Gutkha (72%) and bidi (40%) in comparison to other products. It also shows that they use cheap tobacco products. Most of the auto rickshaw drivers start using tobacco products in age less than 18 years (80%) and associated factors for tobacco use are due to friends and their influence (78%). Awareness level among auto rickshaw driver was high (70%) but still uses tobacco products because of its addiction (66%). In the opinion of auto rickshaw drivers increase in tax may reduce its consumption and the majority of drivers (70%) think that tobacco must be banned.

CONCLUSION: Prevalence of tobacco use among auto rickshaw drivers was very high. Mostly they use tobacco products to reduce stress, to be awake or to remove nervousness but a large number of participants also use them without any reason. Almost one half of the study population was suffering from tobacco related diseases like cough, ulcer on mouth, lung disorder. They are in definite need of tobacco cessation activities.

DEVELOPMENT OF A BILINGUAL MOBILE APP TO IMPROVE ADHERENCE TO ENDOCRINE HORMONE THERAPY AMONG BREAST CANCER PATIENTS

Patricia Chalela, DrPH, MPH¹, Edgar Muñoz, MS¹, Andrea Fernandez, MPH¹, Cliff Despres, BJ¹, Devasena Inupakutika, MA², Chetan Basutkar, MS², David Akopian, PhD², Amelie Ramirez, DrPH¹

¹UT Health San Antonio - Institute for Health Promotion Research, San Antonio, TX; ²University of Texas at San Antonio, San Antonio, TX

Background: Adjuvant endocrine hormonal therapy is highly effective and appropriate for nearly all women with hormone receptor-positive tumors, making such treatment the most widely prescribed therapy for patients with this type of breast cancer. Despite the proven benefits in reducing cancer recurrence and improving survival, hormone therapy adherence is suboptimal (less than 80%). About 33% of patients do not take their medication as prescribed and are at increased risk of disease recurrence and increased mortality.

Objective: We present the design and development process of a theory-based, culturally tailored, interactive mobile app to improve adherence to endocrine hormone therapy among breast cancer patients as the initial phase of a two-group randomized clinical trial study.

Methods: Four focus groups (n=21) were conducted with breast cancer patients and personal semi-structured interviews (n=8) with oncologists, nurses, and patient navigators to assess barriers and facilitators to endocrine hormone therapy adherence, key symptoms, app content, and features. Qualitative data informed the initial design and development of app mock-ups; these were assessed with two additional focus groups (n=10) and based on formative research a functional phone app prototype was developed for beta testing.

Results: Inputs from patients and healthcare team members helped to identify specific app content and features. Key themes included the importance of increasing patient education, enhancing self-efficacy, facilitating communication with the medical team and helping patients to develop self-care skills to promote optimal adherence to hormone therapy. Specific app features included notification pop-ups, reminders, motivational messages, symptom tracking and management tips, educational content, social networking among patients, communication with a patient navigator, local resources, including support groups, and technical support. In addition to colors, background and icon preferences, patients emphasize the need for a user-friendly app that is easy to navigate with simple and clear educational content.

Conclusions: We followed an iterative and patient-centered design process to develop a bilingual, culturally tailored and interactive mobile app prototype to be used in a randomized control trial. The anticipated outcome is a scalable, evidence-based and easily disseminated intervention with potentially broad use to patients using oral anticancer agents.

THE ROLE OF SLEEP LATENCY AND SUBJECTIVE PAIN ON THERMAL PAIN SENSITIVITY IN GYNECOLOGIC CANCER

Janae L. Kirsch, BA¹, Elizabeth L. Kacel, MS¹, Chantel M. Ulfing, MS¹, Adaixa Padron, BS¹, Shan Wong, PhD¹, Diego Esparza-Duran, PhD¹, Stephanie Smith, PhD², Christina S. McCrae, PhD³, Michael E. Robinson, PhD¹, Deidre B. Pereira, PhD¹

¹University of Florida, Department of Clinical and Health Psychology, Gainesville, FL; ²American Psychiatric Association, Arlington, VA; ³University of Missouri Health, Columbia, MO

Background: Pain is a common experience for women diagnosed with gynecologic cancer, contributing to greater depressed mood, sleep disturbances, and likelihood of future chronic pain. However, few studies have used quantitative sensory testing (QST) to examine the relationship between quantitative pain and psychosocial factors in gynecologic cancer.

Methods: Participants were 43 women ($Mage=59.77\text{yrs}\pm 10.06$) enrolled as part of a larger RCT examining psychological intervention effects on health and well-being in gynecologic cancer. Six to eight weeks following gynecologic cancer surgery, participants completed baseline assessment of depressive symptomatology (Beck Depression Inventory-II), sleep quality (Pittsburgh Sleep Quality Index, PSQI), and subjective pain (McGill Pain Questionnaire, MPQ). All participants underwent a temporal summation of pain protocol via QST. Heat was applied to the volar surface of the forearm with stimuli increasing from 45°C to 52°C. Participants were asked to rate their pain during testing (peak pain intensity), and 15 and 30 seconds after stimulus removal (after sensation pain).

Results: After controlling for (a) factors associated with cancer pain (surgical invasiveness, receipt of chemotherapy, poor prognosis cancer type, advanced cancer stage), (b) history of chronic pain, and (c) pain medication use prior to testing, bootstrapped linear regression analyses revealed greater sleep onset latency ($B=3.153$, $p=.042$, BCa 95% CI: .302–6.374) and greater MPQ sensory pain scores ($B=.711$, $p=.022$, BCa 95% CI: .110–1.199) were independently associated with greater after sensation pain at 15 seconds. Only greater MPQ sensory pain scores were associated with greater after sensation pain at 30 seconds ($B=.290$, $p=.031$, BCa 95% CI: .017–.496). Depression was not significantly associated with peak pain intensity or after sensation pain. The overall models accounted for 41.7% and 43.8% of the variance in after sensation pain at 15 and 30 seconds, respectively.

Conclusions: These results suggest that greater time to sleep onset and subjective sensory pain are related to greater after sensation of experimentally-induced pain in women receiving major abdominal surgery for gynecologic cancers. By identifying those with greater sleep disturbances and higher reported subjective pain, we may be able to identify women at-risk for central sensitization of clinical pain. Future research should explore whether interventions that improve sleep and subjective pain may contribute to lower pain sensitivity and better quality of life in women with gynecologic cancer.

A PROSPECTIVE, PILOT STUDY OF A MOBILE APP TO INTERVENE ON CANCER PATIENTS' FINANCIAL BURDEN

George Tran, BS¹, Ian Manners, MBA², Ben Gagosian³, Jonathan Nicolla, MBA⁴, Fred Friedman, BA⁴, Greg Samsa, PhD⁵, Kathryn I. Pollak, PhD⁴, Yousuf Zafar, Associate Professor⁶

¹Duke University School of Medicine, Durham, NC; ²Vivor, New York, NY; ³Vivor, Portland, OR; ⁴Duke University, Durham, NC; ⁵duke university department of biostatistics and bioinformatics, Durham, NC; ⁶Duke Cancer Institute, Durham, NC

Purpose: Patients with cancer are facing increasing treatment-related financial burdens in the form of out-of-pocket expenses and are often unaware of resources available to help them. The primary purpose of this study was to evaluate the usability of Bridge, a mobile app designed to navigate patients to financial assistance programs. The secondary purpose was to determine whether Bridge could increase knowledge of financial aspects of cancer care.

Methods: Adults with cancer who reported out-of-pocket treatment-related costs and were receiving treatment in solid tumor oncology clinics were asked to utilize the app. Bridge uses patients' age, diagnosis, treatment regimen, insurance status, and household income information to determine eligibility and generate a personalized list of financial assistance programs from a proprietary database. Diagnosis and treatment regimen were manually inputted into the app by study staff. Patients manually entered their age, household size, income, and insurance type. Usability of Bridge was assessed via the validated System Usability Scale (SUS; score > 68 is above average). Patients were also asked if: "this tool improved my knowledge of the financial aspects of cancer care and what I can do about it" and "using this app was helpful with my financial concerns." All responses were measured using a 5-point Likert scale. This study was funded on a National Cancer Institute Small Business Technology Transfer grant (R42CA210699).

Results: Thirty patients were enrolled. 36% of patients were male, 73% were white, 97% had high school education or greater, 23% were employed part- or full-time, and 48% had either Medicare or Medicare plus additional insurance. Median annual household income was \$60,500 (mean = \$63,078). The median SUS score was 85 (mean = 84, range = 62.5–100). 83% of patients agreed/strongly agreed that Bridge improved knowledge of the financial aspects of cancer care. 53% of patients agreed/strongly agreed that the app was helpful with financial concerns.

Discussion: Bridge demonstrates high usability and potential to improve patient understanding about financial aspects of cancer care. Interventions such as Bridge could allow for greater dissemination of resources to patients in need, who may not otherwise have the appropriate access or understanding of how to apply for financial assistance.

THE GLEAN RESEARCH STUDY: REDUCING HEALTH DISPARITIES THROUGH INDIGENOUS QUALITY OF LIFE

Maria C. Crouch, M.S.

Alaska Native Tribal Health Consortium, Wasilla, AK

According to the Indian Health Services (2017), Alaska Native (AN) and American Indian (AI) people's leading cause of death is cardiovascular disease (CVD) and mortality rates related to CVD are at a ratio of 189.7 to 1.0 for all other races in the nation. Multiple factors contribute to health disparities related to CVD among AN /AI peoples including smoking, physical activity, nontraditional diet, and medication adherence. The aim of the Goodness of Life for Every Alaska Native (GLEAN) study was to mitigate health disparities and target multiple risk behaviors through understanding quality of life (QOL) as it relates to AN adults in the Norton Sound Region of Alaska. A sample of 15 AN adults (6 male, 9 female) with a mean age of 56 was recruited. After a QOL word association activity, participants were asked write words or statements representing their unique QOL on sticky notes and put them on the wall. Participants completed data analysis as a group by discussing and arranging QOL sticky notes into themes. Five focus groups identified the following 9 QOL themes as most salient: family, subsistence, access to resources, health and happiness, traditional knowledge and values, acts of self, providing, sobriety, and healing. QOL themes, namely, access to resources indicate rural health disparities and highlight the need for community based participatory research (CBPR). Baseline data for participants also indicated social and health inequities, such as average income levels significantly lower than the state and national means, high rates of environmental exposure to tobacco, limited physical activity related to health issues, history of high cholesterol and/or blood pressure, and a family history of cancer and/or CVD. Further research will be used to construct a culturally grounded measure of AN adult QOL aimed at targeting and reducing multiple risk behaviors and improving heart health. Additionally, culturally appropriate approaches to determining strengths, values, and indigenous knowledge are a method of mitigating health disparities, increasing disease prevention, and fostering community health promotion.

USABILITY TESTING OF VENOUS THROMBOEMBOLISM PROPHYLAXIS TOOL

D'Arcy S. King, PhD, Sundas Khan, MD, Jeffrey Solomon, BFA, Kunti Niranjana, BA, David J. Rosenberg, MD

Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Manhasset, New York, Manhasset, NY

Background: Venous thromboembolism (VTE) is a common, preventable hospital acquired event. Northwell Health is launching a system-wide initiative to regulate VTE risk assessment and prophylaxis to reduce VTE events in patients by implementing the Caprini and IMPROVE clinical prediction rules, which have been identified by the Center for Medicare and Medicaid Services as essential components of VTE prevention. Prior to the system-wide implementation, Northwell Health conducted usability testing on the VTE tool prototype to assess provider perceptions and to help facilitate adoption and wide scale usage of the tool.

Methods: This observational study was conducted with 24 healthcare providers (attending, residents, PAs and NPs) across different service lines (gynecology, obstetrics, orthopedics, medicine, neurology and surgery). Participants were given two test cases that mirrored real-world scenarios to assess their likelihood to adopt and use the VTE prototype tool. During each case, participants partook in a think aloud session, verbalizing their decision-making process while interacting with the tool. Following each case, participants completed the system usability scale (SUS) and post task interview. During usability testing all human-computer interactions, including audio and continuous screen capture, were recorded. Participants' comments and interactions with the tool during think aloud sessions and post task interviews were placed into coding categories and then analyzed for generalizable themes by three independent coders.

Results: Of the 26 participants, 50% were female with a mean age of 33.125 (SD 8.237). The average SUS across the different services lines was 72.39 which translates to a C grade. Each participant's comments were grouped into three overarching themes: functionality, visibility/navigation, and content. Several barriers to adoption were identified during this process. They included the need to personalize the workflow for each service line; minimize the number of boxes and clicks; clearly define the risk models for each service line; include additional background and explanation on risk scores; and provide treatment guidelines recommendations for each of the order sets.

Conclusion: An important step towards providing quality healthcare to patients at risk of developing a VTE event is providing user-friendly tools at the point of care. Following usability testing of the VTE prototype tool, we recognized significant opportunities to impact provider behavior and acceptance. The rigor and breadth of this usability testing should increase provider adoption and retention of the VTE tool.

USE OF CANNABIS, SUICIDE, AND MENTAL WELL-BEING AMONG THE YOUTH OF TODAY - THE SOLDIERS OF TOMORROW

Riki Tesler, PhD¹, Yossi Harel-Fisch, Prof.²¹Ariel University, Ariel, Hefa, Israel; ²Bar ilan university, Ramat Gan, HaMerkaz, Israel

Background: In recent years various studies have shown a link between the use of cannabis and reported mental distress, including suicidal thoughts and intent, among youth.^{1,2} Research data from the Israel Anti-Drug and Alcohol Authority found that 11% of teens report using cannabis between the ages of 15–18, a significant increase in the years 2010 to 2017.

Purpose: • Examine the relationship between recreational (non-medical) use of cannabis and suicidal thoughts and behavior.

- Examine the role of mental well-being as a mediator between the use of cannabis and suicidal thoughts and behavior.

- Examine the differences between boys and girls in the usage rates of cannabis and patterns of suicidal thoughts and behavior.

Method: Secondary analysis of the results of the Israeli HBSC survey for 2014, conducted using anonymous self-administered questionnaires in the classroom that include valid and reliable indicators. Target population: Students in grades 10–12 in the public secular and religious schools in Israel.

Sample: A sample of N=5000 based on a national sample by administrative levels by and by grade levels, where the sampling unit is the homeroom class.

Findings: The findings show that nearly 15% of boys and 5% of girls used cannabis at least once in their life. Moreover, about 10% of boys and 4% of girls reported use at least once in the last 30 days. About 11% of the subjects reported suicidal thoughts regardless of gender. Nearly 4% of the boys and 2% of the girls reported at least one suicide attempt in the last 12 months that ended with an injury requiring medical treatment. In the multivariate analysis of subjects who used cannabis at least once compared to those who never used, users were three times more likely to have suicidal thoughts, four times more likely to plan a suicide attempt, and 9.5 times more likely to commit one suicide attempt in the past year. Furthermore, those who reported using cannabis in the last 30 days were five times more likely to have suicidal thoughts, six times more likely to plan a suicide attempt, and 15 times (!) more likely to attempt suicide that ended in injury requiring medical treatment. The findings of the SEM analysis clearly indicate that in both genders cannabis use indeed predicts more mental and physical symptoms and less satisfaction with life.

Conclusions: There is a strong association between cannabis use and suicidal thoughts and behavior among adolescents, above and beyond the association with other variables in the study. In view of the dramatic increase in cannabis use in Israel in recent years, there is a reasonable basis to assume that suicidal thoughts and behavior rates will rise accordingly. Therefore, there is an urgent need to prepare for this eventuality among the youth population as well as soldiers in compulsory military service in the Israel Defense Forces (IDF).

EFFECTS OF ILLNESS REPRESENTATIONS OF DIABETES AND HYPERTENSION ON DEPRESSION IN DIABETES CO-MORBID WITH HYPOTENSION PATIENTS

Lu Ma, Ph.D. student¹, Nelson C. Y. Yeung, Ph.D.², Alice Pik Shan Kong, Ph.D.³, Rong Shi, Master⁴, Joseph Tak Fai Lau, Ph.D.¹

¹School of Public Health and Primary Care, The Chinese University of Hong Kong, Hong Kong, N/A, Hong Kong; ²The Chinese University of Hong Kong, Hong Kong, N/A, Hong Kong; ³Department of Medicine & Therapeutics, The Chinese University of Hong Kong, Hong Kong, N/A, Hong Kong; ⁴School of Public Health, Shanghai University of Traditional Chinese Medicine, Shanghai, Shanghai, China (People's Republic)

Background: Diabetes mellitus (DM) is one of the most prevalent and consequential diseases. In China, more than 77% of DM patients co-morbid with hypertension (HT), which shares common causes with DM and self-care is congruent with that for DM. Co-morbidity substantially increase the odds of having depression in DM patients. It was found that illness representation-DM (IR-DM) (i.e., people's beliefs and perceptions about their DM) was useful predictor of depression in DM patients. However, in DM co-morbid with HT patients, whether illness representation-HT (IR-HT) (i.e., people's beliefs and perceptions about their HT) is also important is still unclear.

Objective: to examine: 1) whether IR-DM could explain the variances in depression; 2) whether IR-HT could explain more variances in depression beyond what is accounted for by IR-DM.

Methods: DM co-morbid with HT adult patients (n=524, 63.5% female, Mean_{age} = 64.9 years) were recruited from community health centers in Shanghai, China. IR-DM, IR-HT and depression were measured in a cross-sectional survey. IR-DM and IR-HT were measured in multiple aspects, including identity, consequence, timeline, personal control, treatment control, coherence, concern and emotional response (using Brief Illness Perception Questionnaire).

Results: Hierarchical regression results showed that after adjusting for background variables, IR-DM dimensions significantly explained 20% of variance in depression; specifically, perceptions of more serious consequence ($\beta=0.11$) and negative emotional response ($\beta=0.34$), shorter timeline ($\beta=-0.12$) and less concern about DM ($\beta=-0.11$) were significantly associated with more depression. Beyond IR-DM, the addition of IR-HT dimensions explained more variance in depression ($R^2_{\text{change}} = 0.06, p < 0.001$); *emotional response* ($\beta=0.25$) was significant, moreover, attributing symptoms to DM (i.e., identity, $\beta=0.09$) and timeline ($\beta = -0.08$) were marginally significant associated with depression.

Conclusions: This study for the first time revealed that in addition to IR-DM, IR-HT has additive values in explaining depression in DM co-morbid with HT patients. Interventions targeting on altering patients' representations of DM (i.e., reducing consequence and emotional response, and increasing timeline and concern) as well as their representations of HT (i.e., reducing identity and emotional response, and increasing timeline) can be expected to reduce depression in these patients.

6:15 PM-7:15 PM

CONFLICT ABOUT CONFLICT: DOES FAMILY DISAGREEMENT ABOUT AMOUNT OF CONFLICT RELATE TO OUTCOMES IN PEDIATRIC DIABETES?

Bret A. Boyer, Ph.D.¹, Christine Gale², Kate Deatrach¹¹Widener University, Philadelphia, PA; ²Widener University, Chester, PA

Children with type1 diabetes (T1D) transition from a parent-managed to a self-managed process of diabetes care across pre-adolescence and adolescence. Previous studies have shown significant relationships between parent-patient conflict about T1D self-care activities, glycemic control, and hypoglycemic episodes. This pilot study explored whether disagreement between family members about conflict may represent a stressor additional to the amount of conflict among 242 children (aged 12–15, 52.5% using insulin pumps, 51.2% female, 79.3% Caucasian) with T1D, their mothers, and fathers. That is, do families experience a meta-level of conflict, or conflict about conflict. Mother-Child disagreement (M-Ccon), Father-child disagreement (F-Ccon), and Mother-Father disagreement (M-Fcon), calculated as absolute values in difference scores to represent degree of discordant report of conflict, were entered into hierarchical multiple regressions after conflict scores reported by child/patients (Ccon), mothers (Mcon), and fathers (Fcon), respectively, to test if difference scores accounted for significant additional variance in Glycosulated hemoglobin (HbA1c), Self Care Inventory (SCI) scores, and severity of reported hypoglycemic episodes. Disagreement about conflict accounted for no additional significant variance in HbA1c or in severity of hypoglycemic episodes. M-Ccon ($R^2\Delta=.02$, $p=.038$, Partial $R=.14$) contributed significantly beyond Mcon to prediction of child SCI scores, beyond Ccon ($R^2\Delta=.09$, $p=.001$, Partial $R=-.31$) to prediction of mother's SCI, and beyond Ccon ($R^2\Delta=.06$, $p=.001$, Partial $R=-.27$) to prediction of fathers' SCI. M-Ccon ($R^2\Delta=.022$, $p=.02$, Partial $R=-.21$) and F-Ccon ($R^2\Delta=.02$, $p=.024$, Partial $R=.16$) scores each accounted for significant variance in mothers' SCI report, beyond that accounted for by Fcon. Results suggest that discordant observations and report of diabetes-specific conflict may represent stress and conflict additional to the general amount of conflict that family members report, and discordance between mothers and patients may constitute a "conflict about conflict," relating to self-management behavior, especially as observed by mothers. Implications may involve differences in coping or communication about conflict between mothers and children, and may warrant further investigation.

EVALUATING THE RELIABILITY AND VALIDITY OF THE SPANISH VERSION OF THE SF-12 IN HISPANICS

Jie Hu, PhD, RN, FAAN¹, Thomas P McCoy, PhD, PStat², Fei Zhan, PhD³, Debra C. Wallace, PhD, RN, FAAN², Sheryl L Coley, DrPH, MPH², Karen A Amirehsani, PhD, FNP-BC²¹The Ohio State University, Columbus, OH; ²The University of North Carolina at Greensboro, Greensboro, NC; ³The University of North Carolina at Greensboro, Greensboro, OH

Purpose: Hispanics in the U.S. often report worse health status and perceive poorer health-related quality of life due to stressors associated with migration, economic hardship, changes in social ties, and cultural differences. Social factors, such as literacy, language, and culture, may influence understanding and interpretation of health-related quality of life in Hispanics. The purpose of this study was to evaluate the reliability and validity of health-related quality of life measure, the Spanish version of the SF-12 v2® among Hispanics with type 2 diabetes and their family members.

Methods: Participants with type 2 diabetes and their family members (N=182) were recruited at clinics, physician offices, and churches in central North Carolina. The data were collected through face-to-face interviews in Spanish from both participants and family members on health-related quality of life measured with the Spanish version of the SF-12 v2®. Reliability and validity were assessed using composite reliability, principal components analysis, and known-groups comparisons.

Results: Reliability of the physical (.82) and mental (.86) component summaries was adequate. Known-groups comparisons revealed lower average health-related quality of life for every subscale of the SF-12 as well as for the two component summaries (PCS $md = -4.06$, $p = 0.001$; MCS $md = -3.76$, $p = 0.021$). Factorial validity was supported for the eight subscale structure but less so for the two component summaries.

Conclusions: The Spanish version of the SF-12 showed good reliability and validity. Health care providers can use the SF-12 to measure health-related quality of life in Hispanics with type 2 diabetes and their family members.

BEVACCINATED: DESIGNING A WEB APP TO PROMOTE TEEN VACCINATION UPTAKE

Julia Berteletti, MSW¹, Sophia Strickfaden, MA², W. Gill Woodall, PhD¹, Randall Starling, PhD³, Gregory Zimet, PhD⁴, Nathan Stupiansky, PhD⁵, Lance Chilton, MD⁶

¹Klein Buendel, Inc., Golden, CO; ²Klein Buendel, Golden, CO; ³Center on Alcohol, Substance Abuse, & Addictions; University of New Mexico, Albuquerque, NM; ⁴Adolescent Medicine; Indiana University, Indianapolis, IN; ⁵The University of Arizona Mel & Enid Zuckerman College of Public Health, Tucson, AZ; ⁶University of New Mexico Pediatrics, Albuquerque, NM

While vaccination rates for *young* children in the United States currently meet recommended standards, the Centers for Disease Control reports *adolescent* vaccine uptake to be less than optimal, and in the case of the Human Papillomavirus (HPV) vaccine, seriously below desired uptake levels. To address this deficit, a web-browser application prototype, BeVaccinated, was developed to test reactions to and feasibility of delivering adolescent vaccine information via smartphone. The app prototype was developed from formative research with focus group participants (n=26) and guided by an Expert Advisory Board comprised of vaccination experts and clinicians. Usability testing on one module, about deciding to vaccinate, was conducted iteratively with parent and teen pairs in New Mexico (n=9 pairs) and Colorado (n=7 pairs). Pairs were comprised of one teen (ages 13–17; mean age 15) and their accompanying parent or guardian (mean age 47). Teen participants were 56% (n=9) female; 50% (n=16) White; and 31% (n=5) Hispanic. Parents were 88% (n=14) female; 75% (n=12) White; and 6% (n=1) Hispanic. Usability testing was conducted individually with the parent and teen by trained research staff. During the testing, participants used the app prototype, answering questions as prompted. At the conclusion of testing, participants completed the 10-item Bangor System Usability Scale (SUS). Parents rated overall user friendliness of the app 5.5 (range 1–7), and teens rated it 6, indicating the app easy to use. SUS data also indicated participants could quickly learn to use the app (parent score = 4.25; teen score = 4.56 on a 5-point scale) and that they would be confident using it (parent score = 3.88; teen score = 4.31). Evidence suggests that a total SUS score of 40 indicates strong usability. Teens' average score of the app was 43.00 and parents' average score was 42.19. The promising SUS scores and feedback from the EAB indicate feasibility, which dictate plans for Phase II development. A specifications document outlines the planned design of the full-scale app based on testing results. Findings included in the specifications document are: 1) provide tailored learning experiences to teens (i.e., game-based) and parents (i.e., didactic) within the same app; 2) integrate individualized information (e.g. clinic preferences); and 3) provide a vaccination record tracking feature. The planned app could improve dissemination of vaccine information, enhance parent/teen communication around health behavior choices, and ultimately, improve the uptake of vaccinations.

AN SBIR INDUSTRY-ACADEMIA PARTNERSHIP IN EVALUATING A HEAD MOUNTED ACTIVITY MONITOR IN SENIORS

Jenna Hua, RD, MPH, PhD¹, Ines Campero, MS¹, Fernando Fierros, BS¹, Dulce Garcia, BS¹, Jylana Sheats, PHD, MPH², Mark Fauci, MBA, BS³, Abby C. King, PhD¹

¹Stanford Prevention Research Center, Palo Alto, CA; ²Tulane University School of Public Health & Tropical Medicine Dept. of Global Community Health and Behavioral Science, New Orleans, LA; ³Gen Nine, Inc., Louisville, KY

The advent of wearable technology to monitor physical activity has created unprecedented opportunities to observe, quantify, and define physical activity in the real-world setting. Funded by the National Institute on Aging SBIR program, a new standalone communication and monitoring tool (CosmoVue) for older adults was developed by Gen-9 Inc. in collaboration with the Healthy Aging and Technology Solutions Laboratory at Stanford Prevention Research Center. It consists of an accelerometer, gyroscope, GPS, and magnetometer in the form of an ordinary-looking pair of eyeglasses, with an entirely voice-activated interface. CosmosVue can make calls, send messages, call 911 if the user needs help, monitor activity and heart rate, and track location with onboard GPS.

To evaluate CosmosVue user acceptance, participants aged ≥65 years were recruited from existing clinical trials, local community centers and websites. The user acceptance study was completed in two segments. Segment I involved an in-clinic user evaluation where participants were supplied with the preproduction CosmosVue eyeglasses. Individually-structured interviews, usability surveys and cognitive and behavioral walk-throughs of the product and its components were conducted. Participants then completed a usability survey and Short Physical Performance Battery in a clinically supervised space. Segment II involves an at-home user evaluation of the CosmosVue eyeglasses, where participants use CosmosVue for seven days, keep a detailed diary of their daily activities, and answer a post-usability survey.

Currently, 30 participants have completed Segment I, and 2 have completed Segment II. The average age of Segment I participants was 76.4, with a roughly 1:1 male to female ratio. Participants' racial and ethnic backgrounds included 60.0% White, 20.0% Hispanic, 16.7% Asian and 3.3% American Indian. More than 80% of the participants had completed some college or above, perceived having good health, and did not use assistive devices. More than 78% of participants wore everyday glasses; 61% responded that they had no caregivers or others checking in with them regularly, and 73% own smartphones and tablets.

Participants in Segment I reported the CosmosVue eyeglasses were comfortable to wear (96.7%), perceived the device to be easy to use and with appropriate functions (100%), and believed that they would benefit from wearing the device (90.4%). The majority of participants (73.2%) reported that wearing the device would not be distracting. Participants also indicated that the device still needs improvements, particularly in terms of battery life and consistency of the voice-activated interface. Overall, participant feedback thus far indicates that CosmosVue may be an attractive hands-free approach for monitoring older adults' activity levels and promoting their safety in home and community environments.

DEVELOPMENT OF BEHAVIORAL JOURNALISM NEWSLETTERS TO ADDRESS COLORECTAL CANCER SCREENING BARRIERS

Yolanda A. Serra- Martinez, MED/ Doctoral Student¹, Vivian Colón-López, PhD, MPH², Camille Vélez, MPH², Ileska M. Valencia-Torres, BS³, Adriana Acevedo-Montanez, MS², Maria E. Fernández, Ph.D.⁴

¹University of Texas Health Science Center at Houston/ School of Public Health, Houston, TX; ²University of Puerto Rico Medical Sciences Campus & PR Comprehensive Cancer Center, San Juan, N/A, Puerto Rico; ³UTHealth Center for Health Promotion and Prevention Research, Houston, TX; ⁴School of Public Health /University of Texas Health Science Center at Houston, Houston, TX

Introduction: In Puerto Rico (PR), colorectal cancer (CRC) is a leading cause of death due to cancer. Colorectal cancer screening (CRCS) can reduce both, the incidence and mortality of CRC through early detection. Data from the 2017 Behavioral Risk Factor Surveillance System, indicates that only 17.8% of the PR population 50+ years has undergone a fecal occult blood testing (FIT/FOBT) within the past year. Additionally, only 50.6% of age-eligible Puerto Ricans report ever having a sigmoidoscopy or colonoscopy. These screening rates are substantially lower than the goal targeted by the National Colorectal Cancer Roundtable which aims to achieve 80% screening rate by 2018. The Guide to Community Preventive Services recommends “one-on-one” education in combination with small media to increase CRCS. Currently, there are few studies examining “one-on-one” education in combination with other communication strategies in the Latino population and none with Puerto Ricans. Using intervention mapping, we designed a newsletter to increase CRCS in Puerto Ricans.

Objective: Develop a behavioral journalism newsletter to address barriers related with CRCS aimed to increase uptakes among men and women 50 years and older in Puerto Rico.

Methods: We developed a newsletter following intervention mapping steps, and using behavioral journalism techniques. We conducted ten in-depth journalistic style interviews with participants who had completed CRCS and had characteristics similar to those of our target population that included specific questions related with barriers related with CRCS and asked about how they felt about the outcomes of screening. We included both individuals who were up-to-date with screenings, or who had survived CRC because completion of the CRCS tests. During the interviews, we used open-ended questions to obtain quotes and keywords from participants to be incorporated into the newsletter. We used these to create stories about the benefits of CRCS and about how these individuals had overcome barriers to receive screening and protect their health.

Results: We conducted focus groups (N=19) and administrated a survey to test the appeal, acceptability, perceived relevance, cultural appropriateness, and motivation to obtain a CRCS of the newsletter. Overall, participants found this educational component to be both attractive and culturally sensitive. We found that Behavioral Journalism was an overarching effective method relevant for addressing the identified personal determinants and environmental factors (barriers for CRCS). This method which is aimed at changing social norms is particularly effective in reaching audiences that may have low literacy, or who are initially unwilling to process the message.

MECHANISMS OF CHANGE IN A MOTIVATIONAL INTERVIEWING BASED INTERVENTION TO PROMOTE USE OF MULTIPLE SCLEROSIS (MS) MEDICATIONS

Rachel Schoor, MA¹, Jared Bruce, PhD², Amanda S. Bruce, PhD³, Kathy Goggin, PhD⁴, Andrea Bradley-Ewing, MPA, MA⁵, Joanie Thelen, MA⁶, Morgan Glusman, M.A.⁷, Delwyn Catley, PhD⁵, Sharon G. Lynch, MD³, Lauren B. Strober, Ph.D.⁸

¹University of Missouri-Kansas City, Kansas City, MO; ²University of Missouri-Kansas City, Kansas City, MO; ³University of Kansas Medical Center, Kansas City, KS; ⁴Children's Mercy Hospital; University of Missouri - Kansas City, Kansas City, MO; ⁵Children's Mercy Hospital, Kansas City, MO; ⁶University of Missouri - Kansas City, Kansas City, MO; ⁷University of Missouri - Kansas City, Kansas City, MO; ⁸Kessler Foundation, East Hanover, NJ

Background: Despite the demonstrated efficacy of disease modifying therapies, (DMT) many MS patients (~ 40%) stop using DMT within 3 years of starting. A cross-over randomized controlled trial demonstrated that a theoretically based Motivational Interviewing- Cognitive Behavior Therapy (MI-CBT) intervention increased DMT re-initiation among relapsing-remitting MS patients compared to a treatment as usual condition.

Purpose: We explored the mechanisms of action responsible for the effectiveness of the MI-CBT intervention. Preliminary mediation analyses were used to examine whether theorized mediator variables (autonomous regulation, personal and treatment control, and motivation and confidence to re-initiate) were impacted by the intervention and whether changes in these variables were related to DMT re-initiation.

Method: Following baseline assessment, participants (N=81; 86.4% female) were randomly assigned to receive either five sessions of MI-CBT or to treatment as usual with brief education. Potential mediators (Autonomous Regulation, Personal Control, Treatment Control, two measures of Motivation to re-initiate, and Confidence to re-initiate) were assessed at end of treatment (week 10) using established measures. Pearson correlations were used to examine associations between treatment group and changes in mediator variables and between changes in mediator variables and outcome (re-initiation) at week 10.

Results: Treatment group was significantly related to both measures of change in Motivation ($r=.32, p=.01$) and re-initiation ($r=.22, p=.04$). No significant relationships were found between Treatment group and changes in Autonomous Regulation, Personal Control, Treatment Control or Confidence to re-initiate (all $p's>.05$). Change in Autonomous Regulation ($r=.25, p=.03$), and both measures of change in Motivation ($r=.33, p's>.05$) related to re-initiation.

Discussion: Enhanced understanding of treatment mechanisms can lead to improved interventions and refined theories of behavior change. Preliminary mediation analyses suggest that the MI-CBT intervention may have increased re-initiation relative to treatment as usual by increasing autonomous regulation and motivation but not through changes in personal control, treatment control or confidence.

Acknowledgement: This work was funded by a grant from the National Multiple Sclerosis Society (HC 0138).

CSC ONDEMAND: A NOVEL TRAINING AND IMPLEMENTATION PACKAGE TO SUPPORT COORDINATED SPECIALTY CARE (CSC) TEAMS

Jeffrey Olivet, MA¹, Catriona Wilkey, M.S.W., M.P.H.¹, Ferreira Kathleen, Ph.D.¹, Mary Brunette, M.D.², Deborah Medoff, Ph.D.³, Ilana Nossel, M.D.⁴, Lisa Dixon, M.D., M.P.H.⁵

¹Center for Social Innovation, Needham, MA; ²Geisel School of Medicine at Dartmouth, Concord, NH; ³Division of Services Research, University of Maryland School of Medicine, Baltimore, MD; ⁴Columbia University Medical Center, New York, NY; ⁵Columbia University Medical Center, New York State Psychiatric Institute, New York, NY

Schizophrenia is a potentially devastating illness that typically begins in adolescence and young adulthood. Early intervention may reduce or eliminate the recurrent exacerbations and functional impairment that can occur with this disease. A growing body of research has found that comprehensive, team-based, multi-disciplinary services provided by CSC teams early in the course of the illness can improve outcomes. For example, the National Institute of Mental Health (NIMH) Recovery After an Initial Schizophrenia Episode (RAISE) projects demonstrated that multi-element, multi-disciplinary interventions improved outcomes in occupational and social functioning, symptoms, and quality of life. As widespread dissemination of CSC programs begins, there is a need for training in evidence-based practices to deliver services to individuals with early psychosis.

Through a Fast-Track Small Business Innovation Research (SBIR) grant from NIMH, the Center for Social Innovation (C4) partnered with expert faculty to develop and evaluate *CSC OnDemand: An Innovative Online Learning Platform for Implementing Coordinated Specialty Care*. This novel training and implementation package supports CSC teams by providing basic training, role-specific content, peer learning, and ongoing access to resources and materials. Using C4's *Omega Courseware*, the package integrates text, videos, audio clips, interactivity, and links to external resources. Expert faculty led live video learning sessions with case discussions that deepen team learning and development.

In a Phase I pilot study, we tested the *CSC OnDemand* prototype, assessing feasibility, acceptability, and preliminary effectiveness among three teams of providers serving individuals with first episode psychosis. A quantitative survey administered pre- and post- intervention assessed knowledge acquisition and a mixed-methods approach assessed participant feedback on feasibility and acceptability of the tool. Results showed high feasibility with 100% of participants using the tool and joining the live sessions. Participants reported high satisfaction and indicated ease of use and early application of skills to practice. There was a statistically significant improvement in knowledge of CSC and first episode psychosis. Findings demonstrate the value of *CSC OnDemand* as a learning tool for providers and agencies serving individuals with early psychosis and support the transition to a Phase II randomized clinical effectiveness trial.

FIELD EVIDENCE OF SYNERGY BETWEEN EXECUTIVE CONTROL AND REWARD SENSITIVITY IN WEIGHT MANAGEMENT

Faith Li¹, Andre Portella, MD PhD², Yu Ma, PhD¹, Spencer Moore, MPH, PhD³

¹McGill University, Montreal, PQ, Canada; ²McGill Centre for the Convergence of Health and Economics (MCCHE), Montreal, PQ, Canada; ³University of South Carolina, Columbia, SC

Obesity and other problems associated with modern diet have been qualified as neurobehavioral diseases. They are tied to a misalignment between the capacity of the dopamine brain systems to support normative behavior and the current environment that differs dramatically from what mankind evolved. However, research has shown that individual differences exist in the dopamine systems that modulate one's behavior and body weight (as indexed by BMI) in the modern obesogenic environment. Differences have been found in neuroimaging, neuro-cognitive task and personality studies for both executive control (EC) and reward sensitivity (RS), two key dopaminergic endophenotypes. The bulk of past research have seen executive control and reward sensitivity as competitive processes with zero-sum-game outcomes, with the immediacy of reward-seeking to account for the high rate of obesity. This field study aims to explore how one's personality on executive control and reward sensitivity interact. The EC was indexed by the sense of control scale (Mirowsky & Ross, 1991) and the RS was assessed by Behavioral Activation System reward responsiveness scale (Carver & White, 1994). The sample consists 620 adults who engaged in the Montreal Neighborhood Networks and Healthy Aging Panel in 2008 and 2010 (Moore, Buckeridge & Dubé, 2014). The dependent variable is the difference of ones' BMI in two years. Linear regression analysis controlling for socio-demographic and socio-economic conditions were performed. High EC was associated with less weight gain ($p=0.02$), whereas no main effect of RS emerged. The interaction of EC and RS is negatively significant ($p<0.001$). For people with a low control level, those with high RS gain more weight as expected. For those with a high control level, people with low RS gain slightly more weight. Turning to the other component, for people with high RS, those with low control gain more weight. Surprisingly, for people with low RS, those with high control gain more weight. Results are discussed in terms of possible mechanisms for future experimental work, namely, reward deficiency syndrome (RDS) and emotion regulation. The RDS theory states that people insensitive to reward take palatable food as self-medication to improve mood. This theory didn't apply to individuals with low EC because they are reluctant to take actions and may stay depressed as studies have shown that low executive control is highly correlated with depression.

EFFICACY OF A WEARABLE-ENABLED PHYSICAL ACTIVITY COUNSELLING PROGRAM FOR PEOPLE WITH KNEE OSTEOARTHRITIS

Linda C. Li, PT, PhD¹, Eric C. Sayre, PhD², Navi Grewal, MSc¹, Juliane Chien, BSc², Greg Noonan, PT³, Ryan S. Falck, MSc¹, John Best, PhD¹, Teresa Liu-Ambrose, PT, PhD¹, Alison Hoens, PT, MSc⁴, Valerie Gray, PT⁵, Karen Tsui, MScPT ACPAC⁶, Wendy Watson, PT⁵, Lynne M. Feehan, PT, PhD¹

¹University of British Columbia, Vancouver, BC, Canada; ²Arthritis Research Canada, Vancouver, BC, Canada; ³Mary Pack Arthritis Program, Vancouver, BC, Canada; ⁴BC SUPPORT Unit, Vancouver, BC, Canada; ⁵Vancouver Coastal Health Authority, Vancouver, BC, Canada; ⁶Fraser Health Authority, Surrey, BC, Canada

Background: Current guidelines emphasize an active lifestyle in the management of knee osteoarthritis (OA), but up to 90% of OA patients are inactive. This study aimed to assess the efficacy of a wearable-enabled physical activity counselling program for improving activity participation and disease status in people with knee OA.

Methods: Eligible participants had a self-reported knee OA diagnosis, or symptoms of knee OA based on a validated questionnaire. After baseline assessment and randomization, the *Immediate Intervention Group (II)* received group education, a Fitbit, and 4 biweekly phone calls by a physiotherapist to counsel activity goals over a 2-month period. The *Delayed Intervention (DI) Group* received the program 2 months later. Participants were assessed at baseline (T0) and the end of 2, 4 and 6 months (T1, 2, and 3). Outcome measures included: 1) mean moderate/vigorous physical activity (MVPA) time measured with a SenseWear® monitor; 2) mean daily step count; 3) mean sedentary behaviour time; 4) Knee Injury & OA Outcome Score (KOOS). Analysis of covariance (ANCOVA) was used to evaluate the effect of the group type on the outcome measures at T1, 2, and 3, after adjusting for T0. We assessed three planned contrasts of changes: 1) compared T0–T1 between the two groups to determine if *II* was superior to *DI* (the control); 2) compared T0–T2 in *II* against T0–T3 in *DI*; 3) compared T0–T2 in *II* against T1–T3 in the *DI*. The last 2 models assessed whether the two-month delay had an impact on the effect of the intervention.

Results: In 2015–2016, we recruited 61 participants (*II*: n=30, 73% women; *DI*: n=31, 90% women). Both groups were similar in age (*II*: 61.3 (9.4) years; *DI*: 62.1 (SD 8.5)), body mass index [*II*: 29.2 (5.5); *DI*: 29.2 (4.8)], and baseline MVPA time [*II*: 62.1 (54.6) minutes; *DI*: 65.3 (77.4)]. Mean MVPA minutes at T1, 2 and 3 for the *II* group were 75.5 (54.3), 62.6 (56.3) and 65.6 (48.5), respectively. A trend of decrease in MVPA time was found in the *DI* group at T1 [49.6 (46.8)], but improved at T2 [60.1 (76.8)] and T3 [70.7 (71.9)]. Pre-specified contrast analyses revealed a significant effect whereby the *II* group improved in the MVPA time at T0–T1 compared to the *DI* (contrast coefficient: 25.2; 95% CI 5.5, 44.9; $p = 0.01$). A significant effect was also found in the mean daily steps at T0–T1 (contrast coefficient: 1519.3; 95% CI 256.2, 2782.3; $p = 0.02$). We found no significant effect in any outcome measures in the other contrast analyses.

Conclusion: Our wearable-enabled counselling program improved MVPA and step counts in people with a diagnosis or symptoms of knee OA. The finding is important since an active lifestyle is recognized as an important component of successful self-management.

ENGAGEMENT WITH CLIENTS ACROSS CULTURAL AND RACIAL DIVIDES: TOWARDS AN EVIDENCED-BASED TOOL FOR ADDRESSING STRUCTURAL RACISM

Marva L. Lewis

Tulane University, New Orleans, LA

In 2018, delivery of mental health services to different race children and their families remains a challenge to counselors, psychologists, psychiatrists, and social workers. Race-based traumatic stress and oppression including discrimination and racial microaggressions, are receiving increasing recognition resulting in adverse mental health outcomes (American Psychological Association, 2016; Carter, 2007). The impact of structural racism, resulting in race-based community violence and racial health inequities, such as high rates of infant mortality, requires a response at every level of society (Author). New clinical tools are needed to engage and deliver equitable services in many community-based mental health clinic organizations and social service agencies. There is often a racial divide with the administrators and providers, helpers predominately White and the clients ethnic minority predominately Black. The larger issues related to race – stereotyping, discrimination, unconscious bias – become the unacknowledged ‘elephant in the room’ in client-therapist interactions. In this poster, we present the development of a paper and pencil survey instrument titled, *The Perception of the Quality of the Working Relationship (PQWR)* between different-race clients and providers/helpers. Using quantitative and qualitative methods over a two-year period, research was conducted with (N = 248) employees at a large urban, residential psychiatric hospital for children. The results of quantitative and qualitative methods, identified a theme that called for improvement in the relationship dynamics across racial divides. These themes were the basis for were used to create a systematic tool that can be used for on-going assessment of organizational change and accountability. The five sub-sections of the PQWR can be used individually or together to provide quantitative evidence to set goals and assess change for racial issues. Sub-sections include:

Perceptions of group relationships;

Self-report of *individual openness* to topics of diversity;

Ethnic identity;

Emotions related to diversity; and

Knowledge of stereotypes of diverse groups.

This measure has now been used with a group of early childhood practitioners (N = 62) and several class cohorts of social work graduate students (N = 138) to set goals for interpersonal relationships of members with the community clients they serve. Results will present a principal components factor analysis of the measure, reliability of the total and subscales and concurrent validity with standardized measures. I conclude with a discussion of the clinical utility of the PQWR tool for planning for organizational diversity training and future direction for research.

DIFFERENTIAL PATTERNS IN ATTITUDES AND SLEEP AMONG A CULTURALLY-DIVERSE PROFESSIONAL SOCCER TEAM

Hannah Peach, PhD¹, Rolf Maijer, Ing., DDS, D.Orth, FRCD(C)², Skylar Richards, BS, MS, NATA, ATC/L³, Annelise Thornton, MHS²

¹UNC Charlotte, Charlotte, NC; ²Population Sleep, Dallas, TX; ³FC Dallas, Frisco, TX

Background: Sleep is important for optimal athletic performance. Attitudes are salient predictors of behavior and should be considered when developing evidence-based sleep interventions. Our study measured sleep attitudes among professional soccer players to (1) investigate differential patterns by region of origin (culture) and (2) observe relationships between attitudes and self-reported and objective sleep outcomes.

Method: Sixteen male soccer players participated in a sleep evaluation; 8 were from North America (NA) and 8 were from Latin America (LA). They completed demographic and sleep surveys, as well as the Charlotte Attitudes Towards Sleep Scale Peach & Gaultney, 2017), a psychometrically sound measurement tool previously validated in a similar age group. Players wore a FDA-cleared, single-lead ECG device overnight to obtain objective sleep data.

Results: LA players self-reported longer sleep duration than NA players, although 87.5% of LA players reported that they felt “fatigued” or “non-refreshed upon awakening”, as compared to 44% of NA players. ECG data confirmed that 75% of LA players showed a biomarker of sleep instability whereas only 11% of NA players did. Independent sample *t*-tests between groups did not differ in total attitude scores and subscales, however LA players scored significantly lower on the single attitude item “I look forward to a full night of sleep.” Among LA players, the Benefits of Sleep attitudes subscale was associated with longer sleep durations ($r = .63, p = .09$), significantly less unstable sleep ($r = -.72, p < .05$), and significantly less sleep interruptions ($r = -.76, p < .05$). However, among NA players, total sleep attitudes were associated with worse sleep outcomes, including more unstable sleep ($r = .74, p < .05$) and higher sleep interruptions ($r = .73, p < .05$).

Discussion: This study suggests associations between attitudes and sleep outcomes differ by culture. LA players were less likely to look forward to sleep than NA players, which contradicts their longer self-reported sleep duration. Among NA players, attitudes were inversely associated with sleep quality, while favorable sleep attitudes appear advantageous for LA players. Results for NA players are puzzling considering behavior change theories incorporating attitudes (e.g., theory of planned behavior). Such contradictory findings warrant further consideration, and our formative research suggests the need for future investigation into the interplay between attitudes, self-reported sleep characteristics, and objectively measured sleep outcomes in these players.

CANCER KNOWLEDGE AND CANCER FATALISM IN THE DEAF COMMUNITY

Marcelo Nieto, B.A.¹, Amy E. Ustjanauskas, M.S.², Tonya M. Pan, M.A., M.S.², Matthew Fager, N/A³, Patricia Branz, N/A⁴, Georgia R. Sadler, BSN, MBA, PhD⁵, Vanessa L. Malcarne, PhD⁶

¹Graduate School of Public Health San Diego State University, San Diego, CA; ²SDSU/ UC San Diego Joint Doctoral Program in Clinical Psychology, San Diego, CA; ³UC San Diego Linguistic Department, La Jolla, CA; ⁴UC San Diego Moores Cancer Center, La Jolla, CA; ⁵UC San Diego, La Jolla, CA; ⁶SDSU Psychology Department, San Diego, CA

Background: The Deaf community is a medically underserved group that faces significant barriers to accessing cancer-related health information, including the fact that they use American Sign Language (ASL) as their primary mode of communication. Cancer fatalism (i.e., the belief that when one has cancer, death is inevitable) and low cancer knowledge are evident among underserved populations, and are associated with low adherence to cancer prevention guidelines. Little research, however, has explored cancer knowledge and fatalism among the Deaf community. The current study describes levels of and explores the relationship between cancer knowledge and cancer fatalism among Deaf adults.

Methods/Approach: Baseline data from three related randomized controlled trials (RCTs) with identical eligibility criteria and methods were analyzed. Deaf adult community participants ($N = 301$) completed ASL versions of a cancer knowledge survey, and the Powe Fatalism Inventory (PFI). For each RCT, average scores for cancer knowledge and cancer fatalism were calculated, and bivariate correlational analyses of total knowledge and PFI scores were conducted to explore the relationship between cancer knowledge and fatalism.

Results: Participants' knowledge scores were on average, for RCT 1: $X = 16.48, SD = 5.67$, range 1–28; for RCT 2, $X = 15.44, SD = 5.22$, range 2–27; and for RCT 3, $X = 14.92, SD = 4.82$, range 3–28. Average scores for the PFI were, for RCT 1: $X = 6.07, SD = 3.32$, range 1–15; for RCT 2, $X = 7.06, SD = 3.39$, range 1–15; and for RCT 3: $X = 6.73, SD = 3.29$, range 1–14. Cancer knowledge and cancer fatalism were found to be significantly negatively associated. Correlations were moderate and significant for RCT 1 ($r = -.445, p < .001$), and weak and significant for RCTs 2 ($r = -.234, p = .022$), and 3 ($r = -.274, p = .007$).

Conclusion: Average scores for cancer knowledge and cancer fatalism were low for Deaf adults across all three RCTs. The current study found that, among Deaf adults, the less cancer knowledge they had, the more fatalistic they were about cancer. A similar negative association between cancer knowledge and fatalism has been found in other underserved groups. Future research is needed to explore additional ways to improve cancer knowledge and fatalism in the Deaf community, as well as the way in which these constructs relate to cancer-related behaviors and outcomes among Deaf individuals.

FACTORS ASSOCIATED WITH DENTAL CARE UTILIZATION IN PATIENTS WITH DIABETES IN CENTRAL TEXAS

Ya-Ching Huang, MSN, RN¹, Julie Zuniga, PhD, RN², Alexandra Garcia, PhD, RN, PHNA-BC, FAAN²¹The University of Texas at Austin, Austin, TX; ²The University of Texas at Austin, School of Nursing, Austin, TX

Purpose: Patients with diabetes are advised to receive regular dental care because of their high risk of dental caries, early gum disease, and periodontitis related to hyperglycemia. However, the number of patients receiving regular dental checks is low. The aim of the present study was to explore factors associated with dental care utilization in patients with diabetes.

Methods: This is a secondary analysis of 2015 data from 8082 adult patients with diabetes from 14 clinics in a network of Federal Qualified Health Center (FQHCs) that serve low-income patients in central Texas. In addition to descriptive analyses, logistic regression models of dental care utilization were estimated with the following set of predictors: (1) background (ethnicity, gender, and age), (2) number of times blood testing (A1C and lipid panel), and (3) laboratory data (A1C, HDL, LDL, triglycerides, total cholesterol).

Result: Participants were aged 18–97 years (mean age = 53.9, SD = 12.8), 59.8% were female, and 65.9% were Hispanic. Seventy percent of participants had an A1C test an average of 3.3 times; about 74% had lipid panel testing an average of 1.2 times. Only 29.2% of participants used dental care. Increased odds of reporting dental care utilization were observed among individuals aged 18–39 (OR = 1.94, $p < .001$), aged 40–64 (OR = 1.52, $p < .001$), and higher frequency of A1C testing (OR = 1.27, $p < .001$), and lipid panel testing (OR = 1.92, $p < .001$). Being male (OR = .86, $p < .05$) was associated with the reduced likelihood of dental care utilization.

Conclusions: Three variables predicted dental care utilization: patients with higher frequency of blood testing (but not actual blood levels), older participants, and males were less likely to have seen a dentist. These results can direct medical providers to target these groups for counseling and patient education.

ASSESSING THE ASSOCIATION BETWEEN SLEEP DISTURBANCES AND COGNITIVE IMPAIRMENT: A PILOT STUDY IN COMMUNITY DWELLING OLDER ADULT

Javad Razjouyan, Fellow

Center for Innovation in Quality, effectiveness and Safety (IQuEst), VHA Houston, HOUSTON, TX

Background: Sleep disturbances are common in older adults. Little is known about the sleep of cognitively intact older adults and its relationship to subsequent cognitive impairment. The objective of this study was to examine the association between objective sleep-wake measures and risk of incident cognitive impairment.

Methods: Thirty subjects (age = 82.2 ± 6.1 years, body mass index = 25.7 ± 4.8 , female = 43.3%) in 3 age-matched groups, 11 healthy, 10 with amnesic mild cognitive impairment (aMCI), and 9 with Alzheimer disease (AD), were recruited. Subjects wear a chest worn physical activity monitor (PAMSys™, BioSensics, LLC, Watertown, MA) for two days. A validated algorithm for sleep-wake detection based on chest worn sensor was used to calculate the average of sleep parameters, i.e. total sleep time (TST), sleep onset latency (SOL), sleep efficiency (SE), wake after sleep onset (WASO), and number of WASO (nWASO), for the first two nights. The association between sleep parameters and the Montreal cognitive assessment (MoCA) test were explored.

Results: The MoCA test has a significant correlation with the SOL ($r = -0.44$, $p = 0.026$) and the nWASO ($r = -0.412$, $p = 0.037$). The participants stratify into two groups based on the MoCA cut-off of 25 and greater. The SOL (59%, $p = 0.019$) and nWASO (53%, $p = 0.027$), and number of sleep position changes (59%, $p = 0.014$) were significantly lower in the normal group in comparison to cognitive impaired group.

Conclusions: The higher SOL, the higher nWASO, and higher sleep position changes are associated with developing cognitive impairment. Further research with larger sample size is needed to confirm the outcome of this study and reveal the mechanisms underlying these associations.

ONLINE SALES OF MARIJUANA: AN UNRECOGNIZED PUBLIC HEALTH DILEMMA

Theodore Caputi, BS¹, John Ayers, PhD²¹University College Cork, New Hope, PA; ²San Diego State University, Chula Vista, CA

Introduction: The internet hosts many unregulated marketplaces for otherwise regulated products. If extended to marijuana (or cannabis), online markets can undermine both the U.S. Controlled Substances Act, which bans marijuana sales, and the regulatory regimes of states that have made efforts to legalize marijuana. Consequently, regardless of the regulatory regime, understanding the online marijuana market should be a public health priority. Herein, the scale and growth trajectory of the online marijuana marketplace was assessed for the first time by analyzing aggregate internet searches and the results searchers typically find.

Methods: U.S. Google searches, geotagged by state, including the terms “marijuana,” “weed,” “pot,” or “cannabis” were monitored monthly from 2005–2017 using data obtained from Google. The subset of shopping searches was then monitored by tracking queries that also included “buy,” “shop,” and/or “order” (e.g., “buy marijuana”). Linear regressions were used to compute pooled means to compare between times and log-linear regressions were used to compute average growth.

Second, searches were executed using the twelve combinations of marijuana and shopping root terms (i.e., “buy marijuana”). The first two pages of links, including duplicates (N=279, with 7–12 links per page), were analyzed.

Results: Marijuana searches grew 98% (95%CI, 84–113) as a proportion of all searches from 2005 to the partial 2017 year. The subset of marijuana searches indicative of shopping grew more rapidly over the same period (199%; 95%CI, 165–243), with 1.4–2.4 million marijuana shopping searches during June 2017. Marijuana shopping searches were highest in WA, OR, CO, and NV. The compounding annual growth rate for marijuana shopping searches since 2005 was significantly positive in 42 of the 44 studied locations.

Forty-one percent (95%CI, 35–47) of shopping search results linked to retailers promising mail-order marijuana. Retailers occupied 50% (95%CI, 42–59) of the first page results and for 8 of the 12 searches, the first link led to a mail-order marijuana retailer.

Discussion: Millions of Americans search for marijuana online, and websites where marijuana can be purchased are often the top search result. If even only a fraction of searches and retailers are legitimate, this unregulated online marketplace poses a number of potential public health consequences. Regulations governing online marijuana markets need to be developed and enforced. Policing online regulations will require careful coordination across jurisdictions at the local, state, and federal level with agreements on how to implement regulations with conflicting enforcement regimes.

ADHERENCE TO THE AMERICAN CANCER SOCIETY GUIDELINES FOR CANCER PREVENTION AMONG WOMEN AT HIGH RISK OF DEVELOPING BREAST CANCER

Natasha R. Burse, B.A., M.S.¹, Karen Basen-Engquist, Ph.D., M.P.H.², Therese Bevers, M.D., F.A.A.F.P.², Robert Yu, M.C.S.², Sanjay Shete, Ph.D.², Powel Brown, M.D., Ph.D.², Abenaa Brewster, M.D., MHS²

¹The University of Texas MD Anderson Cancer Center/The Pennsylvania State Hershey College of Medicine, Hershey, PA; ²The University of Texas MD Anderson Cancer Center, Houston, TX

BACKGROUND: Adherence to the American Cancer Society (ACS) guidelines for cancer prevention has been shown to lower the incidence of breast cancer among average risk women. The majority of average risk women do not adhere to the ACS guidelines. There is limited evidence on the frequency of adherence to the ACS guidelines among high risk women.

PURPOSE: We aimed to examine adherence to the ACS guidelines for cancer prevention with a focus on body mass index (BMI), physical activity (PA), alcohol intake, tobacco, and sitting time among 2,074 high risk women enrolled in the MD Anderson High Risk Breast Cohort Study.

METHODS: At baseline, the participants completed self-administered questionnaires that collected information on age, race/ethnicity, marital status, socioeconomic factors (e.g. education and employment status), and five lifestyle factors (e.g. PA, tobacco, BMI, alcohol intake, and sitting time). High risk women were defined as having a diagnosis or history of one of the five characteristics: ductal invasive carcinoma (DCIS), lobular carcinoma in situ (LCIS), lifetime risk based on these models (Gail+Clau+Couch+Tyler-Cuzick), mantle radiation, or mutation. Logistic regression analyses were used to estimate odds ratios (OR) and 95% confidence intervals (CI) for the association of baseline characteristics and adherence to the ACS guidelines for cancer prevention. Adherence to five ACS guidelines were analyzed via descriptive statistics.

RESULTS: The majority of the cohort were white (78.5%), married (77.8%), and over 55 years (63.6%). Overall, more than half of the cohort met the recommendations for tobacco (69.5%) and alcohol (56.6%) but less than half met the recommendations for PA (27.6%) and BMI (37.6%). Compared to white women, non-Hispanic black (OR=0.09; 95% CI: 0.04–0.19) and Hispanic women (OR=0.59; 95% CI= 0.40–0.87) were less likely to meet the BMI recommendations but were statistically significantly more likely to meet the alcohol and tobacco recommendations. Older age (over 45 years) was statistically significantly associated with nonadherence to the sitting time recommendation. Compared to women with a high school degree, women with some college education (OR=2.17; 95% CI: 1.52–3.08) were more likely to meet the BMI recommendations.

CONCLUSIONS/IMPLICATIONS: The frequency of adherence to the BMI and PA recommendations among this cohort population is relatively low. Future studies should target these low areas of adherence and develop weight loss and PA interventions to reduce the incidence of breast cancer among high risk women.

NO DIFFERENCES FOUND IN LUNG CANCER SCREENING AND AWARENESS AMONG APPALACHIANS COMPARED TO NON-APPALACHIANS

Minal Patel, PhD, MPH¹, Kelly D. Blake, ScD¹, Robin Vanderpool, DrPH, CHES²

¹NCI, Rockville, MD; ²University of Kentucky, Lexington, KY

Background: Appalachian residents experience greater cancer disparities compared to their non-Appalachian counterparts. Specifically, lung cancer incidence and mortality rates are higher in Appalachia compared to the national average. Lung cancer screening may help reduce cancer mortality, but little is known about lung cancer screening and awareness and how it differs among Appalachians and non-Appalachians.

Objective: To examine lung cancer screening and awareness among Appalachian adults vs. non-Appalachian adults, along with related sociodemographic characteristics, in a nationally representative US sample.

Methods: Data from two waves of the Health Information National Trends Survey, a population-based survey collected from 2012–2014, were combined (N = 7307). Descriptive analyses examined sociodemographic variables and lung cancer screening eligibility, as well as lung cancer screening and awareness among Appalachians and non-Appalachians. Individuals were asked whether they had talked with their provider about having a test to check for lung cancer or heard of any tests to find lung cancer. Separate weighted multivariable analyses were conducted to examine lung cancer screening and awareness, controlling for sociodemographics.

Results: Approximately 8% of the sample resided in Appalachia (n=490). We found statistically significant differences for race, general health status, educational attainment, income, and urban/rural status for Appalachians compared to non-Appalachians. There was a statistically significant difference in those eligible for lung cancer screening (age 55–80 and current smokers) among Appalachians (6.1%) compared to non-Appalachians (3.6%) (p=0.001). However, there were no statistically significant differences for talking to a doctor about lung cancer screening (p=0.50) or for hearing about any tests to find lung cancer (p=0.81) among Appalachians compared to non-Appalachians in both bivariate and multivariable analyses.

Conclusions: Consistent with previous research, Appalachians had lower levels of educational attainment and income, and were more likely to report poor health than non-Appalachians. However, no differences in lung cancer screening and awareness were observed. Appalachian communities may be targeted for lung cancer screening services and/or rural programs are doing more outreach to providers. More research is needed to understand these null results despite higher lung cancer burden among Appalachians.

POST-SURGICAL PHYSICAL ACTIVITY ASSESSMENT OF ENDOMETRIAL AND OVARIAN CANCER PATIENTS

Jessica Gorzelitz-Liebhauser, MS¹, Erin Costanzo, PhD², Ryan Spencer, MD², Meredith Rumble, PhD², Stephen Rose, MD², Lisa Cadmus-Bertram, PhD¹

¹University of Wisconsin Madison, Madison, WI; ²University of Wisconsin School of Medicine and Public Health, Madison, WI

Background Physical activity is a key determinant of health and exercise can be an effective for decreasing anxiety and depression and improving quality of life in cancer survivors. However, little is known about the trajectory of physical activity after surgical intervention. The primary aim of this study was to report the trajectory of physical activity over time for post-operative gynecologic cancer patients. The secondary aim was to identify correlates of total physical activity over time.

Methods The study population was patients who underwent surgery for endometrial (n=80) or ovarian cancer (n=43) and wore an accelerometer for a 3-day period 1 week, 1 month and 4 months after surgery. Accelerometer data were captured during all waking hours and were transformed using counts per epoch into categories of light, moderate and vigorous intensity physical activity. The outcome of interest was total minutes of moderate to vigorous intensity physical activity (MVPA) at each time point analyzed using a linear mixed effect model approach, adjusted for age, body mass index (BMI), self-rated health, open surgery vs. laparoscopic (endometrial only) and chemotherapy yes/no (ovarian only).

Results Mean age was 58.8 ± 10.1 years with mean BMI of 35.5 ± 10.3 kg/m². At 1-week post-surgery, patients averaged 7 ± 12 minutes at 1 week, 20 ± 41 minutes of MVPA at 1 month, and 25 ± 36 minutes at 4 months post-surgery (p = 0.01). Federal physical activity guidelines recommend approximately 70 minutes of moderate intensity activity over a three-day period in order to collect 150 minutes of moderate intensity activity a week. Total accumulated MVPA during the wear period increased over time (p=0.01), and better self-rated health at baseline was associated with increased physical activity over time (p=0.02). Other clinical predictors such as BMI, age, type of surgery or use of neoadjuvant chemotherapy did not predict physical activity in patients of either disease site.

Conclusion Physical activity increased over time for endometrial and ovarian cancer patients, yet overall physical was modest. Self-reported health at baseline was positively associated with increased moderate-vigorous physical activity over time. There is insufficient evidence to show that BMI significantly contributes to changes in moderate-to-vigorous physical activity over time. Future research should address barriers to activity and novel interventions to increase activity for post-surgical cancer patients.

RELATIONSHIP BETWEEN POST-SURGICAL DISENGAGEMENT COPING AND DEPRESSIVE SYMPTOMS IN NON-METASTATIC BREAST CANCER SURVIVORS

Hannah M. Fisher, M.S.¹, Chloe Taub, M.A.¹, Suzanne Lechner, PhD², Charles S. Carver, PhD¹, Michael H. Antoni, PhD¹

¹University of Miami, Coral Gables, FL; ²University of Miami Miller School of Medicine, Coral Gables, FL

Introduction: Psychosocial factors such as coping may influence the course of treatment-related physical and psychological sequelae among breast cancer (BCa) survivors. Disengagement coping in particular, may be relevant to the symptom experience. Classification of coping responses into a higher order category of disengagement coping remains ambiguous, and evidence on the role of disengagement coping in the trajectory of physical and psychological symptoms in BCa survivors is inconsistent. This study aimed to test a mediation model elucidating a longitudinal relationship between a latent construct of disengagement coping at the time of diagnosis and depressive symptoms 5 years later, via pain and fatigue interference during the initial 12-month period of primary treatment for BCa.

Method: Stage 0-III BCa patients (N=240) were recruited 4 to 10 weeks post-surgery and completed a baseline (T1) questionnaire measuring coping responses, pain, fatigue, and depressive symptoms. Women were reassessed 6-months (T2), 12-months (T3), and 5-years post-surgery (T5). Using Mplus, a single factor confirmatory factor analysis was conducted to investigate whether several coping scales share a common variance indicative of disengagement coping. Structural equation modeling was used to test the proposed mediation model.

Results: A measurement model consisting of behavioral disengagement, denial, self-blame, and self-distraction exhibited good model fit ($\chi^2(2)=3.50$, $p=.17$; RMSEA=.06 (90% CI=[.00, .15]); CFI=.98; SRMR=0.03), suggesting that these coping strategies may constitute a higher order category of disengagement coping. Results from structural equation modeling did not reveal direct effects relating the latent construct of disengagement coping at T1 with long-term depressive symptoms at T5, or with pain and fatigue interference at T3. There was also no evidence to suggest mediation between T1 disengagement coping and T5 depressive symptoms via T3 pain and fatigue interference.

Conclusions: These findings further characterize disengagement coping and clarify its influence (or lack thereof) on physical and psychological symptoms throughout the BCa experience. Alternative mediation models, examining disengagement coping as the mediator, should be explored to facilitate the development of psychosocial interventions that target coping strategies affecting the physical and mental health of long-term BCa survivors.

VARIANCE IN PERCEIVED COGNITION: PERCEIVED COGNITIVE DIFFICULTIES IN CANCER DISEASE TYPES AS A RESULT OF MEDICAL INTERVENTION

Zachary Oshinbanjo, BA¹, Jessica Hamilton, Ph.D.², Heather Kruse, Ph.D.²¹University of Missouri - Kansas City, Kansas City, MO; ²University of Kansas Health System, Kansas City, KS

Introduction Previous research efforts have confirmed that cancer patients in varying capacity can experience declines in cognitive ability as a result of receiving chemotherapy. There are a multitude of cancer treating agents that each correspond with different types of cancer. The current study aims to observe the relationship between self-reported cognitive function and medical intervention received. **Methods** Data was collected from 176 patients who completed intake at a cancer facility between February 2016 and June 2017. During screening, patients completed the 8-item short form of perceived cognitive difficulties on the Patient-Reported Outcomes Measurement Information System (PROMIS), which consist of self-report measures that evaluate physical, mental, and social health. Individual scores for perceived cognition range from 8 to 40, with higher scores indicative of greater impairment. An independent sample T-Test was utilized to determine the associations between (1) level of self-reported cognition and (2) if chemotherapy was received. In addition, a One-Way ANOVA was completed to assess the relationship between (1) level of perceived cognition and (2) number of treatment modalities received. **Results** Patients' raw mean reported cognition was 20.8 (9.4). The analysis showed no statistical significance between perceived cognition and if chemotherapy was received; $t(173) = .716, p = .475$. The relationship between number of treatment modalities (e.g., chemotherapy, radiation, etc.) and perceived cognition was also examined. A One-way ANOVA found that there were no differences between perceived cognition and number of treatment modalities received by patients; $F(3,172) = .357, p = .784$. **Discussion** These results indicate that modality used to treat cancer in the study did not predict the patients' perceived level of cognition. This is contrary to the results produced in other studies. Further research could assess the association of type of cancer and other self-reported measures, such as fatigue, anxiety, or depression. Medical professionals may look to gathering self-reported conditions in an effort to create a baseline for the patient and be aware of changes that may occur during treatment.

LESSONS LEARNED FROM A MOTIVATIONAL INTERVIEWING BASED INTERVENTION FOR PATIENTS IN CARDIAC REHABILITATION

Kalon R. Eways, M.A.¹, Jillian M. R. Clark, Ph.D.², Kadie M. Harry, M.A.¹, Elizabeth J. Wilson, B.A.¹, Andrew J. Smith, PharmD³, Marcia Waters, RN⁴, Dennis Bergland, B.S.⁴, Kymberley K. Bennett, PhD¹¹University of Missouri-Kansas City, Kansas City, MO; ²VA Center of Excellence for Stress and Mental Health, VA San Diego Healthcare System/University of California, San Diego, San Diego, CA; ³Truman Medical Center; University of Missouri-Kansas City, Kansas City, MO; ⁴Truman Medical Center, Kansas City, MO

Cardiac rehabilitation (CR) is extremely effective in decreasing rates of cardiac-related morbidity and mortality, but participation rates are relatively low. Multiple interventions for increasing participation have been conducted, but there is limited research on their efficacy for low socioeconomic status (SES) populations. The current study tested the effectiveness and feasibility of an intervention aimed at increasing CR participation in low SES patients with cardiovascular disease (CVD).

CR eligible patients ($N = 30$) were recruited from an urban safety net hospital and randomized into a standard of care control group ($n = 15$) or intervention group ($n = 15$). The mean age of the sample was 56 years ($SD = 7.06$). Most participants were male (68%) and European-American (67%). The intervention group received standard of care, plus a brief educational video shown before hospital discharge and a brief telephone-based Motivational Interviewing counseling session one-week post-hospital discharge; both components focused on how to overcome common barriers to CR participation. The intervention group completed items measuring satisfaction with the video, the counseling session, and the counselor five weeks post-hospital discharge. The primary outcome was CR participation at five weeks post-hospital discharge.

The groups were equivalent on baseline demographic, social, and clinical variables (e.g., perceived stress, depressive symptoms, and CVD diagnoses). Contrary to predictions, there were no significant differences between the two groups in CR participation. In addition, participants in the intervention group endorsed significantly more depressive symptoms ($M = 11.79$) than the control group ($M = 4.73$) five weeks post-discharge, $t(27) = -3.76, p = .001$. Despite the intervention not having a significant effect on CR participation, the intervention group expressed high levels of satisfaction with the CR video and counseling session, as well as good working alliances with the counselor and high levels of perceived autonomy support.

These findings offer important lessons for treating low SES patients with CVD. First, satisfaction with a CR intervention does not necessarily translate into CR participation. Second, structural and psychosocial barriers may prevent interested patients from participating in CR programs. Specifically, depressive symptoms may represent a powerful barrier that requires robust screening and treatment efforts by CVD practitioners.

AEROBIC EXERCISE TRAINING AND INDUCIBLE INFLAMMATION: RESULTS OF A RANDOMIZED CONTROLLED TRIAL IN HEALTHY, YOUNG ADULTS

Richard Sloan, PhD¹, Peter Shapiro, MD¹, Paula McKinley, PhD², Matthew Bartels, MD², Daichi Shimbo, MD¹, Vincenzo Lauriola, MS¹, Wahida Karmally, RD¹, Martina Pavlicova, PhD³, Jean Choi, MA⁴, Tse-Hwei Choo, MS¹, Jennifer Scodes, MA⁴, Pamela Flood, MD⁵, Kevin Tracey, MD⁶

¹Columbia University Medical Center, New York, NY; ²Montefiore Medical Center, Bronx, NY; ³Mailman School of Public Health, New York, NY; ⁴New York State Psychiatric Institute, New York, NY; ⁵Stanford University Medical Center, Stanford, CA; ⁶The Feinstein Institute for Medical Research, Manhasset, NY

Background: Aerobic exercise is recommended regularly by consensus panels for its health promoting effects. Many studies, both observational and interventional, suggest that aerobic exercise training has anti-inflammatory effects but many show no effect of training. This significant variation in findings from these studies may be related to differences in study participants, details of the clinical intervention, accumulation of sample, choice and preparation of inflammatory markers, and statistical analysis approaches. This variability makes an unequivocal determination of the nature of anti-inflammatory effects of aerobic exercise training elusive.

Methods: 119 healthy, sedentary young (age 20–45 years) adults were randomized to either 12 weeks of aerobic exercise training or a wait list control condition followed by 4 weeks of sedentary deconditioning. Inducible TNF α and IL-6 by lipopolysaccharide ((LPS) 0.0, 0.1, and 1.0 ng/ml) and toll-receptor 4 (TLR4) as well as aerobic capacity established by cardiopulmonary exercise testing (CPET) were measured at study entry (T1), after training (T2), and after deconditioning (T3). Participants wore Polar heart rate monitors during training to confirm that they exercised at their target heart rate.

Results: The aerobic training group achieved a significantly greater improvement in aerobic capacity on average by 5 ml/kg/min ($t_{85}=7.0$, p release at T2 (LPS 0.0 ng/ml: $t_{88}=0.5$, $p=.62$; LPS 0.1 ng/ml: $t_{93}=1.6$, $p=.12$; LPS 1.0 ng/ml: $t_{92}=1.3$, $p=.19$). Similarly, there was no significant effect of the intervention on inducible IL-6 release (LPS 0.0 ng/ml: $t_{85}=-0.4$, $p=.69$; LPS 0.1 ng/ml: $t_{93}=1.0$, $p=.31$; LPS 1.0 ng/ml: $t_{92}=1.1$, $p=.29$). Additional analyses revealed a differential longitudinal treatment effect by LPS level of LPS stimulation (dichotomized at LPS 0.0 ng/ml vs. LPS 0.1 ng/ml, LPS 1.0 ng/ml) in inducible TNF α ($F_{1,469}=3.7$, $p=.07$) and IL-6 ($F_{1,466}=6.3$, $p=.01$). Post-hoc comparisons showed increases from T1 to T2, rather than decreases, in inducible (LPS 0.1 ng/ml and LPS 1.0 ng/ml) TNF α (estimated percent change 51%, $p=.04$) and IL-6 (estimated percent change 42%, $p=.11$). No significant changes were seen in either the training or waitlist groups for inducible (LPS 0.0 ng/ml) TNF α and IL-6. Training elicited no change in TLR4.

Conclusions: The failure to support the primary hypotheses and the unexpected post-hoc findings of a potential exercise-training-induced proinflammatory response raise questions about whether and under what conditions exercise training has anti-inflammatory effects.

EQUAL DIET QUALITY BETWEEN TWO MOBILE DIET TRACKING DEVICES IN THE DIET MOBILE STUDY: A REMOTELY-DELIVERED WEIGHT LOSS STUDY

Alycia Boutte, MPH¹, Gabrielle Turner-McGrievy, PhD MS RD¹, Sara Wilcox, PhD¹, Brent Hutto, MSPH¹, Eric Muth, PhD², Adam Hoover, PhD³

¹University of South Carolina, Columbia, SC; ²Clemson, Clemson, SC; ³Clemson University, Clemson, SC

Background: Dietary self-monitoring is the cornerstone of behavioral obesity treatment. Mobile health technology has the potential to change dietary intake, which can have significant public health improvements. Compared to examining individual nutrients, diet quality captures the overall pattern of eating. The objective of this study was to examine differences in energy intake and diet quality between individuals using a wearable Bite Counter (Bite) or a mobile app (App).

Methods: A cross-sectional analysis of the DIET Mobile study was conducted. The DIET Mobile study was a 6-month randomized weight loss trial comparing the Bite to App group. The Bite group used the Bite Counter, a wearable device that uses micro-electro-mechanical gyroscope technology to track wrist motion, automatically detecting bites. The App group used FatSecret, a free traditional diet app. Data from overweight adults ($n=81$, mean BMI=34.7 \pm 5.6 kg/m², 81.5% White, 82.7% female), who owned smartphones, and had stable health conditions were analyzed from the remotely-delivered intervention. Participants completed 2 ASA24 diet recalls at baseline, 3-months, and 6-months. Changes in diet quality, assessed by Healthy Eating Index (HEI)-2010 scores (max=100), were compared at baseline, 3-months, and 6-months. Repeated measures ANOVA models were used to assess changes in HEI scores and diet components between groups from baseline to 3- and 6-months. Models included time, group, and group x time interaction. The models use Full Information Maximum Likelihood estimation with robust standard errors to utilize all available data when attrition is present.

Results: Changes in HEI scores from baseline did not differ between the App and Bite groups at either 3- (App: 6.1 \pm 2.6 points, Bite: 2.7 \pm 2.7; $P=0.36$) or 6-months (App: 5.9 \pm 2.7 points, Bite: 3.9 \pm 2.9; $P=0.62$). Examining within-group changes, the App group significantly improved their HEI score at both 3- ($P=0.02$) and 6-months ($P=0.03$), while the Bite group did not. Changes in reported energy intake (kcal/day) did not differ by group at 3- (App: -807.2 \pm 119.3 kcal, Bite: -498.0 \pm 128.1; $P=0.08$) or 6-months (App: -641.5 \pm 127.9 kcal, Bite: -507.6 \pm 135.2; $P=0.47$); however, both the App and Bite groups significantly decreased their energy intake at 3- (both $P < 0.001$) and 6-months (both $P < 0.001$) respectively, when examining within-group changes.

Conclusions: Future interventions should examine ways to target and improve diet quality through mHealth technology.

THE NEWEST VITAL SIGN: MEASURE OF HEALTH LITERACY AND WEIGHT-RELATED BEHAVIORS IN INDIVIDUALS WITH FOOD INSECURITY

Lauren E. Blau, B.S.¹, Jaime A. Coffino, B.A., M.P.H.¹, Julia M. Hormes, Ph.D.²¹University at Albany, State University of New York, Albany, NY; ²University at Albany, SUNY, Albany, NY

Introduction: Health literacy is the ability to understand basic health information and to make informed health decisions. The purpose of the current study was to examine the relationship between health literacy and weight-related health behaviors in individuals living with food insecurity, a population at significantly elevated risk for overweight/obesity and associated health problems. Very few studies have examined this relationship, and to the best of our knowledge, no studies have examined the association between scores on the Newest Vital Sign (NVS), a measure of health literacy, and weight-related health behaviors in a low-income sample.

Methods: 47 food-insecure participants (73.9% male, 57.4% non-white, 66.6% overweight/obese) indicated their current weight and height and filled out a battery of self-report measures, including the NVS, the Dutch Eating Behaviors Questionnaires (DEBQ), the Binge Eating Scale (BES, $\alpha = .89$) and the Eating Attitudes Test (EAT-26, $\alpha = .84$). Other diet-related behaviors that were assessed included frequency of cooking, eating out, and grocery shopping.

Results: The NVS showed good internal consistency (Cronbach's $\alpha = .74$). The average number of correct items on the NVS (ranging from 0 to 6) was 1.38 ± 1.62 with 83% ($n=39$) of participants scoring $r = .35$, $pr = .08$, $p = .58$). Furthermore, there were no significant associations between NVS scores and DEBQ subscale scores, BES and EAT-26 total scores, or other diet-related behaviors such as frequency of cooking, eating-out, and grocery shopping (all uni- and multivariate $p > .05$).

Conclusion: Previous research has found that NVS scores are not associated with better health outcomes (Osborne et al., 2007; Gordon, Singh and Aiken, 2017). These results expand upon existing research by showing that health literacy is not associated with health or diet-related behaviors in a food insecure sample. While the NVS demonstrated good internal consistency and convergent validity, the lack of significant associations between NVS scores and diet- and weight-related behaviors suggest that nutrition psychoeducation may not be a useful target for interventions. Instead, behaviorally-based interventions may be more effective in promoting positive health outcomes.

CHANGES IN ABSOLUTE AND RELATIVE ENERGY INTAKE IN MEN AND WOMEN DURING A 9-MONTH RESISTANCE TRAINING TRIAL

Felicia Steger, MS, RD¹, Lauren T. Ptomey, PhD, RD, LD², Erik A. Willis, PhD, MPH³, Joseph Donnelly, ED.D.¹, Debra Sullivan, PhD, RD¹, Richard Washburn, PhD⁴¹University of Kansas Medical Center, Kansas City, KS; ²University of Kansas Medical Center, Kansas City, MO; ³Cancer Prevention Fellowship Program, Division of Cancer Prevention, Metabolic Epidemiology Branch, Division of Cancer Epidemiology & Genetics, National Cancer Institute, Rockville, MD; ⁴University of Kansas Medical Center, Lawrence, KS

INTRODUCTION: We observed energy intake (EI) in previously sedentary adults completing resistance training (RT) or non-exercise control 3 days/wk over 9 months to determine if this exercise modality may induce dietary compensation for physical activity.

METHODS: 168 normal weight or obese sedentary young adults (18–30 yrs.; 50% female) completed a 9-month trial using either 1 ($n=40$; 19 females) or 3 ($n=39$; 20 females) sets of RT or served as non-exercise controls ($n=39$; 18 females). Exercise participants were required to complete supervised RT exercise sessions 3 days/wk in a dedicated exercise facility. Participants were instructed to maintain their usual *ad libitum* diet and nutrient intake was assessed using 7-day digital photography diet records plus recall methodology and were analyzed using NDSR. General linear mixed modeling was used to examine overall group differences (group effect), change over time (time effect), and group differences in this change (group x time interaction). All analyses were conducted using SAS 9.4 (SAS Institute Inc., Cary, NC).

RESULTS: Absolute EI (kcal/day) significantly decreased in controls and exercise intervention groups (time effect $p=0.035$). There were no significant group effects or group x time interactions. In women, absolute EI significantly decreased in each group (time effect $p=0.042$); there were no significant group effects or group x time interactions. In men, there were no significant effects for group, time, and group x time interaction for absolute EI. Similarly, relative EI (kcal/kg/day) significantly decreased in controls and intervention groups (time effect $p=0.001$). There were no significant group effects or group x time interactions. In women, relative EI significantly decreased in each group (time effect $p=0.014$); there were no significant group effects or group x time interactions. In men, there were no significant effects for group, time, or group x time interactions.

CONCLUSIONS: Energy intake significantly decreased in participants completing a RT trial and this decrease did not differ between intervention and control subjects. Decreases over time may be resulting from the impact of self-monitoring dietary intake or enrolling in an exercise study with the intention of losing weight. Similar evaluations of EI during exercise trials indicate that dietary compensation for energy expended in physical activity is minimal or insignificant, and this study corroborates these findings, demonstrating that RT at this volume and frequency is unlikely to result in clinically meaningful changes in energy intake.

6:15 PM-7:15 PM

SOCIAL DESIRABILITY, FOOD INTAKE, AND RESPONSIVENESS TO MOOD INDUCTIONS

Erin Chatten, B.A.¹, Kristin Schneider, Ph.D.², Jessica Oleski, MA³, Sherry Pagoto, PhD³¹Rosalind Franklin University of Medicine and Science, Great Lakes, IL; ²Rosalind Franklin University of Medicine & Science, North Chicago, IL; ³University of Connecticut, Storrs, CT

Research suggests social desirability is associated with underreporting of unhealthy food intake and overreporting of healthy food intake, but research examining the effect of social desirability on observed food intake is lacking. This secondary data analysis examined if social desirability levels were negatively associated with food consumption. Participants ($n=58$; 26% male, 38% obese) were recruited for an emotional eating study that required responsiveness to anger and anxiety mood inductions for eligibility (at least a 4-pt. increase on the profile of mood states subscales). Participants completed the Marlowe-Crowne Social Desirability Scale and the Health and Taste Attitudes Questionnaire during screening and, if eligible, underwent anger, anxiety, and neutral mood inductions on separate days. Participants were provided with 2400 kcal of palatable foods following each mood induction and instructed to consume as much of the food as they would like so that they could rate each food's palatability. Calories consumed were measured by weighing leftovers. Social desirability levels did not contribute to the variance in food intake in the neutral mood condition after controlling for age, BMI category, and sex, $R^2 \text{ change}=.01$. Inconsistent with the literature, social desirability was not correlated with self-reported preference for healthy foods after controlling for age, BMI category, and sex, $R^2 \text{ change}=.00$. Given the null findings for objective food intake and self-reported food preferences, we conducted post-hoc analyses to explore whether the sample was representative of social desirability levels among adults, and whether the mood responsiveness eligibility requirement for the emotional eating study may have impacted the representativeness of the sample. The mean social desirability score of the sample ($M=25.19$, $SD=2.94$) was significantly higher than published social desirability norms for a comparable sample ($M=15.08$, $SD=5.05$), $t=-11.83$, $p<.001$. Since responsiveness to a mood induction was an eligibility criterion for the emotional eating study, individuals with low social desirability may not have been as responsive to mood inductions compared to individuals with high social desirability, who may have been more suggestible during the mood induction. Social desirability was positively correlated with change in anxiety following the anxiety mood induction, $R=.31$, $p=.02$, but not with change in anger following the anger mood induction. Social desirability was not associated with objective food intake or self-reported food preferences in a sample of adults with lean or obese BMIs. The limited variability in social desirability scores could have impacted our ability to observe a relationship between social desirability and food intake in our sample. Future studies examining the impact of social desirability on objective and subjective food intake are warranted.

THE EFFECT OF A TEXT MESSAGE-BASED INTERVENTION ON ADHERENCE, WEIGHT LOSS, AND DIET QUALITY

Michael Stanton, Ph.D.¹, Marily Oppezzo, PhD², Ariadna Garcia, M.S.³, Joseph Rigdon, Ph.D.³, Christopher Gardner, Ph.D.³¹California State University, East Bay, Hayward, CA; ²Stanford University School of Medicine, Stanford, CA; ³Stanford University, Stanford, CA

Background: One of the main challenges of weight loss trials is participant motivation and adherence after the active intervention ends. Short-message service (SMS)-delivered interventions have shown positive, short-term effect on behavior change. While there is some evidence of success when using mobile technology during the first six months of a weight-loss intervention, less research has been conducted after the first six months.

Objective: The purpose of this paper is to evaluate the effectiveness of SMS on class attendance, diet adherence, diet quality, and weight change post active intervention in a large weight loss trial.

Methods: The SMS intervention was based on the cybernetic model of self-control (CMSC) with participants receiving 3 to 4 messages a week. All participants in the last cohort (cohort 5, $n=128$) of a large randomized weight loss study of 609 participants were offered a SMS-intervention as an attempt to improve participant adherence during the last 6 months of a 1-year weight loss program. A propensity score model (PSM) was estimated using the 97 participants who opted to receive SMS and those 31 who declined in Cohort 5. The PSM was used to match Cohort 5 text message participants to a control group from Cohorts 1–4. A two-sample t-test was used to assess the differences between the intervention and matched control group in four main outcomes: (1) proportion of class attendance from 6 to 12 months, (2) diet adherence measured as total carb for LC at 12 months and total fat for LF at 12 months, (3) diet quality measured by the Healthy Eating Index (HEI) and Alternative Healthy Eating Index (AHEI) at 12 months, (4) 12-month minus 6-month weight change. Scatterplots and Spearman correlations were also used to assess the dose-response relationship between proportion of text messages responded and the four outcomes listed above.

Results: The results suggest that receiving text messages had no effect in participants losing more weight in the last 6 months of the study compared to controls; mean difference=0.26 kgs., 95% CI (-0.96, 1.48), $p=0.68$. Similar results were observed for proportion of class attendance after 6 months; mean difference (of SMS group minus control?) = 4.63%, 95% CI (-4.43, 13.68), $p=0.31$. No significant relationships were observed for diet adherence and diet quality either. The dose response correlation showed a positive significant relationship between percentage of messages to which participants responded and class attendance (correlation=0.45, p

Conclusions: While the current text message intervention did not improve weight loss or class attendance, future studies should pilot different SMS interventions that promote more effective user engagement.

E-HEALTH PORTAL TO SUPPORT SELF-MANAGEMENT IN YOUNG PEOPLE WITH CANCER: A FEASIBILITY STUDY

Olöf Birna Kristjansdóttir, PhD¹, Cecilie Varsi, PhD¹, Marianne Westeng, MSc¹, Kjersti Tveten, MSc², Cornelia Ruland, PhD, professor¹¹Center for Shared Decision Making and Collaborative Care Research, Oslo University Hospital, Oslo, Oslo, Norway; ²Department of Oncology, Oslo University Hospital, Oslo, Oslo, Norway**Background:** Young people with or recovering from cancer report unmet informational and support needs that might be met with e-health interventions.**Aim:** To evaluate the acceptability and usefulness of an e-health portal for young people (age 15–26) with cancer.**Methods:** Participants received access to a portal with 5 modules: 1) self-management-related information, 2) links to relevant HONcode certified websites, 3) a diary, 4) a message service allowing written communication with a nurse and 5) a peer support forum. Modules 3–5 required secure log in with an electronic ID. The portal was open for 13 months from February 2015. Participants received a questionnaire about acceptability and usefulness 3 months after inclusion and were invited to participate in a post-intervention interview on their experience as a user or non-user. Data from questionnaires and portal log were analyzed with descriptive statistics and qualitative data using content analysis.**Results:** Seventeen (8 males) participated (mean age 20.8, range 16–25 years). Eight were currently in cancer treatment. Twelve used the portal, i.e. logged in at least once but median login frequency was only 1.5 (range 1–19). Eleven visited the forum and 4 posted 1–3 posts each. Two participants sent 1 message each and 1 wrote a diary entry. Visits to modules not requiring login were not registered. Only 5 (42%) of the 12 users answered the questionnaire. Of those, 5 reported the log in procedure as non-problematic, 4 reported the forum as easy to use, 3 found the forum posts, the information module and the links useful and 4 found searching in links easy. When asked about the portal's usefulness in meeting informational needs, 2 provided a neutral response and 3 a more negative one. Results from interviews (n=5) confirmed a need for information stored in one place. Barriers for use were inconvenient log in procedure, too general information in the portal, lack of compatibility with smartphones and layout issues.**Discussion:** Despite being developed with user-centered design, the portal did not meet requirements for engagement and benefit. The forum's usefulness was limited due to few participants. Compatibility with smartphones and easier log in procedure might have increased engagement. Providing tailored and more detailed information might also have increased the feasibility. The low response rate is a limitation. E-health portals may be suitable, but more knowledge on users' requirements is needed.

EXAMINING POTENTIAL MODERATORS OF THE PERSUASIVE EFFECTS OF COLORECTAL CANCER SCREENER VS. SURVIVOR TESTIMONIALS

Amy McQueen, PhD¹, Julianne A. Sefko, MPH¹, Charlene Caburnay, PhD, MPH², Matthew Kreuter, PhD, MPH³¹Washington University School of Medicine, St. Louis, MO; ²Washington University in St. Louis, Saint Louis, MO; ³Washington University in St. Louis, St. Louis, MO

Narrative communication styles use storytelling and testimonials to depict events and consequences for characters. Because narratives engage audiences in stories that may not be overtly persuasive, narratives -particularly those of real-life experiences- are generally expected to reduce individuals' tendencies to respond defensively to a message or source and thereby increase message-congruent attitudes. Less is known about audience characteristics that may moderate narrative effects and warrant more tailored messages.

We randomized 477 adults age 50–75 years old who were not adherent to colorectal cancer screening (CRCS) guidelines and had no history of cancer to one of three groups: 1) CRCS information only, 2) CRCS information plus a photo and text narrative of a CRC survivor, or 3) CRCS information plus a photo and text narrative of a CRC screener who did not have cancer. Photos were tailored on the participant's sex, age group and race/ethnicity. Participants completed surveys online before and after exposure to the intervention and 1, 6, and 12 months follow up.

We examined participant's demographic (sex, race (white/other), partnered, age), healthcare (regular doctor, doctor recommended CRCS) and psychological (perceived relevance, attitudes toward prevention, Big 5 personality traits) characteristics as potential moderators of the effect of narrative vs. informational and survivor vs. screener messages on intention (3 items, 0–100) and CRCS by 12 months follow up. Continuous variables were centered and interaction terms were tested with UNIANOVA and logistic regression for intention and CRCS outcomes respectively. Stratified analyses were used to report the few differences found.

Participants who read a narrative and did not have a regular doctor had lower CRCS intention post-intervention (M=57, SD=29) than info only (M=69, SD=27); no difference for those with a regular doctor (narrative M=68, SD=28; info only M=68, SD=26), F=3.68, p=.056. Participants who read survivor (vs. screener) narratives were more likely to get CRCS, but only if they had a regular doctor (OR=2.43, CI:1.36–4.33) vs. no doctor (OR=.58, CI: .20–1.68), p=.021. Neuroticism was significantly associated with intention in the info only (Beta=-.24, p=.005) vs. narrative groups (Beta=-.02), t=1.97, p=.05. Extraversion was related to intention for info only (Beta=.23, p=.009) and the screener narrative (Beta=.19, p=.04) but not the survivor narrative; t=-2.25, p=.026.

Understanding how narratives influence cognitions and behaviors is critical to maximizing their effectiveness, reducing any negative consequences, and developing appropriate applications for diverse settings. Results from our study found few moderating effects that would warrant tailoring narratives to audience characteristics, but having a regular doctor is important for CRCS intentions and behavior.

THE USE OF PRONOUNS DURING PRIMARY CARE VISITS AND THEIR RELATIONSHIP TO PATIENT SATISFACTION

Morgan Snyder, BS, Kelly Haskard-Zolnierrek, Ph.D.

Texas State University, San Marcos, TX

Previous research has shown that the use of pronouns can indicate where the speaker's attention is focused. Singular first-person pronouns (e.g., I, me, my) suggest that the speaker's attention is focused on themselves, whereas plural first-person pronouns (e.g., we, us, our) suggest that the speaker's attention is focused on someone else. Pronoun use has been studied in many areas but little research has examined pronoun use during medical visit communication. The purpose of the current study was to examine associations between physician and nurse pronoun use and patient satisfaction. It was hypothesized that (1) the use of plural first-person pronouns by both physicians and nurses would be positively associated with patient satisfaction and (2) the use of singular first-person pronouns by both physicians and nurses would be negatively associated with patient satisfaction. Linguistic Inquiry Word Count Software (LIWC) was used to analyze transcripts of videotaped medical visits collected as part of a larger study. LIWC gives a percentage of words that fall into each category of its dictionary. Subscales from a modified version of the PSQ 18, used in the RAND Medical Outcomes Study, were used to measure overall satisfaction with the physician and the nurse. Participants ($n=151$) included those who agreed to have their visit recorded and filled out a post-visit questionnaire. Correlations revealed no relationship between physicians' use of singular first-person pronouns or plural first-person pronouns and patients' reported satisfaction with their physician ($r = .10, p = .22; r = .02, p = .86$). Results showed no relationship between nurses' use of plural first-person pronouns and patients' reported satisfaction with their nurse ($r = -.02, p = .78$). Results revealed a significant negative correlation between nurses' use of singular first-person pronouns and patients' reported satisfaction with their nurse ($r = -.17, p = .04$). This negative association could be due to patients' perceptions that their nurses are not solely focused on them, therefore lowering satisfaction with that aspect of their care. Results suggest that medical visit communication should be studied in a comprehensive way; for example, researchers should study word use in addition to nonverbal communication or overall communication quality.

EVALUATION OF DEPRESSION AND SUICIDE SCREENING ON INPATIENT CANCER UNITS

Heather Kruse, Ph.D., Jessica Hamilton, Ph.D., Kelsey Sewell, Ph.D.

University of Kansas Health System, Kansas City, KS

INTRODUCTION: Although suicide is the tenth leading cause of death within the United States, many hospital systems do not have standardized prevention or treatment procedures for suicidal ideation (SI). In response, the University of Kansas Health System created the Suicide Prevention Task Force to assess current hospital wide practices, and determine areas for change. The purpose of this quality improvement study was to evaluate suicide prevention protocols specifically on our cancer inpatient units.

METHODS: Data were collected during May 2017 on all patients who were screened on our three inpatient cancer units. Patients are screened upon arrival by nursing staff. Current protocol is to ask one question about depression, and one question about SI. Patient responses were entered as "yes" or "no" into the patient's electronic medical record (EMR). This data was extracted by our EMR reporting team. For patients who screened positive, we then collected variables from the EMR related to psychotropic use, participation in psychotherapy, and follow up safety interventions.

RESULTS: Of the 151 patients screened, only six endorsed feelings of depression. The majority ($n = 4$) of these patients were female. Half of the patients who endorsed depression were prescribed a psychotropic medication. Most ($n = 4$) had not met with a psychologist at our facility. Zero patients were recorded as endorsing SI. Because no patients were recorded as expressing SI, we did not have any follow up safety interventions upon which to report.

DISCUSSION: These results are surprising, especially given that the suicide rate within in cancer populations is estimated to be twice that of the general population. There are a few possible explanations for our results: 1) The questions the inpatient units are currently utilizing to assess for depression and SI lack validity; 2) Patients are only being screened upon arrival, and thus staff are only capturing comorbid depression and SI, and not that which develops of the course of a month-long hospital stay; 3) Nursing staff may not be able to assess all patients, and therefore the default response within the system is to mark patients as "no" to these questions. Our results suggest that depression and suicide assessment strategies within healthcare systems should be evaluated for validity and feasibility in order to ensure that patients are being properly screened and receiving appropriate interventions.

PEER REJECTION AND EMOTION DEVELOPMENT: THE ROLE OF PEER REJECTION AND COMING OUT ON EMOTIONAL HEALTH AMONG GAY AND BISEXUAL MEN

Joseph Carter, MA¹, H. Jonathon Rendina, PhD, MPH², Jeffrey T. Parsons, PhD²¹Center for HIV Educational Studies and Training, New York, NY; ²Hunter College of the City University of New York (CUNY), New York, NY

Background: Minority stressors, such as stigmatization and rejection, have been associated with emotion dysregulation levels among gay and bisexual men, and sexual identity milestone achievement may be important for understanding this association. Coming out to others, specifically to friends and peers, can be a wholly rewarding, or otherwise difficult experience for gay and bisexual youth; however, research has not fully explored its implication on the association between minority stress and mental health outcomes across the lifespan. To address this gap in research, this study examined the potential mediational role of the age of first coming out to friends on the association between childhood experiences of peer rejection and levels of emotion dysregulation in adulthood.

Method: This study uses baseline computer-assisted self-interviewing (CASI) survey data, measuring key and demographic variables. Surveys were completed among a sample of gay and bisexual men (n=367) recruited in and around the New York City area.

Results: Results from multiple hierarchical regression showed that peer rejection predicted levels of emotion dysregulation, $\beta = 0.29$, $p < 0.01$, and age of first coming out to friends, $\beta = -0.13$, $p < 0.05$. Thus, age of first coming out to friends did not mediate the association between childhood peer rejection and levels of emotion dysregulation in adulthood.

Discussion: Though mediation was not supported, the temporal association between peer rejection experiences and levels of emotion dysregulation suggest that minority stressors experienced in childhood could have lifelong mental health consequences for sexual minority populations. This study adds to a body of research that suggests the importance of early stigmatization and rejection prevention measures, contributing to the development of positive relationships and accepting environments for sexual minority youth. Furthermore, this study contributes to research that informs psychological interventions that target the psychological and environmental factors that contribute to poor mental health outcomes among sexual minority populations.

NEUROENDOCRINE DYSREGULATION IN OEF/OIF/OND VETERANS WITH A HISTORY OF MILD TRAUMATIC BRAIN INJURY

Jenna Gress Smith, PhD¹, Cleo Arnold, PsyD², Nicole A. Roberts, PhD³, Julie Hurd, BA⁴, Mary Lu Bushnell, PsyD²¹Phoenix VA Healthcare System, Gilbert, AZ; ²Phoenix VA Healthcare System, Phoenix, AZ; ³Arizona State University, School of Social and Behavioral Sciences, Glendale, AZ; ⁴Arizona State University, School of Social and Behavioral Sciences, Phoenix, AZ

As the 'signature injury' of the Operation Enduring Freedom/Operation Iraqi Freedom/Operation New Dawn (OEF/OIF/OND) conflict, understanding traumatic brain injury (TBI) has been a prime focus within the VA healthcare system. One aspect of TBI that has received attention is the sequelae of neuroendocrine dysfunction (NED). Studies in civilian populations have found associations between TBI and aspects of neuroendocrine dysfunction, such as hypothyroidism and testosterone deficiency (Englandar, Bushnik, Oggins, & Katznelson, 2010). Similar relationships also have been evident in samples with mild TBI (mTBI; Tanriverdi et al., 2009; Wilkinson et al., 2012). Wilkinson et al. (2012) found 42% of Veterans (N=26) with blast-related mTBI had abnormal hormone levels in one or more pituitary axes while three of these Veterans had testosterone and gonadotropin concentrations consistent with hypogonadism. Further, TBI and possibly NED symptoms also may be associated with PTSD, depression, and sleep complaints. The aim of the current study was to conduct a small pilot test of screenings for NED in OEF/OIF/OND veterans with cognitive complaints. The sample comprised of 137 participants (95% male, 71% Caucasian, ages 21 to 58) who were evaluated in a TBI assessment clinic. A subset (n = 50) of Veterans obtained bloodwork for suspected NED based on responses on a screening questionnaire: levels of thyroid stimulating hormone (TSH) and testosterone were collected for 40 and 14 Veterans, respectively. One Veteran had low TSH and 3 had low testosterone levels. Domains of cognitive were measured by the Neuropsychological Assessment Battery (NAB). These were each significantly and positively related with TSH levels and those with low testosterone showed poorer performance on immediate recognition, executive functioning, and digit forward & backward subscales of the NAB ($ps < .05$). However, self-reported cognitive complaints were not significantly related to TSH or testosterone. There also were no significant correlations among dysregulated TSH or testosterone, PTSD symptoms (per the PTSD Checklist), insomnia symptoms (Insomnia Severity Index), or depression symptoms (Beck Depression Inventory-II). These preliminary findings suggest that aspects of neuroendocrine dysfunction may be related to decrements in objective cognitive performance, but may not have as much of an impact on psychiatric and sleep symptoms as is commonly thought.

CHANGING IMPLICIT ATTITUDES TOWARD PHYSICAL ACTIVITY AND SEDENTARY BEHAVIOR WITH ENVIRONMENTAL CUES DURING REHABILITATION

Guillaume Chevance, Ph.D. Student¹, Tanya Berry, Professor², Julie Boiché, Assistant Professor¹, Nelly Héraud, Research Director³

¹Université de Montpellier, Montpellier, Languedoc-Roussillon, France; ²Faculty of Physical Education and Recreation, University of Alberta, Edmonton, Canada, Edmonton, AB, Canada; ³Groupe 5 Santé, Lodève, Languedoc-Roussillon, France

Objective. Recent frameworks have been developed to encourage the conduct of interventions targeting implicit (i.e., non-conscious, unintentional) motivational processes. The philosophy of those frameworks is to conceive “discrete” interventions that do not require participant reflection, such as exposition to images or posters. Based on past research, this study evaluates the impact of a 4-day exposure to posters associating physical activity or sedentary behavior with positive attributes on (1) implicit attitudes toward physical activity *versus* sedentary behavior, and (2) moderate to vigorous physical activity.

Design. To enhance ecological validity, this study was conducted among participants enrolled in a pulmonary rehabilitation program. Participants (N=79) were randomized into groups (i) exposed to posters of people being physically active, (ii) exposed to posters of people engaged in sedentary behaviors, or (iii) not exposed to posters (control). Over four days, different posters were put in patients’ bedroom. Participants were not informed of the link between the intervention and the evaluations. A third person blinded to the hypotheses conducted the intervention.

Main Outcomes Measure. Implicit attitudes were measured with an Implicit Association Test at the start and at the end of the intervention. Physical activity was measured with accelerometers during the weekend following the intervention.

Results. Regarding implicit attitudes, the analyses showed a non-significant time x group interaction, $F(2, 65) = .462, p = .632$. There were also no significant differences between the three groups regarding physical activity, $F(2, 61) = .331, p = .719$. Confirmatory Bayesian analyses indicated decisive and moderate evidence for the null hypothesis respectively ($BF_{01} = 100; BF_{01} = 6$). Last, an ancillary analysis (i.e., stepwise regression) indicated that baseline implicit attitudes were significantly associated with physical activity after the intervention, controlling for important physical activity covariates ($\beta = .35, p = .048$).

Conclusion. Putting posters in patients’ bedroom during a rehabilitation program did not impact their implicit attitudes nor physical activity behavior. Other studies are needed to develop effective interventions targeting implicit attitudes. Targeting this variable could help to develop innovative physical activity promotion strategies.

TWEET AND RUN: ASSESSING THE IMPACT OF SOCIAL COMPARISON AND SOCIAL MEDIA ON PHYSICAL ACTIVITY

Zeljka Macura, B.S.¹, Philip Moore, PhD¹, Lauren A. Fowler, BS, MPhil¹, Catherine Rudoy, Bachelor of Arts², Paige Tripp, B.A. in Psychology³

¹George Washington University, Washington, DC; ²The George Washington University, West Hills, CA; ³George Washington University, San Francisco, CA

Background. Obesity prevalence in the United States has reached epidemic proportions with a majority of the adult population, ages 18 years and older, overweight or obese. Overweight and obesity is associated with a plethora of health, social, psychological and economic issues. A major contributor to the obesity epidemic is a lack of physical activity. Thus, developing interventions to increase physical activity among young adults is essential in lowering the risks related to being overweight or obese. One potential approach is to utilize social psychological theories, such as social comparison theory. Previous research has successfully manipulated social comparison targets to increase advantageous health outcomes, such as physical activity. Historically, social comparison manipulations have separated upward and downward comparison information into two conditions. The current study includes a combined social comparison condition (i.e., upward and downward comparison information), with all comparisons manipulated within the context of social media.

Method. A sample of undergraduate students ($N=124, 74.2\%$ female), from a Northeastern university, took part in a longitudinal study examining the effects of social comparison theory in the context of social media (i.e., Twitter) lasting 8 days. Participants were randomly assigned to one of four conditions: upward comparison, downward comparison, combined (upward + downward) and control. Participants in the upward condition received tweets from a highly active person, participants in the downward condition read tweets from an extremely inactive individual, those in the combined condition viewed tweets from both active and inactive individuals, and the control condition participants read tweets unrelated to physical activity and diet. The primary dependent variables were physical activity attitudes, intentions and behavior, measured at T1 and T2. Exercise self-efficacy and social comparison orientation information was collected to assess a potential interaction of these two variables on the relationship between condition and the primary outcomes.

Results. A MANOVA revealed that there was no significant main effect of condition on physical activity attitudes, intentions or behavior. In addition, neither exercise self-efficacy nor social comparison orientation, significantly moderated the relationship between condition and physical activity attitudes, intentions or behavior.

Conclusions. Even though the results are not significant, the study informs future social comparison research by providing information about the effects of combining upward and downward information, as well as how this form of research can be carried out in a setting outside of the laboratory and in the context of social media.

CAN JUST-IN-TIME ADAPTIVE INTERVENTIONS IMPROVE SELF-EFFICACY TO PREVENT DIETARY LAPSES?

Edward W. Lieber, MBA, Stephanie Goldstein, MS, Gerald Martin, B.A., Evan Forman, Ph.D., Meghan Butryn, Ph.D., Adrienne S. Juarascio, Ph.D.

Drexel University, Philadelphia, PA

Lapses from a dietary prescription contribute to suboptimal outcomes in behavioral weight loss (BWL) treatments. Recent studies using ecological momentary assessment (EMA) have shown that low self-efficacy is related to increased risk of dietary lapses, but little research has focused on targeted interventions to increase self-efficacy and therefore prevent dietary lapses. This study aims to understand the impact of just-in-time adaptive interventions (JITAI; a method for providing interventions to participants in real-time, daily settings) on self-efficacy in following a dietary prescription. We hypothesized that opening an intervention targeting self-efficacy will be associated with lower likelihood of lapse at the next time point. Participants with overweight/obesity ($n=35$) followed a self-guided, commercial weight loss diet for 8 weeks while also using an app called OnTrack. OnTrack used EMA to assess dietary lapses and self-efficacy through the first 2 weeks of the study. After 2 weeks, OnTrack utilized a machine learning algorithm to predict dietary lapses and subsequently deliver brief micro-interventions personalized to individual risk factors. OnTrack delivered micro-interventions as automatic notifications on a smartphone device. Participants could then choose to open the notification for more information on their risks of dietary lapse. Successful interventions were defined as participants not reporting a dietary lapse at the EMA survey immediately following receipt of a micro-intervention (~3 hours). Participants received an average of 3.72 self-efficacy-focused micro-interventions per week over the 6-week intervention period. Eighty-two percent of interventions were opened by participants. Generalized estimating equations revealed that opening an intervention to increase self-efficacy did not appear to influence lapse behavior during the 6-week period ($B=1.26$, $p=0.27$). However, individuals with generally high levels of self-efficacy (assessed through an average of EMA survey responses) were less likely to lapse ($B=-0.47$, $p<.001$). Further, every one unit increase in self-efficacy (compared to their own average self-efficacy) decreased the likelihood of a lapse by 63% ($B=-0.22$, $p<.001$). Results suggest that self-efficacy can be a protective factor against lapsing, but more research is needed on effective methods for targeting self-efficacy using in-the-moment intervention methods.

DEVELOPMENT OF A MEASURE OF VALUES CLARITY, AND ITS ASSOCIATION WITH WEIGHT CHANGE OVER TIME IN A BEHAVIORAL WEIGHT LOSS PROGRAM

Diane Dallal, B.A.¹, Jena Shaw Tronieri, Ph.D.², Stephanie Manasse, PhD¹, Evan Forman, PhD³¹Drexel University, Philadelphia, PA; ²University of Pennsylvania, Philadelphia, PA; ³Drexel University, Phila., PA

Values, or the overarching principles by which we live, may strongly influence health behaviors. In particular, having clarity of values helps individuals commit to healthy behaviors that may otherwise be difficult to engage in. Especially for overweight and obese populations seeking weight loss, gaining values clarity (VC) may facilitate engaging in less pleasurable behaviors in the service of a health value. However, there are no well-defined measurement tools for VC in the current literature, perhaps because of the challenges of measuring such an individually oriented construct. For example, it would be difficult to create a reliable questionnaire listing all known valued categories to be rated on a Likert scale of importance to the individual. As such, no VC measures have been developed. Thus, we aimed to create a measure of VC, and test its association with weight loss in a large obesity trial to assess its reliability in predicting acceptance-based treatment (ABT) outcomes. Participants who were overweight ($n=129$) were randomized to receive 25 sessions of either ABT or standard behavioral treatment (SBT) for weight loss over 1 year. Assessments were conducted at baseline and post-treatment, in which weights and VC measure responses were collected. On a lab computer, participants were asked to type several of their most important values. Responses were coded using a scoring system from 1–3 (where 1 indicated evasion of the question, 2 indicated an attempted response that constituted a goal, and 3 indicated a value). Higher scores indicated greater VC. We hypothesized that 1) an increase in VC from baseline to post-treatment would be associated with greater percent weight change (PWC) from baseline to post-treatment, and 2) that treatment condition would moderate the association, such that those in the ABT condition who experienced an increase in VC would exhibit greater PWC. We also expected that the coding system would be feasible, in that each unique response would fit into a scoring category. Results showed that the system was feasible. However, average change in VC ratings was not significantly associated with PWC ($r=.10$, $p=.27$). Additionally, treatment condition did not moderate VC's relation with PWC ($F=2.33$, $p=.13$, $\eta^2=.02$). Data is not yet available to evaluate the measure's psychometric properties, but results suggest that the measure requires refinement to be reliable. Limitations and implications for its future iterations will be discussed.

WEIGHT LOSS AND PERCEPTIONS OF HOME-PREPARED FOOD CONSUMPTION

Reid Havka, B.A., Chelsey Solar, M.S., Ed.S., Robert Carels, Ph.D., MBA

East Carolina University, Greenville, NC

Introduction: There has been a continuous shift from foods prepared at home to food prepared outside of the home. Approximately one-third of daily energy intake comes from fast-food outlets and restaurants. Increased home food preparation is associated with an increased likelihood of meeting dietary objectives, improved overall health and survival, and decreased BMI. The current investigation examined home-prepared food consumption and weight loss, and perceptions of preparing and consuming home-prepared food utilizing ecological momentary assessment during a 16-week self-administered weight loss intervention.

Method: The current sample consisted of 47 individuals (79.6% female) with $M_{BMI} = 36.71$, $SD_{BMI} = 5.48$. Participants completed ecological momentary assessment (EMA) following each eating episode for the first two-weeks of an internet-based, self-administered weight loss intervention providing automated tailored feedback. Participants reported on food preparation behaviors, perceptions of consuming home-prepared food, and barriers associated with preparing and consuming home-prepared food.

Results: Participants in the current investigation achieved an average weight loss of 1.7% of total body weight ($M = 4.07$ lbs., $SD = 10.34$). There was a moderate effect ($r = -.455$) of home-prepared food consumption on weight loss following the intervention trending in the predicted direction ($p = .077$). Within-subjects effects indicated that relative to meals prepared outside of the home, home-prepared meals were associated with greater perceptions of: 1) eating consistently with nutrition goals, 2) being able to maintain one's diet, and 3) success with one's diet, all of which were significant at $p < .001$. Between-subjects effects indicated that home-prepared food consumption was associated with greater perceived consistency with meeting nutrition goals, $p < .05$.

Discussion: This investigation provides evidence that home-prepared food consumption has daily impacts on weight loss and perceptions of successful dietary behaviors. Home preparation may enable individuals to consume a more balanced and healthful diet. Foods prepared outside the home have been shown to consist of energy dense meals and are high in fat and saturated fat. Substituting foods outside the home for those home-prepared may increase the likelihood of avoiding a caloric surplus that would otherwise prevent successful weight loss or weight maintenance. Further, increased perceptions of eating consistent with nutrition goals, and success and ability to maintain one's diet, may lead to increased treatment adherence that promote successful weight loss outcomes. Taken together, home-prepared food consumption appears to support weight loss and may foster beliefs that enable individuals to overcome barriers related to healthful food choices.

EXAMINING PERCEPTIONS OF KNEE JOINT REPLACEMENT AND PHYSICAL ACTIVITY AMONG WOMEN WITH KNEE OSTEOARTHRITIS (OA): DAPPA STUDY

Courtney A. Peters¹, Erica Anderson, MSC², Warren Feaster, AS¹, Jaquisha Durant², Bridgett Rahim-Williams, MA, MPH, PHD³¹Bethune Cookman University, Daytona Beach, FL; ²Bethune-Cookman University, Daytona Beach, FL; ³Bethune Cookman University, Daytona Beach, FL

Background: Knee Osteoarthritis is a degenerative, debilitating condition affecting functional mobility and pain. The aim of this study was to examine perceptions (beliefs, attitudes and knowledge), towards knee joint replacement (KJR) and physical activity among aging women with knee OA.

Methods: Four focus groups (9 African-American [AA], 7 non-Hispanic White women [nHW]) were conducted to examine the experience of living with and managing knee OA pain among women; ages 51- 72. Sessions were facilitated by researchers trained in qualitative methodology, and were approximately two hours, audio-taped, text transcribed verbatim, coded and analyzed using content analysis to identify emergent themes, categories and meanings.

Results: Diagnosis of knee OA ranged from four months to 20 years. Sixteen (16) women participated in the focus group; nine AA and seven nHW. Women reported their perceptions of KJR and physical activity. When asked, "would you consider KJR?" six white women would consider: one would not; seven AA would not. Of those reporting having had KJR, two AA women had a positive response. While none of the nHW reported having had the surgery. Responding to "do you engage in physical activities?" women were similar in reporting types of activities in which they engaged: water aerobics, bicycling, and walking. When asked "how does pain affect physical activity?" women were also similar in reporting activities of daily living (gardening, shopping, house chores) that limited their physical function due to pain.

Conclusion: Although KJR surgery and PA are beneficial for improving health related quality of life among individuals diagnosed with knee OA, this study suggest that AA women are less likely to undergo KJR. Thus, KJR may not be a culturally acceptable treatment option. Moreover, task appropriate recommendations for PA may improve physical functioning necessary to cope with pain limitations.

¹University of Southern California, Los Angeles, CA; ²University of Southern California, Los Angeles, CA; ³NIH, Bethesda, MD; ⁴National Institutes of Health, Krieneri Attikis, N/A, Greece; ⁵National Cancer Institute, Bethesda, MD; ⁶National Institutes of Health, Boston, MA; ⁷Western University of Health Sciences - COMP, Los Angeles, CA; ⁸National Institutes of Health, Bethesda, MD; ⁹NIH Clinical Center --Nutrition Department, Bethesda, MD; ¹⁰NHLBI/NIH, Bethesda, MD; ¹¹National Cancer Institute, Bethesda, MD; ¹²Energy Metabolism Section, Diabetes, Endocrinology, and Obesity Branch (NIDDK), Bethesda, MD

Introduction: Overweight children are more likely to be lower in positive affect, higher in negative affect, and are more likely to have anxiety as compared to their healthy weight peers. Evidence indicates that aerobic physical activity can be an effective method for improving affect and anxiety in children. Therefore, the aim of this study is to assess whether brief interruptions in sitting with short bouts of low-intensity walking over 3 hours is sufficient to influence anxiety, positive affect, or negative affect in 7-11-year-old children; as well as to test how weight status may influence the efficacy of reducing sitting time for improving affect and anxiety.

Design/Methods: In this secondary analysis of a randomized crossover study, children (N=64; mean (SD) age=9.54 (1.32); 44% healthy weight) completed two experimental conditions: continuous sitting for 3 hours, and sitting for 3 hours interrupted with moderate-intensity walking for 3 minutes every 30 minutes. Anxiety, positive affect, and negative affect were assessed at pre-test and post-test. Separate multilevel models for repeated measures assessed whether experimental condition predicted post-test scores. All models were adjusted for randomization order and pre-test scores. Sex, age, and race were tested as covariates, and weight status was tested as a moderator of the relationship between experimental condition and post-test scores.

Results: Experimental condition was not significantly related to post-test anxiety, positive affect, or negative affect in the overall sample. The relationships between post-test anxiety, post-test positive affect and experimental condition were not moderated by weight status. However, weight status was a significant moderator ($p < 0.05$) of how experimental condition affected post-test negative affect. Negative affect was significantly lower in the healthy weight children after the interrupted sitting ($p < 0.05$); while negative affect was slightly higher in the overweight children after the interrupted sitting condition ($p = 0.16$).

Conclusions: Interrupting prolonged sitting with mini-bouts of walking predicted lower negative affect scores at post-test in healthy weight children and demonstrated no effects in the overweight children. Interrupting sitting with brief bouts of moderate-intensity walking did not significantly influence anxiety or positive affect. This study indicates that weight status may influence the efficacy of reducing sitting time for improving affect. Further research is needed to understand how reducing sitting time with different dosages of short bouts of walking may influence affect and anxiety in order to inform effective interventions.

INDICATORS OF ACCULTURATION ARE NOT ASSOCIATED WITH EVER CIGARETTE USE AMONG HISPANIC/LATINO COLLEGE STUDENTS

Edgardo Ramirez, B.S.¹, Nancy Jao, M.S.¹, Marcia M. Tan, PhD, MPH¹, Anuj Mubayi, PhD², Christina Ciecierski, PhD³, Brian Hitsman, PhD¹

¹Northwestern University Feinberg School of Medicine, Chicago, IL; ²Arizona State University, School of Human Evolution and Social Change, Simon A. Levin Mathematical Computational Modeling Science Center, Tempe, AZ; ³Northeastern Illinois University, Chicago, IL

Background: Higher levels of acculturation have been shown to be associated with smoking in Hispanic/Latino adults. Informed by Schwartz and colleague's bidimensional model of acculturation (behavioral, values, and identity domains), we examined the associations between behavioral and identity-based acculturation and ever smoking among Hispanic/Latino and non-Hispanic/Latino students attending a Hispanic-Serving Institution (HSI) in Chicago. We hypothesized that less acculturated students, particularly those identifying as Hispanic/Latino, would be more likely than more acculturated students to report ever smoking.

Methods: Students (N=709) completed a health behavior survey in the fall of 2015 in which they reported their primary language (a behavioral indicator of acculturation), immigration status (first, second, or third generation American; an identity-based indicator of acculturation), and lifetime smoking. We used logistic regression analysis to examine the association between the two acculturation indicators (primary language, immigration status) and ever smoking, controlling for potential confounders (race, ancestry, age, gender, household smoking, and ever binge drinking). Analyses were conducted in Hispanic/Latino and non-Hispanic/Latino students separately to compare groups.

Results: The sample comprised 39% Hispanic/Latino, 71% women, and 42% racial minority. The mean age was 28.1 (SD=9.4) years. Seventy-nine percent of the sample was U.S. born, 49% lived at home, 74% reported English as their primary language, and 47% were first generation Americans. Primary language and immigration status were not associated with ever smoking for either the Hispanic/Latino or non-Hispanic/Latino groups. Among the Hispanic/Latino group (n=276), students living with a smoker (OR=2.20, 95% CI=1.10–4.41) or those reporting ever binge drinking (OR=8.17, CI=2.78–24.02) were more likely to report ever smoking.

Conclusion: In this large sample of Hispanic/Latino students, neither behavioral nor identity-based acculturation was associated with ever smoking. Examination of other indicators of acculturation, such as cultural values (individualism vs collectivism), is needed, as students drawn to an HSI may experience a unique acculturation process. These findings warrant further investigation on the specific subtypes of acculturation that may influence smoking and other health risk behaviors among Hispanic/Latino college students.

USING A REASONED ACTION APPROACH TO PREDICT COMMUNITY-BASED GROUP EXERCISE BEHAVIOR IN HISPANICS: PRELIMINARY FINDINGS

Mariana Arevalo, MSPH¹, Yefei Zhang, MS¹, Louis D. Brown, PhD²¹University of Texas Health Science Center at Houston, Houston, TX; ²University of Texas Health Science Center at Houston, El Paso, TX

Background: Engagement in community-based group exercise remains understudied in Hispanic populations. Researchers have used reasoned action approaches (RAA) to identify determinants of exercise behavior, but this approach has not been tested to identify beliefs and predictors of group exercise in Hispanics. Thus, the aims of this study were use a RAA framework to explore beliefs and assess the impact of participants' attitudes, perceived norms, perceived behavioral control, and self-efficacy on their attendance and intentions to attend community-based group exercise activities.

Methods: We conducted an elicitation study among a cohort of participants from a larger study conducted in El Paso, TX. Participants completed a questionnaire containing open- and closed-ended questions to identify salient beliefs and practices about attending organized exercise activities. We conducted two separate negative binomial regression models in SAS to assess the effects of RAA predictors on intentions, and the effects of intentions on behavior, both adjusting for demographics; We performed qualitative content analysis by hand.

Results: The majority of our participants (N=76) were female (80%), married (52.63%), homemakers (39.62%), with a household annual income of less than \$19,999 (61.84%), with no formal education (36.84%), and a mean age of 45 ± 13 years. Our qualitative findings suggest that participants 1) value health and behavioral benefits of attending organized exercise activities; 2) feel the approval of family and friends to attend these; 3) identify transportation, time, distance, and costs as factors that could enhance or impede their attendance to organized exercise activities. Quantitatively, we found that instrumental attitudes and perceived behavioral control significantly predicted intentions ($B = 0.45$, $p < .05$; $B = 0.62$, $p < .05$), while adjusting for demographics. However, intentions did not predict behavior at follow up. Our convergent findings suggest that participants who reported intentions to participate in fewer organized exercise activities reported more barriers to attend, compared to those who had intentions to participate in more activities.

Conclusions: We identified beliefs about engagement in community-based organized exercise activities, which could help in the development of persuasive messages to promote this behavior in our sample. We also found that intentions did not predict behavior, a limitation of the RAA approach; thus, future studies should examine other environmental factors.

CONFORMITY TO GENDER NORMS AS A MODERATOR OF THE ASSOCIATION BETWEEN RELIGIOUS ORIENTATION AND CONDOM USE AMONG YOUNG ADULTS

Cecilia Bess, M.A.¹, Mike C. Parent, Ph.D.²¹Texas Tech University, Lubbock, TX; ²University of Texas at Austin, Austin, TX

Young adults engage in sexual behaviors that may compromise their health (e.g., unprotected sex) and contribute to sexually transmitted infection health disparities. Intrinsic religious orientation has been associated with less involvement in unhealthy behaviors. Additionally, there are mixed findings in regards to religiousness and condom use. Furthermore, conforming less to gender norms appears to be related to engaging in less risky sexual behavior (e.g., condom-protected vaginal sex) suggesting that gender norms may moderate the association between intrinsic religious orientation and risky sexual behavior. To test the hypothesis that the association between intrinsic religiousness and unprotected vaginal sex will be moderated by conformity to gender norms, participants ($N=234$; 18–25 years; $M=22.9$ years) completed an online survey with measures of religious orientation, conformity to gender norms, and sexual behaviors. Covariate (e.g., age and partner type) adjusted logistic regression and moderation analyses examined the association between religious orientation, gender norms, and condom use at the most recent sexual encounter ($n=198$; 85%). The regression model showed no significant main effects (AOR=0.88, 95% CI 0.593–1.31), and no significant interaction between masculine gender norms and religious orientation ($b=1.35$, $p=.15$, 95% CI -0.48–3.18) or between feminine gender norms and religious orientation ($b=.07$, $p=.91$, 95% CI -1.30–1.46) in predicting condom use at the most recent sexual encounter. Although, religious orientation and gender norms were not significantly associated with condom use at the last encounter, partner type (steady vs. non-steady) was significantly associated ($b=-.75$, $p=.01$, 95% CI -1.35–-.016). Further research is needed to identify other variables that may play a role in the relation between religious orientation and risky sexual behaviors (e.g., sexual health knowledge).

COUNTING SLEEP: THE EFFECTIVENESS OF MESSAGE FRAMING TO INCREASE SLEEP DURATION AND QUALITY

Melissa A. Shepherd, PhD¹, Mary A. Gerend, PhD², E. Ashby Plant, PhD²¹University of Montevallo, Montevallo, AL; ²Florida State University, Tallahassee, FL

This study examined the effectiveness of message framing to promote sleep behaviors. Participants (156 American college students) were randomly assigned to read either a gain- or loss-framed message. The gain-framed message focused on the benefits of sufficient sleep duration and good sleep quality, and the loss-framed message focused on the costs of insufficient sleep duration and poor sleep quality. Participants' motivational orientation (the extent to which they seek out positive outcomes or avoid negative outcomes) and sleep behavior were assessed at baseline. Potential mediational measures were assessed including time participants spent reading the message, recall of message content, and the extent to which participants elaborated on the message. Before participants left the lab, they reported their sleep-related intentions for the following week. One week later, participants reported their sleep duration, sleep quality, and sleep hygiene behaviors. Because previous research suggests a gain-framed advantage for preventative health behaviors, we predicted a gain-framed message would outperform the loss-framed message. Contrary to this hypothesis, a gain-framed message did not promote sleep intentions, sleep duration, sleep quality, or sleep hygiene behaviors better than a loss-framed message. Further, inconsistent with previous research and our prediction, motivational orientation did not moderate message framing effects on sleep behaviors. Because there was no effect of message framing or the interaction of motivational orientation and message framing on sleep behaviors, mediational effects were not examined. The results of the present study suggest that a gain-framed message was not more effective at promoting sleep behaviors than a loss-framed message. Perhaps, sleep is too complex of a behavior for such a subtle manipulation as message framing.

DUAL EFFECTS MODEL OF SOCIAL CONTROL: EXTENDING THE MODEL TO 24-HOUR HEALTH BEHAVIOR

Michael P. Mead, MS¹, Li Cao, MS², Leah A. Irish, PhD¹¹North Dakota State University, Fargo, ND; ²Neuropsychiatric Research Institute, Fargo, ND

The influence of biobehavioral factors on human health and functioning has been well documented, though the majority of the research has examined this only at the level of the individual. Many health behaviors occur in a social context, with romantic partners exerting a particularly strong influence over health-related behaviors through processes such as social control. Findings to date support a Dual Effects Model of Social Control, which suggests that partners can positively and negatively influence the waking health behaviors of their partners. However, the current model has a limited scope, and fails to consider the impact of control on non-targeted health behaviors, such as sleep. The purpose of this study was to expand the Dual Effects Model of Social Control by including sleep continuity and duration as outcomes related to social control efforts targeted at diet and exercise behaviors. It was hypothesized that, in comparison to no receipt of control or receipt of positive control, negative control would be associated with shorter sleep duration and less continuity. Participants (N=66) completed a 7 day assessment period. Partner control and objective sleep data were collected via daily sleep diaries and Fitbit Charge HR, respectively. Mixed linear models were used to test the daily, direct effects of partner control on subsequent sleep duration and continuity. Analyses revealed no significant relationships between daily control and subsequent sleep. Although results were non-significant, this study's novelty is twofold. It is the first study to expand the model to include the effect of control on non-targeted health behaviors and to include 24-hour health. It is also one of few studies to examine the effects of daily control on immediate health behavior, and questions the influence of social control on daily health behaviors. Recommendations for future research using the proposed model are presented.

EXPLORING THE EFFECT OF SEXUAL ORIENTATION ON CARDIOVASCULAR DISEASE RISK AND HEALTH BEHAVIORS IN EMERGING ADULTHOOD

Leia Harper, PhD¹, Kyungeh An, PhD, RN²¹California State University, Monterey Bay, Santa Cruz, CA; ²Virginia Commonwealth University, Henrico, VA

Background: Previous research has shown that sexual minority individuals (SM) are twice as likely to smoke, twice as likely to be overweight or obese, and less likely to be physically active than heterosexual persons; all of which place SMs at an increased risk for cardiovascular disease (CVD). While information on CVD risk by race/ethnicity and socioeconomic status is well documented, there is scant literature examining the potential risk in SMs. The purpose of this study was to examine the impact of sexual orientation on CVD risk in terms of the Framingham Risk Score (FRS) to predict individual's 10-year likelihood of developing a CVD and their vascular age (VA). We hypothesized that the SMs will have higher FRS and VA than HS and MH.

Method: The current study used data from the National Longitudinal Study of Adolescent Health (Add Health). A total of 5,060 samples were extracted and split into three groups based on self-identified sexual orientation: heterosexual (HS, n=4363), mostly heterosexual (MH, n=509), and sexual minority (SM, n=188). The FRS and VA were calculated by entering age, diabetes status, smoking status, body mass index for obesity, and blood pressure into the equation. One-way ANOVA was used to assess differences among sexual orientation groups in FRS and VA.

Results: Results from the current study did not provide evidence indicating a significant relationship between sexual orientation and the FRS or VA [$F(2, 4648)=2.40, p=.091$; and $F(2, 4648)=2.66, p=.070$]. However, SM were twice as likely to be current smokers than HS; to have more drinks than both HS and MH (4.5 vs. 3.80 and 3.38 per occasion, respectively, $p<.001$); and reported significantly higher stress levels than both HS and MH $F(2, 4648) = 30.06, p<.0001$.

Conclusion: The findings from our study did not provide sufficient evidence to support our hypothesis on the impact of sexual orientation on FRS and VA, potentially because of the young age of the study population. However, other findings remain noteworthy by confirming the risk behaviors among SMs that will lead to the development of CVD in the future. Given the presence of increased risk behaviors, monitoring of CVD risk and modification of health behavior are warranted in SM young adult.

RETHINKING REAPPRAISAL: EVIDENCE FOR A CONTEXT-BASED MODEL OF COGNITIVE REAPPRAISAL

William N. Koller, BA

Yale Magnetic Resonance Research Center, New Haven, CT

Emotion regulation (ER) is a process with widespread implications for quality of life in both general and clinical populations. While past research has identified many different ER techniques, some have seen more positive attention in the literature than others. Cognitive reappraisal, or the generation of positive interpretations of stressful situations, is one ER strategy that has been historically seen as "adaptive". More recent research, however, has suggested that its degree of efficacy may be contextually dependent. The present study expands on this research, providing evidence that reappraisal may not be as universally effective as once thought. In this study, 62 participants underwent a stress-induction paradigm where, after an initial baseline (T1) had been established, they were informed of an upcoming impromptu speech task (T2). Before beginning the speech, participants engaged in reappraisal via a writing prompt (T3; "Write about all of the positive aspects of giving this speech, including what you may learn and how you may grow through the experience"). Participant distress was assessed at each time point using heart rate variability (HRV) – the beat-to-beat variation in one's heart rate. In this study, HRV reflected parasympathetic nervous system (PNS) activity, where higher HRV indicated greater PNS activation and less distress. Based on past research using a similar procedure, mean HRV was hypothesized to increase between T2 and T3, reflecting the successful reframing of the stressor and subsequent reduction of physiologic arousal. However, while a significant decrease in HRV was seen between T1 and T2, this distress was not soothed by reappraisal. Instead, mean HRV *continued* to decrease between T2 and T3, indicating that in addition to failing to reduce pre-speech anxiety, the reappraisal task was associated with a significant increase in distress. Overall, this study points to the limitations of reappraisal in a response-focused context (where participants attempted to reframe an already-formulated emotional response), and serves to challenge its role as an infallible ER technique. While future research should test this effect with a control group, these unexpected findings contribute to a growing body of literature that suggests that no form of ER is inherently "good" or "bad." Rather, its value is defined by the situation in which it is used – in this case suggesting that one must understand not only *how* to implement reappraisal, but *when*.

DISTRESS AND QUALITY OF LIFE IN RURAL LATINA CANCER SURVIVORS FOLLOWING A 10-WEEK SPANISH-LANGUAGE SUPPORT PROGRAM

Rachel M. Ceballos, PhD¹, Genoveva Ibarra, Y², Monica Escareno²¹Fred Hutchinson Cancer Research Center, Seattle, WA; ²Fred Hutchinson Cancer Research Center, Sunnyside, WA

INTRODUCTION. Rates of cancer survivorship are increasing for most cancers. However, Latina cancer survivors tend to experience lower quality of life and higher levels of distress following cancer compared to non-Latina Whites (NLW). While social support resources can alleviate the negative psychosocial impact of cancer sequelae, there are often limited resource availability and uptake among Latina breast and gynecological cancer survivors.

OBJECTIVE. Evaluate the affect of a 10-week *promotora*-led Spanish-language support group on distress and quality of life outcomes.

METHODS. The study was a randomized-control trial of 59 Latina breast and gynecological cancer survivors living a rural setting in Washington State. Eligibility required participants be post-acute treatment (e.g., chemotherapy and radiation) for cancer. The intervention content was developed using Social Cognitive Theory as a framework. Participants attended a weekly session where they received health education on the topics of: stress, nutrition, physical activity, body image, sexuality and intimacy, medical self-advocacy, and social support. A 30–45 minute discussion of the topic was then facilitated by the *promotora*. Following the discussion, participants engaged in an activity that reinforced the educational content/topic. A baseline (T1) assessment of distress (Perceived Stress Scale, Hispanic Stress Inventory) and quality of life (physical, mental, social, functional well being) was followed by a 3-month (T2) assessment upon completion of the intervention. Analyses were conducted using descriptive statistics and independent samples t-tests of T2-T1 change scores for each of the outcome measures.

RESULTS: The participants were diagnosed with breast (n=41), cervical (n=5), endometrial (n=3), ovarian (n=5), and uterine (n=9) cancers. Approximately 60% had less than an 8th grade education and 85% were born in Mexico. Thirty participants were randomized to the control group and 29 to the intervention group. No statistically significant differences were observed between the intervention and control groups for any of the outcome variables. Results for stress were: perceived stress scale [t(57)=0.37, p=0.72], Hispanic Stress Inventory extra-familial subgroup [t(57)=1.8, p=0.09], and Hispanic Stress Inventory intrafamilial subgroups [t(57)=1.5, p=0.18]. Results for quality of life subscales were physical well-being [t(57)=-1.66, p=0.10], social well-being [t(47)=-0.32, p=0.75], emotional well-being [t(57)=-0.41, p=0.97], and functional well-being [t(57)=1.38, p=0.17].

CONCLUSION: The 10-week Spanish language intervention did not affect levels of distress or quality of life among post-treatment Latina breast and gynecological cancer survivors. Implications of these findings will be discussed.

EXAMINING THE RELATIONSHIP BETWEEN ACCULTURATIVE STRESS, MARIJUANA USE, AND SELF-ESTEEM AMONG HISPANIC COLLEGE STUDENTS.

Robert Yockey, B.S.¹, Jennifer L. Brown, PhD¹, Amelia Talley, Ph.D.², Andrew K. Littlefield, PhD²¹University of Cincinnati College of Medicine, Cincinnati, OH; ²Texas Tech University, Lubbock, TX

Background: Acculturative stress has been associated with increased substance use and psychological distress, especially among minority populations. For example, there is increasing evidence to suggest that factors related to acculturative stress (e.g., language barriers) has been linked to increased alcohol use among Hispanic U.S. college students. Yet, other research has not demonstrated a relation between acculturative stress and substance use. Further examination is needed to assess additional psychosocial factors related to acculturative stress and substance use. The aim of this study was to investigate whether self-esteem may mediate the association between acculturative stress and lifetime marijuana use among Hispanic college students.

Methods: A subset of Hispanic participants (n=190, 133 females, 57 males) completed an online survey examining measures of acculturative stress, substance use, and other psychosocial variables. Participants ranged in age from 17–48 (M = 20.27, SD = 3.44) This study used the Multigroup Ethnic Identity Measure (MEIM) Affirmation/Belonging subscale (as a measure of acculturative stress), the Rosenberg self-esteem scale to assess levels of self-esteem, and a dichotomous item regarding lifetime marijuana use. Mediation analyses using the SPSS PROCESS Macro examined whether elevated acculturative stress was associated with increased likelihood of lifetime marijuana use as mediated by self-esteem.

Results: A total of 38.4% (n=71) reported lifetime marijuana use. Regression analyses examined the hypothesis that increased levels of acculturative stress may be associated with increased likelihood of lifetime marijuana use, mediated by levels of self-esteem. Results indicated that increased acculturative stress was not associated with a lifetime history of marijuana use (b = .09, SE = .07, p = .19). Additionally, self-esteem did not mediate the relationship between acculturative stress and marijuana use (b = .03, SE = .037, p = .48). The indirect effect was tested using a bootstrap estimation approach with 5000 samples; the indirect effect was not significant (b = .002, SE = .004).

Conclusion: Results suggest that acculturative stress was not associated with differential marijuana use among a sample of Hispanic college students, nor was this relation mediated by self-esteem as hypothesized. Researchers should consider longitudinal examinations of acculturative stress and substance use along with constructs that may mediate this relation among Hispanic populations.

TOBACCO RETAILERS' PROXIMITY TO SCHOOLS IN A PREDOMINANTLY HISPANIC COMMUNITY

Giovanna Perez, B.A.¹, Dessaray Gorbett, B.S.¹, Stephen Nunez, II, N/A¹, Thomas Taylor, Ph.D.¹, Nora Hernandez, MBA², Annette Torres, B.A.¹, Jose Rivera, PharmD¹

¹The University of Texas at El Paso, El Paso, TX; ²The University of Texas at El Paso, El Paso 7475072, TX

Disparities have been observed in tobacco retailer density among minority and lower socioeconomic communities. In a nationwide assessment of tobacco outlet density (TOD), race, ethnic, and socioeconomic factors were positively associated with TOD. Specifically, higher TOD was observed in communities with lower socioeconomic status regardless of whether it was a rural or an urban community and also in communities that were predominantly Hispanic and African American. Accessibility of tobacco is an important component in smoking behavior and has been correlated to smoking initiation in adolescents. Therefore, the density of tobacco retailers around schools is crucial for tobacco control and policy efforts. The purpose of this study was to identify areas near public and private schools in El Paso, TX with higher density of tobacco retailers. Areas of higher density would help determine the need for policy advocacy (e.g., limiting the number of tobacco vendors in close proximity to schools). School lists were provided by City of El Paso Department of Public Health and tobacco retailers were identified from publically available data on YellowPages. Sample search terms used to identify tobacco vendors included "convenience store," "gas," "tobacco," "vape," "hookah," and "cig." Based on previous literature, a tobacco retailer was considered to be in close proximity if it was within 800 meters of a school. A cross-classified mixed model was used to identify predictors of distance between a school and a tobacco retailer. Analyses indicated non-significant findings. No relationship was found between tobacco vendors (95% CI: -0.17, 0.27) and the 800m buffer zone or between vaping product vendors (95% CI: -0.43, 0.56) and 800m buffer zone. These findings demonstrated a general dispersion of tobacco retailers not specific to areas around schools. Although the findings from this study yielded null results, this baseline data could be used to restrict future businesses. In addition, more populated zipcodes could be an additional area of focus where a higher density of tobacco retailers may be present. Considering the relationship between accessibility and smoking behavior in adolescents, future research should focus on policy efforts restricting the accessibility of tobacco around schools.

NURSE-FACILITATED BEHAVIORAL INTERVENTIONS FOR HEALTH PROMOTION AND DISEASE MANAGEMENT ACROSS THE LIFE COURSE

Laura L. Hayman, PhD, MSN, FAAN¹, Randal K. Wada, MD, MS², Sara Baldwin, PhD, RN, APHN-BC³, Amanda Blok, PhD, MSN,PHCNS-BC⁴, Elizabeth Galik, PhD, CRNP,FAAN, FAANP⁵, Marcia Holstad, PhD, FNP-BC, FAANP, FAAN⁶, Barbara Resnick, PhD, CRNP⁵

¹College of Nursing & Health Sciences, UMass Boston, Boston, MA; ²University of Hawaii at Manoa, Honolulu, HI; ³College of Nursing & Health Sciences, Corpus Christi, TX; ⁴UMass Medical School, Worcester, MA; ⁵University of Maryland, Baltimore, MD; ⁶Emory University, Atlanta, GA

Nurse scientists as part of inter-professional teams generate and apply evidence central to holistic care management of individuals and families from diverse populations. As exemplified in this symposium, nurse scientists make unique and collaborative contributions to behavioral interventions designed to optimize health across the life course and across health care and community settings. Using both inductive and deductive approaches to develop multi-component interventions and working with inter-professional teams, nurse scientists focus on engaging patients and caregivers in tailoring such interventions to characteristics of the target population including physical health status, cognitive-developmental capacity, culture, as well as identified needs, preferences, and resources. The purpose of this symposium is to highlight the designs, methods and selected findings of nurse-facilitated, behavioral interventions for optimizing health, functional capacity, and quality of life across the life course and across a variety of clinical settings. Presenters will illustrate the utility of nurse-facilitated, theory-based, multi-component interventions focused on: family-decision making for children approaching end-of-life, engaging grandparents as change agents in Latino family health behaviors, implementing evidence-based technology interventions for behavior change in hospital settings, engaging older adults with dementia in physical activity, and advanced care planning in individuals with HIV/AIDS. The presentations will provide information about the innovative ways in which nurses can integrate these interventions into real world clinical settings. In addition, the incorporation of other members of the health care team will be addressed and ways to optimize those relationships identified.

Symposium 64A

THEORY-BASED FACILITATION OF FAMILY DECISION- MAKING FOR CHILDREN APPROACHING END OF LIFE: INTER-PROFESSIONAL TEAM APPROACH

Dr. Randal K. Wada, MD, MS

Therapeutic decisions for children approaching end of life pose major challenges for both parents and the health care team, as they seek to balance the likelihood of cure and toxicity of therapy with quality of life and minimization of pain and suffering. Conversations regarding choices for care can be so hard on the person initiating the discussion that physicians often defer them, or concentrate only on treatment options and fail to identify and incorporate key family values and priorities into the decision making process. Nurses and other health care team members might recognize when end of life discussions are needed, but are unsure of the roles they should play in facilitating the process, or are relegated to damage control after they have taken place. Together these factors frequently result in aggressive therapy being administered to patients who are so ill that it is not only ineffective, but also aggravates morbidity and erodes their remaining quality of life. To address these challenges a pilot pediatric oncology clinical protocol was created using an inter-professional team consisting of an oncologist, oncology nurse coordinator, social worker, and chaplain. Team members were introduced to playing multiple roles, such as key informant, sounding board, scribe, empath, and emotional monitor, so that they could switch roles as the conversation evolved, depending on the responses and needs of the family. Cognitive roadmaps consisting of sequences of suggested questions were used to structure and guide conversations so that the team could help parents articulate their hopes and identify their priorities as they grappled with the fate of their child. Orientation included practice in communicating with parents using Fuzzy Trace and Prospect Theories, behavioral constructs that facilitate decision making by condensing complex information into meaningful bottom line messages that capture the gist of the clinical situation, and by framing possible choices and recommendations according to the patient's condition and elicited family values. Positive feedback from team members participating in this pilot clinical protocol led to the development of an inter-professional simulation teaching exercise involving pediatric residents, nursing students, social work students, and chaplaincy interns. Pre/post surveys will be used to evaluate the effectiveness of this educational activity to familiarize multi-disciplinary learners with this theory based team approach.

Symposium 64B

NOVEL FOCUS ON GRANDPARENTS AS CHANGE AGENTS IN LATINO FAMILY HEALTH BEHAVIORS: THE HEALTHY US GRANDPARENT STUDY (HUGS)

Dr. Sara Baldwin, PhD, RN, APHN-BC

Problem/Purpose: Latinos face staggering social inequities largely contributing to growing health disparities in obesity and type 2 diabetes. The purpose of this study is to explore a novel approach to family-centered obesity prevention through the Latino grandparent as the agent for sustained health behavior change in the family.

Background: Almost 8 million children are being raised by their grandparents nationwide. In Texas, 45% of children being raised by grandparents are Latino. The need for exploratory, descriptive work is indicated to assess if South Texas Latino families exhibit a *familismo* culture, where grandparents may influence the health behaviors and outcomes of other family members.

Research Questions: (1) How much time do Latino children spend under the direct care of grandparents? and (2) What is the relationship between the type of care/ provided to the child outside of school and the child's diet and physical activity routines?.

Sample/Setting: This study will be conducted in a large (800 student) public elementary school made up of 95% Latino students, an estimated 40% of whom are cared for primarily by grandparents.

Methods: An exploratory descriptive design will use written bilingual surveys directed toward parents and grandparents and bi-lingual in-person interviews with children. Surveys of adults will focus on time spent with grandparents and the diet and physical activity routines of the family. Interviews with children will focus on their dietary and physical activity preferences and routines. Child height and weight will be measured.

Expected Significance: This investigation will build a deeper understanding of the specific impact grandparents may have on their family's health. This study is a pilot for a planned public school-wide intervention program involving grandparents and grandchildren participating in educational and health promoting activities together to influence the health of the family as a whole.

Symposium 64C

NURSE ENGAGEMENT IN IMPLEMENTING EVIDENCE-BASED TECHNOLOGY INTERVENTIONS FOR HEALTH BEHAVIOR CHANGE IN THE HOSPITAL SETTING

Dr. Amanda Blok, PhD, MSN,PHCNS-BC

Background. Nurses are key stakeholders in implementing evidence-based initiatives in the hospital setting. Nurse engagement in facilitating technology use, such as patient mobile phones for behavior change or care management, in the hospital setting is understudied. There are few studies of nurse-directed implementation of a technology intervention in the hospital setting, and those do not attempt to examine the process of nurse confidence, preparedness and engagement on the use of technology by patients. The aim of this analysis is to describe nurse confidence and engagement in facilitating technology use for behavior change, and to examine their relationship with patient use.

Methods. In the context of a 30-week quasi-experimental study examining a dose-effect of active implementation strategies on the use of a mobile health intervention by smokers (Technology Inpatient Program for Smokers—TIPS) at four hospital units from two same-network Northeast hospitals, quantitative and qualitative data were collected from nurse managers and staff. Survey data from nurses on confidence pre-implementation and engagement post-implementation were categorized and reported by unit. A text message database collected number of smokers using the program, reporting their unit over text. Reach of patients in the 30 weeks of implementation is reported. Qualitative interviews of nurse leaders and staff provide insight into nurse engagement.

Results. Forty nurses participated in providing feedback on pre- and post-implementation measures. The majority of nurses were female (89.2%), white (78.4%), bachelors prepared (73.0%), and work day shift (67.7%). All but one nurse said they had a good understanding of their role in implementing the intervention (97%). There was a range of confidence, with over half were very confident in implementing TIPS (58.1%), while others were somewhat or moderately confident. Unit 2 had the highest confidence scores in implementation, the highest engagement, and the highest reach of patients measured over the 30 weeks. Qualitative analyses revealed additional engagement strategies and suggestions with additional strategies to further engage nurses in implementation programs, such as CEUs and videos.

Conclusions. Further testing of nurse engagement in implementation of technology for behavior change is needed. Future research is needed on the validation of nurse engagement measures for implementing evidence-based practices.

Symposium 64D

ENGAGING OLDER ADULTS WITH MODERATE TO SEVERE DEMENTIA IN PHYSICAL ACTIVITY

Dr. Elizabeth Galik, PhD, CRNP,FAAN, FAANP

Forty-one percent of nursing home residents in the United States have moderate to severe dementia; 21–45% of these individuals exhibit challenging behavioral symptoms such as physical aggression, agitation and resistance to care. During care interactions, such as bathing and dressing, behavioral symptoms are most commonly exhibited. Some non-pharmacological interventions successfully address behavioral symptoms; however, many utilize sedentary and soothing activities such as massage, reminiscence, music, quiet environments, Snoezelen rooms, and quiet explanations about care. These interventions ignore function and propagate deconditioning and disuse. Residents have limited opportunities to engage in functional and physical activities due to: assumptions by caregivers that cognitively impaired residents cannot actively participate in their own care; persistent use of custodial care approaches that focus on task completion and reinforce dependent behaviors; and institutional policies that restrict resident mobility so as to avoid falls. Staff respond to residents' functional decline by performing the task for the resident rather than encouraging some level of activity. We proposed that it would be possible to maintain or improve function, increase physical activity, and decrease falls among nursing home residents with severe cognitive impairment with no worsening of behavioral symptoms through implementation of Function and Behavior Focused Care (FBFC). FBFC is based on a Social Ecological Model and Social Cognitive Theory and focuses on having nursing home staff teach, cue, model, and assist cognitively impaired residents to perform functional tasks and engage in physical activity. A total of 12 nursing homes and 336 residents participated. The residents were mostly female (n=242, 72%), white (n=199, 59%), widowed (n=131, 38%), and had a mean age of 82.6 (SD=10.1) years and severely cognitively impaired (MMSE=7.8, SD=5.0). Function and Behavior Focused Care was implemented by a research nurse and included 3 components: **Component I** Environmental and Policy Assessments; **Component II** Education and Training of Nursing Home Staff; and **Component III** Ongoing Training and Motivation of Nursing Home Staff. Generalized estimating equations (GEE) were used to perform repeated measures analyses with outcome measures as the dependent variable. Intention-to-treat (ITT) paradigm was followed. Four months post implementation results indicated improvement in physical activity based on actigraphy ($p < .05$), no worsening of behavioral symptoms and no increase in falls. Findings provide some support that nursing home residents with severe cognitive impairment can engage in physical activity safely. Findings have potential to guide and inform future interventions designed to optimize function and physical activity in this population.

Symposium 64E

EARLY PALLIATIVE CARE PLUS NURSE-LED MOTIVATIONAL INTERVIEWING INCREASES ADVANCED CARE PLANNING IN PERSONS WITH HIV/AIDS

Dr. Marcia Holstad, PhD, FNP-BC, FAANP, FAAN

We conducted an RCT to examine the efficacy of early palliative care (PC) plus nurse-led motivational interviewing (MI) sessions (EPC package) compared to standard care (SC) on the outcome of advanced care planning (ACP). MI focused on disease adjustment and discussion of ACP which occurred prior to PC. PC included ≥ 1 visit to the subspecialty and multidisciplinary PC clinic at the large urban HIV care center where the study was conducted.

Eligibility criteria were: Age ≥ 18 , AIDS diagnosis, no current antiretroviral therapy, a detectable viral load; speaks and writes English, able to provide and understand consent. Participants were randomized 1:1 after baseline (BL) to either the EPC package ($n=61$) or SC ($n=60$). ACP was measured by an adapted self-report ACP questionnaire that asked (yes/no) if the participant formally asked someone to be their medical decision maker, signed advanced directives, etc. Multilevel mixed longitudinal modeling was used to test for group, time and group-by-time effects, followed by Sidak-adjusted pairwise post hoc comparisons for significant main effects.

121 participants were followed for 12 months. The mean age was 42.6 years. The sample was predominately male (74.4%), African American (87.6%), un-partnered (91%), had a high school education or less (75%), with an average monthly income of \$654. Over a third were unstably housed and 48% self-identified as gay/homosexual or bisexual. The EPC group tended to have higher rates of signed advanced directives (group effect, 37% vs 21% SC, $p=.055$) at 12m. For those who did not have signed advanced directives, the EPC group had significant 12 month improvements in feeling well-informed about ACP ($p=.005$) and thought about ACP more than the SC ($p=.010$). Compared to their BL rates, the EPC group also had significantly greater improvements at 12 months related to requesting (65%, $p=.043$), discussing with a doctor (50%, $p=.061$); and signing papers to name a surrogate medical decision maker (43%, $p=.028$).

We found a high rate of ACP following the EPC in this predominately African American and vulnerable group. Our rate of 37% for advance directives is well above that of 26% for US consumers and 17% for African American consumers. The EPC intervention shows promise for conducting ACP in persons with AIDS and could be translatable to improve ACP in other groups with chronic disease.

Symposium 65

8:30 AM-9:45 AM

ETHICAL CHALLENGES IN PRECISION MEDICINE: BUILDING CAPACITY, INFORMED CONSENT AND ENGAGEMENT OF DIVERSE COMMUNITIES

Mona AuYoung, PhD, MS, MPH¹, Camille Nebeker, Ed.D, M.S.,², Elizabeth Cohn, RN, PhD³, Karriem S. Watson, DHSc, MPH, MS⁴, Elizabeth Cohn, RN, PhD⁵

¹Scripps Translational Science Institute, La Jolla, CA; ²UC San Diego, La Jolla, CA; ³Columbia University, New York, NY; ⁴University of Illinois at Chicago (UIC), Chicago, IL; ⁵Columbia University, Sea Cliff, New York, NY

Precision medicine is gaining momentum as an innovative approach in research. Within the context of precision medicine, there is a growing number of large cohort studies being launched both nationally and globally. A common goal is to study the intersection of genes and health by collecting biospecimens. Across precision medicine initiatives, there is variation in the extent that multidimensional data is collected to understand how lifestyle and the environment influence health. A shared outcome is increasing the speed of research that can advance prevention and treatment of disease. There are many important factors to consider in multidimensional, longitudinal cohort studies – especially with the introduction of digital strategies to facilitate engagement and real time data collection. Our focus is on the ethical, regulatory and social implications of large scale, longitudinal research programs – including recruitment and consent, ongoing engagement and inclusion of diverse populations. The aims of this symposium are to address key ethical issues in the: 1) potential challenges with capacity building such that participants are able to fully participate as partners; 2) use of digital strategies to facilitate access and obtaining authentic informed consent; and 3) recruitment and retention of a diverse cohort with a goal of recommending best practices. The first speaker will discuss the need for capacity building among the cohort with a focus on increasing research, technology and data literacy. The second speaker will examine the research ethics and understanding broad and dual consent, and therapeutic misconception, particularly in large-scale, multifaceted cohort studies. The third speaker will explore the best practices in bi-directional engagement highlighting the difference between engagement and recruitment and how to engage community partners to facilitate diverse participation in research. The discussant will consider how all of these factors influence the development of large-scale studies and the implications for the future.

Symposium 65A

BUILDING RESEARCH CAPACITY AMONG PARTICIPANTS THROUGH ACCESSIBLE EDUCATION DESIGNED TO IMPROVE ENGAGEMENT AS PARTNERS

Dr. Camille Nebeker, Ed.D, M.S.,

Historically, participants in biomedical research have lacked in diversity making results less likely to generalize beyond caucasian males, who are typical research participants. Research programs designed to facilitate precision medicine, seek to change that paradigm by focusing enrollment targets to be inclusive of people typically under-represented in biomedical research. This includes people from minority ethnic and racial groups; low income populations; low educational attainment populations; rural and remote geographical locations; urban centers; and those with low health literacy. However, the enrollment goal is just one step to demonstrating inclusivity of these populations. Likewise, a few research programs stress the need to reflect the interests of the participants by including participants in programmatic decisions. However, for participant to be included in this process, we need to acknowledge the diversity in professional expertise and gap in requisite knowledge. Lack of formal research and clinical training may diminish participant interest in active involvement due to discomfort in expressing views, which subsequently can jeopardize the value of participants being authentic partners. Speaker 1 will describe an educational initiative designed to increase research literacy among lay-research staff and volunteers and how accessible and tailored education can be used creatively as a capacity building tool for increasing engagement among research participants.

Symposium 65B

RESEARCH ETHICS/UNDERSTANDING OF BROAD AND DUAL CONSENT

Elizabeth Cohn, RN, PhD

Recently, several large national studies have emerged that include genetic and genomic testing as an outcome. Exacerbated by an egregious history of the misuse of genetics for “science” such as eugenics, and stories in the public dialogue such as the Immortal Life of Henrietta Lacks, the issues of consent and ethics are front and center, and are a critical focus in communities of color and those who have been previously harmed by the research enterprise. Novel issues in research ethics and informed consent include blurred lines between research and treatment, understandably confusing patients, participants and researchers. As informed consent mechanisms are developed for these studies, in addition to overarching issues such as the trust in the research, specific issues in consent such as the therapeutic misconception (mistakenly thinking that research results will have a direct health benefit), clarity in explaining when and how samples will be used (such as consent to store samples indefinitely and use them for yet undeveloped testing), the mechanisms for and actual utility of returning genetic (of varying certainty) and the tension between sequencing for research and treatment have all been front and center. This speaker will consider the most pressing issues in research ethics and consent for large scale studies with a precision medicine component.

Symposium 65C

BI-DIRECTIONAL ENGAGEMENT WITH COMMUNITY PARTNERS TO SUPPORT ENGAGEMENT AND RECRUITMENT

Dr. Karriem S. Watson, DHSc, MPH, MS

There is a growing emphasis on community engagement to address the challenge of diverse inclusion in clinical and translational research. Central to this discussion is the role of community partners and stakeholders. The engagement and early involvement of community partners/stakeholders has been documented to advance trust and confront ethical concerns such as medical mistrust and lack of transparency in research. However, there are often blurred lines related to recruitment and engagement and there is also a paucity in data to note best practices for ethical bidirectional engagement of community partners/stakeholders to advance trust and ultimately participation in clinical and translational research. The growing momentum of precision medicine is built upon that premise that a diverse group of participants are included and that a diversity of data and information is collected from lifestyle to biomedical. This panel will examine the role of bidirectional engagement of community stakeholders to advance trust in the era of precision medicine.

Symposium 66 8:30 AM-9:45 AM

THE NEED TO ADDRESS WEIGHT STIGMA FROM A PATIENT, TREATMENT, PUBLIC HEALTH AND RESEARCH PERSPECTIVE

Scott Kahan, MD, MPH¹, Patricia Nece, J.D.², Dori Steinberg, PhD, RD³, Dawn K. Wilson, Ph.D., FSBM⁴

¹George Washington University, Washington, DC; ²Office of the Solicitor, Alexandria, VA; ³School of Nursing, Durham, NC; ⁴University of South Carolina, Columbia, SC

Weight stigma is a serious and pervasive public health issue with wide-ranging mental and physical health consequences. This symposium will highlight the need to address weight stigma from a patient, treatment, public health and research perspective. The speakers are internationally known and each brings a unique perspective on understanding the issues of weight stigma and how to increase awareness and develop solutions for addressing this problem from a variety of settings and perspectives. After each presentation, the discussant will provide a summary of critical issues and future recommendations from each perspective presented.

Symposium 66A

WEIGHT STIGMA FROM A CLINICAL AND PUBLIC HEALTH PERSPECTIVE

Dr. Scott Kahan, MD, MPH

Weight stigma is among the most prevalent reported types of discrimination and, unlike most other types of discrimination, rates of weight stigma are increasing. Weight stigma is commonly reported among family members, healthcare providers, coworkers and other settings. Weight stigma is associated with adverse mental health and physical health outcomes, and experiencing weight discrimination increases the risk for maladaptive eating behaviors and further weight gain. This presentation will review basic epidemiology and consequences of weight stigma, with a focus on weight stigma in healthcare settings. Actionable recommendations for reducing weight stigma will be discussed.

Symposium 66B

WEIGHT STIGMA FROM A PATIENT PERSPECTIVE

Ms. Patricia Nece, J.D.

This presenter will provide a patient perspective on weight stigma. She has lived with obesity her entire life. Along with her excess weight came a lifetime of teasing, bullying and ridicule from peers, relatives, educational institutions, health care providers and even strangers. She internalized these experiences over the years, shaming and blaming herself for not having enough “willpower” to shed her excess weight. Internalizing the stigma made it virtually impossible for her to address her weight in any meaningful way. She will share her experiences of living with severe obesity in a weight-biased society that believes obesity can be solved simply by eating less and exercising more. She will discuss how the bias and stigma she experienced affected her, including when it occurred in medical settings. Patty will also discuss how properly trained physicians and psychologists helped her reduce the stigma’s impact so that she could move forward to constructively manage her weight and obesity.

Symposium 66C

INVESTIGATING “MAINTAIN, DON’T GAIN” APPROACHES TO WEIGHT CONTROL FOR PATIENTS NOT READY OR INTERESTED IN WEIGHT LOSS

Dr. Dori Steinberg, PhD, RD

Up to 50% of patients with obesity are not interested in, or ready for, weight loss. Many patients often feel stigmatized by providers because of their weight, attributed in part to a perceived lack of empathy and trust. Yet for patients not ready for weight loss, clinical practice guidelines clearly recommend that patients with obesity avoid gaining weight. Doing so might contain, or even attenuate, the adverse cardiometabolic risks that accrue with additional weight gain. A focus on weight gain prevention may also reduce perceived weight stigma, particularly if programs focus on body acceptance. However, despite this clinical guideline, weight gain prevention interventions are not available in primary care practice. Our Shape Program trial was the first to evaluate a weight gain prevention intervention in primary care practice. Shape’s participants were medically vulnerable Black women with overweight and obesity who were not explicitly interested in weight loss. We conducted Shape in a multi-site community health center system in rural North Carolina (NC). Shape focused on overall wellness and maintaining one’s “shape” to improve health. The intervention emphasized benefits of changing behaviors independent of weight, such as increasing energy, reducing stress and improving sleep. Specifically, the 12-month Shape intervention, with 18-month follow up, consisted of tailored behavior change goals to improve diet and physical activity, weekly self-monitoring and tailored feedback via mobile technologies and monthly coaching calls from a clinic-based registered dietitian. Intervention participants lost significantly more weight than usual care at 18 months. They were also more likely to have maintained their weight than those receiving usual care (62% vs 45% $p=.02$). Shape also led to significantly greater improvements in mood, sleep, and body satisfaction independent of weight change as compared to usual care. Balance aims to help overweight adults and men and women with obesity who are not quite ready for weight loss, or who experience barriers to losing weight, to live a healthier lifestyle and prevent further weight gain. We launched recruitment for Balance in February 2017 and expect to enroll 442 patients; about one-third of which are monolingual Spanish-speakers. Balance expands what we tested in Shape by further integrating the intervention into the health center and using mobile technologies to provide social support and conserving human coaching for those patients that exhibit large weight gains. Both trials are examples of how emphasizing weight gain prevention, rather than weight loss may afford clinical benefit for patients with obesity. Because without intervention, 90% of adults will gain weight in midlife which may influence perceived weight stigma. As such, a focus on weight gain prevention is of high priority.

Symposium 67

8:30 AM-9:45 AM

UNDERSTANDING AND LEVERAGING THE INFLUENCE OF CLOSE OTHERS ON HEALTH BELIEFS AND BEHAVIORS: INSIGHTS FROM A DYADIC PERSPECTIVE

Alexander Rothman, PhD¹, Richie L. Lenne, BA¹, Rebecca Ferrer, PhD², Katelyn Gettens, M.A.³¹University of Minnesota, Minneapolis, MN; ²National Cancer Institute/ NIH, Rockville, MD; ³University of Connecticut, New York, NY

Psychological models of health behavior have traditionally adopted an intrapersonal perspective that prioritizes specifying when and to what degree an individual’s thoughts and feelings influence her or his behavior. Although this perspective has advanced our understanding of the determinants of people’s health behavior across an array of health domains and has informed the development of effective intervention strategies, there is a growing understanding that people’s behavior is shaped by the interpersonal relationships they have with close others, whether they be spouses, parents, children, or friends. Yet, there has been limited integration of the dominant *intrapersonal* models of health behavior and advances in models of *interpersonal* influence in relationships. The speakers in this symposium are all actively pursuing innovative research programs that advance the integration of these two perspectives. Moreover, these lines of work highlight the different perspectives research groups are using to engage with these issues. First, Speaker 1 and colleagues leverage data from over 1,600 parent-adolescent dyads to demonstrate how adopting a dyadic approach to intrapersonal models such as the Theory of Planned Behavior can reveal how beliefs held by a close other influence a person’s eating and activity behavior and how these patterns of interpersonal influence are contingent on relationship dynamics. Second, Speaker 2 and colleagues leverage the same dyadic data set to delineate how the different forms of social influence strategies parents use can affect their adolescent children’s goal pursuits and, in particular, their eating and activity behavior and their weight. Third, Speaker 3 and colleagues examine the use of social influence strategies within the context of a couples-based behavioral weight loss intervention trial, with a particular focus on how spouse’s beliefs about the quality of their relationship regulates the effect that social influence strategies have on weight control behavior and weight-loss outcomes. Finally, the Chair will moderate a discussion among the speakers and the audience regarding issues that need to be addressed in order to advance the integration and application of these two theoretical perspectives.

Symposium 67A

MODELING PARENTS' AND TEENAGERS' IMPACT ON EACH OTHER'S EATING AND PHYSICAL ACTIVITY USING THE THEORY OF PLANNED BEHAVIOR

Richie L. Lenne, BA

Background: The Theory of Planned Behavior (TPB) provides an influential framework for how a person's beliefs influence her or his behavior. However, the TPB's intrapersonal perspective provides limited guidance for how the beliefs of close others affect one's behavior. We situate the TPB in a dyadic framework to examine how parents' and teenagers' beliefs about health behaviors influence not only their own behaviors (actor effects), but also each other's behaviors (partner effects). Additionally, we explore conditions under which partner effects may be most potent.

Methods: Our sample includes over 1,600 parent-teen dyads from the Family Life, Activity, Sun, Health, and Eating study conducted by the National Cancer Institute. Participants reported eating and physical activity behaviors, and indicators of attitudes, subjective norms, perceived behavioral control (PBC), and intentions for each behavior. Constructs related to parent-teen relationship dynamics were also measured.

Findings: Consistent with the TPB, path analyses showed that each individual's attitudes, norms, and PBC predicted her/his intentions, which in turn predicted her/his behaviors. We also found evidence of partner effects. Teen and parent attitudes, norms, and intentions predicted each other's intentions, and their intentions predicted each other's behaviors, above and beyond actor effects. Across behaviors, parents had a greater impact on their teens' behavior than vice versa. Finally, partner effects were moderated by relationship dynamics. For example, parents' intentions to eat well and be active had more influence on their teens' eating and physical activity behaviors when their teens' need for autonomy was supported.

Discussion: By situating the TPB in a dyadic framework, we show that a person's behavior is associated with both her/his own intentions/beliefs and those held by a close other (i.e., parent or child). These findings broaden our understanding of health behavior models and point to new targets for intervention strategies.

Symposium 67B

PARENT INSTRUMENTALITY FOR ADOLESCENT EATING AND ACTIVITY

Dr. Rebecca Ferrer, PhD

Background: Parent-adolescent interactions have important health implications for the adolescent. Parents can be instrumental to healthy eating by purchasing fruits and vegetables or refraining from purchasing hedonic (i.e., low nutrient, high energy-dense) foods. Parents can be instrumental to healthy activity by modeling exercise behavior or by discouraging sedentary activities.

Purpose: This research leverages psychological theory on goal pursuit within relationships to investigate whether parents are instrumental to their adolescent's eating and activity.

Methods: Using data from a national sample of 1556 parent-adolescent dyads, we conducted dyadic analyses to examine whether parent instrumentality (both parent-perceived and adolescent-perceived) for healthy behaviors predicted adolescent engagement in those behaviors. Further, we examined whether there was a link between parent instrumentality and adolescent body mass index (BMI) was statistically mediated by parent instrumentality.

Results: As predicted, greater adolescent-perceived parent instrumentality was associated with greater fruit and vegetable consumption and physical activity and lower hedonic food consumption and sedentariness. Parent-perceived parent instrumentality was associated with all but hedonic food consumption. Mediation modeling suggests that variance in adolescent body mass index (BMI) is partially attributable to parent instrumentality for these behaviors.

Conclusions: We found that both visible (i.e., adolescent-perceived) parent instrumentality and invisible (i.e., parent-perceived, when controlling for adolescent-perceived) instrumentality predicted independent variance in adolescent eating and activity behaviors, and in adolescent BMI via these behaviors. These findings have implications for the promotion of healthy eating and activity patterns among adolescents. Parental instrumentality for behavior may be an important target for interventions to improve adolescent health, and interventions may be most successful in facilitating adolescent behavior change if they target both parent-perceived and adolescent-perceived parent instrumentality.

Symposium 67C

SOCIAL CONTROL, RELATIONSHIP SATISFACTION, AND THE DYADIC SUPPORT ENVIRONMENT IN A COUPLES-BASED WEIGHT LOSS INTERVENTION

Katelyn Gettens, M.A.

Background: Spouses are key agents in health behavior change and their attempts at social control (e.g., persuasion) elicit a range of responses, both helpful and harmful. What determines responses to social control, and how these responses may impact health outcomes, are not clear. Studies have considered the impact of spousal involvement in health behavior interventions broadly (Pietromonaco et al., 2013), and adults reporting low relationship satisfaction may be more likely to report negative reactions to social control (Tucker, 2002) suggesting it is necessary to consider the quality of the dyadic relationship. This study examined the impact of relationship satisfaction on behavioral reactions to social control and weight loss outcomes among married dyads participating in a behavioral weight loss intervention. We predicted that spouses reporting higher relationship satisfaction would exhibit healthier behavioral responses to social control from partners and that healthier responses would predict greater weight loss.

Methods: Cohabiting spouses (N dyads=64) participating in a randomized controlled trial of couples-based behavioral weight loss were examined. Spouses completed questionnaires about health-related indirect social control (e.g., “I feel a sense of responsibility to my spouse to stay in good health”), behavioral reactions to social control (e.g., “I did what my spouse asked”), and relationship quality at baseline, 3, and 6 months. Weight was measured at baseline and 6 months.

Results: Analyses controlled for intervention group, gender, age, baseline indirect social control, and behavioral reactions. Higher baseline relationship satisfaction predicted less unhealthy behavioral responses to indirect social control at 3 months, including lower reported “doing nothing” ($B = -.02, p = .02$), “doing the opposite of what my spouse asked” ($B = -.02, p = .05$), and “hiding behaviors from spouse” ($B = -.03, p < .01$). Unhealthy behavioral responses at 3 months predicted lower percent weight loss at 6 months (“doing nothing”, $B = 2.15, p < .01$; “hiding the behavior”, $B = 1.57, p = .06$). Behavioral responses mediated the effect of relationship satisfaction on 6-month weight loss: “doing nothing,” $a*b = -.05, p = .03$; “hiding behaviors,” $a*b = -.04, p = .06$.

Discussion: The impact of spousal indirect social control on behavioral responses to social influence and weight loss outcomes appear to depend on the quality of the relationship. Relationship satisfaction may reduce negative reactions to indirect social control, indicating that support and influence operate differently in satisfied (versus unsatisfied) relationships. Healthier behavioral responses to indirect social control may also improve weight loss outcomes. These findings highlight the importance of the dyadic environment: simply put, the quality of the relationship matters.

CORRESPONDING AUTHORS: Talea Cornelius, Ph.D., Columbia University Medical Center; talea.cornelius@gmail.com; Theodore A. Powers, Ph.D., University of Massachusetts Dartmouth; tpowers@umassd.edu; Amy A. Gorin, Ph.D., University of Connecticut; amy.gorin@uconn.edu

Symposium 68

8:30 AM-9:45 AM

USING IMMERSIVE VIRTUAL REALITY TO STUDY AND CHANGE HEALTH-RELATED BEHAVIOR

Megan Lewis, PhD¹, Laura K. Wagner, MPH², Susan Persky, PhD³, Patrick Bordnick, PhD⁴, William Riley, PhD⁵

¹RTI International, Seattle, WA; ²RTI International, Research Triangle Park, NC; ³National Institutes of Health, BETHESDA, MD; ⁴Tulane University, New Orleans, LA; ⁵NIH Office of Behavioral and Social Sciences Research, Bethesda, MD

Immersive virtual reality (VR) is seeing a rapid rise in consumer popularity, but its potential to enhance health and well-being is largely untapped by researchers. Primarily discussed as a gaming and entertainment technology, it has several inherent characteristics that fill important needs in behavioral medicine research and practice. For example, VR environments can provide several benefits to researchers, including: manipulation of contextual factors via highly controlled experimental conditions, realistic environments that allow participants to practice behaviors before doing enacting them in the real world, and facilitating embodiment and immersion experiences that can support positive emotions and behavior. In addition, it provides the opportunity to collect unique behavioral data that would be impossible in real world contexts, helping researchers triangulate behavior change data. It can be flexibly applied to rigorous experimental studies, support learning of new behaviors as a training tool, and used as an outcome assessment tool. This symposium will draw on the findings and experiences of three VR research programs. These three innovative research presentations will illustrate the important potential advantages of VR technology use in arenas relevant to behavioral medicine researchers. These projects also represent different points in the lifecycle of VR tool development, from preliminary assessment, to validation, and finally to clinical application.

Symposium 68A

PRELIMINARY ASSESSMENT OF THE VIRTUAL GENETIC COUNSELOR'S OFFICE

Ms. Laura K. Wagner, MPH

Recent advances in and lower costs for genomic sequencing tests are changing the types of genomic risk information that clinicians and parents have access to related to an infant's or child's health. In addition, studying how clinicians communicate the practical benefits and risks of this information to parents is still unexplored. Few systematic opportunities to study decision-making exist outside of busy, uncontrolled clinic workflows. Although researchers have used hypothetical vignettes in surveys to study decision-making, this method lacks psychological realism.

To study parents' perceptions of the risks and benefits of genetic sequencing tests for their children, we developed the Virtual Genetic Counselor's Office (VGCO), an immersive VR environment. In the VGCO, parents hear from a genetic counselor about the risks and benefits of genetic sequencing tests. They also have the choice to learn about information that varies by age of onset and medical actionability. The VGCO allows us to maintain experimental control of the order of the presentation of risk and benefits for various types of information that parents could learn.

We will highlight a research project conducted to assess the usability and acceptability of the VGCO. This presentation will focus on the iterative framework used to develop the environment: the Define, Design, Develop, and Deploy phases. As part of the Deploy phase, 39 parents of young children completed the VGCO activity. We collected self-report data on usability, acceptability, and presence. Presence, the perception that the virtual environment is reality, is an important factor in engagement and learning. Participants reported that the interface was easy to use, and that they had few, if any, signs of physical discomfort. They reported feeling mentally present in the interaction with the genetic counselor. However, despite feeling mentally present, participants did not report feeling as physically present, for example, they did not forget about their physical surroundings. The presentation will share the lessons learned from this pilot study and provide insights into the early stages of developing VR environments for research.

CORRESPONDING AUTHOR: Megan Lewis, PhD, RTI International; melewis@rti.org

Symposium 68B

VIRTUAL REALITY FOR HEALTH BEHAVIOR MEASUREMENT: THE VR BUFFET

Susan Persky, PhD

Childhood nutrition and obesity are priority research areas and require research to understand the feeding behaviors of parents. However, child feeding is difficult to measure, particularly in laboratory settings where formative research often takes place. VR behavioral measures provide high levels of experimental control, yet place research participants in a psychologically realistic, ecologically-valid scenario, and allows automated collection of fine-grained behavioral data. In the VR buffet, parents choose a meal for their child from among a variety of foods and beverages that vary in nutrient and calorie density. Data collected include type and amount of each food selected, nutritional metrics, timing, and orderings of selections. This presentation will highlight a research project that was conducted to validate the use of the VR Buffet as a child feeding measure. In this study, the amount of food served in the VR Buffet was highly correlated with real-world serving amounts $r_s = .613, p < .0001$ for food and, $r_s = .822, p < .0001$ for beverages. In addition, food serving patterns conformed to predicted patterns based on the age and gender of the child for whom food was chosen. For example, parents chose 100 calories more for boys than girls. Findings from substantive parent feeding studies that use the VR Buffet as an outcome measure will also be presented to demonstrate its versatility and sensitivity to detect experimental effects. The Mothers' TAKE Trial used the buffet to assess calories chosen for one's child following presentation of family health history-based obesity risk information for that child. The nTech Trial assessed the influence of parental emotion and framing of a message about fruit and vegetable consumption on parents' serving of fruit and vegetables from the VR Buffet. As such, the VR Buffet is an example of an evidence-based application of VR technology to tackle challenges of behavioral measurement in a behavioral medicine research context.

Symposium 68C

VIRTUAL REALITY: THE FUTURE OF SUBSTANCE ABUSE RESEARCH AND TREATMENT

Patrick Bordnick, PhD

Envision a world where humans interact seamlessly with technology, to improve behavioral health and aid in knowledge building. This presentation will describe a mature program of research using immersive virtual reality (VR) that addresses clinical and laboratory investigations of substance abuse using technology. The scope of VR application to substance abuse involves developing and testing VR environments for alcohol, nicotine, marijuana, heroin and other behavioral disorders. Key findings indicate that significant increases in drug craving were evoked in virtual parties, bars, restaurants, and drug using environments, demonstrating that VR is a viable medium to explore relapse behaviors. Because VR is a method to study craving in virtual contexts that emulate the real world, it can also provide a foundation to use VR environments to teach coping skills and relapse prevention strategies to improve cessation rates. Our work demonstrated that coping and relapse prevention skills learned in VR decreased smoking rates and led to increased confidence to resist smoking in the real world 6-months post-trial. Data supports the theory that skills learned in virtual environments translate to actual skill use in the real world. Building upon previous research, the path forward for using VR in substance abuse and behavioral health areas will involve the use of portable smartphone based VR to bridge the gap between clinical and real world settings. Overall, VR is a novel tool that can be used to augment traditional intervention approaches and enhance therapeutic gains beyond traditional clinical settings. This research program has implications for VR as a clinical intervention tool.

Symposium 69

8:30 AM-9:45 AM

PARENT PERSPECTIVES ON HEALTHCARE DECISIONS AND HEALTH BEHAVIORS

Erin Turbitt, Ph.D.¹, Megan C. Roberts, PhD², Yelena P. Wu, PhD³, Christine Rini, PhD⁴, Jennifer L. Hay, Ph.D.⁵

¹National Human Genome Research Institute, Bethesda, MD; ²National Cancer Institute, Bethesda, MD; ³Huntsman Cancer Institute, University of Utah, Salt Lake City, UT; ⁴John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, NJ; ⁵Memorial Sloan Kettering Cancer Center, New York, NY

The majority of decision making research focuses on individuals making decisions about their own health; however, we know comparatively little about surrogate decision making. The most prevalent context in which surrogate decision making occurs is when parents make decisions on behalf of their child. The limited evidence available on this topic suggests that making decisions for others differs from choosing for yourself, demonstrating a need to further study surrogate decision making. This symposium will explore parental decision making in a variety of contexts, using inherited conditions as an exemplar.

Data from three different studies will be presented under the topic of parent decision making. The first presenter will describe development and novel application of the methodology best worst scaling; a choice assessment task used to elicit patient preferences in healthcare. Data from parents of children with Fragile X Syndrome (the most common inherited form of intellectual disability) include motivating and discouraging factors to enrolling their child in a clinical drug trial. The presentation will also explore decisional conflict about trial participation, and the roles of various stakeholders in the decision-making process. The second presenter will discuss results from a study with parents who have a history of melanoma and their children who are at increased risk for the disease. Qualitative and quantitative findings demonstrate that parents perceive both barriers to and facilitators of their children's melanoma preventive behaviors, and that these factors can influence reported implementation of preventive behaviors. The third presenter will discuss decision-making processes among couples asked to make a joint decision about newborn screening using genomic sequencing. Analyses will examine factors associated with decisional conflict, decision regret, and collaborative decision making, with implications for development of decision support interventions.

This symposium aims to address issues such as (1) assent or involvement of children in decision making; (2) understanding the factors that may influence decisions made by parents, children and clinicians; (3) parental decision support interventions.

Symposium 69A

PARENT DECISION MAKING IN CLINICAL DRUG TRIALS

Dr. Erin Turbitt, Ph.D.

Compared to adults, children have historically been underrepresented in drug development research. Furthermore, pediatric drug trials are more often terminated due to poor recruitment and retention of subjects. Instrumental to the recruitment process, informed consent is an ethical and legal requirement for individuals to participate in research. Because children lack the capacity to independently consent to research participation, parents play a key role in making decisions for trial participation on their behalf. Given the central role parents have in the decision to enroll their child, it is important to understand the trial decision-making process from their perspective. Delineating the motivating and discouraging factors parents weigh may improve recruitment and retention rates.

We carried out a study to assess parental decisional factors for enrolling their child into a drug trial. We focused on parents of children with the most common form of inherited intellectual disability, Fragile X Syndrome (FXS), which is associated with behavioral challenges and autism spectrum disorder. There are no FDA approved drugs to treat FXS, though recent advances in understanding the disease mechanism have led to an increase of FXS clinical drug trials.

This presentation will describe a use of the Best Worst Scaling (BWS) technique for studying decision making. BWS is a choice assessment experiment used in market research and health economics to evaluate goods and services by identifying their most and least highly valued attributes. These techniques present respondents with a range of different combinations of attributes require preference choices. We developed a BWS choice assessment task about decisional factors for drug trial participation among parents of individuals with FXS. Evidence from five sources contributed to development of the BWS task: published literature, qualitative interviews with 34 parents, method and topic expert consultations, pre-testing with clinicians and researchers, and piloting with the target population.

Data from the development of the BWS task will be presented. Findings will include a ranked list of the factors parents prioritize when deciding about entering their child into a drug trial. This presentation will also explore ease of decision making and the roles of others (i.e. family, clinicians, and affected individuals) in the decision-making process.

Enhancing our understanding of parental decision making for drug trial enrollment enables us to develop appropriate support to ensure parents make informed decisions that align with their personal values and in turn improve retention and recruitment to trials.

Symposium 69B

BARRIERS TO AND FACILITATORS OF MELANOMA PREVENTIVE BEHAVIORS PREDICT REPORTED SUN PROTECTION IN CHILDREN WITH FAMILIAL RISK

Dr. Yelena P. Wu, PhD

Implementation of melanoma preventive behaviors during childhood is particularly important for children at elevated risk for melanoma due to family history of the disease. However, prior literature suggests that engagement in melanoma preventive behaviors can be suboptimal. Few studies have identified factors that may influence children's engagement in melanoma preventive behaviors. The current study identified parent- and child-reported barriers and facilitators to child engagement in melanoma preventive behaviors using qualitative (focus group) and quantitative (survey) methods, and examined how reported barriers and facilitators are related to engagement in preventive behaviors. Thirty-nine parents and 37 children participated in focus group discussions (6 parent, 6 child groups) and 69 parents and 63 children completed questionnaires. Qualitative results highlighted several barriers and facilitators that have not been previously described in the literature. For instance, barriers included challenges associated with implementing sun protective behaviors across different settings (e.g., at school, extracurricular activities) and tailored to children's preferences (e.g., preference for protective clothing instead of slimy feeling of sunscreen), and facilitators included receipt of healthcare provider recommendations about prevention and screening behaviors. Cross-sectional quantitative findings indicated that both parent- and child-reported barriers to child sunscreen use significantly predicted child sunscreen use ($b = -.12, p = .03$; $b = -.21, p = .04$, respectively). In addition, parent-reported barriers to child protective clothing use significantly predicted parent-reported child use of protective clothing for long-sleeved shirts and long pants ($b = -.14, p = .01$; $b = -.17, p = .005$). Parent-reported facilitators to children's long-sleeved shirt wearing significantly predicted parent-report of children's wearing of long-sleeved shirts ($b = .20, p = .04$). These findings demonstrate that at-risk children and their parents experience multiple barriers to and facilitators of children's engagement in melanoma preventive behaviors. Further, these factors (barriers and facilitators) may predict children's engagement in melanoma preventive behaviors. Interventions aiming to support children with a family history of melanoma in engaging in melanoma preventive behaviors could provide families with strategies to address their barriers and facilitators.

Symposium 69C

DECISION MAKING IN COUPLES OFFERED GENOMIC SEQUENCING FOR NEWBORN SCREENING: OUTCOMES OF A SURROGATE, JOINT DECISION

Dr. Christine Rini, PhD

The North Carolina Newborn Exome Sequencing as Universal Screening (NC NEXUS) study is investigating whether genomic sequencing enhances the benefits of newborn screening. *Next Generation Sequencing Newborn Screening* (NGS-NBS) could identify a greater proportion of infants at risk for conditions that are actionable. We are recruiting parents with a healthy pregnancy (*well-child* cohort) and parents of children aged 0–5 diagnosed with a condition included in standard NBS or that is not currently screenable but would be a good candidate for NBS (*diagnosed* cohort). Parents are asked not only to make a surrogate decision on behalf of their child, but also to work together to make it. After each parent completes a baseline (T1) assessment, they are instructed to work together to complete an online decision aid (DA) that includes values clarification, using the DA to record a joint initial decision about whether they are interested in NGS-NBS for their child. If their decision is *yes* or *undecided*, they are invited to a clinic visit to learn more and/or consent to NGS-NBS. Each parent also completes a post-decision assessment (T2). Of 103 couples who have completed T1 and the DA to date, 47% have made an initial decision to accept NGS-NBS, 16% were undecided, and 37% declined. Of the 86 (83%) invited for the clinic visit, 60 (70%) attended and all consented to NGS-NBS. Analyses of T2 data showed little agreement between mothers' and fathers' decision regret ($r = .18, p = .13$) and only modest agreement about the difficulty of decision making (decisional conflict; $r = .40, p < .001$). Mothers reported more decision regret ($p = .02$) and decisional conflict ($p = .002$) than fathers. These outcomes did not differ across cohorts nor did they differ according to whether parents accepted or declined NGS-NBS. Mothers and fathers reported similar perceptions that their joint decision making was a positive, collaborative experience ($p = .12$). For each parent, this perception was negatively related both to their own decision regret and decisional conflict and to their partner's decision regret and decisional conflict, with only one exception. Findings suggest that parents' decisional conflict and, especially, decision regret could differ substantially and that parents' perceptions about positive collaboration in their joint decision making were related to the psychological experience of the decision making process and the decision outcome.

PROMOTING HEALTH ENGAGEMENT BEHAVIORS WITH UNDERSERVED POPULATIONS: PSYCHOLOGISTS AND PHYSICIANS WORKING TOGETHER

RoseAnne Illes, Florida¹, Amanda Danley, M.D.², Scott J. Nyman, Ph.D., ABPP, LP³, Andrew Champine, PsyD⁴, Erin O'Connor, PhD⁵

¹FSU Family Medicine Residency @Lee Health, Fort Myers, FL; ²FSU Family Medicine Residency @ Lee Health, Fort Myers, FL; ³Ascension Genesys / Michigan State University College of Human Medicine, Burton, MI; ⁴McLaren Flint / Michigan State University College of Human Medicine, Bay City, MI; ⁵McLaren-Flint, Flint, MI

Underserved populations struggle with access to resources in many healthcare areas ranging from medical/mental health services to health literacy. Often times various providers can become overwhelmed by attempting to meet the challenging needs of this population. Primary care has always been a discipline that focuses on prevention, being patient-centered, and addressing the whole person context. Recently it has been an area in which focus has turned to for further coordination of care, such as creating Patient Centered Medical Homes (PCMH) and Accountable Care Organizations (ACO).

Although these programs have placed an emphasis on quality vs revenue, it has not provided guidance on how to address the complicated needs of underserved populations. The demands that healthcare places on primary care physicians, specifically the time constraints, impacts the delivery of care to a population that needs extra support. Programs are being developed to meet the demands of working with low SES/underserved populations while assisting providers in providing appropriate patient-centered care. This symposium will present different examples of programs that were created to address this need, which include focusing on health improvement and advocacy efforts using collaborative psychological and medical providers for comprehensive approaches.

With the movement toward more integration between interdisciplinary providers and patient centered medical homes, this symposium will demonstrate examples of opportunities for psychologists and physicians to collaborate for the goal of improving healthy lifestyle management for underserved/low SES populations. The first presentation will demonstrate an example of a diabetic group visit that was created and run by resident physicians in collaboration with a health psychologist. This has a twofold purpose in that it was created to address the needs of the clinic population who often struggle with understanding diabetes management from only the 20 minute visit, in addition to assisting resident physicians with frustration of balancing desire to educate patients but under time constraints. The second will present a model of collaboration between psychologists and physician residents, within the physician's office visit, to address health behavior change for obesity and smoking. They will provide insight into physician's self-perceptions of barriers to their work with managing low SES patients on healthy lifestyle goals. The third will present a community outreach program where psychologists and resident physicians together provide screening and interventions on various health concerns including asthma, physical activity, and blood pressure.

Symposium 70A

CAN DIABETIC GROUP VISITS IMPROVE HEALTH LITERACY IN AN UNDESERVED POPULATION

Dr. Amanda Danley, M.D.

Diabetes is a significant burden in the United States of America with an estimated prevalence of 29.1 million people or 9.3% of the total population; which is associated with significant complications and increased mortality. Patient education focusing on knowledge and behaviors has shown to improve diabetic glycemic control. This management is an even greater concern in a population with low health literacy and health disparities. Group medical visits have historically been implemented to improve self-management and peer support; however in a population which has multiple barriers to chronic disease management, group visits have provided an alternative to the quick primary care visits. Our clinic population faces challenges with managing chronic diseases and struggled with gaining understanding solely from the primary care physician's traditional 20 minute visit. Physician residents in collaboration with a health psychologist created a group to address the needs of the patient population served.

The group visits have provided a twofold benefit of addressing the needs of the patients. While these groups permit residents to learn skills in facilitating groups, it provides the physicians the reward of working with patients outside of the 20 minute visit. Secondly it provides opportunity for patients to have more time with a physician and to explore aspects of diabetes management of which they may not in the traditional medical visit. The health psychologist is an attending of the program and serves as a supervisor during the visits, however inclusion of the psychologist in collaboration with the facilitators occurs throughout the visits as topics are appropriate (i.e. discussion of stress and glucose). Curriculum development and content will be discussed as factors relevant to our underserved population were included, such as learning how to pick foods when eating out, food options to buy on limited funds, and ways to make traditional meals healthier for DM management.

We conducted pre and post-test measures to identify patient outcomes and will present the findings regarding changes in perceived diabetic knowledge, empowerment, and overall management. Challenges and strengths of this experience will be discussed, which includes recruitment, patient engagement, factors unique to this population regarding DM management, patient interest, patient appreciation, and resident education on the facilitation process of group visits with patients with low health literacy.

Symposium 70B

IMPROVING HEALTH BEHAVIORS OF UNDERSERVED PATIENTS IN THE PRIMARY CARE OFFICE: A TRANSDISCIPLINARY APPROACH

Scott J. Nyman, Ph.D., ABPP, LP

Research has highlighted the importance of patient *health engagement* and *activation* in implementing long-term healthy behaviors (Hibbard & Greene, 2013), yet the health behaviors of traditionally underserved patients are often influenced by factors such as socio-economic status (SES), housing, transportation, education, health literacy, and at times cultural customs and norms, some or all of which may impact, and even impede, engagement in healthy behaviors (Bowers, 2015; Orzech, Vivian, Huebner-Torres, Armin, & Shaw, 2012). This presentation will describe collaborative efforts between psychologists and physicians, working as a team, to address the unique health behavior needs and challenges of underserved patient populations in the primary care medical office. The presentation will address A) Collaborative patient care initiatives focused on improving patient engagement and activation regarding health-related behaviors in the primary care office and B) Medical education curricula focused on healthy behavior change designed for Family Medicine Residents. Upon conclusion of the presentation the audience will be able to utilize this information to inform their own clinical and teaching practices to better reach underserved primary care patient populations and teach medical and psychology learners evidence-based practices to increase patient health engagement and activation levels.

Our urban primary care Family Medicine residency training program contains fully licensed psychologists and physicians, as well as Psychology Postdoctoral Fellows and Family Medicine Residents, to provide outpatient care to a diverse, low SES patient population with high rates of tobacco use, obesity, sedentary lifestyle, and Type II Diabetes Mellitus, often coupled with low health literacy levels. The presentation will describe our Lifestyle Change Clinic (LCC), which was designed as a collaborative medical-psychology clinic to offer customized patient treatment planning and follow-up care to replace unhealthy behaviors with long-term health-promoting behaviors using concepts of Motivational Interviewing (M-I; Miller and Rollnick, 1991, 2002) and the Transtheoretical Model of Behavior Change (TTM: Prochaska & DiClemente, 1982; 1983; Prochaska, DiClemente, & Norcross, 1992). Our 3-year Family Medicine residency program uses a 4-week block rotation model in which residents spend a portion of 1 block / year with our Behavioral Science Department. In addition to working with us in the LCC during the rotation, we also provide a self-directed learning curriculum in each residency year with ongoing individualized follow-up discussion throughout the rotation. The presentation will describe elements of this curriculum focused on healthy behavior change with underserved patient populations.

Symposium 70C

DELIVERING POPULATION HEALTH MEDICAL EDUCATION THROUGH COMMUNITY PARTNERSHIP: COLLABORATIONS TO SEVERE THE UNDERSERVED

Dr. Andrew Champine, PsyD

Motivation/Problem Statement: The governing body of medical education (ACGME) has realized the importance of population health approaches to address quality healthcare delivery, reduce per capita healthcare expenditures, and provide greater patient satisfaction (IHI Triple Aim). As such, current requirements for residency training often include some formalized component of population health education. In response, our medical education program, led by the efforts of clinical health psychology, devised a curriculum focusing on serving the underserved in the Flint, Michigan community. This program was created as an opportunity to meet the demands of working with underserved populations on health improvement while providing medical education on the core concepts of population health. This collaboration includes a transdisciplinary approach that combines the knowledge and expertise of clinical health psychology, family medicine, and community public health organizations.

Approach: The approach for developing a program to educate about population health with the underserved followed the *Kern's Six Step Model of Curriculum Development*. This involved clinical health psychology at an academic hospital leading networking and needs analysis with a public health organization, The Crim Fitness Foundation. Various partnership goals were generated and a formalized set of activities to serve the underserved was delineated. Activities all included some form of integration between behavioral medicine and family medicine. These activities included health improvement and advocacy efforts such as providing health education, screening and assessment, mindfulness interventions, resource development, amongst others. A continuous cycle of quality improvement examined feedback on the success of the program. Various points of evaluation examine the impact in terms of education, community engagement, and feedback from underserved populations.

Product: The final product of this project will be realized in twofold. First, the medical education curriculum provided for McLaren Flint serves as a cornerstone teaching opportunity to explore core concepts and approaches to population health. The second, is the ongoing health improvement and advocacy efforts that have a direct impact on community engagement, community partnership, and associated outcomes for the underserved.

Conclusion: Though we have experienced tremendous support and success with the development of this teaching/service platform, the program continues to evolve and grow. A discussion will be provided as to how to construct population health education using community based activities and partnerships, including strengths and weaknesses of this specific model. In addition, future quality improvement cycles, quantification of metrics, and emerging opportunities is explored in the conclusion.

Symposium 71

8:30 AM-9:45 AM

EHEALTH CARBOHYDRATE-REDUCED DIET AND LIFESTYLE PROGRAMS FOR ADULTS WITH TYPE 2 DIABETES: THREE APPROACHES

Laura Saslow, PhD¹, James McCarter, MD, PhD², Charlotte Summers, BSc³¹School of Nursing, Department of Health Behavior & Biological Sciences, University of Michigan, Ann Arbor, MI; ²Virta Health., San Francisco, CA; ³Diabetes.co.uk, Coventry, England, United Kingdom

For the past few decades, diet and lifestyle programs for adults with type 2 diabetes have included recommendations to follow a low-fat diet, often using in-person programs. In parallel, however, research has shown that carbohydrate-reduced diets may more effectively reduce body weight, improve glycemic control, and reduce hypoglycemic medications. Plus, online interventions have shown promise for encouraging these dietary changes. Several programs now have combined these approaches, teaching a carbohydrate-reduced diet to adults with type 2 diabetes supported by digital approaches.

The goals of this symposium are to:

- (1) describe two carbohydrate-reduced diets for type 2 diabetes (low-carb or ketogenic)
- (2) illustrate how three digital interventions support dietary adherence to carbohydrate-reduced diets
- (3) examine the preliminary efficacy of these carbohydrate-reduced diet digital interventions for reducing body weight, improving glycemic control, and reducing hypoglycemic medications in adults with type 2 diabetes.

The first presenter will describe a commercially available, continuous remote care medical clinic that supports patient behavior change and utilizes nutritional ketosis. The clinic includes mobile delivered remote care by a health coach and physician, online nutrition education, biometric feedback, and peer support. Results will be presented from a prospective longitudinal study.

The second speaker will describe a free, commercially available digitally supported program that teaches a low-carbohydrate diet using online video- and handout-based lessons, weight self-monitoring, dietary self-monitoring, digital social support groups, and medication management through the participants' own healthcare team. Results will be presented from a prospective longitudinal study.

The final speaker will present the development of an online program that teach a ketogenic diet using online video- and handout-based lessons, text messages, mailed cookbooks and food gifts, remote breath or urine ketone monitoring, remote weight monitoring, dietary self-monitoring, e-mail/phone coaching, digital social support groups, medication management through the participants' own healthcare team, and psychological supports based on a variety of approaches including positive affect and mindfulness.

Overall, it is our hope that the ideas and approaches presented during this symposium will provide the audience with new ways to think about diet and lifestyle interventions with adults with type 2 diabetes.

Symposium 71A

OPTIMIZING AN ONLINE VERY LOW-CARBOHYDRATE DIET AND LIFESTYLE INTERVENTION FOR ADULTS WITH TYPE 2 DIABETES

Dr. Laura Saslow, PhD

Background: Overweight adults with type 2 diabetes may benefit from advice to follow a very low-carbohydrate diet and lifestyle advice. However, the optimal intervention components necessary to support these behavioral changes in an online intervention are unclear. Using a full-factorial design, we designed a screening experiment to examine the effects of three experimental treatment components on 12-month outcomes in adults with type 2 diabetes. Our objective was to evaluate whether the addition of three intervention components (text messages, gifts of foods and books, and type of ketone meter) would improve glycemic control and percent weight lost over 12 months among adults with type 2 diabetes assigned to follow an online ad libitum very low-carbohydrate diet and lifestyle intervention.

Methods: Using 2x2x2 randomized factorial experiment, we assigned overweight or obese adults (BMI 25–45) with type 2 diabetes (HbA1c > 6.5%) on either no hypoglycemic medications or just metformin to a 12-month online intervention with three extra intervention components: (a) nearly daily versus no text messages to inform, inspire, and remind participants about the intervention's recommended behaviors (yes n=22, no n=22), (b) six versus zero bursts of mailed gifts of diet-relevant foods and/or books (yes n=21, no n=23), and (c) urine- or breath-based ketone measurement type, to provide feedback about the participants' dietary adherence (breath meter n=23, urine strips n=21). A priori we set a cutoff of efficacy of a Cohen's d of .5 or greater.

Results: We performed an interim analysis at 8 months post baseline. A total of 44 overweight adults were randomized, and 35 had outcome information (80% retention; mean±SD; full sample: 52 ± 11 y, HbA1c 8.4 ± 2.2%, 100 ± 20kg, 75% female). HbA1c reduced to 7.4 ± 2.3% (P<.001), 42% of patients achieved HbA1c <6.5% while taking no diabetes medications or metformin only, and participants lost 6.3 ± 6.6% of their baseline body weight (P<.001). Only the ketone measurement type had an impact with a Cohen's d of .5 or greater for either HbA1c or weight reduction, with urine strips outperforming the breath meter. With the breath meter HbA1c reduced by a unit of -0.5 ± 1.4% and weight reduced by 4.5 ± 6.3%; with the urine strips HbA1c reduced by a unit of -1.5 ± 1.8% and weight reduced by 8.6 ± 2.1%.

Conclusions: This research found that overall, our online intervention improved glycemic control and weight loss in adults with type 2 diabetes. Urine strips, an easy-to-use biologically based dietary adherence measurement, improved health outcomes at 8 months. Future research could investigate other intervention components to better improve outcomes and reduce dropout, so that online interventions can be effective and scalable solutions for national type 2 diabetes treatment efforts.

Symposium 71B

EFFECTIVENESS OF CONTINUOUS REMOTE CARE AND NUTRITIONAL KETOSIS FOR TYPE 2 DIABETES

James McCarter, MD, PhD

Background: Multiple studies demonstrate that reduced dietary carbohydrate can significantly improve glycemic control and reduce medication use; however, the safety and sustainability of this approach has not been tested in a large population. We evaluated if patients with type 2 diabetes (T2D) could be supported by a remote care team to maintain nutritional ketosis, improve glycemic control, reduce weight, and reduce medications over one year.

Methods: 262 adults with T2D enrolled in a prospective, longitudinal study of this intervention where they received personalized nutrition and behavioral recommendations via continuous remote care by a health coach, medication management by a physician, biometric feedback, and peer support. Primary outcomes were hemoglobin A1c (HbA1c), medication use, and weight. Secondary outcomes included blood lipids, high-sensitive C-reactive protein (hsCRP), and liver function markers.

Results: At the time of this interim analysis, 158 subjects had reached one year. 130 of 158 remained actively enrolled (82% retention). Of these, we have data from 111 patients (mean \pm SEM; 54 ± 1 y, 40 ± 1 kg-m⁻², 75% female) who have completed 1-yr testing. HbA1c at enrollment ($7.4 \pm 0.1\%$) improved to $6.1 \pm 0.1\%$ ($p < .0001$) at 1 yr, and 58% of patients achieved HbA1c $< 6.5\%$ at 1 yr while taking no diabetes medications or metformin only. Insulin was reduced or halted in 97% of users; oral glucose control medications (excluding metformin) were reduced from 51 prescriptions at baseline to 8 prescriptions at 1 yr. Weight was reduced $13.6 \pm 0.8\%$ at follow up (116 ± 2 kg to 100 ± 2 kg, $P < .0001$). At 1 yr, significant improvements in triglycerides (176 ± 13 to 132 ± 11 mg-dL⁻¹, $P = .002$), high-density lipoprotein cholesterol (46 ± 1 to 53 ± 1 mg-dL⁻¹, $P < .001$), hsCRP (7.5 ± 0.6 to 5.0 ± 0.6 mg-dL⁻¹, $P < .0001$), and alanine aminotransferase (29.7 ± 2.7 to 20.8 ± 1.2 U-L⁻¹, $P = .0011$) were achieved. Low density lipoprotein particle number (1269 ± 42 to 1218 ± 39 mmol-L⁻¹, $P = .16$) was unchanged. There were no significant adverse events attributed to the intervention.

Conclusions: These initial data demonstrate that adults with T2D can be supported by a remote care team to maintain maintain nutritional ketosis and achieve significant reductions in HbA1c, weight, and medications. Ongoing work will assess 2-yr safety, efficacy and sustainability.

Symposium 71C

A DIGITALLY DELIVERED LOW-CARBOHYDRATE TYPE 2 DIABETES SELF-MANAGEMENT PROGRAM

Charlotte Summers, BSc

Background: Type 2 diabetes is prevalent, burdensome, and costly. The standard treatment includes a low-calorie, low-fat diet. However, other research and theory suggests that a carbohydrate-restricted diet would be a more effective approach.

Objectives: Our objective was to evaluate the 1-year efficacy of Low-Carb Program (LCP), a digitally delivered, nutrition-focused, structured, automated, 10 weekly session lifestyle intervention for glycemic control and weight loss for adults with type 2 diabetes. The LCP provides behavior change support and reinforcement about carbohydrate restriction using a solution-focused approach, behavioral self-monitoring, and peer support.

Methods: We randomly selected adults with type 2 diabetes ($N = 1000$, mean \pm SD; 56 ± 15 y, HbA1c $7.8 \pm 2.1\%$, kg, 90 ± 23 kg, 59% female) who joined the Low-Carb Program (LCP) to be followed for 1 year.

Results: After 1 year, for participants with elevated baseline HbA1c ($\geq 7.5\%$), HbA1c reduced from 9.6% to 8.4% ($P < .001$) and they lost an average of 2.4% of their body weight ($P < .001$). If these participants engaged with all 10 weekly LCP modules, their HbA1c reduced from 9.2% to 7.1% ($P < .001$) and they lost an average of 6.9% of their body weight ($P < .001$). For participants with a slightly elevated baseline HbA1c (6.4–7.5%), HbA1c reduced from 6.9% to 6.2% ($P < .001$) and they lost an average of 5.1% of their body weight ($P < .001$). If these participants engaged with all 10 weekly LCP modules, their HbA1c reduced from 6.9% to 6.0% ($P < .001$) and they lost an average of 7.3% of their body weight ($P < .001$). The percentage of individuals with an HbA1c level of $< 6.5\%$ increased from 26% (257/1000) to 50% (503/1000).

Conclusions: Especially for participants who fully engage, an online program that teaches a carbohydrate-reduced diet to adults with type 2 diabetes can be effective for glycemic control and weight loss.

Symposium 72

8:30 AM-9:45 AM

FEMALE SEXUAL HEALTH AND CANCER: NEW FRONTIERS IN BEHAVIORAL RESEARCH

Kristine A. Donovan, PhD, MBA¹, Jennifer B. Reese, PhD², Clara Hungr, PhD³, Kristen M. Carpenter, PhD⁴, Sharon Bober, Ph.D.⁵

¹Moffitt Cancer Center, Tampa, FL; ²Fox Chase Cancer Center, Philadelphia, PA; ³Dana-Farber Cancer Institute, Cambridge, MA; ⁴Ohio State University, Upper Arlington, OH; ⁵Dana-Farber Cancer Institute/Harvard Medical School, Boston, MA

PURPOSE: Profound sexual dysfunction and related psychological distress are prevalent and persistent effects of treatments experienced by a majority of female cancer survivors. As the number of long-term cancer survivors continues to grow, this understudied area of women's health continues to garner more attention. New frontiers in this growing field of psychosexual oncology include examining sexual problems and their sequelae in understudied female cancer populations, developing and evaluating novel behavioral interventions for addressing cancer-related sexual problems, and understanding the mechanisms behind the effectiveness of such interventions. The purpose of this symposium is to present cutting edge data from behavioral research studies in each of these new frontiers.

METHOD: The following empirical findings will be presented: (1) Data examining the sexual health and overall quality of life (QOL) in women ($N = 21$) with life-limiting gynecological cancer who undergo pelvic exenteration surgery; (2) Results of a randomized pilot couple-based telephone intimacy enhancement intervention trial for breast cancer survivors and their partners ($N = 28$); (3) Results of mediational analyses from a sexual health intervention trial with both gynecological and breast cancer survivors ($N = 99$) focusing on the relationship between pain, distress and sexual function; and (4) Data examining self-efficacy, sexual knowledge, and emotional regulation in relation to outcomes of a psychosexual intervention trial on sexual function for ovarian cancer survivors ($N = 46$).

RESULTS: Findings highlight the unmet needs of female cancer survivors including women with advanced gynecologic cancer, underscore next steps for improving QOL for these women, demonstrate the positive effects of novel behavioral interventions for female cancer survivors across a variety of sexual health and relationship outcomes, and illuminate critical factors such as pain, distress and self-efficacy as factors that can play a role in determining the efficacy of interventions.

CONCLUSION: Novel and effective aspects of psychosexual intervention for female cancer survivors will be presented. Important and understudied areas for future research will be also be discussed by the presenters. The Discussant, an expert in clinical treatments for women with cancer-related sexual dysfunction, will comment on all studies.

Symposium 72A

SEXUAL HEALTH AFTER PELVIC EXENTERATION FOR GYNECOLOGIC CANCER

Kristine A. Donovan, PhD, MBA

Background Pelvic exenteration (PE) has been performed historically in women with gynecologic cancer for symptomatic palliation of recurrent disease. With the advent of new surgical techniques and advances in perioperative care, PE in the carefully selected patient can produce 5-year survival rates as high as 60%. The result is a growing cohort of long-term survivors dealing with the effects associated with such a radical surgery. In the current study, we sought to characterize women's sexual health after PE and examine its association with overall quality of life (QOL).

Methods In a mixed-methods study of QOL after PE, 21 women who underwent PE between 6 months and 10 years previously completed the Female Sexual Function Index (FSFI), the Sexual Self-Schema Scale for Women (SSSW) and the EORTC-Quality of Life questionnaire (EORTC-QLQ). Participants (n = 16) also participated in a semi-structured qualitative interview about their experience.

Results Participants ranged in age from 43 to 75 years (mean=58) and were a mean of 4 years post-PE. Seventy-six percent underwent a total PE and 57% had vaginal reconstruction. Mean FSFI total score was $17.6 \pm$ (range = 11.4 to 32.6). Scores for all but two women were indicative of sexual dysfunction. Partnered women and women with vaginal reconstruction reported higher FSFI total scores (Cohen's $d = .33$ for partnership status and $.49$ for reconstruction). Women attributed their dysfunction to PE itself, challenges with reconstruction, changes in physical appearance and spouse/partner concerns. Relatedly, some expressed profound changes in perceptions of one's self as a female and/or a sexual being. Self-reported global QOL was below average (42.5 ± 22 ; range=0 to 66.7) and significantly associated ($p < .05$) with the domains of sexual desire and pain and a more negative self-view.

Conclusions Findings suggest women's sexual health after PE is relatively poor. Findings also suggest targets for clinical interventions to improve sexual and psychological well-being and enhance QOL in long-term survivors. This study highlights the need for clinicians to attend not just to women's physical symptoms following this life-altering surgery but to monitor and attend to women's sexual health as well.

Symposium 72B

A RANDOMIZED PILOT TRIAL OF A COUPLE-BASED TELEPHONE INTIMACY ENHANCEMENT INTERVENTION FOR BREAST CANCER SURVIVORS AND THEIR PARTNERS

Jennifer B. Reese, PhD

PURPOSE: We previously piloted a couple-based telephone Intimacy Enhancement (IE) intervention addressing sexual concerns in colorectal cancer patients and their partners and then adapted the IE intervention for breast cancer survivors. In this randomized pilot trial, the IE intervention is compared to education control condition equating for therapist time and attention called Living Healthy Together (LHT). The objectives are to assess the feasibility and acceptability of the newly adapted IE intervention, and to generate effect sizes to inform the design of a larger trial.

METHOD: Adult females diagnosed with Stage I-III breast cancer who are 6 months – 5 years post-acute treatment, are partnered, and report some degree of sexual concerns (≥ 3 ; possible range 0–10) are eligible. Couples are randomized 2:1 to the IE or LHT condition, with stratification by age at diagnosis. Feasibility is assessed using rates of recruitment, retention, and session completion. Acceptability is assessed through the Client Satisfaction Questionnaire (CSQ-8), administered at post-intervention program. Preliminary efficacy is assessed through pre- and post-intervention measures of sexual outcomes [patient sexual distress (FSDS-R), patient and partner sexual function (FSFI, IIEF total scores), and sexual satisfaction (PROMIS Sexual Satisfaction Items), and sexual intimacy (PAIR Sexual Intimacy subscale); relationship outcomes [intimacy (PAIR Emotional subscale) and intimacy-related communication (DSCS), and relationship quality (DAS-7)]; and psychosocial outcomes [patient body image distress (BIS) and depressive and anxiety symptoms (PHQ-9, GAD-7)]. Between-group effect sizes will be calculated for study outcomes (group-wise difference in mean change scores/pooled change score SD).

RESULTS: Of 177 women screened, 91 were eligible (51%); 31 couples consented, 28 were randomized, and 1 couple is in process (31% acceptance rate; 19 to IE; 9 to LHT). Twenty-seven of the 28 randomized couples completed both study surveys (96%), and 24 completed all 4 telephone sessions (83%; 16 in IE, and 8 in LHT). CSQ-8 scores were high across both study conditions (median=29.5; possible range=8–32). Effect sizes will be presented using final data.

CONCLUSION: Findings support the feasibility and acceptability of the IE intervention for breast cancer survivors reporting sexual concerns and their intimate partners. Efficacy findings, implications, and future directions will be discussed.

Symposium 72C

SELF-EFFICACY, KNOWLEDGE AND EMOTIONS: EFFECTS OF A SEXUAL HEALTH INTERVENTION FOR SURVIVORS OF OVARIAN CANCER

Dr. Clara Hungr, PhD

Background: Sexual dysfunction is a prevalent and distressing side effect of ovarian cancer (OC) treatment. Little is understood about how to best treat sexual dysfunction after OC treatment, with few interventions available to extend to OC survivors. To bridge this gap, a recent study demonstrated that a one-time psychosexual intervention significantly improved sexual function in OC survivors. Data from this study was analyzed to examine the roles of self-efficacy, sexual knowledge and emotional distress on improved sexual function. Patient demographic and clinical characteristics were examined as potential moderators.

Methods: 46 OC survivors with documented sexual dysfunction attended the intervention, which provided sexual health psychoeducation and mindfulness-based cognitive strategies to address emotional distress and promote sexual behavior change. Measures of sexual function, self-efficacy, sexual knowledge, & emotional distress were completed prior to and two-months following a single session group intervention. Change in these variables pre- to post-intervention were assessed using t-tests. Correlational analyses assessed direct effects on sexual function, and bootstrapping analyses evaluated the role of emotional distress as a mediator of improved sexual function. Correlations assessed moderating effects.

Results: All four variables (sexual function, self-efficacy, sexual knowledge, emotional distress) improved significantly post-intervention. Improved self-efficacy ($p = .017$) and decreased emotional distress ($p = .015$) were both directly associated with improved sexual function; while change in knowledge was not ($p = .735$). The relationship between self-efficacy and sexual function was not mediated by change in emotional distress (effect size = .04). Age, time since diagnosis, medical co-morbidity and use of maintenance chemotherapy did not moderate results.

Conclusions: Increased self-efficacy and decreased emotional distress had separate and direct influence on significantly improving sexual function in women who had been treated for OC. Moderator analyses suggest that this brief intervention would be effective for a broad range of OC survivors. Implications from these results underscore the importance of promoting self-efficacy and decreasing emotional distress in the context of delivering sexual rehabilitation after cancer.

Symposium 72D

PAIN, DISTRESS, AND SEXUAL FUNCTION AMONG GYNECOLOGIC AND BREAST CANCER SURVIVORS: RESULTS FROM PROJECT SHARE

Kristen M. Carpenter, PhD

Sexual morbidities are among the most common and distressing sequelae of breast and gynecologic cancer treatments. Many survivors report multiple sexual concerns, including issues with desire, arousal, lubrication, orgasm, and pain with sexual activity. The present study examines the complex interrelationships among sexual pain, desire, and distress.

Participants enrolled in one of two clinical trials of a psychosexual intervention for cancer survivors and included survivors of stage I-III gynecologic ($n=70$) and breast ($n=29$) patients. Participants completed identical baseline measures assessing pelvic, sexual, and bodily pain (Pelvic Pain Assessment, Patient -PPA), sexual function (Female Sexual Function Index-FSFI; subscales for desire, arousal, orgasm, satisfaction, lubrication), and sexual distress (Female Sexual Distress Scale-FSDS). The joint significance test and bootstrapping analyses were used to assess whether sexual function mediated the relationship between pain and distress.

There were no differences in demographic, disease stage, treatment, FSFI, or FSDS scores between gynecologic and breast cancer survivors, so the groups were collapsed for analyses. Sexual pain (PPA) was associated with FSFI-orgasm ($b=-.24, p<.05$), FSFI-arousal ($b=-.25, p<.05$), and FSFI-desire ($b=-.20, p<.01$). Among the FSFI subscales and the FSDS, only desire was significantly correlated with sexual distress ($b=-2.48, p<.05$), consistent with our hypothesis that desire mediates the relationship between pain and distress. When utilizing bootstrapping analysis, the residual direct effect of PPA-sexual pain on FSDS (c') was significant ($b=-2.25, p<.001$), corroborating the joint significance test. The indirect effect of PPA-sexual pain on FSDS score ($ab=.40, 95\% \text{ CI } .05, 1.70$) suggested partial mediation ($R^2 = .24$).

Sexual pain is associated with poorer sexual function among gynecologic and breast cancer survivors, beyond other reported bodily pain. However, sexual function – namely desire – also partially mediates this relationship. Thus, it appears that the negative effect that of pain on desire is a considerable source of distress. Desire is complex, with a variety of physical, hormonal, behavioral, and psychological contributors. These results support a nuanced approach to sexual morbidity following cancer treatment and highlight the importance of considering multiple targets for intervention.

Symposium 73

8:30 AM-9:45 AM

ADAPTATIONS OF MEANING-CENTERED PSYCHOTHERAPY FOR PARENTS BEREAVED BY CANCER, CANCER CAREGIVERS, AND LATINOS WITH CANCER

Allison Marziliano, PhD¹, Allison Applebaum, Ph.D.², Rosario Costas-Muniz, PhD², Michael A. Diefenbach, Ph.D.¹¹Northwell Health, Manhasset, NY; ²Memorial Sloan Kettering Cancer Center, New York, NY

Background Meaning-Centered Psychotherapy (MCP) is an intervention initially designed to help patients with advanced cancer sustain or enhance a sense of meaning, peace and purpose in life despite the limitations of their illness. Since its inception, MCP has demonstrated efficacy in improving not only meaning/peace, spiritual well-being and faith, but also anxiety, desire for hastened death, overall quality of life and physical symptom distress in individual and group-format randomized controlled trials. In an effort to “extend our research,” this symposium both describes the process of adapting MCP for three different populations- parents bereaved by cancer, cancer caregivers, and Latino patients with advanced cancer- and/or presents findings from randomized controlled trials (RCTs) evaluating the efficacy of these MCP adaptations. Presentation 1 evaluates the effects of Meaning-Centered Grief Therapy (MCGT), compared to supportive therapy (SP), for parents who have lost a child to cancer. Results demonstrated that both MCGT and SP led to general improvements, but MCGT led to significantly greater reductions in symptoms of Prolonged Grief Disorder (PGD), increased sense of meaning and general improvements in well-being post-intervention. Presentation 2 describes the development of the Meaning-Centered Psychotherapy-Caregivers (MCP-C) manual and the adaptation of MCP-C for delivery over the Internet. In addition, results of the RCT evaluating the efficacy of web-based MCP-C among 84 caregivers randomized to the web-based MCP-C or the waitlist control arm showed a significant differential increase in benefit finding in favor of the MCP-C arm. Presentation 3 explores the formative process of the cultural and linguistic adaptation of MCP for Latinos with advanced cancer. Utilizing a mixed-methods approach, data was collected via a survey of 64 mental health professionals who service Latino or Hispanic cancer patients, a questionnaire completed by 32 Latino patients with advanced cancer, and an in-depth interview with 24 Latino patients. Quantitative findings showed that most MCP topics were acceptable for Latino cancer patients, but discussion about having a meaningful death was less acceptable. Main qualitative findings to inform adaptation included the need to use more simple language, using words that are common to all cultures or more than one word when needed, and use of culturally-congruent metaphors.

Symposium 73A

EFFECTS OF MEANING-CENTERED GRIEF THERAPY FOR PARENTS BEREAVED BY CANCER

Dr. Allison Marziliano, PhD

Background: Parents who lose a child to cancer not only experience profound grief but also often face challenges to their sense of meaning and identity. This ongoing pilot study is evaluating Meaning Centered Grief Therapy (MCGT), a novel one-on-one psychotherapeutic intervention adapted from Meaning-Centered Psychotherapy and designed to enhance bereaved parents' sense of meaning/purpose and to reduce symptoms of prolonged grief.

Methods: Parents bereaved by cancer (target N=66; current analysis focuses on first 16 enrolled with baseline data) were randomized to receive 16 one-hour sessions of MCGT or supportive psychotherapy (SP). Blinded evaluator assessments of prolonged grief (PG-13), sense of meaning (single item assessment from McGill Quality of Life), and global improvement (Clinical Global Impression [CGI] scale) were conducted at baseline, post-intervention, and 3 months post-intervention. Effect size estimates (Cohen's d) were calculated to compare MCGT and SP on the outcome measures, centering scores by baseline values.

Results: The majority of the sample (N=16) was female (n=12, 75%), white not of Hispanic origin (n=16, 100%), and married (n=12, 75%), with an average age of 49.87 (SD=10.16). Results showed that MCGT led to greater reductions in prolonged grief symptoms (d = .76) and increases in sense of meaning (d = .92) post-intervention when compared to SP. The effects of MCGT were not maintained at the three month follow-up assessment, with no improvements in prolonged grief (d = -.09) and small effects on sense of meaning (d = .31). MCGT had a large effect on CGI global improvement scores when compared to SP post-intervention (d = .91) and at the 3-month follow-up (d = .21).

Conclusions: Both MCGT and SP led to general improvements, but MCGT led to greater reductions in prolonged grief symptoms, increased sense of meaning, and general improvements in well-being post-intervention. Efforts should focus on strengthening the intervention so that treatment gains can be maintained after the intervention concludes.

Symposium 73B

MEANING-CENTERED PSYCHOTHERAPY FOR CANCER CAREGIVERS (MCP-C)

Dr. Allison Applebaum, Ph.D.

Background: Comprehensive care for cancer patients involves attending to the psychosocial needs of their informal caregivers (IC), among whom burden is well documented. A critical, potential driving mechanism of burden is existential distress, which includes feelings of hopelessness, demoralization, loss of personal meaning and dignity, burden towards others, and the desire for death or the decreased will to leave. Meaning-Centered Psychotherapy for Cancer Caregivers (MCP-C) was developed specifically to address this existential distress arising in the setting of caring for a patient with advanced cancer.

Method: The process of developing the original MCP-C manual and the adaptation of MCP-C for delivery over the Internet will be described. Next, the results of a randomized controlled trial evaluating the efficacy of web-based MCP-C among 84 ICs randomized to the web-based MCP-C or the waitlist control arm will be presented. Quantitative assessments of meaning, burden, anxiety, depression, benefit finding and spiritual well-being were conducted pre-intervention (T1), within 2 weeks post-intervention (T2) and 2–3 months' follow-up (T3). In-depth semi-structured interviews were conducted with a subset of participants.

Results: Forty-two caregivers were randomized to web-based MCP-C. Attrition was moderate at T2 and T3, with caregiver burden and bereavement as key causes of drop-out. At T2 and T3, some observed mean change scores and effect sizes were consistent with hypothesized trends (e.g., meaning in caregiving, benefit finding, depressive symptomatology), though no pre-post significant differences emerged between groups. However, a longitudinal mixed effects model found significant differential increases in benefit finding in favor of the MCP-C arm.

Conclusions: MCP-C shows great promise in addressing existential distress among ICs of patients with advanced cancer. In addition to an increased sense of meaning and purpose, MCP-C has the potential to protect against poor bereavement outcomes, including prolonged grief disorder and post-traumatic stress symptoms. MCP-C delivered over the Internet is feasible and acceptable. A larger study will likely establish the efficacy of web-based MCP-C, which can address unmet needs of caregivers who underutilize in-person supportive care services.

Symposium 73C

ADAPTING MEANING-CENTERED PSYCHOTHERAPY FOR LATINOS

Dr. Rosario Costas-Muniz, PhD

Background/Purpose: Psychosocial and psychotherapeutic interventions tailored for Latino cancer patients are scarce. This study delves into the formative process of the cultural and linguistic adaptation of a psychotherapeutic intervention for Latinos with advanced cancer, Meaning Centered Psychotherapy (MCP), as well as presents considerations for the process of adapting a psychotherapeutic intervention.

Methods: The planning and adaptation model will be described. The mixed-method approach of the formative research phase included: 1) a survey of mental health professionals (n=64) who offer services to Latino or Hispanic cancer patients, 2) a questionnaire with Latino patients with advanced cancer (n=32) measuring relevant concepts of the intervention, and 3) an in-depth interview with 24 Latino patients.

Results: The Ecological Validity Model (EVM) guides the adaptation of this intervention. Results from the mixed methods will be presented for the EVM dimensions: language, persons (facilitators), content, treatment concepts, treatment goals, treatment methods or strategies, metaphors, and context. Quantitative findings showed that most goals and concepts were highly acceptable for patients and providers; however, talking about what is a meaningful death was less acceptable. The main qualitative findings were the need to adapt the intervention to include more simple definitions (i.e. legacy); change phrases that are challenging to translate and comprehend (i.e. sources of meaning); use terms with equivalent semantic meaning (i.e. attitude); use words that are common to all cultures or more than one when needed (i.e. meaning as *significadolsentido*); simplify the questions/reflections (i.e. double-barreled questions); change the metaphors for culturally-congruent metaphors, and modify content to make it responsive to Latino cultural values and norms.

Discussion: Findings show the need to adapt the intervention to achieve the aims of the intervention, while accounting for both language and cultural considerations, with special consideration to issues related to literacy, cultural and linguistic diversity, cultural values, and culturally-congruent content.

Symposium 74

8:30 AM-9:45 AM

COUPLE-BASED INTERVENTIONS TO INCREASE PHYSICAL ACTIVITY:

Laura Porter, PhD¹, Kerri M. Winters-Stone, PhD², Kathryn I. Pollak, PhD³, Ida Griesemer, BA⁴, Laura Porter, PhD¹

¹Duke University Medical Center, Durham, NC; ²Oregon Health & Science University, Portland, OR; ³Duke University, Durham, NC; ⁴University of North Carolina at Chapel Hill, Carrboro, NC

There is overwhelming evidence for the benefits of physical activity in preventing morbidity and mortality and enhancing quality of life. However, only about 20% of in the U.S. are sufficiently active, leading researchers to develop and test interventions to increase physical activity. Despite the fact that physical activity occurs in a social context, the vast majority of physical activity interventions target individual patients only. Including partners is likely to help patients initiate and maintain increases in physical activity for several reasons. First, it capitalizes on the natural social support system. Social support is a critical element in behavior change, and most people prefer support from domestic partners. Interventions that enhance naturalistic social support for physical activity are likely to increase the likelihood that individuals will be able to initiate and maintain behavior changes. Second, a couple-based intervention creates a social environment that is conducive to activity. Physical activity behaviors often occur with, or are substantially influenced by, domestic partners, as reflected in high correlations of levels of physical activity among married couples as well as correlations between partners' positive health changes. Thus, involving both patients and their partners as active participants could lead to reciprocal benefits of health improvements from exercise on each partner. Additional benefits of a couple-based intervention may include increases in physical activity among partners as well as patients, resulting in a "2-for-1" effect, and enhancements in couples' relationships.

This symposium will highlight three approaches to developing and implementing couple-based interventions for increasing physical activity: (1) a 6-month supervised strength training intervention conducted with prostate cancer survivors and their partners; (2) a four-session intervention conducted via videoconference with cancer survivors and their partners that included training in communication skills to help couples identify and implement effective social support strategies, and behavior change techniques adapted to a communal coping approach; and (3) a one-session informational intervention conducted with patients with osteoarthritis and their partner in which the primary goal was to examine between-couple differences in patterns of social support for physical activity over time. Findings identified four patterns with implications for intervention design. The discussion will highlight theoretical and practical issues around enhancing partner support for physical activity, similarities and differences among intervention approaches with regard to conceptual issues and treatment components, and recommendations for future research.

Symposium 74A

BENEFITS OF PARTNERED STRENGTH TRAINING FOR PROSTATE CANCER SURVIVORS AND SPOUSES: RESULTS FROM A RANDOMIZED CLINICAL TRIAL

Prof. Kerri M. Winters-Stone, PhD

Purpose: Prostate cancer and the treatment of prostate cancer can have a negative impact on quality of life of the patient and his spouse caregiver, but interventions rarely target the health of both partners simultaneously. We tested the feasibility and preliminary efficacy of a partnered strength training program on the physical and mental health of older prostate cancer survivors (PCS) and their spouse caregivers.

Patients and Methods: Sixty-four couples were randomly assigned to six months of partnered strength training (Exercising Together, N=32) or to usual care (UC, N=32). Couples assigned to Exercising Together attended two 1-hour group-based strength training sessions per week for 6 months. Couples perform the exercise session as training partners where each member of the couple would act as a trainer/coach while the other performed an exercise and in some cases partners performed an exercise in tandem with each other. Partners assisted one another to get into proper exercise form, monitor to ensure form was maintained, corrected form as needed and verbally encouraged completion of the set. Tandem exercises were performed by both partners simultaneously and in coordination with each other. The partnered approach to training was used to facilitate a sense of teamwork and in order to facilitate interaction and communication, both verbal and physical, between training partners during training. We hypothesized that this partnered aspect of the training program might enhance communication and relationship quality outside of the training room. Outcomes included objective measures included body composition by DXA, maximal upper and lower body muscle strength by 1-repetition maximum, and physical function by the physical performance battery (PPB). Self-reported measures included the physical and mental health summary scales and physical function and fatigue subscales of the SF-36 and self-reported physical activity.

Results: Couple retention rates were 100% for Exercising Together and 84% for UC. Median attendance of couples to Exercising Together sessions was 75%. Compared to men in UC, men in Exercising Together became stronger in the upper body ($p<0.01$) and more physically active ($p<0.01$). Compared to women in UC, women in Exercising Together increased muscle mass ($p=0.05$) and improved upper ($p<0.01$) and lower body ($p<0.01$) strength, PPB scores ($p=0.01$), and mental health ($p=0.06$).

Conclusions: This novel couples-based approach to exercise was feasible as demonstrated by strong retention and adherence to the program. Exercising Together improved several health outcomes for both PCS and their spouses indicating that dyadic approaches should be considered in cancer survivorship programs.

Symposium 74B

MOVE 2 HEALTH: A COUPLE-BASED PHYSICAL ACTIVITY INTERVENTION FOR CANCER SURVIVORS

Kathryn I. Pollak, PhD

Background: Physical activity (PA) is an essential part of cancer survivors' treatment plan. Physical activity helps prevent recurrence and improves downstream cardiovascular risk, the cause for most deaths in cancer survivors. Additional benefits include improvements in physical function, psychological outcomes, and quality of life. However, most survivors are not sufficiently active, and prior PA interventions for cancer survivors have had mixed success. Involving partners in a PA intervention is a novel approach that could increase the efficacy of the intervention and the sustainability of effects by capitalizing on the survivor's natural social support system and addressing important interpersonal and intrapersonal factors relevant to behavior change.

Methods: We developed a home-based intervention, Move2Health, and conducted a two-arm, waitlist randomized controlled pilot study to test the intervention's feasibility and acceptability. We also explored pre-post changes in survivor and partner PA, partner support for PA, and survivor physical well being. The intervention, guided by interdependence theory, consisted of four sessions conducted via videoconference to survivors together with their partners. It provided training in communication skills to help couples identify and implement effective social support strategies, and behavior change techniques adapted to a communal coping approach.

Findings: Participants were 14 female and 6 male cancer survivors (mean age= 63.0 years, SD=8.9) and their partners (7 females and 13 males; mean age=62.8 years, SD=7.7). Nine dyads were randomized to intervention and 11 to waitlist control. 92% of randomized participants completed post-intervention surveys, and 78% dyads assigned to the intervention arm completed all four sessions. Most survivors and partners reported they would recommend the program to others, with 67% and 78% reporting 4 or 5 on this item, respectively. Mean difference scores suggested that participants in the intervention arm tended to report greater improvements in PA, partner support, and physical well being than those in the control arm.

Discussion: These preliminary findings suggest that a couple-based intervention may be a promising approach to increasing PA in cancer survivors. We will discuss recommendations for conducting a larger study to test the efficacy of the intervention.

Symposium 74C

A QUALITATIVE STUDY OF BETWEEN-COUPLE DIFFERENCES IN PATTERNS OF SOCIAL SUPPORT: IMPLICATIONS FOR INTERVENTIONS

Ida Griesemer, BA

Background: Social support from a spouse or partner can motivate people to engage in physical activity (PA); however, couples approach exchanging social support for PA in different ways. These between-couple differences are important for designing couples-focused PA interventions that succeed in helping people initiate lasting changes in PA.

Purpose: This study aimed to elucidate relationship dynamics in provision and receipt of support for PA in couples, with the goal of informing targeted intervention strategies that effectively leverage couple characteristics to increase support for PA.

Methods: We conducted a qualitative study of couples who completed a longitudinal study investigating differences in couples' social support for PA. The sample consisted of people with osteoarthritis who were not meeting recommendations for PA and their cohabiting partners ($N=19$ couples). We conducted in-depth semi-structured telephone interviews with participants and analyzed transcripts using a narrative analysis process.

Results: The sample was 79% non-Hispanic White with a mean age of 62 years. We identified two continua in the data: 1) participants' attitudes about working with their partner to be more active (highly positive to highly negative) and 2) couples' narrative concordance (high to low shared reality between partners). We developed a couple typology with four categories: "Working together works" (positive attitudes about working together to increase PA/high shared reality; $n=4$ couples), "Doing our own thing" (range of attitudes about working together, with practical and preferential barriers/high shared reality; $n=5$ couples), "Conscious conflict" (discrepant attitudes/high shared reality; $n=5$ couples), and "Different realities" (discrepant attitudes/low shared reality; $n=5$ couples). We describe examples of each couple type.

Discussion: There are notable differences in couples' attitudes about working together to be more active and the level of couples' shared reality around those attitudes. These differences result in four patterns of working together to become more active that may require different intervention approaches. Future research should investigate implications of this typology for the efficacy of PA interventions and, if warranted, develop methods for screening to identify different types of couples and offer intervention approaches that meet their specific needs.

Symposium 75

8:30 AM-9:45 AM

EXTENDING THE REACH OF PSYCHOLOGICAL INTERVENTIONS FOR CHRONIC PAIN: INNOVATIVE METHODS FOR INCREASING UTILIZATION

Sara N. Edmond, PhD¹, Amy Wachholtz, PhD², Tamara J. Somers, PhD³, Sara N. Edmond, PhD¹, Robert D. Kerns, PhD⁴¹VA Connecticut Healthcare System, West Haven, CT; ²University of Colorado Denver, Denver, CO; ³Duke University Medical Center, Durham, NC; ⁴Yale University, West Haven, CT

A growing number of non-pharmacological approaches for the management of chronic pain have demonstrated at least modest evidence of efficacy, and for some, there is emerging evidence of their effectiveness in relatively large scale trials. These include approaches that can be categorized as psychological or behavioral in nature and include teaching patients skills to cope with chronic pain (e.g., cognitive-behavioral therapy [CBT], biofeedback, mindfulness meditation). Despite the body of evidence for these approaches, psychological and behavioral interventions to manage chronic pain are often underutilized, and several barriers to utilization of these treatments exist. Barriers to utilization include access to care factors such as a shortage of providers, travel related problems for in person services, and costs (e.g., cost of travel, cost of co-pays, lack of insurance coverage) as well as patient factors such as patient adherence and attendance, economic or cultural barriers, lack of understanding about the rationale for treatment, or dual diagnoses that may interfere with treatment engagement. It is critical for researchers and healthcare providers to collaborate and discover overcoming these barriers in order to engage more patients in evidenced-based interventions for chronic pain. This symposium will provide three examples of ways that we can extend the reach of psychological treatment for chronic pain. First, we will hear about a treatment that is tailored to meet the needs of patients with chronic pain and comorbid opioid use disorders using psychophysiology. Second, we will hear about the development and pilot testing of an mHealth intervention for patients with cancer and pain. Finally, we will hear about the development of an intervention designed to address chronic pain in the context of a telephone-based smoking cessation protocol. By using targeted psychotherapy techniques, using mHealth technologies, and/or developing integrated treatments for patients with dual diagnoses, we can begin to extend the reach of chronic pain treatment to a wider range of patients.

Symposium 75A

USING PSYCHOPHYSIOLOGY NEEDS TO INFORM TREATMENT DEVELOPMENT FOR COMORBID PAIN AND OPIOID ADDICTION

Dr. Amy Wachholtz, PhD

Introduction: It is critical to develop psychotherapy interventions to improve treatment for patients with comorbid opioid addiction and pain (COAP); but getting patients to attend those treatments is even more important. Understanding factors that increase patient adherence and attendance are important along with strategies targeted to address each of those issues.

Method: In developing a treatment for COAP patients we integrated techniques and assessed (qualitatively and quantitatively) for strategies that encouraged ongoing treatment participation. COAP participants (N=14) on medication assisted treatment completing Stage 1A pilot STOP (Self-regulation Therapy for Opioid addiction and Pain) was used to identify treatment needs for this specific population, factors that increased attendance at sessions, adherence to treatment recommendations, and improved outcomes. Qualitative analysis identified themes in responses to short answer questions and quantitative analyses used ANOVA and correlation data.

Results: STOP is a novel 90-minute 12-week rolling-entry group therapy intervention based on the findings of a previous study identifying psycho-physiological needs of patients with comorbid pain and opioid addiction that can be seamlessly integrated into a community addiction treatment clinic. STOP had extremely high attendance rate (80%), urine toxicology showed no illicit drug use after week 8, and active patient engagement. Patients reported the in-session visual aids, applicable information about pain psychology, take home worksheets, biodots for take home relaxation practice to increase salience of the weekly topics, and learning to apply the therapy tools. Participants indicated having unique tools to immediately counteract physiological activation during a pain flare or craving. Instrumentally, participants reported that small weekly payments to cover transportation costs in addition to “banking” the larger weekly amount until the end of the study kept them attending the sessions. While not a fully powered study, quantitative data analysis from pre-intervention to a 3 month followup did show significant functional improvement ($F(1,12)=45.82;p<.001$) and decreased pain severity levels ($F(1,12)=37.62;p<.01$). Discussion: By using targeted psychotherapy techniques that were developed to directly respond to the needs identified by a thorough psycho-physiological assessment of COAP patients, therapy is more likely to maintain participant engagement and improve treatment outcomes.

Symposium 75B

DEVELOPMENT AND PILOT TESTING OF AN MHEALTH BEHAVIORAL CANCER PAIN PROTOCOL FOR MEDICALLY UNDERSERVED COMMUNITIES

Dr. Tamara J. Somers, PhD

Cancer patients in medically underserved areas (i.e., shortage of providers, services, and economic or cultural barriers to healthcare) report inadequate pain management and more negative pain-related outcomes. Women with breast cancer in these areas are particularly vulnerable to pain; they may be diagnosed at a later stage, increasing risk factors for pain. Behavioral cancer pain interventions can help with pain management. However, persistent barriers (e.g., transportation) inhibit the use of these interventions in medically underserved areas. We thus developed (phase 1) and pilot tested (phase 2) a mobile-health (mHealth) Pain Coping Skills Training protocol (mPCST) tailored for women with breast cancer in medically underserved areas (mPCST-Community). In phase 1, patient focus groups were conducted. Participants ($N=19$) were women (M age=60; 53% African American; 75% no college degree) with breast cancer and pain in medically underserved areas. Major themes were used to refine the intervention, including: bothersome pain-related fatigue (e.g., added content on fatigue); challenges with technology (e.g., created clear instructions with illustrations); and lack of psychosocial services (e.g., increased content focused on psychosocial support). In phase 2, we tested feasibility and acceptability of the mPCST-Community intervention in 20 women (M age=58; 75% African American; 75% no college degree) with breast cancer and pain in medically underserved areas. Feasibility was demonstrated by meeting planned accrual ($N=20$ in 10 months), low attrition (90% completion), and excellent adherence (90% completed all sessions). Acceptability was demonstrated by high satisfaction ratings ($M=3.7/4.0$). Data suggest that mPCST-Community had benefits for participants, with significant improvement in pre- to post-intervention pain severity scores (Hedges' $g=0.57$, 95%CI [0.10, 1.08], $p=0.01$), pain interference (Hedges' $g=0.62$, 95%CI [0.12, 1.16], $p=0.01$), and self-efficacy for pain management (Hedges' $g=0.98$, 95%CI [0.37, 1.66], $p<0.01$). Results suggest that an mPCST intervention designed for breast cancer patients in medically underserved areas is feasible, acceptable, and likely to lead to improvement in pain-related outcomes. Appropriately adapted mHealth technologies may provide an avenue to reach underserved patients and implement behavioral interventions to improve pain management in this vulnerable population.

Symposium 75C

DEVELOPMENT AND INITIAL TESTING OF AN INTEGRATED PAIN AND SMOKING INTERVENTION

Sara N. Edmond, PhD

Cigarette smoking represents the leading precipitant of preventable death in the United States. It is linked to the development and progression of many chronic painful conditions including arthritis and back pain. Among persons with pain, concomitant cigarette smoking is associated with poorer pain outcomes, namely, greater pain intensity and pain-related functional impairment. Furthermore, smokers with chronic pain report lower self-efficacy to quit and less successful quit attempts; some smokers even report using cigarettes to cope with pain. Prior research has posited a model of pain and smoking wherein biopsychosocial factors associated with both mutually maintain a feedback loop that promotes more pain and increased smoking. Given established associations between smoking and chronic pain, efforts to integrate evidence based pain coping skills into standard smoking cessation protocols have the potential to increase quit rates while simultaneously improving pain outcomes. Such an initiative is apt to be particularly beneficial within the Veterans Health Administration (VHA) where rates of smoking and pain each exceed those observed in the general population and where 40–50% of Veterans with pain also report smoking. Consequently, a cognitive behavioral intervention integrating these elements of evidence-based behavioral pain and smoking interventions was developed for Veteran smokers with chronic pain. Because uptake of smoking cessation and behavioral pain self-management programs are often limited by time and travel, the intervention is designed to be brief (5 sessions) and delivered via telephone in order to optimize reach. A small feasibility pilot ($n=8$), tested this brief Pain And Smoking Study (PASS) protocol. Results were promising and they have informed a recently launched randomized controlled VHA Health Services Research & Development comparative effectiveness trial wherein PASS is measured against standard smoking cessation telephone counseling in a sample of Veteran smokers with chronic pain. This presentation will describe the rationale and development of the integrated cognitive behavioral intervention which includes a physical activity component, highlight the strategies utilized to promote uptake and reach, define optimal outcomes, and summarize the sample to date. Finally it will relay preliminary lessons learned from our efforts to extend the reach of evidence-based pain coping strategies by integrating them into smoking cessation interventions.

“MAKING WEIGHT” AND PTSD: HOW MILITARY EXPERIENCES INFLUENCE EATING AND WEIGHT IN VETERANS

Lindsey Dorflinger, Ph.D.¹, Robin M. Masheb, Ph.D.², Niloofar Afari, Ph.D.³, Jessica Breland, Ph.D.⁴

¹Walter Reed National Military Medical Center, Bethesda, MD; ²PRIME Center, VA Connecticut, West Haven, CT; ³VA San Diego Healthcare System / UC San Diego School of Medicine Department of Psychiatry, La Jolla, CA; ⁴VA Palo Alto Health Care System, Menlo Park, CA

It has become clear that disordered eating may be more prevalent among military personnel and Veterans than the general US population. There has been increased effort to understand how the military experience shapes and influences the attitudes and behaviors that military personnel may have engaged in during their service, and how these experiences then impact eating behavior later in life. The objective of this symposium is to provide insight and understanding into the pathways between military service and disordered eating behaviors. Each presenter will report on a timely and relevant aspect of the relationship between military service and eating pathology based upon quantitative and qualitative data collected from Veteran users of the Veterans Health Administration (VHA). The first presenter, Dr. Dorflinger, will present findings on the relationship between Post-Traumatic Stress Disorder (PTSD) and disordered eating behaviors among Veterans seeking weight management services at the VHA. The next presenter, Dr. Masheb, will discuss the development of a new scale, the Making Weight Inventory, used to measure eating disordered behaviors used to meet military weight requirements, and how these practices relate to eating disorder pathology and weight in Veterans. Finally, Dr. Breland will discuss qualitative findings regarding the relationship between pressure to meet military weight and eating habits among women Veterans. The symposium Discussant will direct a conversation about how to move forward with research in this area so that we may reduce and/or prevent the adoption of disordered eating behaviors that can result from military experiences.

Symposium 76A

THE RELATIONSHIP BETWEEN PTSD AND DISORDERED EATING BEHAVIORS AMONG VETERANS ENROLLING IN TREATMENT FOR OBESITY

Lindsey Dorflinger, Ph.D.

Treating overweight and obesity among Veterans is a high priority for the Veterans Health Administration (VHA) given that the rate of overweight/obesity among Veterans treated within VHA is approaching 80%. PTSD is also a significant concern among Veterans treated within VHA, and is associated with higher rates of overweight/obesity among Veterans, as well as with disordered eating contributing to weight gain among military service members. Several studies have reported significant associations between PTSD and eating disorders. While disordered eating behaviors such as emotional eating and night eating are not formal diagnoses these behaviors, are important to study given their potential to contribute to weight gain and/or impede weight loss efforts among Veterans. The current study therefore examines night eating and emotional eating, and their relationships to PTSD, among Veterans enrolling in treatment for obesity. The sample consisted of 126 veterans referred to the MOVE! weight management program at VA Connecticut Healthcare System. Veterans completed questionnaire batteries during orientation sessions during which they learned about the program and options for participation. All participants completed measures assessing demographic characteristics, PTSD screening and symptoms, emotional eating, night eating syndrome (NES), and insomnia. Both emotional eating and night eating were common among participants and were associated with higher BMI. Participants screening positive for PTSD reported more frequent emotional overeating than those screening negative for all emotions (all p 's < .01). Higher scores on the PTSD screener were also associated with more frequent emotional eating (p < .001). Participants screening positive for PTSD were significantly more likely to screen positive for NES and to endorse eating in order to return to sleep after waking at night than those screening negative for PTSD (p 's < .01). However, when controlling for presence of insomnia, the relationship between NES and PTSD was no longer significant. Findings suggest that both emotional eating and NES are common among Veterans seeking weight management services, particularly among those with PTSD, and that Veterans with PTSD may attempt to cope with difficult emotions and insomnia by eating. Given the increasing rates of obesity and related comorbidities among Veterans, these findings have important implications for treating obesity among Veterans with PTSD.

Symposium 76B

DEVELOPMENT OF THE MAKING WEIGHT INVENTORY: ASSESSING EATING DISORDER PATHOLOGY TO MEET MILITARY WEIGHT REQUIREMENTS

Robin M. Masheb, Ph.D.

Objective: To develop a measure of maladaptive eating behaviors provoked by pressure to meet military weight requirements (“making weight”).

Methods: Participants were Veterans ($n = 114$, mean age 61.8, mean BMI 38.0, 91.2% male, 75.2% Caucasian) with overweight/obesity who attended MOVE! orientation sessions at VA Connecticut Healthcare System for weight management treatment. The Making Weight Inventory, designed specifically for this study, was administered alongside validated measures of eating behavior (Eating Disorder Examination-Questionnaire, Yale Emotional Overeating Questionnaire, Night Eating Questionnaire, and Yale Food Addiction Scale) and mental health. The Making Weight Inventory asks, “When you were in service, how frequently did you use the following to make weight?” Eating disordered behaviors (vomiting, laxatives, diuretics, fasting/skipping meals, excessive exercise, and sauna/rubber suit) intended to counteract the effects of food intake/weight gain were rated on a scale from 0 (never) to 6 (always).

Results: Thirty-six participants (31.6%) engaged in a minimum of one making weight behavior at least some of the time. The most frequently engaged in compensatory behavior was excessive exercise (25.4%), followed by fasting/skipping meals (17.5%), sauna/rubber suit (9.6%), laxatives (7.9%), diuretics (4.4%), and vomiting (1.8%). Participants screening positive for making weight behaviors reported significantly greater shape concern ($F = 22.1$, $p < .001$), weight concern ($F = 33.4$, $p < .001$), emotional overeating ($F = 22.5$, $p < .001$), night eating ($F = 6.3$, $p = .014$), food addiction ($F = 12.3$, $p = .001$), insomnia ($F = 14.6$, $p < .001$), symptoms of depression ($F = 8.4$, $p = .004$), and PTSD ($F = 11.7$, $p = .001$) than patients screening negative for these behaviors. There were no differences between the two groups on current BMI or alcohol misuse.

Conclusion: Nearly one-third of veterans with overweight/obesity screened positive for engaging in compensatory behaviors to make weight during their service. Findings from the present study support the construct validity of the Making Weight Inventory and provide evidence that maladaptive eating behaviors during military service are related to eating pathology and mental health after service. More research is needed to understand which aspects of military life might elevate risk for disordered eating so that preventative efforts may begin before Veterans are struggling with their weight.

Symposium 76C

UNDER PRESSURE: WOMEN VETERANS' VOICES ON MAKING WEIGHT

Jessica Breland, PhD

Background. Almost 80% of veterans using the Veterans Health Administration (VHA) are overweight or obese. This may be partly due to the fact that military service exposes people to numerous stressors that affect eating habits. Most research in this area focuses on the role of traumatic experiences, but emerging evidence suggests pressure to meet military weight requirements ("making weight") may also play an important role.

Methods. To understand relationships between disordered eating and military service and to generate hypotheses for future work, we conducted five focus groups and two dyadic interviews with women at a VHA medical center between spring 2013 and fall 2014. We used inductive and deductive coding of transcripts to identify common themes. The present results focus on the relationship between eating habits and making weight.

Results. The 20 women participating in this study had a mean age of 48 years (SD=15) and came from diverse racial/ethnic groups – nine (45%) reported White race; four (20%) reported Black race; one (5%) reported Asian-American race; and six (30%) reported their race as "Other". Women independently brought up making weight as a stressor that affected daily eating habits and led to various forms of disordered eating, including unhealthy restriction and compensatory behaviors to reduce weight before being weighed. In some cases, women described this restriction as leading to a lasting pattern of restriction and binge eating. Participants felt that pressure to make weight was especially strong for women, given the general difficulty of being a woman in predominantly male military settings and the short amount of time given to lose weight after pregnancy. Most women said they did not feel supported in weight management efforts during military service.

Conclusions. Women veterans reported considerable stress related to meeting military weight requirements, which some women said led to disordered eating. Combined with findings from past quantitative work, the present results provide additional support for the hypothesis that pressure to make weight negatively affects health. There is a need for additional work in this area, including investigating whether resources to facilitate healthy eating and weight management, particularly for women around pregnancy, improve health outcomes among military personnel and veterans.

Symposium 77

8:30 AM-9:45 AM

SPIRITUALITY MAY INFLUENCE HEALTH THROUGH HEALTH BEHAVIORS: AN UNDERSTUDIED BUT POTENTIALLY KEY PATHWAY

Crystal L. Park, PhD¹, Cheryl L. Holt, PhD², Crystal L. Park, PhD¹, Crystal Y. Lumpkins, PhD³, Karen HK. Yearly, PhD⁴

¹University of Connecticut, Storrs Mansfield, CT; ²University of Maryland, College Park, College Park, MD; ³University of Kansas Medical Center, Kansas City, KS; ⁴University of Arkansas for Medical Sciences, Little Rock, AR

Religiousness and spirituality (R/S) have typically been found to relate to better mental and physical well-being in many general populations samples as well as in those of people dealing with specific health conditions (see Koenig, 2012, for a review). Multiple pathways through which R/S may influence physical health have been proposed, including increased social support, better immune functioning, lower cardiac reactivity, and other biopsychosocial mechanisms. However, one oft-proposed pathway, enhanced engagement in health behaviors, has seldom been examined aside from studies noting the health prescriptions and proscriptions of specific religious denominations. This symposium features three studies that highlight this potentially key pathway. In the first presentation, Cheryl Holt will summarize the findings of a large longitudinal study with a national probability sample of African-Americans. This study tested a sophisticated theoretical model of mediators (e.g., social support, coping, social capital) of the relationship between religious involvement and a host of health behaviors including diet, physical activity, cancer screenings, and alcohol and tobacco use. She will conclude with practice recommendations based upon these findings. In the second presentation, Crystal Park will present results of a longitudinal study of 191 people living with congestive heart failure. Different dimensions of religiousness and spirituality were found to predict different aspects of health behavior, including treatment adherence, diet, physical activity, sleep and alcohol use one year later. In the third study, Crystal Lumpkins will present results of a randomized cluster trial to promote colorectal screening in African-American churches with multimodal interventions based partly on religious capital. The promising results will be described and implications for future research and implementation will be described. Our discussant, Kevin Masters, will integrate themes across these studies, highlighting implications for potentiating individuals' own religiousness and spirituality to improve multiple health behaviors.

Symposium 77A

RELIGION AND HEALTH: RECOMMENDATIONS FOR PRACTICE FROM A LONGITUDINAL NATIONAL STUDY OF AFRICAN AMERICAN MEN AND WOMEN

Dr. Cheryl L. Holt, PhD

The Religion and Health in African Americans (RHIAA) study aimed to: 1) empirically test a theoretical model of mediators (e.g., social support, coping, social capital) of the relationship between religious involvement and health behaviors and outcomes longitudinally in a national probability sample of healthy, African American adults, and 2) develop recommendations for practice based upon the findings. Findings from aim 1 will be reviewed as well as implications on how best to integrate relevant religion-health mediators into health promotion activities for African Americans. Mediators between religious involvement (beliefs and behaviors) and health-related outcomes were analyzed longitudinally among N=766 participants who completed waves 1–3 over a 5-year period. In a cross-lagged panel analysis of religious involvement and health over time, religious beliefs predicted better physical and mental health outcomes at wave 2, while health did not significantly predict changes in religious involvement. This finding helped rule out the possibility of reverse causality. In longitudinal mediation analysis, positive religious support mediated the relationship between religious behaviors and fewer depressive symptoms and less heavy drinking over time. No longitudinal mediational effect was found between religious coping and the outcomes. Previous cross-sectional analyses of the RHIAA sample indicated perceived religious influence on health behaviors, belief in illness as punishment, and religious coping mediated the relationship between religious beliefs and more fruit and vegetable intake and less smoking and alcohol use. Social support, religious influence, and illness as punishment explained the relationship between religious behaviors and better physical and emotional functioning, fewer depressive symptoms and healthy diet, smoking, and alcohol use. Negative religious coping influenced the relationship between religious beliefs and greater alcohol use and illness as punishment explained the relationship between religious behaviors and higher binge drinking. These findings describe the explanatory role of religious involvement in health-related outcomes in African American men and women. We discuss implications for health promotion activities for African Americans. The current findings suggest that targeting specific attributes of religious involvement could improve the impact of health promotion activities, including those delivered in faith-based settings.

Symposium 77B

DIMENSIONS OF RELIGION AND SPIRITUALITY AS DETERMINANTS OF HEALTH BEHAVIOR AND ADHERENCE IN HEART FAILURE PATIENTS

Crystal L. Park, PhD

Although researchers have often suggested that some of the well-documented associations between religiousness/spirituality (R/S) and health may be due to the influences R/S exerts on individuals' health behaviors, little research has empirically evaluated these findings. Such links may be particularly important in the context of older adults living with serious illnesses, who may have fewer available resources to help them cope. The present study investigated links between R/S and health behaviors in a sample of older adults living with a life-limiting illness. A sample of 191 congestive heart failure (CHF) patients (64% male; 82% white; *M* age = 68.6 years) completed questionnaires at two time periods, one year apart, assessing five dimensions of R/S (service attendance, private prayer, daily spiritual experience, spiritual well-being and spiritual struggle) and five health behaviors (diet, exercise, sleep, alcohol use, and adherence). Results of hierarchical multiple regression analyses controlling for age and education indicated that higher consumption of fruits and vegetables, sleep, alcohol use, and adherence were positively associated with most of the R/S variables, especially FACIT meaning/peace. Spiritual struggle was inversely related to most measured health behaviors, with the exception of frequency of moderate/vigorous physical activity, which was only associated with FACIT-meaning/peace. These results suggest that R/S has complex but potentially important associations with health behaviors in CHF patients. Further, different dimensions have different effects and strengths. More research is needed to understand these relationships and to determine whether and how different dimensions of R/S may play useful roles in lifestyle change interventions.

Symposium 77C

IT'S TIME TO A.C.T.: ASSESSING A HEALTH COMMUNICATION PILOT INTERVENTION TO IMPACT CANCER SCREENING AMONG FAITH COMMUNITIES

Dr. Crystal Y. Lumpkins, PhD

Background: Colorectal cancer (CRC) screening among African Americans is increasing however these rates remain disproportionate when compared to all other racial and ethnic groups in the U.S. This study describes the development of the pilot intervention, study design and baseline characteristics. Social marketing principles and the socio-ecological model were used to implement the intervention and the theory of planned behavior and religious and spiritual capital guided construction of intervention messages.

Method: The study followed a cluster randomized design where 8 churches were grouped into either an intervention (n=4) (CRC tailored) or control arm (n=4) (standard information). Church members who were 45; not up to date with CRC screening and who had no other CRC related symptoms (e.g. blood in stool, first degree relative with CRC prior to the age of 60) were eligible for the study. The protocol included a standard procedure to measure baseline characteristics but also to disseminate health communication. Primary outcome measure was change in CRC screening completion with a FIT (Fecal Immunochemical Test) kit from baseline to 6 months. The secondary outcome measure was CRC knowledge at baseline to follow up at 6 months. Members from the faith and research communities followed a CBPR approach and collaborated on recruitment, research design, stimulus material development, training of church health promotion workers (CHPWs) for the pilot intervention.

Results: Researchers and faith-based community members successfully collaborated to enroll church members and individuals affiliated with participating churches (n=157) across the bi-state area of Kansas and Missouri. The sample was mostly female (77%), married (40%), Baptist (52%) or Non-Denominational (21%); the largest church congregation size was more than 2,500 and included 27% of the study population. At pre-screening, more than half (62%) indicated that they did not know the recommended age to begin screening. At baseline 78.4% indicated during the next 4–6 weeks that they were *extremely likely* to complete a stool test and to mail it in; in addition, 15.4% of the sample responded that they were *quite likely* to complete and return the stool test. The number of kits returned (n=122) surpassed the study goal (80.2%).

Conclusion: A high percentage of participants from both arms of the pilot intervention study reported they were *extremely likely* or *quite likely* to complete and return a FIT at baseline. While we have demonstrated the feasibility of developing a faith-based pilot intervention study and recruiting individuals from faith-based populations, there were fidelity issues and thus lessons learned for conducting the larger randomized controlled trial and future RCT (randomized controlled trials) with faith communities following a CBPR approach.

Symposium 78

8:30 AM-9:45 AM

THE ROLE OF SEXUAL COMPULSIVITY IN HIV RISK AND MENTAL HEALTH

Jeffrey T. Parsons, PhD¹, Brett M. Millar, PhD², Matthew Wachman, BA³, H. Jonathon Rendina, PhD, MPH¹¹Hunter College of the City University of New York (CUNY), New York, NY; ²Graduate Center CUNY, New York, NY; ³Center for HIV Educational Studies and Training, New York, NY

Sexual compulsivity—the experience of compulsive sexual urges, thoughts, or behaviors which interfere with personal, interpersonal, or vocational pursuits—has received considerable attention in recent decades. In relation to HIV-positive gay and bisexual men, sexual compulsivity has been linked with numerous adverse behavioral and mental health outcomes—and these links to poorer HIV-related health, increased sexual transmission risk rates, greater substance use problems, and heightened mental health distress highlight its importance in efforts to combat the HIV epidemic. A greater understanding of sexual compulsivity and of intervention efforts to address it in the context of its behavioral and mental health correlates is required to extend the reach of public health and psychology researchers to help individuals struggling with sexual compulsivity. The papers in this symposium present three approaches to empirically investigating links between sexual compulsivity and health for HIV-positive gay and bisexual men. The first paper documents longitudinal links between sexual compulsivity and subsequent HIV transmission risk behaviors measured three months later (here, condomless sex, alcohol use with sex, and suboptimal medication adherence) in a national sample of 807 HIV-positive gay and bisexual men. The second paper reports on 337 highly sexually-active gay and bisexual men and uncovers substantially higher rates of psychiatric comorbidities for those who report sexual compulsivity, particularly past trauma. The third paper presents the development of and initial findings from a comprehensive intervention (combining cognitive behavioral therapy and motivational interviewing techniques to improve emotion regulation and reduce minority stress) to address sexual compulsivity in connection with substance use problems and sexual transmission risk behaviors for HIV-positive gay and bisexual men. Together, these three presentations illustrate the importance of addressing sexual compulsivity in attempts to combat the HIV epidemic and to improve the physical, psychological, and behavioral health of gay and bisexual men. Following these three talks, the Discussant will highlight the etiologic role of minority stress, shame, and emotion dysregulation in sexual compulsivity, and describe ongoing efforts to intervene on sexual compulsivity and to reduce its downstream effects on a variety of health outcomes.

Symposium 78A

TAILORING AND REFINING AN INTERVENTION TO ADDRESS SEXUAL COMPULSIVITY AND MENTAL HEALTH AMONG HIV-POSITIVE GAY AND BISEXUAL MEN

Dr. Jeffrey T. Parsons, PhD

Background: Sexual compulsivity has been consistently linked with a range of adverse mental health and behavioral outcomes (including HIV sexual risk and HIV seroconversion) in gay and bisexual men (GBM) for over 20 years, and yet there are still no empirically validated treatments. Accordingly, interventions aimed at gay and bisexual men addressing sexual compulsivity remain a priority. We tested the initial effectiveness of a targeted, manualized intervention combining Cognitive Behavioral Therapy (CBT) and Motivational Interviewing (MI) with a focus on sexual compulsivity, emotion regulation, and substance use, in a sample of GBM reporting problems with sexual compulsivity.

Method: The initial 10-session intervention was tested with 11 HIV-positive GBM, and a revised 8 session intervention was tested with an additional 6 men. Data from the 17 participants were analyzed utilizing mixed models to measure treatment gains in various psychosocial and behavioral outcomes from baseline to a post-treatment 3-month assessment: depression, anxiety, emotion dysregulation, sexual compulsivity, number of days of club drug use, number of total sex partners, and number of HIV-negative sex partners.

Results: Participants had a mean age of 37.9 years (range: 24–56) and were largely GBM of color. Significant treatment gains were made from BL to 3M in key mental health outcomes. On average: depression went from 28.2 to 21.6 ($b=6.65$, $p=.01$); anxiety went from 8.5 to 5.6 ($b=2.94$, $p=.01$); emotion dysregulation went from 105.4 to 94.0 ($b=11.35$, $p=.02$); and sexual compulsivity went from 28.1 to 23.9 ($b=4.24$, $p=.05$). Number of club drug days decreased from 5.6 to 2.4 ($b=3.2$, $p=.05$), number of total sex partners decreased from 7.5 to 4.3 ($b=3.3$, $p=.01$), and number of HIV-negative sex partners decreased from 5.8 to 3.3 ($b=2.6$, $p=.03$). While attendance in the earlier 10-session treatment was suboptimal (only four of 11 attended all sessions), four of the six participants in the revised 8-session treatment attended all eight sessions.

Discussion: The findings indicate that our tailored intervention combining CBT and MI achieved substantial improvements in mental health and behavioral outcomes in a sample of HIV-positive GBM. Addressing shortcomings noted in our previous 10-session treatment, results showed improved attendance in a revised 8-session treatment and overall improvements pre-to post-treatment in depression, anxiety, emotion dysregulation, and sexual compulsivity.

Symposium 78B

HIV-RELATED BEHAVIORAL OUTCOMES ASSOCIATED WITH SEXUAL COMPULSIVITY AMONG HIV-POSITIVE GAY AND BISEXUAL MEN: LONGITUDINAL LINKS

Brett M. Millar, PhD

Background: Sexual compulsivity (SC) in HIV-positive gay and bisexual men has been associated with increased rates of sexual risk behavior and poorer medication adherence in numerous cross-sectional studies. However, studies have rarely investigated the role of SC in longitudinally predicting HIV-related behaviors, including condomless anal sex, heavy drinking before or during sex (i.e., 6 or more drinks), and medication non-adherence. We investigated SC as a predictor of subsequent behavioral outcomes among HIV-positive gay and bisexual men enrolled in a national online longitudinal HIV prevention study.

Methods: In 2015–2016, 807 HIV-positive gay and bisexual men completed the SC scale in their 3-month survey. We assessed behaviors reported in their 6-month survey. Men with and without SC at 3 months, indicated by a score of ≥ 24 on the SC scale, were compared on rates of condomless anal sex and events of heavy drinking before or during sex (in negative binomial regressions), and on the odds of medication non-adherence (in binary logistic regression).

Results: The sample was mostly White (65%), with a mean age of 39.5 (range: 19–77). SC measured at 3 months was associated with behaviors at 6 months: more condomless anal sex events, ARR=1.46, $p < .001$; more heavy drinking before or during sex, ARR=1.49, $p < .01$; and increased odds of having missed doses of HIV medication, AOR=1.79, $p < .01$. Each of these associations remained significant in multivariable analyses, which adjusted for age and treatment condition.

Conclusions: The current findings situate SC in the context of various adverse health behaviors among HIV-positive gay and bisexual men—condomless anal sex, heavy drinking before or during sex, and medication non-adherence. However, our findings extend previous literature by detecting longitudinal associations between sexual compulsivity and the three behaviors measured three months later. This study therefore highlights the importance of addressing SC within HIV-positive gay and bisexual men, with the aim of also reducing adverse health behaviors among this high-risk population.

Symposium 78C

COMPULSIVE SEXUAL BEHAVIOR AND PSYCHIATRIC COMORBIDITY AMONG HIGHLY SEXUALLY-ACTIVE GAY AND BISEXUAL MEN

Matthew Wachman, BA

Background: Significant differences have been found in rates of HIV transmission risk behaviors between gay and bisexual men (GBM) who are classified as sexually compulsive (SC) versus those who are just highly sexually active. In the age of treatment as prevention, discovering treatable comorbid variables that have the power to influence overall health outcomes becomes paramount. We sought to examine how a history of trauma comorbid with various other psychological and behavioral issues may contribute to the emergence of the SC maladaptation.

Methods: A diverse sample of 337 highly sexually active (≥ 9 partners in previous 90 days) GBM, aged 18–73 ($M=36.8$), completed a survey including measures of socio-demographics, childhood sexual abuse, sexual compulsivity, and the Computerized Diagnostic Interview Schedule (CDIS). The sample was classified as having SC if they were above the threshold (SC score > 23).

Results: Fifty-one percent of the sample was classified as SC. Chi-square analyses revealed significant differences between GBM with SC and GBM without SC in rates of PTSD, ADHD, Major Depressive Episode, Obsessive Disorder, and Manic Episode. Multivariable analyses included significant demographic covariates, childhood sexual abuse, and significant psychological disorders from our bivariate analyses. In multivariable models, men with PTSD had 2.16 times greater odds of being in the SC group compared to the non-SC group. History of a manic episode was associated with 2.53 times greater odds of being in the SC group.

Conclusions: Our findings suggest that SC presents in the context of a range of comorbid mental illness conditions, among our sample of highly sexually-active GBM. PTSD and manic episodes were both associated with a higher likelihood that SC would be manifest. Future studies should be conducted in order to determine the efficacy of concurrently treating SC as well as underlying comorbid psychiatric conditions, particularly regarding past trauma experiences, as a means of lowering HIV risk, and improving overall health outcomes.

BODY IMAGE CONCERNS AND HIGH-RISK TANNING BEHAVIOR

Jerod L. Stapleton, Ph.D., Zhaomeng Niu, Ph.D., Veenat Parmar, MPH

Rutgers, The State University of New Jersey, New Brunswick, NJ

Objective: There is a need to study the beliefs and motives underlying high-risk ultraviolet tanning behavior. The hypothesis of this study was that individuals with elevated body image concerns would be more likely to report frequent indoor tanning behavior as well as other high-risk UV behaviors including sunbathing.

Methods: Participants were 823 young adult women recruited from a probability-based web panel in the United States. Latent profile analysis was used to identify subgroups of participants based on patterns of responses to survey items related to tanning beliefs, perceived sociocultural influences on tanning behavior, and tanning-related body image.

Results: We found evidence for 4 subgroups with distinct survey response patterns: tanning unfavorable, tanning favorable, ambivalent tanning-related body image, and negative tanning-related body image. Participants with negative tan body image were more likely to be frequent indoor tanning users and report higher rates of other high-risk UV behaviors.

Conclusion: Findings suggest that body image concerns are prevalent among frequent, high-risk tanners and there may be a benefit to targeting body image-related risk factors and promoting positive body esteem in skin cancer intervention and prevention efforts.

Objective: To communicate details of the development, design, and content of a web-based physical activity (PA) support program and exercise plan (www.exerciseguide.ca) tailored to the needs and preferences of breast cancer survivors (BCS).

Methods: A literature review was conducted to determine appropriate frameworks and content. Mixed-methods surveys determined barriers to increasing PA and decreasing sitting time and strategies to overcome these barriers using open and closed-ended questions. Theory-based content was adapted from previously developed guidebooks and websites for BCS. In addition, we followed the recommendations for reporting tailored interventions to ensure consistency across the literature.

Results: We surveyed 20 adults (12 BCS and 8 support people) to determine successful strategies used to increase PA and decrease sedentary time. We have produced six modules of tailored content, including an exercise plan. Modules address specific exercise guidelines, personalized feedback on current PA measured with Fitbits, the benefits of PA for cancer survivors, information on benefits of light PA and reducing sitting time, how to build a habit, identifying barriers and how to overcome them, how to build motivation, and other lifestyle advice. Literature and experts were consulted on best practice for prescribing aerobic and resistance exercise to women diagnosed with breast cancer. Tailoring decisions were based on previous research and the participant's physical status (current amount of activity, current treatment status, level of disability, working status, PA values, PA knowledge and capabilities, and comorbidities). Modules are individually tailored with brief questionnaires asked at the beginning of each module. Action plans incorporate strategies from the surveys which found common barriers of time constraints, weather, cost, and being too tired, among others. Strategies to overcome these barriers included making a schedule, doing small increments of PA throughout the day, work out at home or go somewhere inside to walk (i.e., a mall or recreation centre).

Conclusion: This content and design have been rigorously developed using previous research and expert and target audience consultation. This will ensure the next phase, an iteratively tested proof of concept usability study among the target population, will yield as much valuable information as possible.

ELECTRONIC PATIENT-REPORTED SYMPTOMS: FEASIBILITY STUDY FOR UNIVERSITY ROCHESTER NCI COMMUNITY ONCOLOGY RESEARCH PROGRAM

Marie Flannery, PhD¹, Christian Adonizio, MD², Mark Wojtowicz, MS MBA², Molly Goodman, BS³, Spencer Obrecht, BS³, Sandy Plumb, BS³, Christopher Seiler, MD², Amber Kleckner, PhD³, Chintan Pandya, PhD³, Supriya Mohile, MD³

¹University of Rochester School of Nursing, Rochester, NY; ²Geisinger Medical Center, Danville, PA; ³University of Rochester Medical Center, Rochester, NY

In oncology, research has demonstrated that routine electronic collection of patient-reported symptoms improves symptom relief, quality of life, and survival. Despite the widespread use of electronic medical records (EMR), the potential to leverage it for patient reported outcomes (PRO) collection in routine clinical care and extracting existing outcome data has been minimal. To determine the feasibility of routine collection of symptom data and extraction of variables via the EMR, we conducted a pilot study at two different thoracic oncology practice sites. The aims were 1) to establish the feasibility of electronic capture of symptoms as part of routine clinical operations, 2) to design and implement a scalable infrastructure for the extraction of patient outcomes from the EMR and 3) identify challenges.

At Site1, symptom collection via EMRs was in place and, at Site2, symptom collection was initiated with study evaluation. A minimum data set for symptoms and outcome measures was established. Data were collected for one month, and symptom survey completion rate was noted. For Aim 2, a data dictionary and program code was developed for EMR extraction of demographics, tumor and treatment characteristics and health care utilization measures.

At Site1, 78 patients were asked to complete surveys and 33 were completed (42%); at Site2, 163 symptom surveys were requested and 40 were completed (26%). For Aim2, extraction was 100% successful for 21/30(70%) variables at both sites (e.g., demographic, treatment data, utilization variables), partially successful for some variables (e.g., staging, referrals) and unsuccessful for 2 variables (e.g., pathology). We encountered multiple barriers to real-world implementation of routine electronic collection of symptoms including resistance to changing standard practice (by patients, providers and staff), challenges to establishing an integrated workflow and non-discrete nature of data in the current EMR.

At 1-month symptom survey completion rate was low at both sites. Significant resources are required to implement routine symptom collection with the EMR and overcome barriers. However, extracting data from the EMR was highly successful, and additional variables were identified that may need to be integrated into discrete fields for extraction. Theory-informed behavioral change interventions need to be tested for successful implementation of PRO collection in routine clinical care.

EMPOWER 2.0: A STAKEHOLDER-INFORMED DECISION INTERVENTION TO EMPOWER PATIENTS WITH METASTATIC CANCER

Adina Kazan¹, Wasef Atiya¹, Laura M. Perry, BS¹, Elise Goff¹, Ashley Beggin, BS², James Rogers³, Douglas J. Meffert, PhD⁴, David G. Morrison, MD, PhD¹, Gwendolyn L. Garrison⁵, Michael Hoerger, PhD, MSCR¹

¹Tulane University, New Orleans, LA; ²University of Pennsylvania, Philadelphia, PA; ³Tulane University, Monroe, NY; ⁴National Audubon Society, New Orleans, LA; ⁵New Orleans, LA, New Orleans, LA

Background: Palliative care has been shown to improve the quality of life of patients with serious illnesses, but is underutilized. Expanding on our prior pilot study, our goal in EMPOWER 2.0 is to increase palliative care utilization by developing a psychoeducational intervention for patients with metastatic cancer that uses a multimedia format suitable to low-literacy populations, rests on meta-analytic medical evidence and national guidelines, and integrates stakeholder feedback from patients, caregivers, and oncology clinicians.

Methods: Using Community-Based Participatory Research (CBPR) methods, we aimed to engage a stakeholder advisory board of patients, caregivers, and oncology clinicians for quarterly meetings designed to provide feedback on the design and implementation of the psychoeducational intervention and iteratively improve the intervention using that feedback. A systematic review and meta-analysis were used to summarize medical evidence and national guidelines. The intervention was developed using multimedia video software.

Results: At the mid-point of this 3-year project, the study has been successful in convening on a quarterly basis 11 stakeholders consisting of 4 oncology clinicians, 4 patients, and 3 caregivers. Stakeholders emphasized the need for the intervention to be appropriate for patients, caregivers, and clinicians with a wide range of literacy and education. In response to this feedback, two versions of a video-based intervention explaining palliative care were created, one that provides more empirical evidence and one that is less cognitively demanding, allowing patients to choose which content they prefer. Both videos were made using GoAnimate software and provide information regarding local palliative care resources. The beta versions of these video-based interventions will be displayed alongside this poster, and based on a final round of stakeholder feedback, we will begin implementing the intervention locally in July 2018 to increase utilization.

Discussion: This study demonstrated the feasibility of engaging community stakeholders in alpha-testing psychoeducational interventions that may increase palliative care utilization. Our team's experience can provide practical strategies for other investigators seeking to utilize stakeholder engagement to create materials that are customized to their target population.

EXPOSURE TO HPV-RELATED STORIES AND PARENTS' INTENTION TO VACCINATE

Marjorie Margolis, MSPH¹, Melissa B. Gilkey, PhD², William A. Calo, PhD, JD³, Susan Alton Dailey, MPH, MSW⁴, Noel T. Brewer, PhD²

¹University of North Carolina, Chapel Hill, Durham, NC; ²University of North Carolina, Chapel Hill, NC; ³Penn State College of Medicine, Hershey, PA; ⁴University of North Carolina, Chapel Hill, Chapel Hill, NC

Introduction: Over one-third of parents refuse or delay HPV vaccination for their children. Little is known about what information parents receive about HPV vaccination through media and social interactions or how that information influences their vaccination decisions. Thus, we assessed the association between recalling HPV vaccine-related “stories” and parents’ intention to vaccinate.

Methods: In 2017, we conducted a national, online survey of parents ($n=1,207$) of adolescents ages 9 to 17 who had not completed the HPV vaccine series. The survey assessed whether and where respondents had heard stories of people who had experienced: 1) harms related to HPV vaccination (“HPV vaccine harms”); or 2) diseases that could have been prevented by HPV vaccination (“HPV vaccine preventable diseases”). We used multivariable linear regression to assess the association between story type (none/vaccine harms only/vaccine-preventable diseases only/both) and parents’ intention to get the next dose of HPV vaccine. The model controlled for child’s sex and age, and parent’s education.

Results: About one-third (34%) of parents recalled having heard stories of HPV vaccine harms, including long-lasting serious harms (16%), mild side effects (12%), temporary serious harms (9%), or death (7%). Common sources of these stories were conversations (14%), social media (13%), and local or national news (13%). Compared to harms, a smaller proportion of parents (26%; $p<0.001$) recalled having heard stories of HPV vaccine preventable diseases. Stories included those about abnormal Pap smears (12%), HPV infection (11%), HPV-related cancers (10%), genital warts (9%), or HPV-related cancer death (4%). Sources of stories about diseases were similar to those for harms. In multivariable analysis, intention to vaccinate was higher among parents who recalled stories about HPV vaccine preventable diseases only ($b= 0.27$; SE: 0.13, $p= 0.03$), but lower among those recalling stories about HPV vaccine harms only ($b= -0.74$; SE: 0.10, $p<0.001$) or both diseases and harms ($b= -0.59$; SE: 0.11, $p<0.001$).

Discussion: Stories of HPV vaccine preventable diseases are associated with higher intentions to vaccinate, but only in the absence of stories about HPV vaccine harms, which are more common. Findings of this national study may suggest a deleterious effect of stories of harm on HPV vaccination intentions and could help explain why awareness campaigns have done little to improve HPV vaccination coverage nationally.

FINANCIAL HARDSHIP AND HEALTH BEHAVIORS AFTER CANCER DIAGNOSIS: RESULTS FROM THE DETROIT ROCS PILOT COHORT STUDY

Theresa Hastert, Ph.D., M.P.P.¹, Ezinne Ndukwe, M.P.H.², Amanda Reed, M.P.A.¹, Ann G. Schwartz, Ph.D., M.P.H.¹, Tara Baird, M.A.¹, Jennifer Beebe-Dimmer, MPH, PhD³

¹Wayne State University School of Medicine/Karmanos Cancer Institute, Detroit, MI; ²University of Michigan, Ann Arbor, MI; ³Wayne State University, Detroit, MI

Background: Nearly one-third of cancer survivors in the United States experience financial hardship due to cancer but it is not known whether financial hardship is associated with health behaviors among survivors. We examined whether experiencing financial hardship was associated with cancer-related health behaviors among diverse cancer survivors in Metropolitan Detroit.

Methods: Data from the Detroit Research on Cancer Survivors (ROCS) pilot cohort include responses from 1,000 (414 white, 586 African-American) adults (ages 27–79) diagnosed with a first primary breast, colorectal, lung, or prostate cancer since January 1, 2013 and diagnosed or treated at the Karmanos Cancer Center. Financial hardship included experiencing a decrease in income, borrowing money from friends or family, experiencing lasting debt, or accessing existing assets (refinancing/selling a home, selling investments, withdrawing money from retirement savings) due to cancer. Health behaviors included physical activity, diet, and alcohol consumption in the past 4 weeks; current smoking; and receipt of cancer screening tests in the previous year. Results of bivariate analyses and linear regression models are reported.

Results: Overall, 46% of participants experienced some form of financial hardship. Financial hardship was associated with lower levels of participation in any moderate activity in the previous four weeks (39.9% vs. 33.1%, $p=0.03$) and with higher levels of weekly consumption of non-diet sodas (45.0% vs. 38.8%, $p=0.05$). Financial hardship was inversely associated with alcohol consumption—fewer survivors who experienced financial hardship consumed alcohol in the past 4 weeks compared to those who did not (44.7% vs. 54.2%, $p=0.01$) and experiencing financial hardship was associated with consuming 0.84 (95% CI: 0.20, 1.48) fewer alcoholic drinks per week on average. Financial hardship was marginally associated with current smoking (19.4% vs. 14.9%, $p=0.07$), but was not associated with receipt of cancer screening in the previous year or with other dietary behaviors including consumption of fruits, vegetables, red or processed meats, or dessert foods.

Conclusions: Financial hardship was inversely associated with alcohol consumption and physical activity and positively associated with regular soda consumption. Cancer survivors experiencing financial hardship may be an appropriate population to target for behavioral interventions in addition to financial assistance.

FLORIDA BIOBANK FOR BLACK MEN: FEASIBILITY OF RECRUITING AFRICAN-AMERICAN PROSTATE CANCER PATIENTS FOR BIOSPECIMEN RESEARCH

Siddhartha Roy, DrPH¹, Jennifer C. Damonte, MA¹, Carmen G. Benson¹, Hyun Park, MS¹, Heloise N. Borges, MPH¹, Mmadili N. Ilozumba, BS², Alan Pollack, MD-PhD³, Shahla Masood, MD⁴, Youngchul Kim, PhD¹, Jasreman Dhillon, MD¹, Kosj Yamoah, MD-PhD¹, Julio Powsang, MD¹, Thomas A. Sellers, PhD¹, Clement K. Gwede, PhD¹, Jong Y. Park, PhD¹

¹Moffitt Cancer Center, Tampa, FL; ²University of South Florida/Moffitt Cancer Center, Tampa, FL; ³University of Miami, Coral Gables, FL; ⁴University of Florida at Jacksonville, Jacksonville, FL

Background: Prostate cancer affects African-American (AA) men disproportionately compared to men of all other racial/ethnic groups. To identify behavioral and biological bases for this health disparity, we sought to create a state-wide biospecimen bank of AA prostate cancer patients in Florida. This goal required the recruitment of patients, collection and management of patients' data, tumor tissue samples and saliva.

Methods: Self-identified Blackprostate cancer patients diagnosed between 2013 and 2015 who were living in Florida at the time of diagnosis were identified through the Florida Department of Health, Florida Cancer Data System (FCDS). Potential participants were mailed an information packet developed with the help of prostate cancer survivors and other community partners containing information about the study, with follow-up by telephone to establish connections between researchers and patients. Interested patients were screened for eligibility and asked to complete a questionnaire, provide a saliva sample, and provide permission to obtain their tumor tissue sample. Patients were offered up to \$30 for participating in the study.

Results: Information packets were sent to 1872 AA patients, 46 of whom were ultimately found to be ineligible. To date, among patients who were reached via mail or phone, 324 have consented to participate, 736 declined, and 449 have not responded to the initial information packet resulting in a participation rate of 21.5% (324/1509). Primary reasons for declining include patients stating that they are not interested (72%), too sick (8%), or too busy (5%). Examination of demographic factors, such as age, insurance status, tumor grade, and cancer status, associated with participation is currently ongoing.

Discussion/Conclusion: Our results show that the recruitment of AA prostate cancer patients through a cancer registry for participation in biobank research is feasible. However, challenges do exist that impede response and hinder recruitment. Additional avenues for targeting and reaching this population to increase participation in biospecimen science and research are needed to address cancer disparities among this population.

MEANING-CENTERED PSYCHOTHERAPY FOR ADVANCED CANCER PATIENTS: AN EXAMINATION OF MODERATORS OF TREATMENT EFFICACY

Login George, PhD¹, Barry Rosenfeld, PhD², Iris Crespo, PhD³, William Breitbart, MD⁴

¹Memorial Sloan Kettering, Belleville, NJ; ²Fordham University, Department of Psychology, Bronx, NY; ³Memorial Sloan Kettering, New York, NY; ⁴Memorial Sloan Kettering Cancer Center, New York, NY

Advanced cancer patients may face challenges to their spiritual well-being as they approach end of life. Meaning-centered psychotherapy (MCP), which enhances a sense of meaning, has been found to effectively improve spiritual well-being in multiple pilot and randomized control trials (RCTs; Breitbart et al., 2015). Further research is needed however to examine potential moderators of treatment efficacy — in other words, is MCP equally effective across different populations?

The present study pools together data from four pilot studies and RCTs of MCP, and examines potential moderators of treatment efficacy. Specifically, key demographic (e.g., race), medical (cancer stage), and baseline religiosity/spirituality (R/S) variables are examined.

Methods: Sample consisted of participants who received MCP treatment in the experimental arm of four previous studies (N = 301). In all studies, data were collected pre-treatment, post-treatment, and at follow-up, six to thirteen weeks after treatment; in one of the studies, data were also collected mid-treatment. The outcome variable, spiritual well-being, was assessed at all time points using the Functional Assessment of Chronic Illness Therapy-Spiritual Well-being Scale (Brady et al., 1999).

Moderators assessed included:

1. Age
2. Sex
3. Years of education
4. Race (white vs. black)
5. Marital status (single vs. married)
6. Cancer stage (III vs. IV)
7. Self-rated religiosity
8. Self-rated spirituality
9. Attendance at religious services

Results and Discussion: Multi-level modeling was used to model the rate of improvement in spiritual well-being across study span (level 1), and to examine if moderators predicted the rate of improvement (level 2). Results showed that participants as a whole improved in their spiritual well-being across study span ($b = 1.12, p < .001$). More importantly, level two coefficients showed that none of the demographic variables and cancer stage moderated the rate of improvement. Thus, MCP appeared to be equally effective across patients of different age, gender, and education, and regardless of whether they were black or white, single or married, and had stage III or IV cancer.

One of the three baseline R/S variables — attendance at religious services — however showed a significant moderation, such that individuals who *regularly* attended services experienced less improvements ($b = -.70, p < .05$), whereas those that did not attend at all, experienced more. Further examination indicated that those who did not attend services started the study with much lower well-being. Comparing this pattern to the other two R/S variables indicated that, although there was no statistically significant moderation, there was a similar trend. Thus, the results seemed to suggest that MCP may be particularly suited for individuals low on R/S, who may be more prone to experiencing lower spiritual well-being (Peterman et al. 2002).

MEDITATIVE INTERVENTIONS AND MENTAL HEALTH OUTCOMES AMONG MALE CANCER SURVIVORS: A META-ANALYSIS

C. Graham Ford, MS¹, Kevin Vowles, PhD¹, Laurie Steffen, PhD², Anita Kinney, PhD¹¹University of New Mexico, Albuquerque, NM; ²Wake Forest School of Medicine, Winston Salem, NC

Cancer is a major public health problem that entails unique psychosocial stressors. Meditative interventions (e.g., Mindfulness-based interventions, yoga, and tai chi/qigong) have been shown to be effective adjunctive cancer treatments, especially for psychosocial concerns, such as depression, stress, and anxiety. Most of the research to date examining these interventions in cancer populations includes predominantly female participants. Thus, the impact of these interventions on men is largely unknown. Therefore, the present study sought to evaluate the effectiveness of meditative interventions on psychosocial outcomes in men with cancer diagnoses. Data were extracted from randomized controlled trials of meditative interventions for adjunctive cancer care in which more than 20% of the participants were men. In total, 18 studies were included in the final analysis which included 921 total male participants. The participants were 68 years of age on average ($SD = 9.15$) and predominantly non-Hispanic white (91%). Psychosocial outcomes extracted included measures of psychological distress (anxiety and depression), stress, and quality of life. Preliminary analyses indicate a weighted average of effect sizes (Cohen's d) combined for all psychosocial outcomes of .086 (95% CI: -.164, .337) in favor of meditative interventions. For psychological distress (e.g., anxiety and depression), there was a small weighted effect size found of .197 (95% CI: -.221, .615). These effects are significantly more modest than the moderate to large effects found in other meta-analyses for meditative interventions in cancer populations, particularly for women with breast cancer. This summary suggests that these meditative interventions may be less effective for men overall, may need to be tailored specifically for men, or may only be effective for some subgroups of men. Extending the evidence base of these promising interventions includes more careful outcome measurement, implementation science considerations, and tailoring to different populations.

PHYSICAL ACTIVITY AND SYMPTOMS IN YOUNG ADULTS WITH CANCER AT THE BEGINNING OF CHEMOTHERAPY

Jeanne M. Erickson, PhD, RN¹, Ann Swartz, PhD, FACS², Nathan Tokarek, MS²¹University of Wisconsin-Milwaukee College of Nursing, Milwaukee, WI; ²University of Wisconsin-Milwaukee Department of Kinesiology, Milwaukee, WI

Staying physically active has important short- and long-term benefits for patients with cancer, including less severe symptoms, improved physical function, and better tolerance to treatment. During chemotherapy, multiple cancer-related symptoms may increase the likelihood of being inactive. Young adults with cancer are an understudied group of patients, and little is known about their physical activity during cancer treatment.

This report provides baseline data about physical activity and symptom severity for 16 young adults (18–39 years old) enrolled in a randomized trial examining the effect of a physical activity intervention. To document their baseline physical activity, participants wore an accelerometer (ActiGraph GTX3+) for seven days during a week of chemotherapy administration. Accelerometer data were analyzed to determine steps per day and the amount of time participants spent per day in light, moderate, and vigorous physical activity using established cut points (Freedson et al., 1998; Matthews et al., 2012). Symptom severity was documented using the PROMIS-29 Profile.

These young adults (62.5% female, mean age = 33.3 years) were in the first two months of treatment for diagnoses including breast cancer (5), lymphoma (5), leukemia (4), myeloma, and melanoma. Most were partnered (62.5%), and most (62.5%) were parents. The sample averaged 5137 steps/day with 242 minutes/day of light physical activity, 19 minutes/day of moderate physical activity, and no vigorous physical activity. The mean standardized PROMIS-29 profile scores for physical function, fatigue, sleep disturbance, depression, anxiety, pain interference, and ability to participate in social roles and activities for this sample ranged from 49.45 (physical function) to 55.16 (pain interference).

This group of young adults receiving chemotherapy engaged in a sufficient amount of health-enhancing physical activity (at least 150 minutes/week), similar to an age-matched national cohort (Troiano, et al, 2008). Their symptom severity scores were similar to average scores for a sample of healthy US adults (PROMIS® Adult Profile Instruments, 2015). The larger study will examine how physical activity changes during the course of chemotherapy and how supportive interventions may be used to optimize physical activity for young adult patients.

10:00 AM-11:00 AM

REALLOCATION OF TIME SPENT IN SLEEP, ACTIVITY AND SEDENTARY BEHAVIOR: ASSOCIATIONS ON QUALITY OF LIFE IN KIDNEY CANCER SURVIVORS

Allyson Tabaczynski, B.S.¹, Kerry Courneya, PhD², Linda Trinh, PhD¹¹University of Toronto, Toronto, ON, Canada; ²University of Alberta, Edmonton, AB, Canada

Background: High levels of sedentary behavior has been linked to negative health outcomes in cancer survivors including decreased physical and mental functioning. Cancer survivors, including kidney cancer survivors (KCS) are more likely to report engaging in higher levels of sedentary behavior, minimal time spent light or moderate-to-vigorous physical activity (MVPA), and poor sleep patterns. These behaviors may independently or in combination with one another contribute to poorer quality of life (QoL). To optimize interventions aimed at improving QoL in KCS, investigating the effects of replacing sedentary time with physical activity (PA) or sleep on QoL is warranted.

Purpose: To examine the potential associations of reallocating 10-min of sedentary time with 10-min of sleep, light, or MVPA on QoL in a KCS.

Methods: 1,985 KCS from a Canadian Provincial Registry were mailed a survey consisting of the Godin Leisure-Time PA Questionnaire, domain-specific sitting time, sleep duration, and several Functional Assessment of Cancer Therapy (FACT) scales. Demographic and medical variables were collected via self-report. Isotemporal substitution analyses were conducted to estimate the effects of relocating time spent in sedentary time with sleep, light PA or MVPA on QoL.

Results: Completed surveys were received from 481 KCS ($M_{age} = 62.9 \pm 10.5$). The substitution of 10-min of sedentary time with 10-min of light PA or MVPA was associated with better functional status on the Trial Outcome Index-Fatigue scale ($B = .084$, $SE = .037$, $p = .025$ and $B = .069$, $SE = .026$, $p = .009$, respectively). Substituting 10-min of sedentary time with 10-min of light PA was associated with better physical well-being (PWB) ($B = .021$, $SE = .010$, $p = .028$), but lower emotional well-being ($B = -.021$, $SE = .009$, $p = .016$). No associations were found with substituting 10-min of sedentary time with 10-min of sleep, light PA, or MVPA with FACT-Fatigue, FACT-General, or the FACT subscales of social well-being and functional well-being.

Conclusion: Replacing sedentary time with 10-min of light PA is associated with less fatigue and better physical functioning but worse emotional functioning. Modest reductions in sedentary behavior result in significant changes in certain aspects of QoL when substituted with physical activity. These findings demonstrate that even 10-min bouts of PA, which represents the minimum bout of time accrued to meet the current PA guidelines, can result in potentially meaningful changes in QoL.

THE ASSOCIATION BETWEEN LIGHT PHYSICAL ACTIVITY AND FATIGUE AMONG POST-TREATMENT CANCER SURVIVORS

Elizabeth Fallon, MPH, Ph.D., Bennett McDonald, MPH, JOHANN L. Westmaas, PhD, Tenbroeck Smith, MA, Kassandra I. Alcaraz, PhD, MPH, Alpa Patel, Ph.D.

American Cancer Society, Atlanta, GA

Substantial research demonstrates a negative association between moderate-to-vigorous physical activity (MVPA) and fatigue among cancer survivors. Less is known about the association of light physical activity (LPA) and fatigue. This study aimed to examine the associations of LPA and fatigue, and explore the moderating effect of MVPA on the LPA-fatigue association, among post-treatment cancer survivors.

Methods: Self-report data from the American Cancer Society's Studies of Cancer Survivors I and II were merged. Using the Leisure Time Exercise Questionnaire, four LPA groups (0, 1–59, 60–119, and 120+ minutes/week) and three MVPA groups (0, 1–149, and 150+ minutes/week) were created. ANCOVAs assessed the main and interactive effects of MVPA and LPA on SF-36 vitality (fatigue/energy) subscale. Covariates included age, time since diagnosis, race/ethnicity, cancer type by gender, cancer stage, SF-36 mental health subscale and number of comorbidities.

Results: The sample ($N = 10,213$) was primarily white/Caucasian (80.8%), female breast (29.4%) or male prostate cancer survivors (21.4%), with localized cancer (69.2%), 4.8 years ($SD = 3.3$) from diagnosis, having 1–2 comorbidities (49.9%), and mean age of 64.1 years ($SD = 12.4$). Almost 27% of the sample reported no leisure-time LPA or MVPA. MVPA [$F(2) = 295.33$, $p < 0.001$] and LPA [$F(3) = 14.11$, $p < 0.001$] were independently, negatively associated with fatigue. An LPA by MVPA interaction [$F(6) = 10.65$, $p < 0.001$] indicated that among those reporting no MVPA, fatigue was greater among those reporting no LPA compared to those reporting ≥ 120 min/week of LPA [mean difference = 2.58 ($SE = 0.27$), $t = 9.71$, 95% CI: 2.06, 3.10]. A significant linear trend showed that fatigue declined with increasing levels of LPA among those with no MVPA [$p < 0.001$]. Among those reporting 1–149 and 150+ min/week of MVPA, there was no association between LPA and fatigue.

Conclusion: Leisure-time MVPA and LPA are independently, negatively associated with fatigue among cancer survivors. Leisure-time LPA may be particularly beneficial for fatigue among cancer survivors engaging in no leisure-time MVPA. The potential of LPA to improve fatigue among survivors should be investigated using measures of LPA that include occupational, transportation, and activities of daily living, and using longitudinal and RCT designs.

THE STUPID CANCER APP: INITIAL FINDINGS FROM AN MHEALTH TOOL FOR YOUNG ADULT CANCER SURVIVORS

Catherine Benedict, PhD¹, Allison J. Lazard, PhD², Brad Love, PhD³, Matthew Zachary, BA⁴, Dave Fuehrer, MBA⁵¹Hofstra Northwell School of Medicine, Manhasset, NY; ²University of North Carolina at Chapel Hill, Chapel Hill, NC; ³University of Texas at Austin, Austin, TX; ⁴Stupid Cancer, New York, NY; ⁵GRYT Health, Inc., Rochester, NY

Background: Young adult (YA) cancer survivors report unmet needs for emotional and informational support. The Stupid Cancer app is a publicly available, free mobile app that provides instant, anonymous peer support and targeted cancer information for anyone affected by YA cancer including caregivers/loved ones. Users complete a profile and are matched with peers based on self-selected criteria or can participate in unstructured, moderated group chats.

Objective: Evaluate app performance and user feedback in the 3 months post-launch.

Methods: A product and user analysis evaluated app functioning, user engagement, and user feedback using quantitative app metrics and qualitative feedback from solicited and unsolicited app reviews.

Results: 1402 people downloaded the app and completed 209,995 interactions (profile set-up, discovering peer matches, and messaging). Users were mostly YA survivors (77.4%), female (77.0%), post-treatment (45.1%), and US-based (92%); international users represented 50 countries (1100 cities). In-app interactions averaged 16,153 per week, amounting to an average of 215.3 hours spent by users in the app per week. Average user session time was 10.5 minutes, with a trend showing longer session durations over time (peaking at 14.5 minutes). Session time appeared to vary by user location with more rural and international users spending more time than larger city and US-based users, respectively. Private one-to-one messages made up the majority of total message exchanges (n=22,672). The most popular group chat discussions were about defining the cancer experience, finding support, and anxiety. User feedback suggested the app is well-liked by the YA cancer community. Public reviews (n=28) were positive (mostly 5-star ratings), highlighting the value and benefit of being able to find peers with similar cancer experiences to connect with. Suggestions from solicited reviews (n=6) included increasing user control and flexibility over the peer searching/matching process; and a few expressed hesitation or nervousness initiating/joining conversations.

Conclusions: Findings suggest this app-based support tool may be a promising way to reach this underserved population and provide support. Future research should evaluate whether access to app-based support leads to improvements in psychosocial outcomes. Strategies to address possible in-app social anxiety, facilitate initial connections, and support meaningful in-app experiences need to be explored.

A COMPARISON GLOBAL AND DAILY REPORTS OF SUBJECTIVE COGNITIVE COMPLAINTS AMONG BREAST CANCER SURVIVORS

Stacey Scott, PhD¹, Jacqueline Mogle, PhD², Sarah Eisel, BA³, Heather Jim, FL⁴, Brent Small, PhD³¹Stony Brook University, Stony Brook, NY; ²Pennsylvania State University, University Park, PA; ³University of South Florida, Tampa, FL; ⁴Moffitt Cancer Center, Tampa, FL

Background: More than 50% of cancer survivors report problems with concentration since their diagnosis and treatment; however, these reports may contain retrospective or emotional bias. That is, individuals with possible cognitive difficulties must retrospect across weeks or months about a distressing problem. These ratings could be influenced by peak (i.e., when functioning was worst) or recency (i.e., how functioning has been lately). The goal of this study was to test whether these conventional retrospective reports predict memory lapses in daily life.

Methods: Breast cancer survivors (N=47, M age = 53.3, 6–36 months post chemotherapy-treatment) completed a standard global survey of subjective cognition (FACT-Cog) over the past week. Following this assessment, participants completed smartphone-based evening surveys for 14 days. Surveys included a checklist of types of memory lapses (i.e., forgot keys, missed appointment). Multilevel logistic models were used to test whether FACT-Cog ratings predicted likelihood of reporting a memory lapse in daily life (an index of frequency) and number of types of daily memory lapses (an index of pervasiveness across everyday tasks).

Results: Retrospective ratings of cognitive complaints over the last week aligned with daily reports of subjective cognitive function. Higher scores on the FACT-Cog, indicating better perceived cognition, were associated with lower likelihood of reporting a memory lapse on a given day (OR = 0.96, $p < .01$); survivors 1 standard deviation above average on FACT-Cog were 66% less likely to report a memory lapse on a given day than the average survivor. Additionally, higher FACT-Cog scores related to fewer types of memory lapses each day (Rate Ratio = .98, $p < .0001$). High FACT-Cog (+1SD) survivors reported .44 times fewer types of memory lapses on a given day than the average. These results (p 's $< .0001$) held when controlling for depression, perceived stress, time since treatment and age.

Conclusion: A widely-used assessment of subjective recall of cognitive function over the last week predicted daily reports of occurrence and variety of memory lapses in the following 2 weeks. This suggests that although a discrepancy remains between widespread subjective reports of post-chemotherapy cognitive problems compared to clinical assessments of cognitive impairment, the subjective recalls over relatively short time windows (e.g., weeks) align with incidences of forgetting events in daily life.

A MIXED METHODS EVALUATION OF SYMPTOM BURDEN AND QOL AFTER CURATIVE HNC TREATMENT

Allison Marziliano, PhD¹, Sewit Teekie, MD², Caitlin DeCoster, MPH¹, Colm M. Mulvany, BA¹, Roshni Bhat, BS¹, Michael A. Diefenbach, Ph.D.¹

¹Northwell Health, Manhasset, NY; ²Hofstra Northwell School of Medicine, New York, NY

Purpose We hypothesize that head-&-neck cancer (HNC) patients who receive multimodality treatment (i.e., surgery, radiation and chemotherapy), experience short and long-term treatment-related effects that negatively impact quality of life (QoL).

Materials/Methods A mixed methods study evaluated the effects of multimodality treatment on HNC patients. First, charts of 20 patients with HNC were reviewed; short-term scores on the MD Anderson Dysphagia and Symptom Inventories were compared among those receiving Trans Oral Surgery (TOS) followed by chemotherapy and radiation (CRT; n=6, 30%) and those receiving CRT only (n=14, 70%). Second, long-term QoL experiences were further explored through a facilitated focus group (FG) with 11 HNC survivors.

Results Chart review results: HNC Sample was mostly male (n=16, 80%), and on average 61 years. At 6–9 mos. post treatment, patients who received TOS and CRT reported significantly (p=.04) worse dysphagia (M=69.47, SD=14.61) compared to those who received only CRT (M=48.43, SD=27.63). FG results: Sample was 64% female and all completed treatment > 3 yrs. ago. Three patients had surgery first, and more than half had CRT. Coders identified three themes: Theme 1: Variability in symptoms. Dysphagia was endorsed by a majority of patients (n=6), plus overproduction of saliva/mucus (n=5), loss of taste and sense of smell (both n=4), neuropathy, pain (both n=3), fatigue, dental issues, weight loss, severe burns, muscle/throat tightness, and dry mouth (all n=2). Psychological symptoms were also frequently reported: uncertainty (n=5), loss of control (n=3), feeling lonely (n=3), and depression/anxiety (n=2). Theme 2: Long-standing negative impact on QoL. Even years post-treatment, patients (n=7) reported that treatment-related symptoms negatively and substantially impacted their QoL. Theme 3: Lack of information about recovery. All patients reported that they were unaware of the magnitude/extent of symptoms during recovery. Patients reported that providers minimized the overall impact of disease and treatment (n=9), or did not communicate at all about effects (n=5) or pain relief (n=2).

Conclusions HNC survivors reported significantly impaired QOL due to increased levels of dysphagia, as well as a host of other unanticipated effects. More data on recovery trajectories are needed to improve communication of these potential responses to treatment. Supportive measures are necessary to assist patients in managing the effects.

“CREATING A FAMILY AFTER BATTLING CANCER IS EXHAUSTING AND MADDENING”: YOUNG ADULT SURVIVORS’ FAMILY-BUILDING EXPERIENCES

Catherine Benedict, PhD¹, Jody-Ann McLeggon, MPH², Bridgette Thom, MS³, Joanne Kelvin, MSN, RN, AOCN, CNS⁴, Jennifer Ford, New York³, Michelle Landwehr, MPH⁵, Samantha Watson, MBA⁵

¹Hofstra Northwell School of Medicine, Manhasset, NY; ²Northwell Health, Manhasset, NY; ³Memorial Sloan Kettering Cancer Center, New York, NY; ⁴Memorial Sloan Kettering, New York, NY; ⁵The Samfund, Boston, MA

Purpose: Young adult (YA) cancer survivors who received gonadotoxic therapy are at risk for impaired fertility and/or childbearing difficulties. This study explored the experiences and financial concerns of YA survivors pursuing family-building through assisted reproductive technology (ART) or adoption.

Methods: Retrospective study of data collected from grant applications for financial assistance with family-building (N=53). Descriptive statistics characterized sociodemographic, medical, and financial information. Grounded theory methodology using an inductive data-driven approach guided qualitative data analysis.

Results: Participants (N=53) averaged 31 years old (SD=3.6), were primarily female (81%) and married/partnered (72%), and averaged 5 years (SD=5.6) post-treatment. Positive and negative emotions surrounding family-building processes were reported, which were greatly influenced by cancer experiences and financial stressors. Family-building costs were described as overwhelming and unexpected. Financial stress of family-building was exacerbated by cancer financial effects. Factors that increased distress during the family-building process included cancer-related health problems, perceived reproductive time pressure, peer comparisons related to life trajectory and financial solvency, and interpersonal concerns.

Conclusion: After cancer, YAs trying to build their families face a number of psychosocial and financial difficulties. A broader approach to managing fertility in post-treatment survivorship is needed to support survivors in making informed, values-based decisions including support related to financial planning.

Implications for Cancer Survivors: YA cancer survivors interested in having future children should receive follow-up fertility counseling post-treatment including discussion of alternative family-building options such as use of ART, surrogacy, and adoption, as appropriate, and potential barriers. Planning for the financial cost, in particular, may help to avoid or mitigate financial stress later on.

ACCEPTABILITY AND EFFECTIVENESS OF AN ONLINE AND IN-PERSON PEER NAVIGATOR TRAINING PROGRAM FOR PROSTATE CANCER SURVIVORS

Jacqueline L. Bender, PhD¹, Parminder Flora, Ontario², Elizabeth Milosevic, BKin², Shima Soheilipour, PhD³, Mihaela Dirlea, BSc(Hons) MSW RSW⁴, Nandini Maharaj, PhD candidate³, Lisa Parvin, MMSc⁵, Andrew Matthew, PhD¹, Arminee Kazanjian, DrSoc⁶

¹Princess Margaret Cancer Centre, Toronto, ON, Canada; ²University Health Network, Toronto, ON, Canada; ³University of British Columbia, Vancouver, BC, Canada; ⁴Department of Supportive Care, Toronto, ON, Canada; ⁵Harvard Medical School, Boston, MA; ⁶Professor, School of Population & Public Health/UBC, Vancouver, BC, Canada

Background: Peer navigation enables cancer survivors to provide informational, emotional and practical support to new patients and their partners/ family caregivers. True NTH Peer Navigation Training Program (PNTP) is a competency-based blended online and in-person training program designed to equip prostate cancer (PC) survivors (patients, caregivers) with the requisite knowledge, skills, and resources for supporting matched peers as they navigate the health and social service systems. The PNTP consists of eight facilitated online modules and two full-day in-person sessions delivered over the course of six weeks.

Objective: To evaluate the acceptability and effectiveness of the PNTP among PC survivors.

Design/Methods: This is a one-arm pre-post feasibility study informed by the Kirkpatrick framework and Bandura's Self-Efficacy Theory. We employed an explanatory mixed method design consisting of online questionnaires and in-person focus groups.

Results: We delivered the PNTP to three cohorts of 26 participants in two Canadian cities. PNTP acceptability was high. Program satisfaction was rated as 9.4/10 (SD=0.7) and website usability was rated as 84.5/100 (SD=10.1). Perceived learning scores were also high: 4.5/5 (SD=0.4). In addition, there were statistically significant increases in pre/post scores for all learning outcomes: understanding of learning objectives $t(23)=6.13$, $p<0.001$; self-efficacy to perform peer navigator competencies $t(23)=5.2$, $p<0.001$; and eHealth literacy $t(23)=4.4$, $p<0.001$. Qualitative findings support and expand on these findings. Participants valued (1) flexibility of online learning, (2) relationship building via in-person learning and social events (3) group-based learning activities (e.g. online forum and role plays), and (4) practice-based learning opportunities. Areas for improvement were (1) more content on the needs of caregivers, (2) more practical health information technology content, and (3) distribute content more evenly across units.

Conclusions: A blended online and in-person training program is a highly acceptable and effective format to train PC survivors and caregivers to become peer navigators. Addressing areas for improvement may further enhance positive outcomes.

ADDRESSING CAREER-RELATED NEEDS IN AYA CANCER SURVIVORS: UNIVERSITY CAREER SERVICE PROFESSIONALS' EXPERIENCE AND RESOURCES

Danielle Blanch-Hartigan, PhD, MPH
Bentley University, Waltham, MA

Many adolescent and young adult (AYA) cancer survivors face a double transition- the transition from patient to survivor and the career-related transition from student to career. AYA survivors report concerns about career development and employment, including job-seeking, employment discrimination and disclosure of cancer history, and concerns about work demands and accommodations. University career service professionals are well-positioned to provide targeted resources, but no study has focused on those providing career-related services to AYA survivors. The goal of the present study was to assess university career service professionals' experience working with AYA survivors, preparedness for working with AYA survivors, and openness to resources for students who are AYA cancer survivors. Randomly selected career service offices at colleges and universities in the United States were sent an online survey. Forty career service professionals participated in the survey. Half of participants (N =20) reported an experience working with a student who was a cancer survivor. Some reported these students had cancer-specific concerns including flexibility related to internships, values and vocational goals, addressing cognitive deficits as a result of treatment, and switching to a career in health promotion and cancer prevention. Only two career service professionals reported providing cancer-specific resources. A majority of participants reported a lack of awareness to the specific career-service needs of cancer survivors (55%) or resources available resources available for student who were survivors (85%). Sixty-five percent agreed that career services resources specifically designed for college-aged cancer survivors would be useful and 87.5% said they would provide these resources to cancer survivors if available. Age, gender, years of experience, job level (director, counselor, administrator), and size of the career services office did not predict preparedness or openness to resources in unadjusted bivariate correlations or fully adjusted linear regression models. University-based career services may prove a significant resource for many AYA survivors. Career service professionals acknowledge a lack of training and awareness of AYA survivors' specific needs and report a desire for targeted resources. Future interventions can provide tailored career-service resources to both AYA survivors and career service professionals.

ADOLESCENT AND YOUNG ADULT CANCER SURVIVORS' UNMET NEEDS AND MOTIVATIONS FOR ATTENDING AN ONCOLOGY AND SOCIAL NETWORKING EVENT

Catherine Benedict, PhD¹, Allison J. Lazard, PhD², Adam Safer, PhD³, Brad Love, PhD⁴, Dave Fuehrer, MBA⁵, Matthew Zachary, BA⁶

¹Hofstra Northwell School of Medicine, Manhasset, NY; ²University of North Carolina at Chapel Hill, Chapel Hill, NC; ³University of North Carolina, Chapel Hill, NC; ⁴University of Texas at Austin, Austin, TX; ⁵GRYT Health, Inc., Rochester, NY; ⁶Stupid Cancer, New York, NY

Introduction: Adolescent and young adult (AYA) cancer survivors are an understudied and underserved patient group. To address AYAs' unmet needs, the non-profit organization Stupid Cancer hosts an annual AYA oncology and social networking event called CancerCon.

Aims: This study aimed to evaluate AYAs' unmet needs and quality of life (QOL) and their motivations for attending CancerCon.

Methods: Registered attendees were emailed one week before CancerCon and completed a brief online, anonymous survey, including validated measures for AYA cancer impact, unmet needs, and QOL. Descriptive statistics and bivariate analyses were used.

Results: Participants (N=192; 62% response rate) averaged 31 years old (SD=7.2), were primarily White (81%), employed (77%), and most had completed treatment (63%). A range of unmet needs were endorsed related to informational/resource needs (61%), medical care interactions (45%), psychosocial concerns (85%), school (42%) and employment (74%), finances (71%), and health insurance (39%; with 85% reporting fears about change in coverage). Primary reasons for attending CancerCon included a desire to spend time with peers and feel connected to the AYA cancer community, access age-appropriate resources, be an advocate, gain confidence managing disease-related changes, and learn about latest research. On a 0–10 scale, average QOL was 6.4 (SD=2.0) and social support was 5.1 (SD=1.6). perceived social isolation related to lower QOL (median split; $t[157]=-3.8$, $p<.001$). Those currently in treatment had the lowest QOL and those with chronic disease had the greatest unmet support needs, compared to completed treatment and ongoing therapy subgroups ($p's<.05$). Differences in motivations for attending CancerCon and unmet needs based on treatment status were identified.

Discussion/Conclusion: Given high rates of unmet survivorship needs and barriers to informational and support resources, patient organizations may fill a critical gap in care. Future work should identify optimal ways for multidisciplinary collaboration to address AYAs' needs across their cancer trajectory. Targeted approaches that incorporate evidence-based support strategies and dissemination efforts, such as through digital platforms, should be explored.

AN RCT OF CBTH FOR DISTRESS DURING RADIOTHERAPY

Guy Montgomery, Ph.D.¹, Julie Schnur, Ph.D.²

¹Icahn School of Medicine at Mount Sinai, New York, NY; ²Icahn School of Medicine at Mount Sinai, new york, NY

Radiotherapy is a common and effective treatment for women with breast cancer. However, radiotherapy has also been shown to adversely affect patients' emotional well-being. Currently, few mind-body interventions are designed to improve patients' quality of life during radiotherapy. One intervention which has demonstrated clinical efficacy in the breast cancer radiotherapy setting is CBTH (Cognitive-Behavioral Therapy plus Hypnosis). The goal of this study was to investigate the impact of CBTH on emotional distress in women with breast cancer undergoing radiotherapy. One hundred patients were randomly assigned to either the CBTH ($n=50$) or Attention Control (AC) ($n=50$) group. Results revealed significant benefits of CBTH on emotional distress at the midpoint ($d=0.54$), the conclusion ($d=0.64$), and four weeks following the conclusion ($d=0.65$) of radiotherapy (all $p's < .05$). In conclusion, results support further study of CBTH as an evidence-based intervention to reduce emotional distress women with breast cancer. CBTH has the benefits of being brief, noninvasive, lacking side-effects, and producing beneficial effects which last beyond the conclusion of radiotherapy. Given these strengths, we propose that CBTH is a strong candidate for greater dissemination and implementation in cancer populations.

ANXIETY AND DEPRESSIVE SYMPTOMATOLOGY IN ADULTS WITH STAGE IV NON-SMALL CELL LUNG CANCER (NSCLC) AT DIAGNOSIS

Stephen B. Lo, MA¹, Peter G. Shields, MD², Sarah Hwang, BA³, Matthew McShane, BS⁴, Marlana Ryba, PhD⁴, Barbara L. Andersen, PhD³

¹Ohio State University, Columbus, MA; ²Ohio State University Comprehensive Cancer Center - James, Columbus, OH; ³The Ohio State University, Columbus, OH; ⁴Ohio State University, Columbus, OH

Background: In large studies of cancer patients, lung cancer is associated with the highest levels of depression, anxiety, and risk of suicide. These symptoms may impact quality of life and survival in lung cancer. This study examined the prevalence of anxiety and depression in advanced non-small cell lung cancer (NSCLC) patients seeking outpatient treatment.

Methods: Preliminary data (8/2017) consisted of a sample of 18 (out of an estimated 140) newly diagnosed Stage IV NSCLC patients ($n=9$ females) enrolled in a single site trial investigating advanced genomic testing's impact on survival. Patients completed self-report measures assessing anxiety, depression, and psychiatric history over the phone with a trained interviewer at baseline. Using American Society of Clinical Oncology guidelines for the screening, assessment and treatment of depression (i.e., none/mild [score 1–7], moderate [score 8–14], moderate to severe [score 15–19], and severe [score 20–27] symptomatology based on the PHQ-9) and anxiety (i.e., none/mild [score 0–9], moderate [score 10–14], moderate to severe [score 15–21] symptomatology based on the GAD-7), the recommended measures were used and patients exhibiting moderate to severe symptomatology were identified. Future analyses will examine the relationship of depression and anxiety with psychological (e.g., cancer-related stress, hopelessness) and other patient-reported outcomes (e.g., cancer-related symptoms, income).

Results: PHQ-9 cutoff was exceeded for 27.8% of patients while 16.7% exceeded the GAD-7 cutoff. 16.7% reported at least moderate levels of comorbid depression and anxiety. Moreover, 50.0% reported experiencing at least some difficulties related to depression or anxiety affecting their daily functioning with 11.1% reported suicidal ideation. 16.7% reported having a previously diagnosed psychological disorder. 38.9% reported previously seeking mental health outpatient treatment and 55.6% reported previously taking medication to help treat an emotional or psychological problem.

Discussion: Preliminary analyses demonstrate a number of advanced NSCLC patients needing follow-up care to address mental health problems. For comparison, the 12-month prevalence in the general population for mood and anxiety disorders are estimated to be 9.5% and 18.1%, respectively. Advanced NSCLC in an outpatient setting exemplify an underrepresented group with a clear need for more research addressing their psychosocial needs and characteristics.

BUILDING CURVES? A MIXED-METHODS EVALUATION OF A COMMUNITY PHYSICAL ACTIVITY PROGRAM FOR BREAST CANCER SURVIVORS

Catherine Sabiston, PhD¹, Angela Fong, PhD², Erin O'Loughlin, MA³¹University of Toronto, Toronto, ON, Canada; ²Queen's University, Toronto, ON, Canada; ³Concordia University, Montreal, PQ, Canada

Background: Based on recommendations from the ACSM Roundtable on exercise guidelines for cancer survivors, the purpose of this multi-study research was to partner with, and evaluate, a community-based physical activity program (Curves™) as support for increasing physical activity behavior among women diagnosed and treated for breast cancer.

Methods: All women were recruited from a local breast cancer clinic in a large metropolitan city through chart review and physician discussion. All eligible participants (N = 203) were provided with a free one-year Curves™ membership. In study one, a group of women (n=14) who were provided with memberships Curves™ plus physical activity guidelines and a pedometer was compared to women (n=16) who were provided physical activity guidelines and a pedometer on changes in physical activity. In study two, (n=66) women who were provided with Curves™ memberships completed self-report questionnaires one year later to assess access, feasibility, attitudes and beliefs on the program. Study three was a qualitative study exploring the benefits and barriers of Curves™ as a community-based physical activity program for breast cancer survivors. A purposeful sample of six women who attended the program regularly were interviewed.

Results: In the small quasi-experimental study, the provision of memberships to Curves™ did not improve physical activity levels beyond educational and information resources. Based on the self-report responses (study 2) and qualitative findings (study 3), there are a number of advantages to community-based physical activity programs like Curves™ (e.g., women-only, short time commitment, circuit exercise), yet the women offer a number of suggestions for improvements for physical activity opportunities aimed at breast cancer survivors (e.g., variety, knowledge of staff on cancer, more feedback). Furthermore, the year-long free membership may have undermined autonomy and value of Curves™.

Conclusion: Community-based physical activity programs may be best for helping women to transition from cancer clinic/hospital services in the aftermath of cancer treatments, and may help build competence for autonomous physical activity. In this way, partnerships between local fitness organizations and cancer care facilities may be essential. Nonetheless, subsidized memberships (rather than free) may offer the best support for breast cancer survivors.

CANCER FEAR AND COLORECTAL CANCER SCREENING USING THE FAECAL OCCULT BLOOD TEST IN ENGLAND: A POPULATION-BASED STUDY

Christian von Wagner, PhD¹, Sandro Tiziano, Stoffel, N/A¹, Rachael H. Dodd, PhD², Jo Waller, PhD¹, Charlotte Vrinten, MSc³¹UCL, London, England, United Kingdom; ²The University of Sydney, Sydney, New South Wales, Australia; ³University College London, London, England, United Kingdom

Background: Uptake of colorectal cancer screening is affected by cancer fear, but previous studies have found both motivating and deterring effects. Comparison between studies is hindered by inconsistencies in measuring frequency of cancer fear versus intensity. In this study, we compare measures of frequency and intensity of cancer fear on intentions and uptake of the faecal occult blood test (FOBT) in England.

Methods: Across four population-based studies from 2014-2016, we collected data from 2,878 men and women aged 60-70 years who were eligible for the FOBT via the national NHS Bowel Cancer Screening programme. Measures included a single item about frequency of cancer worry, an item about intensity of anxiety about cancer, self-reported past FOBT uptake (ever vs never), intention to do the FOBT when next invited (yes vs no), and sociodemographic characteristics. Using logistic regression analyses, we compared a model containing only socio-demographic characteristics (Model 1) with four models adding cancer worry frequency (Model 2), cancer anxiety intensity (3), both (4), or a combined measure of frequency and intensity (5).

Results: For screening intentions, all four cancer fear models explained significantly more variance in the data than Model 1 (all $p < .001$), with most variance explained by Models 3 and 4 (Nagelkerke's $R^2 = .060$ and $.061$, respectively). The difference between these models was non-significant ($p = .63$). For screening uptake, Models 3, 4, and 5 explained more variance than Model 1 (all $p < .05$), with no difference between models 3 and 4, which again explained most variance (Nagelkerke's $R^2 = .054$ vs $.057$, $p = .11$). In Model 4, cancer worry frequency was not associated with screening intentions or uptake, so Model 3 appeared the most parsimonious model. In this model, being slightly or quite/extremely anxious about cancer was positively associated with FOBT screening intentions (OR=1.99, 95% CI 1.53-2.59, and OR=1.59, 95% CI 1.17-2.18, respectively) and uptake (OR=1.49, 95% CI 1.20-1.86, and OR=1.58, 95% CI 1.19-2.09).

Conclusion: Despite many studies using measures of cancer worry frequency to predict engagement with cancer screening, intensity of cancer anxiety seems to be a better predictor of FOBT screening for bowel cancer. Future studies should explore whether the same is true for other cancer screening programmes such as breast and cervical screening.

CANCER PATIENT EXPERIENCE AND SELF-MANAGEMENT OF SIDE EFFECTS OF ORAL CHEMOTHERAPY

Yun Jiang, PhD, MS, RN¹, Karen Farris, PhD², Marcelline Harris, PhD, RN¹¹University of Michigan, Ann Arbor, MI; ²University of Michigan College of Pharmacy, Ann Arbor, MI

With the increasing use of oral anticancer medications for cancer treatment, patients face the challenge of self-management of medication side effects in the home setting. The purposes of this study were to describe patients' experience of side effects of an oral chemotherapy, capecitabine, self-management activities for side effects, and identify factors associated with performance of self-management activities.

A prospective descriptive study included 41 gastrointestinal cancer patients who had finished at least one cycle of capecitabine therapy. Measures included symptom severity and interference (MD Anderson Symptom Inventory, MDASI), and self-management activities for 7 known common side effects of capecitabine (Modified Self-Care Diary, MSCD). Descriptive statistics correlation analysis, and Mann-Whitney and Kruskal-Wallis tests were used.

Results from the MSCD indicated patient experience of moderate to very severe side effects "in the last 7 days" varied by side effect: fatigue (39.1%), constipation (31.7%), diarrhea (29.3%), nausea (21.9%), hand-foot syndrome (19.5%), sleep difficulties (12.2%), and mouth or throat sores (4.9%). In total, 836 out of 3075 self-management activities were reported. *The most commonly used self-management activities* were: Maintained activity level (fatigue); Kept busy to keep my mind off it (nausea); Read or watched TV (sleep difficulties); and Drank extra fluid (constipation), while *the most effective activities* were: Interaction with family or Applying relaxing oil (fatigue, self-developed by patients); Took prescribed anti-nausea medication (nausea); Took prescribed sleeping medication (sleep difficulties); and Took a stool softener or laxative (constipation). Non-white patients, patients with more severe symptoms as reported in the MDASI, and patients who had concerns of taking chemotherapy performed more self-management activities ($p=0.01$, 0.03, and 0.04, respectively). The influence of age, gender, education, depression, social support, and self-efficacy cannot be confirmed due to limited sample size.

This is among early studies to describe activities used for self-management of side effects of oral chemotherapy. Overall, non-pharmaceutical self-management activities were most frequently used, while taking medications was reported as the most effective activity for most side effects. The most effective activity reported for self-management of fatigue was patient self-developed. Future studies are needed to further understand self-management of side effects of oral chemotherapy behavior pattern among individuals, and provide personalized self-management support for patients at high risk for severe side effects.

CONCERNS ABOUT FERTILITY, GENETIC RISK, AND FAMILY BUILDING: AYA ONCOLOGY PATIENT PERSPECTIVES

Monica L. Kasting, PhD, Paige Lake, BA, Damon Reed, MD, Gwendolyn P. Quinn, PhD, Susan T. Vadaparampil, PhD

Moffitt Cancer Center, Tampa, FL

Background: Adolescent and Young Adult (AYA) oncology patients have identified having children as an important future goal. However, concerns regarding the impact of cancer on fertility and the perception of cancer as a hereditary disease may influence AYAs' family building decisions. This study explored these topics along with preferences for information among AYA cancer patients.

Methods: As part of an ongoing study to create an intervention aimed at improving knowledge and patient-provider communication misperceptions regarding inherited cancer risk, fertility preservation, and assisted reproductive technologies (ART), patients diagnosed between the ages of 18–39 were recruited from an institutional cancer registry. Interviews were conducted from November 2016–March 2017. Using a pre-interview survey and a semi-structured qualitative interview guide, we explored AYA cancer patients' current experiences, practices, and preferences for information to address genetics, fertility, and reproductive health needs. We examined preferences for patient information/education regarding hereditary cancer and fertility. Interviews were analyzed using content analysis and survey items were summarized with descriptive statistics.

Results: Patients ($n=17$), were majority female (59%) and Non-Hispanic (88%). The majority of patients indicated they had not met with a reproductive endocrinologist (77%) or received genetic counseling (71%). While the majority of patients said they would not personally engage in genetic counseling, they cited potential benefits for other AYA patients including the potential for future cancer risk management and also identified barriers such as worry and fear of the results. Participants indicated a positive genetic test result was not likely to alter their family building decisions. However, few demonstrated awareness about ART options to investigate inherited cancer risk in future offspring. The majority preferred to discuss genetic counseling and ART after the time of diagnosis because they felt this period of time was emotionally charged and confusing to add additional information.

Conclusion: These results identify awareness and attitudinal barriers to providing patients with information regarding fertility, hereditary cancer risk, and the possibility of passing the risk to children. Data from this phase of the study will be used to inform the development of a psychoeducational intervention to address these concerns.

DYSREGULATION IN CORTISOL RHYTHM AMONG MPN CANCER PATIENTS

Maricarmen Vizcaino, PhD¹, Jennifer Huberty, PhD¹, Linda Larkey, PhD¹, Heidi Kosiorek, MS², Krisztina Gowin, MD³, Ruben Mesa, MD⁴

¹Arizona State University, Phoenix, AZ; ²Mayo Clinic, Phoenix, AZ; ³Mayo Clinic/Salish Cancer Center, Phoenix, AZ; ⁴UT Health San Antonio, Phoenix, AZ

Introduction. Myeloproliferative neoplasms (MPNs) are rare hematological malignancies that are characterized by a heterogeneous symptom burden including debilitating fatigue. Abnormal diurnal cortisol rhythms have been found among breast, ovarian, and lung cancer patients, and have been associated with fatigue severity, immune dysfunction, disease progression, and earlier mortality. Alterations in the cortisol rhythm may indicate an immune-hypothalamic-pituitary-adrenal axis disturbance and may contribute to fatigue among MPN patients. The purpose of this abstract is to present findings on diurnal cortisol profiles of MPN patients from ad-hoc analyses at baseline from a pilot study that examined the feasibility of remotely collecting saliva samples prior to an online yoga intervention.

Methods. MPN patients were recruited nationally through internet-based strategies (e.g. social media, email listservs). Salivary collection instructions and materials were mailed to participants to collect saliva at four different time points (upon awakening, 30 min after waking, noon, and bedtime) over the course of one day prior to the yoga intervention. Saliva samples were mailed for cortisol content analysis. The area under the curve (AUC-indicator of slope) of MPN patients was calculated using the trapezoidal formula with all four cortisol values and compared to a normative AUC derived from data collected in a US sample of adults.

Results. Sixty-two MPN patients enrolled into the study, 34 were randomized into the yoga group, and 15 returned saliva samples at week 0. Visual inspection of individual cortisol curves showed a flattened cortisol profile in five MPN patients that lack the typical rise observed 30 minutes after waking in healthy populations. Statistical analysis revealed that the overall AUC of MPN patients was significantly lower compared to a normative AUC (MPN $M=2.42$, $SD=0.93$ $\mu\text{g/dL}$ vs. normative $M=3.33$ $\mu\text{g/dL}$; $p=0.002$).

Discussion. Similar to previous studies in other cancer populations, MPN patients showed alterations in cortisol rhythm. Larger clinical trials are needed to confirm these results and to investigate the role of cortisol dysregulation in symptom severity, disease progression and prognosis of MPN cancer patients. Cortisol stabilization may offer a unique therapeutic target in the management of MPN symptom burden.

EDUCATING IMMIGRANT POPULATIONS ABOUT HPV: HEALTH EDUCATORS' READINESS TO TACKLE HEALTH LITERACY CHALLENGES

Lenna Dawkins-Moultin, PhD¹, Kimlin Ashing, PhD²

¹Beckman Research Institute - City of Hope, Katy, TX; ²City of Hope, Duarte, CA

Background: Human Papillomavirus Virus (HPV) and HPV related cancers are higher among immigrants, especially those from Africa, Latin America, and the Caribbean. Limited health literacy is also more prevalent among immigrant groups. Community and parental education are central to HPVV facilitation and improvements, but there is a dearth of research on health educators' understanding of how to educate populations with health literacy deficits. The purpose of this study was to assess the health literacy knowledge and experience of advanced health education students.

Methods: A modified Health Literacy Knowledge and Experience Survey (HL-KES) was used to collect data from 250 junior and senior students who reported an intention to take the Certified Health Education Specialists (CHES) examination. Univariate and bivariate (Spearman rho correlations) analyses were conducted.

Results: Composite score on the 29-item knowledge scale ranged from 5–28. Most students (84%) scored below 70%, and only five percent of the sample scored above 80%. Majority of students reported “never” or only “sometimes” engaging in experiences related to health literacy, even though 94% of students reported HL was emphasized in their training program. There was a significant negative correlation between health literacy knowledge and health literacy experience ($\rho = -.189$, $p < .05$).

Conclusion: The results suggest health education students have deficient health literacy knowledge and limited opportunities to develop practical health literacy experience. Increasing HPV knowledge and HPVV in immigrant populations demand an ability to educate and facilitate communities with varying health literacy skills. Interventions to optimize cancer prevention and reduce HPV related cancer disparities should also examine the health literacy competence of health professionals such as health educators. Health education professional programs may also need to revise their curricula to address health literacy deficiencies in course offerings.

EFFECTS OF EDUCATION LEVEL ON PSYCHOLOGICAL SYMPTOMS IN CANCER PATIENTS

Natasia Adams, MA, MPH¹, Marcus Alt, Ph.D.², Elizabeth Muenks, Ph.D.²¹University of Kansas, Lawrence, KS; ²University of Kansas Health System, Department of Psychiatry and Behavioral Sciences, Kansas City, KS**TITLE:** Effects of Education Level on Psychological Symptoms in Cancer Patients**PURPOSE/BACKGROUND:** Research has clearly established that individuals diagnosed with cancer are susceptible to an array of psychological symptoms. As a result, cancer care is increasingly incorporating supportive services and psychological support for psychosocial stressors. Although literature has considered multiple predictive factors, there has been little examination into the relationship between education level on psychological distress in cancer patients. The purpose of the current study is to examine differences in reported symptoms of anxiety, depression, sleep concerns, and cognitive complaints across individuals with differing education status.**METHODS:** We utilized the Patient-Reported Outcomes Measurement Information System (PROMIS) survey to evaluate reported symptoms related to anxiety, depression, sleep concerns, and cognitive complaints. PROMIS surveys were collected from 166 cancer patients from an NCI-designated cancer center. Education status was captured through demographic information provided by patient.**RESULTS:** Majority of the participants were female (73%) and had a mean age of 51.37 (SD=13.90). A statistically significant difference between different levels of education and reported depressive symptoms was found. Post-hoc tests indicated that those with less than high school education level (25.89 +/- 6.05) reported more depressive symptoms compared to those who identified having a Bachelors degree(17.85 +/- 7.60) or above. A similar trend was seen in individuals with a high school education (22.8 +/- 9.05) reporting more depressive symptoms than those with a graduate/professional degrees. We found no other statistical significance differences between reported symptoms among differing levels of education.**CONCLUSIONS:** Our results suggest that those with less than high school and high school level of education may be at a higher risk of experiencing depressive symptoms. This could be because of other contributing factors, such as financial strain, transportation, childcare, health literacy, etc, increasing the likelihood of depressive symptoms. Regardless, individuals with less than high school or high school education may benefit from psychosocial interventions aimed at addressing depressive symptoms early on as a preventative strategy. Future research should continue to explore the relationship between distressing symptomatology and demographic information to identify populations at higher risks, allowing for implementation of preventative psychosocial interventions.**CORRESPONDING AUTHOR:** Natasia Adams, MA, MPH, University of Kansas, Lawrence, KS; n191a081@kumc.edu

FACTORS ASSOCIATED WITH FREQUENCY OF SEXUAL ACTIVITY OVER TIME AFTER PROSTATECTOMY

Kelsey Sewell, Ph.D.¹, Heather Kruse, Ph.D.¹, Donald Strassberg, Ph.D., ABPP², Christopher Dechet, MD³¹University of Kansas Health System, Kansas City, KS; ²University of Utah, Salt Lake City, UT; ³University of Utah, Huntsman Cancer Institute, Salt lake City, UTIntroduction Prostate cancer is one of the most common cancers in men. A known side effect of treatment is impact on sexual functioning. Sexual activity after prostate cancer treatment has not yet been directly examined through measurement over time. This exploratory study sought to answer the following research question: After prostatectomy, what between-subjects factors account for differences in men's frequency of sexual activity over time? Methods Participants were recruited from Huntsman Cancer Institute (HCI) and included 527 men preparing for prostatectomy. Prior to treatment and up to 9 times across 5 years, participants were administered the Sexual Functioning subscale of the long version of the Expanded Prostate Cancer Index Composite. The outcome variable was frequency of sexual activity in the past 4 weeks on a 1 (none at all) to 5 (daily) scale. Results Multilevel modeling procedures were used. Results for the intercept suggested that the average post-treatment baseline level of sexual functioning after surgery was 1.96 (as measured by the 100-point EPIC subscale). For the intercept (i.e., post-treatment baseline), there were significant main effects of age ($B = -.02$, $SE = .005$, $p < .001$), degree of nerve sparing ($B = .38$, $.10$, $p < .001$), and pre-treatment sexual activity ($B = .43$, $SE = .04$, $p < .001$). None of the level-2 variables were significantly associated with the trajectory of men's rate of sexual activity across time. Conclusion Thus, results suggested that younger men with higher pre-treatment sexual activity who had nerve sparing procedures had higher rates of sexual activity early after surgery than did other men. These differences in rates of sexual activity did not remain significant over time. This has clinical implications for improving the accuracy of the information provided to men about what to expect after surgery.**CORRESPONDING AUTHOR:** Kelsey Sewell, Ph.D., University of Kansas Health System, Kansas City, KS; kelseys@kumc.edu

10:00 AM-11:00 AM

FACTORS ASSOCIATED WITH MONTHLY RATES OF SEXUAL ACTIVITY AFTER PROSTATECTOMY

Kelsey Sewell, Ph.D.¹, Heather Kruse, Ph.D.¹, Donald Strassberg, Ph.D., ABPP², Christopher Dechet, MD³¹University of Kansas Health System, Kansas City, KS; ²University of Utah, Salt Lake City, UT; ³University of Utah, Huntsman Cancer Institute, Salt lake City, UTIntroduction Sexual activity after prostate cancer treatment has largely been ignored in the literature. This exploratory study sought to answer the following research question: After prostatectomy, is there a monthly association across time between time-varying factors (i.e., level of desire, perceived erectile ability, perceived orgasm ability, confidence in ability to satisfy one's partner, and use of sexual aids) and the frequency of sexual activity? It was hypothesized that the within-person monthly variation of the time varying covariates (TVC) would be associated with a similar monthly change in the frequency of sexual activity. Methods Participants were recruited from Huntsman Cancer Institute (HCI) and included 527 men preparing for prostatectomy. Prior to treatment and up to 9 times across 5 years, participants were administered the Sexual Functioning subscale of the long version of the Expanded Prostate Cancer Index Composite, and were asked about sexual aid use (e.g., PDE-5 inhibitor) and to rate their confidence in their ability to please their partner (1–5 scale). The outcome variable was frequency of sexual activity in the past 4 weeks on a 1 (none at all) to 5 (daily) scale. Results Multilevel modeling procedures were used. Each of the TVCs were significant in the final model, suggesting that on those months when a given man used sexual aids ($B = .20$, $SE = .04$, $p < .001$) and/or had a 1-unit increase above his average levels of desire ($B = 0.15$, $SE = .21$, $p < .001$), confidence in satisfying his partner ($B = .05$, $SE = .02$, $p < .05$), perceived orgasm ability ($B = .23$, $SE = .04$, $p < .001$), and/or perceived erectile ability ($B = .11$, $SE = .04$, $p < .01$), he had a corresponding increase in frequency of sexual activity. Further, the slope of time in months was significant ($B = .003$, $SE = .001$, $p < .05$), suggesting that in addition to the monthly varying association between the TVCs and sexual activity, there was a steady, slight improvement over time in men's frequency of sexual activity. Conclusion Thus, results suggested that there is there a monthly association across time between time-varying factors and the frequency of sexual activity, as well as a slight improvement over time. This has clinical implications for assisting couples with sexual intimacy and expectations after surgery.**CORRESPONDING AUTHOR:** Kelsey Sewell, Ph.D., University of Kansas Health System, Kansas City, KS; kelseys@kumc.edu

10:00 AM-11:00 AM

HUMAN PAPILLOMAVIRUS VACCINATION INITIATION AMONG FOREIGN-BORN WHITE, BLACK, LATINA, AND ASIAN YOUNG ADULT U.S. WOMEN

Madina Agénor, ScD, MPH¹, Sarah Abboud, PhD², Ashley E. Pérez, ScM³, Sonya Borrero, MD, MS⁴

¹Harvard T.H. Chan School of Public Health, Boston, MA; ²University of Illinois at Chicago, Chicago, IL; ³University of California, San Francisco, Millbrae, CA; ⁴University of Pittsburgh School of Medicine, Pittsburgh, PA

Background: Foreign-born women are more likely to live with and die from cervical cancer but less likely to have initiated human papillomavirus (HPV) vaccination compared to U.S.-born women. Although foreign-born women come from diverse racial/ethnic backgrounds and HPV vaccination varies in relation to race/ethnicity, no study has assessed how HPV vaccine uptake relates to both nativity status and race/ethnicity among U.S. girls and women.

Methods: Using 2011–2015 National Health Interview Survey data, we used logistic regression to test for an interaction between nativity status and race/ethnicity in relation to HPV vaccination initiation ($p < 0.00001$) among U.S. women aged 18–31 years. We assessed differences in the odds of HPV vaccination initiation between foreign-born white, black, Latina, and Asian women and U.S.-born white women and between foreign-born women and U.S.-born women in each racial/ethnic group, adjusting for sociodemographic factors. We then included health insurance status and usual source of care in the models to ascertain whether these factors may help explain observed disparities.

Results: The overall prevalence of HPV vaccination initiation among U.S. women aged 18–31 years was 33.2%. Foreign-born white ([odds ratio=] 0.64; [95% confidence interval:] 0.45–0.91), Latina (0.39; 0.16–0.95), and Asian (0.25; 0.09–0.71) women had significantly lower adjusted odds of HPV vaccination initiation compared to U.S.-born white women. Moreover, foreign-born women had significantly lower adjusted odds of initiating HPV vaccination relative to their U.S.-born counterparts among white (0.64; 0.45–0.91), black (0.58; 0.38–0.87), Latina (0.47; 0.38–0.58), and Asian (0.29; 0.20–0.43) women. Including health care factors in the models attenuated the odds ratios comparing foreign-born Latina and Asian women and U.S.-born white women as well as the odds ratios comparing foreign-born black and Asian women and their U.S. counterparts.

Conclusions: The association between nativity status and HPV vaccination initiation varies across and within racial/ethnic groups. Foreign-born Latina and Asian women may be particularly underserved as a result of a lack of access to health insurance and a usual source of care. Tailored interventions are needed to facilitate access to HPV vaccines and help prevent cervical cancer among foreign-born women from diverse racial/ethnic backgrounds.

IDENTIFICATION OF AREAS OF PATIENT NEED USING THE CANCER SUPPORT SOURCE™ PROGRAM

Emily Jayne Ross, B.S., M.A.¹, Chelsea Wiener, B.S., M.S.¹, Diane Robinson, PhD, Neuropsychologist², Jeffrey Cassisi, Ph.D., Clinical Health Psychologist¹

¹University of Central Florida, Orlando, FL; ²Orlando Health, Orlando, FL

Understanding, screening, and providing resources for quality of life factors and psychosocial distress have become an important area of focus in cancer care. Psychosocial distress prevalence rates range from 30% to 40%, the magnitude of distress intensity varying from cancer treatment side effects, disease progression, and individual states and traits. Elevated psychosocial distress levels increase the risk of developing clinical levels of depression and anxiety, immune suppression; lengthened hospital stays, increased treatment costs, and overall impacting suicidality, morbidity, and mortality rates. Clearly, measuring and addressing the psychosocial needs of cancer patients is crucial for their quality of life.

The Cancer Support Source™ (CSS) has been widely implemented for psychosocial distress screening in 100 community affiliates and outpatient treatment centers across the nation. Orlando Health UF Health Cancer currently uses the CSS as a standard of clinical care for all patients screened for psychosocial distress. This study investigated the underlying factor structure of the 25-item CSS using a sample of 332 patient data responses from the Cancer Center, the only one in Central Florida to be recognized by the State of Florida as a Cancer Center of Excellence. The goal was to explore the underlying factor dimensions to facilitate and optimize clinic operations for the utilization of distress screening. A PCA (an exploratory, dimension reduction approach) identified five coherent factors: Factor 1 (Emotional Distress/CSC Referral) 14 items, Factor 2 (Physical Health Concerns/Medical Clinic Referral) 5 items, Factor 3 (Resource Needs/Case Management Referral) 4 items, Factor 4 (Reproductive Health) 1 item, and Factor 5 (Substance Use) 1 item.

Results indicated the 25-item CSS has meaningful, underlying dimensions. Further work is underway to develop easily scored Referral subscales to ascertain more parsimonious areas for referral presented by the cancer patient population. The 25-item CSS could be refined and enhanced to include Referral subscales to better identify areas of referral for each individual patient that is screened for psychosocial distress.

These findings provide an opportunity to impact patient care, patient experience, and resource allocation in cancer care in a community or hospital setting using this psychosocial distress screening instrument.

ILLNESS PERCEPTIONS AND PERCEIVED STRESS IN PATIENTS WITH ADVANCED CANCER

Jessica Miceli, MS¹, David Geller, MD¹, Allan Tsung, MD¹, Wallis Marsh, MD¹, Michael H. Antoni, PhD², Frank Penedo, PhD³, Lora Burke, PHD, MPH, RN, SBM, FAHA, FAAN¹, Kathleen Ell, DSW⁴, Jennifer Steel, PhD¹, Shutian Shen, N/A¹

¹University of Pittsburgh, Pittsburgh, PA; ²University of Miami, Coral Gables, FL; ³Northwestern University, Chicago, IL; ⁴University of Southern California, Los Angeles, CA

Background/Objective: According to the Common Sense Model of Self-Regulation of Health and Illness, when a person is faced with a perceived threat, they make assumptions about their illness which influences treatment decisions. The Life Course theory also puts an individual's life within a historic, social, and cultural context. The aims of this study were to (1) describe perceived stress and illness perception according to a patients' demography and (2) examine whether duration since the cancer diagnosis influenced perceived stress and/or illness perception.

Methods: Participants were administered a battery of questionnaires that included a Sociodemographic Questionnaire, the Illness Perception Questionnaire, Brief Version (Brief-IPQ), and the Perceived Stress Scale (PSS). Descriptive statistics, Pearson correlations, and ANOVA were performed to test hypotheses. A total score on the Brief-IPQ represents degree of threat, wherein a higher score demonstrates increased perceived threat.

Results: Of the 627 patients enrolled in the study, the mean age at cancer diagnosis was 62 (SD=11); the majority of patients were male (63%) and Caucasian (91%). Thirty-six percent of patients had been diagnosed with cancer within the past month and 64% had received a diagnosis greater than one month prior to the administration of the questionnaires. The mean PSS score was 21.9 (S.D.=8.3) which is higher than the mean for the general population. The mean IPQ score was 48.7 (S.D.=19.5). Time since diagnosis was not related to the total PSS score [F(1,545)=1.286, p=0.257] or to IPQ [F(1,489)=0.250, p=0.617]. The PSS and IPQ were correlated ($r=0.234$, p).

Conclusions: Our findings suggest that people who perceive their illness as more threatening experience increased rates of stress. Alternatively, those who have high levels of stress may also perceive their illness as more threatening. The prospective study of the link between perceived stress and illness perception is warranted to determine if reducing an individuals' stress may improve their illness perception.

MINIMIZING DIFFERENTIAL ATTRITION IN A LONGITUDINAL STUDY OF LUNG CANCER PATIENTS ON ACTIVE ONCOLOGIC TREATMENT

Julie C. Kim, B.A.¹, Timothy J. Williamson, M.A., MPH¹, Annette L. Stanton, Ph.D.²

¹University of California, Los Angeles, Los Angeles, CA; ²Department of Psychology, University of California, Los Angeles, Los Angeles, CA

Background: Participant attrition is important to understand and address, particularly if participants who discontinue in a study differ systematically on demographic, medical, or psychological characteristics, as compared to participants who complete all phases of the study (i.e., differential attrition). Underrepresented groups in oncology research (e.g., racial/ethnic minorities) evidence high rates of attrition, and strategies (i.e., flexibility for participants, collaboration with medical team, fostering relationships, minimizing financial and transportation burden) have been suggested by researchers to reduce disparities in research participation. However, less is known about whether these strategies mitigate differential attrition. The current study describes a 12-week longitudinal study in lung cancer patients on active oncologic treatment. The aforementioned strategies were implemented in this study a priori to prevent differential attrition. As such, we aim to evaluate demographic characteristics (i.e., age, education, race/ethnicity, socioeconomic status [SES]), medical information (i.e. cancer stage, time since diagnosis), and symptoms (i.e., depressive symptoms, cancer-related anxiety, bothersome physical symptoms) as predictors of attrition.

Method: Participants (n=82; 52% male, mean [SD] age = 64.0 [10.4]) were men and women receiving medical treatment for lung cancer. Participants completed questionnaires on sociodemographic and medical information and validated measures of depressive symptoms, cancer-related anxiety, and physical symptoms at study entry. Logistic regression determined whether demographic characteristics, medical information, and physical and psychological symptoms predicted attrition. Predictors were entered simultaneously to assess each predictor's independent contributions to participant attrition. Zero-order relationships between predictors and attrition were also explored with logistic regression.

Results: No predictor was associated significantly with attrition (LR $\chi^2 = 8.16$, $p = .518$, $R^2 = .18$), despite potentially meaningful odds ratios for race/ethnicity and SES. Additionally, each zero-order logistic regression indicated nonsignificant relationships between each predictor and attrition ($ps > .106$).

Conclusions: No demographic, medical, or symptom variable significantly predicted attrition, which is inconsistent with previous research. It is possible that the strategies implemented to address differential attrition reduced participant burden. Experimental research is needed to strengthen causal inference for these claims.

PHYSICAL ACTIVITY AND ANNUAL MEDICAL OUTLAY IN U.S. COLORECTAL, BREAST AND PROSTATE CANCER SURVIVORS

Alice Yan, MD, PhD

School of Public Health/University of Wisconsin, Milwaukee, WI

Background: Multiple chronic conditions in cancer survivors are highly prevalent and may increase health care costs for both patients and the health care system. Studies of cancer survivors reveal positive effects of physical activity (PA) on reducing risk of cancer recurrence, other chronic conditions, and secondary cancer. Few nationally representative studies have examined how physical activity levels have affected survivors' annual economic burden in the United States.

Methods: Leisure-time physical activity data from the National Health Interview Survey was linked to health care expenditure data from the Medical Expenditure Panel Survey data (2008 – 2012). We calculated per-person annual total medical expenditures for identified colorectal, breast, and prostate cancer survivors. We conducted multivariable analyses controlled for survival years and other sociodemographic variables. Generalized linear models were performed to measure correlation between medical expenditure and PA level using STATA 14. All analyses considered the complex survey design.

Results: Of 1,015 cancer survivors sampled, 30% (n=305) adhered to physical activity recommendation, while the other 70% (n=710) did not. Multivariate-adjusted expenditure in adherence group was \$9,108.8 (95% CI 7,410.9–10,806.7) versus 12,899.1 (95% CI 11,450.2–14,348) in non-adherence group. Stratified analyses revealed cancer survivors who adhered to their PA recommendation saved \$4,686.1 (1–5 years' survival time) and \$2,874.5 (11 or more years' survival time) on average for total health care expenditure, respectively.

Conclusions: Analyses of the national representative sample revealed that the economic burden of survivors from the three most prevalent cancers is substantial. Increasing survivor's physical activity to guidelines may reduce U.S. health care expenditure.

PHYSICAL ACTIVITY IN OLDER SURVIVORS: WHAT ROLE DO MULTIMORBIDITY AND PERCEIVED DISABILITY PLAY?

Shirley M. Bluethmann, PhD, MPH¹, Wayne Foo, MPH², Renate Winkels, PhD¹, Kathryn H. Schmitz, MSeD, MPH, PhD³

¹Penn State College of Medicine/Penn State Cancer Institute, Hershey, PA; ²Penn State Cancer Institute, Hummelstown, PA; ³Penn State University College of Medicine, Hershey, PA

Background: Older survivors experience physical deterioration from aging and cancer treatment. Physical activity (PA) may mitigate these symptoms but is underutilized. The extent to which physical limitations from chronic conditions ("multimorbidity") affect PA post-diagnosis is not well understood. Further, the role of perceived disability due to these conditions as a factor in PA participation among older survivors is not known. The purpose of this paper is to 1) describe the relationship of multimorbidity and PA in cancer survivors and 2) explore perceived disability relative to PA in older survivors.

Methods: We collected data from multi-site cancer survivors (n=523), identified using the Pennsylvania Cancer Registry, who were mailed a BRFSS-based questionnaire. We created age-related subgroups (e.g., 45–54, 55–64, 65–74, 75+) and calculated a composite score of 7 common comorbidities (e.g., COPD, heart disease) to assess multimorbidity. Perceived disability was assessed by asking participants if multimorbidity limited activities. Logistic regression estimated the association of demographic and behavioral risk factors (e.g., multimorbidity, perceived disability) with PA.

Results: Most respondents were female (62%), older (mean age 66 years; range 45–95 years) and represented diverse cancer sites, including breast (n=132), gynecologic (n=106), prostate (n=111), colorectal (n=95) and lung (n=72) cancer survivors. PA participation was generally high; 68% reported exercise at least once in the past month. However, PA varied by cancer site. Lung (OR=0.41, CI 0.23–0.76) and gynecologic (OR=.55, CI 0.32–0.95) cancer survivors were significantly less likely than breast cancer survivors to report PA. Survivors age 75+ were half as likely (OR=0.51, CI 0.25, 1.05) as younger groups to report doing PA.

Survivors that did not do PA had a higher average multimorbidity score by 0.51 (p<.001). Lung cancer survivors had the greatest multimorbidity (mean score 2.04) compared to survivors overall (mean score 1.24). Most survivors (65%) did not perceive disability limited their activities, but more lung cancer survivors (51%) indicated this was the case than other survivors overall (22%). Survivors that did not perceive themselves as disabled were nearly three times more likely to do PA (OR=2.86, CI 1.9–4.3) than survivors with perceived disability, controlling for covariates.

Conclusion: Multimorbidity and perceived disability were negatively associated with PA and varied by age and cancer site. More Lung and gynecologic survivors perceived themselves as disabled than other survivors. Designing interventions that address multimorbidity and reduce perceived disability, especially for lung and gynecologic cancer survivors, may provide opportunities for these older survivors to use PA to mitigate their symptoms and improve quality of life.

PREDICTORS OF BLACK & WHITE MEN'S WILLINGNESS TO DISCUSS PROSTATE CANCER CLINICAL TRIALS

Lauren M. Hamel, PhD¹, Nicole Senft, PhD¹, Louis Penner, PhD¹, Terrance Albrecht, PhD¹, Elisabeth Heath, MD¹, Dina Lansey, MSN, RN², Michael Carducci, MD, FACP, FASCO², Tanina Foster, PhD¹, Mark Manning, PhD¹, Seongho Kim, PhD¹, Mark Wojda, MA¹, Susan Egely, PhD¹

¹Wayne State University/Karmanos Cancer Institute, Detroit, MI; ²Johns Hopkins/Sidney Kimmel Cancer Center, Baltimore, MD

Background: Few cancer patients, especially racial/ethnic minorities, enroll in clinical trials (CTs) in the United States, in part due to factors related to patient-physician communication. As part of a larger study on improving minority enrollment in prostate cancer CTs, we report preliminary analyses of how patients' demographics, attitudes, and perceptions predict willingness to discuss a CT with a physician.

Method: Black and White patients of 11 participating physicians at one data collection site (a comprehensive cancer center in Detroit, MI) were recruited if they had \geq intermediate-risk prostate cancer. Baseline surveys assessed: demographics (age, education, income, and race); health literacy; perceived economic burden; trust in physicians; group-based medical mistrust (mistrust in the healthcare system's treatment of one's racial/ethnic group); and willingness to discuss a CT with a physician. Using linear regression, we first assessed the effects of demographics on willingness to discuss a CT; then we tested these effects along with attitudes and perceptions known to covary with demographics including: health literacy, perceived economic burden, trust in physicians, and group-based medical mistrust.

Results: In the first regression model, patients (n=93; 49 Black and 44 White) were more willing to discuss a CT if they were White (B=.56, p=.03), younger (B=-.04, p=.02), and had higher levels of education (B=.15, p=.03); the association with income was not significant. With the inclusion of additional variables in the second regression model, neither race nor education remained significant predictors. Patients were more willing to discuss a CT if they reported less economic burden (B=.31, p=.04) and less group-based medical mistrust (B=-.40, p=.05), suggesting these factors may mediate the effects of race and education on willingness to discuss a CT.

Discussion: After controlling for demographics, patients' willingness to discuss a CT with a physician was associated with perceived economic burden and mistrust in healthcare systems' treatment of members of their racial/ethnic group, which covary with patient race. Findings suggest that to increase Black cancer patient enrollment in CTs, providers and healthcare systems should better address patients' concerns about economic burden and their mistrust in healthcare systems.

PREDICTORS OF HPV VACCINE SERIES COMPLETION AMONG LOW-INCOME HISPANIC ADOLESCENTS: FINDINGS FROM A LONGITUDINAL STUDY

Mary A. Gerend, PhD¹, Yesenia P. Mendez, Medical Student², Michelle M. Kazmer, Ph.D.¹, Elizabeth H. Slate, PhD¹, Elena Reyes, PhD³

¹Florida State University, Tallahassee, FL; ²Florida State University College of Medicine, Tallahassee, FL; ³Florida State University College of Medicine, Immokalee, FL

Background: Cancers caused by human papillomavirus (HPV) occur at disproportionately higher rates among Hispanic men and women. Many of these cancers can now be prevented with HPV vaccination. Although rates of HPV vaccine initiation have been steadily increasing in the United States, the proportion of adolescents who complete the series (receive 2 or 3 doses depending on age at initiation) remains alarmingly low. The purpose of this longitudinal study was to identify predictors of HPV vaccine series completion among low-income Hispanic adolescent girls and boys.

Methods: Data collection took place at a Federally Qualified Health Center in rural southwestern Florida. Children/adolescents (aged 11–17 years) and their caregivers (N=162 dyads) completed the baseline assessment immediately after the child received the first dose of HPV vaccine. The interview assessed demographics, psychosocial (e.g., health beliefs) and cultural (e.g., acculturation) factors, past medical history, and characteristics of the visit when the first dose was administered. HPV vaccine completion status (defined as receipt of 3 doses) was obtained from the child's electronic health record one year after initiation. Predictors of series completion were identified using logistic regression.

Results: One year after initiating the series, 58% (n=94) completed the 3-dose series, 28% received two doses, and 14% received no additional doses. Caregiver predictors of completion included higher self-efficacy and intentions for series completion, as well as knowledge of the number of doses required. Child/adolescent predictors of completion included receiving the first dose at the recommended age (age 11 or 12 vs. 13–17), receiving written information about HPV vaccination, and having a discussion with the doctor about returning for more doses.

Conclusions: Findings suggest several practical strategies for boosting HPV vaccine completion rates. When administering the first dose it is important for health care providers to clarify the number and timing of doses required, provide written information about HPV vaccination, and remind patients about the need to return to the clinic for additional doses. Administering the vaccine when it is routinely recommended (age 11 or 12) and enhancing caregiver self-efficacy and intentions to complete the series may also increase series completion. Ultimately, implementing such practices could serve to reduce disparities in HPV-related cancers.

PSYCHOLOGICAL ADJUSTMENT TO HEALTH CHALLENGES: DO MEN AND WOMEN COPE DIFFERENTLY WITH A DIAGNOSIS OF CHRONIC DISEASE?

Claudia Trudel-Fitzgerald, PhD¹, Shelley S. Tworoger, PhD², Laura D. Kubzansky, PhD, MPH¹¹Harvard T.H. Chan School of Public Health, Boston, MA; ²Moffitt Cancer Center, Tampa, FL

Cardiometabolic diseases and cancer are the most commonly diagnosed diseases worldwide. Other illnesses, such as rheumatism arthritis (RA), are long-standing conditions that reduce physical functioning. There is a general perception that psychological states are permanently altered by having a chronic disease, resulting in increased distress; such distress may be higher in women. Yet, as study participants are often recruited shortly after diagnosis, it is difficult to test if psychological states are permanently altered due to disease onset. We examined Nurses' Health Study women (NHS; aged 30–55 years at baseline) with psychological scales (anxiety 1988/2004; depression 1992/2000; optimism 2004/2012; life satisfaction 2008/2012) at 2 time points and diagnosed with cancer, stroke, diabetes, myocardial infarction (MI) or RA between assessments (case N's range 55 [RA] to 4,200 [cancer] across time frames). To assess burden of multi-morbidity, women diagnosed with more than one illness were categorized as "Multi-diagnosis". Those with no diagnoses were controls ("Healthy"). Linear mixed models tested if distress and well-being levels significantly changed from pre- to post-diagnosis (or over a similar time frame for controls), adjusting for demographics, social support, physical functioning, medication use, year of and time since diagnosis. Inverse probability weights to account for attrition were included in models. Effect sizes (Cohen's *d*) characterized magnitude of change in psychological states between two time points. To explore possible differences by age and sex, similar models were evaluated in younger women (NHSII; aged 25–42 years at baseline) and in men (Health Professional Follow-up Study; aged 40–75 years at baseline). Compared to healthy women, positive states were slightly reduced in older women before and after developing stroke (life satisfaction: $d = -0.25$) or multiple diagnoses (optimism: $d = -0.22$). No other changes in psychological states were evident in older women. Likewise, men solely reported increased depression after stroke ($d = 0.27$) and decreased life satisfaction after multiple diagnoses ($d = -0.29$). Younger women showed more changes, including a moderate increase in depression with multiple diagnoses ($d = 0.39$). Overall, both men and women show little to modest changes in psychological states after a chronic disease diagnosis. Yet, some subgroups may require more clinical attention, including younger women and those with stroke or more than one illness within a few years.

QUALITY OF LIFE AMONG CANCER SURVIVORS BY DELIVERY MODEL OF SURVIVORSHIP CARE: A LONGITUDINAL SURVEY

Hannah Arem, PhD¹, Sarah Raskin, PhD², Mandi Pratt-Chapman, MA³, Katherine H. Mead, PhD¹¹George Washington Milken Institute School of Public Health, Washington, DC; ²Virginia Commonwealth University, Ashburn, VA; ³Institute for Patient-Centered Initiatives and Health Equity at the GW Cancer Center, Washington, DC

Introduction: There were an estimated 15.5 million cancer survivors in the U.S. in 2016, with projected growth to an estimated 20.3 million survivors by 2026. Despite general guidelines for cancer survivorship care, there is still wide variation in care delivery; patient-reported outcomes associated with distinct care delivery systems are unknown. We thus examined differences in patient-reported quality of life (QoL) (physical, emotional, and practical) by three models of cancer survivorship care.

Methods: We conducted a comparative effectiveness research trial, receiving survey responses from $n=991$ cancer survivors at 32 high-performing Commission on Cancer-accredited centers in 2015. There were a total of four data collection time points: baseline (pre-survivorship visit, 1 week post-survivorship visit, 3 months post-baseline, and 6 months post-baseline). Organizational surveys and interviews were used to categorize these 32 sites into one of three survivorship care models: A single consultative survivorship visit with care provided primarily onsite, ongoing survivorship care with visits scheduled at predetermined intervals onsite, and survivorship care embedded into oncology. We used SAS proc Anova to compare the differences in QoL by survivorship care model.

Results: The most common cited baseline physical QoL complaints were pain, fatigue, sleep disturbance, memory, weight change, neuropathy, loss of strength, and hot flashes. The most common emotional complaints were defining a new sense of normal, managing difficult emotions, living with uncertainty, fear of recurrence, managing stress, and having a sense of well-being. The most common practical complaints were financial concerns and medical debt. At baseline, there were significant differences in percentage reporting these common physical complaints by care model, with more physical complaints among the single consultative visit model ($p=0.024$), however at six months there were no significant differences by care model ($p=0.212$). For emotional concerns there were significant differences by model at baseline ($p=0.011$), as well as at 6 months ($p=0.028$), with concerns lowest among the oncology-embedded model. For practical concerns, there were no significant differences by model at baseline ($p=0.725$) or at 6 months ($p=0.123$). Across all models, there were significant reductions in the percentage of items reported as a concern from baseline to 6 months.

Conclusions: While there were differences in self-reported quality of life metrics by care model for both physical and emotional concerns at baseline, only differences in emotional concerns persisted over 6 months. These findings suggest that specialized programs may want to consider how oncology embedded programs are addressing emotional concerns in order to improve survivorship care programs.

REDUCING BARRIERS TO FLEXIBLE SIGMOIDOSCOPY WITH ACTIVE CHOICE OF ENDOSCOPIST: AN EXPERIMENTAL ONLINE SURVEY

Sandro Tiziano, Stoffel, N/A¹, Lesley M. McGregor, PhD², Robert S. Kerrison, N/A³, Yasemin Hirst, PhD², Jo Waller, PhD¹, Alexander Ghanouni, BSc MSc PhD², Christian von Wagner, PhD¹

¹UCL, London, England, United Kingdom; ²University College London, London, England, United Kingdom; ³University College London, London, N/A, United Kingdom

Background: Flexible Sigmoidoscopy (FS) screening has been introduced in England. However, uptake is low. Strikingly, uptake among women is only half that of breast and cervical screening. This might be improved by offering women their preferred choice of the sex of the endoscopist. We tested whether offering an active choice increases intention compared with standard defaults (either male or female endoscopist) or usual care (i.e. no information) in a sample of women who had stated that they did not intend to have FS screening.

Method: 4,358 women aged 35–54 years living in England took part in an online survey. After being informed about FS screening, 1,060 (24.3%) stated that they did not intend to participate. These participants were randomised to one of four experimental conditions with different information about the sex of the practitioner: 1) usual care (unknown sex); 2) male endoscopist default 3) female endoscopist default and 4) active choice (the patient can choose the endoscopist). The primary outcome was intention to participate after receiving information on sex of the endoscopist. Respondents also answered comprehension and manipulation checks. We used multivariable logistic regression adjusting for age, employment, socio-economic deprivation, living condition, ethnicity and self-reported health status.

Results: Respondents were mostly White-British (83.6%), married or living with someone (62.4%), working (63.3%) and with low individual social deprivation (42.2%). 1,010 of 1,060 (95.3%) women successfully completed all comprehension and manipulation checks. A large share of women in the active choice group (64.4%) expressed a preference for a female practitioner and there was partial support for our hypothesis. Compared with usual care, active choice and offering a female endoscopist by default significantly increased intention among disinclined women (16.0% vs. 9.3%; OR 1.83; 95%CI 1.06–3.15; Female: 17.9% vs 9.3%, OR 2.08, 95% CI 1.24–3.50). There was no difference between usual care and offering a male endoscopist (9.3% vs. 9.8%; $p > .05$). However, active choice did not increase intentions to have FS screening compared with offering a female endoscopist by default (16.0% vs 17.9%, $p > .05$).

Discussion: While offering disinclined women an active choice of the sex of the endoscopist increased intention, there was no added benefit over simply allocating them a female endoscopist. This suggests that active choice does not outperform standard defaults in settings where the default complies with the dominating preference. Future research should test whether active choice may be more effective in settings where people have more diverse preferences. A Randomised Controlled Trial should test whether providing a female endoscopist improves FS screening uptake in women.

RESULTS OF AN INTERNET-BASED INTERVENTION TO IMPROVE ADHERENCE AND PSYCHOSOCIAL OUTCOMES IN CANCER PATIENTS

Philip J. Fizur, PsyD¹, Nataliya Zelikovsky, Ph.D.², Cori E. McMahon, PsyD³, Michael E. Sude, PhD²

¹Cooper University Hospital, Camden, NJ; ²La Salle University, Philadelphia, PA; ³Tridium, Inc., Wayne, PA

Research suggests interventions targeting distress and adherence in cancer patients may improve their physical and emotional health as well as treatment outcomes. Such interventions exist and are effective but are underused due to patient and organizational roadblocks; few studies examine adherence in this population. The present study piloted an Internet-based intervention to address many of these issues. The study asked 45 cancer patients in active treatment to use this intervention for 3 months, assessing distress and adherence at baseline and post-intervention using the Depression Anxiety Stress Scales (DASS) and Morisky Medication Adherence Scale (MMAS) respectively. Usability and acceptability were also examined. The intervention included psycho-education (information on problem solving therapy and mindfulness), brief intervention (worksheets and recordings relevant to the education), regimen planning tools (electronic reminders for appointments and medication), and a social networking component. Results suggested good acceptability and usability with limited effectiveness. Specifically, 70 of the 86 subjects approached for participation (81%) consented to the study and, of those who completed the study, the majority at least somewhat agreed (rating of ≥ 3 on a Likert scale of 1 to 5) that the intervention was easy to use and navigate, that the content was helpful, and that they were at least somewhat satisfied with the site. Data suggests the education and brief intervention components were used most and, on average, received the highest possible rating for usability and helpfulness. The number of subjects who completed the study, however, was lower than expected (35%) and there were no significant differences from baseline to post-intervention in the measures of adherence (MMAS ($t(24) = -1.38, p = .18$)) or distress (DASS ($t(24) = 0.41, p = .68$)). A possible ceiling effect (e.g., distress and adherence were minimal at baseline); a preference for using commercial products whose functionality were replicated in this intervention; and feedback suggesting the content was better suited for post-active treatment may explain the limited effectiveness. Overall findings suggest potential for this intervention but that more focus on education and brief intervention is required while integrating existing commercial products to reduce redundancies. The latter finding also highlights the utility of the emerging trend of academic-industry partnerships.

SIGNS VERSUS SYMPTOMS: AN INVESTIGATION OF COGNITIVE DYSFUNCTION IN CANCER PATIENTS AND HEALTHY CONTROLS

Thomas R. Valentine, MA¹, David M. Weiss, MA¹, Mary Y. Carson¹, Abigail S. Robbertz², Marcia F. Burns¹, Barbara L. Andersen, PhD¹¹The Ohio State University, Columbus, OH; ²The Ohio State University, New Albany, OH

Introduction: Cognitive dysfunction is common in cancer patients. Patient perceptions of cognitive functioning are readily assessed via self-report measures such as the Patient-Reported Outcomes Measurement Information System (PROMIS) Cognitive Function scale. However, it is unclear whether cancer patients' responses on PROMIS Cognitive Function are a stronger indicator of objective cognitive functioning or emotional health. The current study examines the relationships between PROMIS Cognitive Function, objective cognition, and emotional health in patients with chronic lymphocytic leukemia (CLL) and non-cancer controls.

Methods: Forty-four (44) patients with CLL were evaluated at baseline in a phase Ib/II trial of obinutuzumab, ibrutinib, and venetoclax. An equal number of age- and gender-matched non-cancer controls provided data for comparison. All participants completed measures of perceived cognitive functioning (PROMIS Cognitive Function), objective cognitive functioning [NIH Toolbox Auditory Verbal Learning Test (AVLT), Controlled Oral Word Association Test (COWAT)], and emotional health (Patient Health Questionnaire-9, Generalized Anxiety Disorder-7, Profile of Mood States). Bivariate correlations examined relationships among these constructs. Independent-samples *t*-tests examined differences between patients with CLL and non-cancer controls.

Results: PROMIS Cognitive Function was significantly correlated with depressive symptoms, anxiety symptoms, and mood disturbance in patients with CLL ($\rho = 0.61, p < 0.001$; $\rho = 0.40, p < 0.001$; $\rho = 0.69, p < 0.001$, respectively) and non-cancer controls ($\rho = 0.53, p < 0.001$; $\rho = 0.78, p < 0.001$; $\rho = 0.73, p < 0.001$, respectively). Correlations between PROMIS Cognitive Function and objective cognitive measures were non-significant in both samples ($ps > 0.05$). Non-cancer controls outperformed patients with CLL on objective measures of cognition [AVLT: $t(86) = 3.020, p = 0.003$; COWAT: $t(86) = 2.92, p = 0.004$], but there were no significant differences on PROMIS Cognitive Function or measures of depressive symptoms, anxiety symptoms, or mood disturbance. Six patients with CLL (13.6%) exhibited cognitive impairment (z -score ≤ -1.5) on at least one objective cognitive measure, compared to one non-cancer control participant (2.3%).

Conclusion: PROMIS Cognitive Function is associated with depressive symptoms, anxiety symptoms, and mood. There is little evidence to support the relationship between PROMIS Cognitive Function and objective cognitive measures. Clinicians should consider PROMIS Cognitive Function to be reflective of emotional health. Assessment of cancer-related cognitive changes should be based on objective measures.

SMOKING STATUS DIFFERENCES IN PARTNER SUPPORT FOR SMOKING CESSATION IN CANCER PATIENTS

Diana Kwon, B.S.¹, Elyse Park, Ph.D., MPH², Giselle K. Perez, PhD³, Julia T. Rabin, B.A.³, Emily Friedman, B.A.³, Jamie Ostroff, PhD¹¹Memorial Sloan Kettering Cancer Center, New York, NY; ²MGH, Boston, MA; ³Massachusetts General Hospital, Boston, MA

Introduction: Continued smoking after a cancer diagnosis is associated with treatment complications, disease recurrence, and second primary cancers. Yet, a significant proportion of patients continue smoking such that a need to identify factors associated with smoking cessation following cancer diagnosis exists. In the general population, prior studies have examined the impact partner/spousal support has on smoking cessation. Positive behaviors, such as reinforcement, from a partner/spouse increase patients' abstinence rates, while negative behaviors, such as nagging, decrease quitting and increase relapse rates. We examined partner/spouse smoking status differences in expected partner support for smoking cessation among newly diagnosed cancer patients.

Method: Newly diagnosed cancer patients (≤ 4 months of diagnosis) who live with a partner/spouse ($N = 90$) completed baseline questionnaires assessing demographic characteristics, smoking history and type of smoking cessation support they expect to receive from a spouse/partner (items from Partner Interaction Questionnaire (PIQ); Cohen & Lichtenstein, 1990; range = 0 to 4; higher scores indicate behaviors expected more frequently) as part of a larger, ongoing study.

Results: Patients' median age was 56, 59% were female, and 80% identified as non-Hispanic White. Patients were recruited from various cancer clinics: breast (26%), thoracic (24%), GU (22%), GI (12%), head and neck (9%), lymphoma (3%), and gynecologic (3%). In terms of partner/spouse smoking status, 64% ($N = 58$) were identified as current smokers. Partner/spousal smoking status does not impact expected *positive* cessation support, ($t(83) = 0.986, p > 0.05$). However, partner/spousal smoking status did significantly impact expected *negative* cessation support; patients with partners/spouses identified as current smokers expected more negative cessation support (PIQ $M = 9.9, SD = 5.4, N = 29$) than patients with nonsmoking partners/spouses ((PIQ $M = 7.5, SD = 4.8, N = 57$), $t(84) = 2.117, p < 0.05$).

Discussion: Partner/spousal smoking status may be an important driver of expected cessation support, such that patients with nonsmoking partners/spouses are more likely to expect negative cessation support. These preliminary findings suggest that greater education concerning cessation support preferences may be important, particularly for nonsmoking partners/spouses.

SOCIODEMOGRAPHIC VARIATION IN A NOVEL BEHAVIOURAL RISK FACTOR INDEX FOR CANCER

Samantha Quaipe, PhD¹, Jo Waller, PhD², Claire Stevens, MSc¹, Charlotte Vrinten, MSc¹, Samuel Smith, PhD³, Lion Shahab, PhD¹, Christian von Wagner, PhD²

¹University College London, London, England, United Kingdom; ²UCL, London, England, United Kingdom; ³University of Leeds, Leeds, England, United Kingdom

Background: Modifiable behavioural and environmental risk factors are estimated to cause 43% of cancers in the UK. Behavioural risk factors often cluster within individuals; particularly those from socioeconomically deprived backgrounds, exacerbating cancer risk. Previous studies of behavioural risk have typically summed the number of exposures. We propose a novel behavioural risk factor index which accounts for the relative contribution of each behaviour to cancer incidence by creating a weighted composite risk score.

Methods: A population-representative sample of English adults (n=2027; aged 18–70 years) participated in computer-assisted face-to-face surveys. Data were used to determine adherence to UK cancer prevention guidelines for tobacco smoking, body weight, alcohol, fruit and vegetable intake, and physical activity. Two indices were compared. First, the number of behavioural risk factors was summed (summary index). Second, a novel behavioural risk factor index was created by weighting the scores for individual behaviours according to their relative contribution to cancer incidence (weighted index). Knowledge of cancer risk factors was assessed using a subscale from the Cancer Awareness Measure. We also collected data on age, sex, ethnicity, marital status, education, social grade, self-rated health and cancer experience.

Results: In unadjusted analyses, male sex, older age, single relationship status, White ethnicity, lower education, lower social grade, poorer self-rated health and lower knowledge of cancer risk factors predicted higher scores on the weighted index (all p's <.05). These associations remained in adjusted regression models. For the summary index, sex, age, ethnicity, education, social grade, self-rated health and risk factor knowledge were also associated with higher scores (all p's <.05). However, age, sex, education and social grade were no longer statistically significant predictors after adjusting for self-rated health and cancer risk factor knowledge in multivariate regression analyses.

Conclusions: Independent of knowledge, there was greater demographic variation in behavioural risk when the severity of risk conferred by each type of behaviour was taken into account. We had not anticipated an association with White ethnicity, which deserves further study. A more nuanced understanding of demographic variation in behavioural risk profiles could inform population initiatives driven to reduce cancer incidence.

SPRAY TANNING PREVALENCE AND MOTIVATIONS AMONG UNDERGRADUATE AND GRADUATE STUDENTS AT A SOUTHEASTERN U.S. UNIVERSITY

Casey L. Daniel, PhD, MPH¹, Alyssa M. Fernandez, MPH², Danielle Keyes, MPH³, Natalie R. Gassman, Ph.D.⁴, Sejong Bae, Ph.D.⁵, Marcus Tan, MBBS, FACS³

¹University of South Alabama Mitchell Cancer Institute, Mobile, AL; ²USA Mitchell Cancer Institute, Mobile, AL; ³University of South Alabama, Mobile, AL; ⁴University of South Alabama Mitchell Cancer Institute, MOBILE, AL; ⁵University of Alabama at Birmingham, Birmingham, AL

Background: Rates of melanoma have risen dramatically in the United States in recent decades, particularly among young women. A major contributing factor for this is exposure to ultraviolet radiation (UV) through indoor and outdoor tanning. Sunless tanning methods, such as spray tanning (ST), have been promoted as safer alternatives to UV tanning. While ST appears to be increasingly popular, its adoption as an alternative to UV tanning is still largely undefined. This study assessed ST prevalence and associated factors among undergraduate and graduate students at the same university.

Methods: Students at a public university in the southeastern United States were invited to complete an online survey about their participation, knowledge, and attitudes regarding indoor, outdoor, and spray tanning. Univariate and multivariate analyses were performed to identify factors associated with ST among undergraduate and graduate students, respectively.

Results: 566 of 2,668 (21.2%) of undergraduate and 373 of 1193 (31.3%) of graduate students reported ever ST. Variables significantly associated with increased likelihood of spray tanning in undergraduate and graduate students included: self-reported outdoor tanning (OR=6.61, 95% CI [4.95, 8.83], and OR=15.40 [11.49, 20.65], respectively); current indoor tanning (OR=2.24 [1.78, 2.82] and OR=12.47 [3.91, 39.77]); concern about skin damage (OR=2.12 [1.72, 2.62] and OR=1.78 [1.35, 2.34]); agreement that, "tanning beds can definitely cause skin cancer" (OR=1.60 [1.23, 2.06] and OR=1.87 [1.33, 2.63]); and family history of melanoma (OR=1.48 [1.05, 2.07] and OR=2.26 [1.56, 3.26]).

Conclusions: Both student populations demonstrated substantial engagement in ST. Variables with the strongest association with ST were engagement in outdoor and indoor tanning, suggesting that ST is used as a supplement to, rather than a substitute for, UV tanning. Future work is needed to examine tanning methods in combination and to examine the effectiveness of interventions promoting sunless tanning methods as alternatives to UV tanning. Additionally, future research should explore the dissonance between reported perceptions and attitudes regarding the dangers of tanning behaviors despite continued participation.

TAKING A STEPPED CARE APPROACH TO TREATING INSOMNIA IN CANCER SURVIVORS

Eric S. Zhou, PhD, Ann Partridge, MD, MPH, Alexis L. Michaud, BA, Christopher J. Recklitis, PhD, MPH

Dana-Farber Cancer Institute, Boston, MA

Background: Cognitive-behavioral therapy for insomnia (CBT-I) is highly effective and widely endorsed as a preferred first-line treatment. Unfortunately, cancer survivors are unlikely to receive CBT-I, even in centers delivering specialized cancer survivorship care. Their untreated insomnia is associated with a broad range of physical and psychological health consequences. Treatment barriers include a lack of trained clinicians, as well as standard treatment duration and format (6–8 individual sessions). To improve CBT-I access, we delivered insomnia therapy using a stepped care model, with treatment intensity increased only for survivors not responsive to initial treatment.

Methods: 41 survivors (mean age=54 years; 91% female) with insomnia enrolled. They were primarily breast (61%) and blood cancer (28%) survivors, an average of 11.3 years post-diagnosis. Participants completed the Insomnia Severity Index (ISI) at baseline before initially receiving the low-intensity treatment: a single, 30-minute sleep hygiene education session. After 4 weeks, they completed the ISI again. If their insomnia was not resolved by low-intensity treatment (ISI <12), they were offered the high-intensity treatment: a three session CBT-I group program (60 minutes/session) developed for cancer survivors. Participants completed the ISI again prior to the CBT-I groups, and 4 weeks later.

Results: Twenty-one (51%) of the 41 survivors who completed the low-intensity treatment were no longer experiencing clinically elevated insomnia (ISI score <12). Of the 20 survivors whose insomnia persisted, to date 9 have received the high-intensity treatment, with 6 (67%) no longer experiencing clinically elevated insomnia following therapy. Effect sizes for insomnia symptom improvement was large at 4-week follow-up for both the low (d=1.1) and high-intensity (d=1.2) treatments.

Conclusions/Implications: Both low and high-intensity therapies are efficacious at treating cancer survivors' insomnia. Data from this ongoing trial will investigate how these gains are maintained over time. The efficacy of a brief sleep hygiene education intervention at treating insomnia in cancer survivors has meaningful dissemination implications as it can be delivered by a non-sleep specialist, and could be developed as a mobile intervention. However, it is worth noting that almost half of survivors required more intensive treatment. Future research should continue to explore ways of leveraging the relatively scarce insomnia expertise to optimize treatment access for cancer survivors.

TECH-BASED APPROACH TO INFORMING MHEALTH PRODUCT CREATION: PARENT PERSPECTIVES OF HPV USING ONLINE SYNCHRONOUS FOCUS GROUPS

Elisabeth R.B. Becker, MPH¹, C. Mary Healy, MD², Erica L. Frost, MPH³, Stanley W. Spinner, MD⁴, Maria E. Fernández, Ph.D.⁵, Lara S. Savas, PhD⁶

¹University of Texas Health Science Center at Houston, School of Public Health, Houston, TX; ²Baylor College of Medicine, Houston, TX; ³The University of Texas Health Science Center at Houston, Houston, TX; ⁴Texas Children's Pediatrics, Houston, TX; ⁵School of Public Health /University of Texas Health Science Center at Houston, Houston, TX; ⁶University of Texas Health Science Center, Houston, School of Public Health, Houston, TX

Background: While Healthy People 2020 has established a goal of 80% completion for adolescent HPV vaccination (13–15 years), series completion rates in a large, primarily insured pediatric clinic network in Houston, TX were 53% in 2016. Understanding attitudes, perceptions and vaccination decision-making processes of parents is an important step in assessing needs to inform vaccine promotion strategies that can be delivered via mHealth applications. Synchronous online focus groups offer a qualitative research method for assessing attitudes and perceptions that provides easy reach, convenience, and cost savings without compromising data fidelity.

Objectives: The objectives of the study were to: (1) Determine how parents make decisions related to HPV vaccination, (2) Understand how the clinic network could facilitate vaccination decision-making via a mHealth application, and (3) Evaluate the feasibility of conducting online synchronous focus groups, an emerging qualitative research method.

Research Design: In October 2016, we conducted four Skype, text-based focus groups with parents of adolescent patients aged 11–13 years. Participants were recruited via flyers and targeted requests by network clinical staff and practice managers. Participants were provided an e-gift card as compensation.

Results/Evaluation: Parents (n=22) from 16 of 51 clinics participated in four 60-minute focus groups, with 4–7 participants per group. Participants were 42 years old on average, mostly female (95%), White (59%), had a college or graduate degree (81%), and had private insurance for their child (82%). Parents cited physician recommendation as a major influence on their decision to vaccinate their child. Parents suggested the clinic network could support HPV vaccine decision making by providing: (1) detailed and reliable information about the HPV vaccine, (2) opportunities to discuss HPV vaccine well in advance of the recommended age, (3) extended appointment days/times, and (4) reminders for follow-up doses. Most parents used Skype sometimes or regularly (86%). Of those indicating a preferred focus group format, 54% preferred text-based, 8% preferred video-based, and 38% had no preference. Cost-savings for the project were estimated at \$260 per session.

Conclusions: Themes emerging from the discussions relating to attitudes, barriers and perceptions of HPV vaccination were similar to other published studies. Synchronous online focus groups provided anonymity and convenience for participants and cost-savings for the project.

Future Plans: This research informed the context and design of a HPV-vaccination parent-focused mHealth application that is currently being tested in a randomized trial within the clinic network.

FAMILY RELATIONSHIPS AND INHIBITION CONTROL IN EMERGING ADULTS WITH ADHD

Erin T. Kaseda, N/A¹, Wendy C. Birmingham, PhD²¹Brigham Young University, Draper, UT; ²Brigham Young University, Provo, UT

Background: It is estimated that between 5–10% of adolescents in the United States have been diagnosed with attention-deficit/hyperactivity disorder (ADHD) with subsequent lower levels of inhibitory control and higher stress. This may negatively impact family dynamics and leave ADHD adolescents perceiving their parents as less-supportive, resulting in lower seeking of self-control advice from parents. ADHD emerging adults (18–19) transitioning to university may be particularly influenced by parental support during this transition to independence. Perceptions of high parental support may reduce stress and increase inhibitory control in this transition. We expect perceptions of greater parental support will be associated with better inhibitory control in emerging adults.

Methods: 10 emerging adults aged 18–19 ($M=18.2$, $N=7$ female) with a diagnosis of ADHD completed surveys on their attitudes towards each of their parents and their perception of their overall family functioning, and participated in cognitive testing using the NIH Toolbox to assess inhibitory control, working memory, and processing speed. Additionally, participants completed a semi-structured interview examining their parents' support, their own self-control, and perceptions of how transition to university has affected self-control and family relationships. The interviews were transcribed and coded for factors that decrease the likelihood of the participants turning to their parents for support or advice.

Results: Participants were white (80%), Latino/a (10%), and Asian (10%) and from middle to high income families. The majority of participants (80%) reported overall supportiveness from both father and mother. Performance on the inhibitory control test was negatively correlated with perception of maternal support ($p=.03$), perception of paternal support ($p=.04$), and perception of overall family functioning ($p=.05$). There was no significant effect of family support on working memory or processing speed. Participants who reported low levels of supportiveness from their parents also reported rarely or never turning to one or more parents for support or advice regarding self-control.

Conclusions: Emerging adults with ADHD face special challenges in adjusting to university and independence particularly in terms of inhibitory control. However, contrary to our expectations, greater perceptions of parental support were not associated with better inhibitory control in these emerging young adults. Research indicates higher network support can actually increase stress via feeling of intrusiveness and obligation. It may be that emerging adults view their parents' support as intrusive, rather than helpful. Future work should examine benefits and detriments of parental support.

PARENT-CHILD RELATIONSHIP QUALITY AND PARENTAL MONITORING AS PREDICTORS OF CHILD EXTERNALIZING BEHAVIORS OVER TIME

Alexander Sokolovsky, PhD, Lauren Micalizzi, PhD, Suzanne Colby, PhD, Nancy Barnett, PhD, Kristina Jackson, PhD

Brown University, Providence, RI

Purpose: Increased parental monitoring and better parent/child relationship quality protect adolescents from externalizing behaviors such as substance use and delinquency. Parental monitoring, consisting of child disclosure (CD), parental control (PC), and parental solicitation (PS) of child behavior is a dyadic interpersonal process between parent and child that likely depends on the quality of the relationship. However, it is unclear if the protective effect of parental monitoring differs across levels of parent/child relationship quality and if these effects change across adolescence.

Methods: Children ($N=911$; 52.4% female; grades 6–8) reported on parental monitoring, two aspects of relationship quality (social support, negative interactions), substance experimentation, and delinquent behaviors in four annual assessments. Substance experimentation indexed the number of substances tried (alcohol, tobacco, marijuana, other drugs). Delinquent behavior indexed six problem behaviors (e.g., truancy, property damage). We fit linear mixed-effects regressions, controlling for sex, race, ethnicity, age, and familial drinking problems. Focal terms were main effects and interactions between linear growth in substance experimentation or delinquency, parental monitoring, and relationship quality.

Results: PC protected against substance experimentation, but only in highly supportive relationships. Greater CD predicted less substance experimentation across adolescence. Contrary to our hypothesis, this effect did not vary as a function of relationship quality. More negative interactions with parents predicted increased substance experimentation over time.

For delinquency, greater CD, PS, and PC predicted less delinquent behavior. These strategies also dampened the increase in delinquency across adolescence, but only in highly supportive relationships. Effects did not vary as a function of negative interactions.

Conclusions: Interventions aimed at increasing CD and improving the quality of parent-child relationships may buffer against externalizing behaviors in adolescence. Further, parents who engage in PC as a protective strategy against externalizing behaviors can increase the effectiveness of these strategies by also providing increased social support for their child.

PRENATAL MOTIVATIONAL INTERVIEWING FOR ENHANCING BREASTFEEDING OUTCOMES: FEASIBILITY AND PRELIMINARY FINDINGS

Sarah H. Addicks, MS, MPH¹, Chelsey L. Morgan, MA², Daniel W. McNeil, PhD³¹West Virginia University, Cleveland, OH; ²Grand Valley State University, Shippensburg, PA; ³West Virginia University, Morgantown, WV

Introduction: Breastfeeding promotes health and well-being for both mother and infant. Many environmental and individual factors, including psychological ones, affect infant feeding practices. The purpose of this study was to determine the feasibility and effectiveness of a single-session Motivational Interviewing (MI) intervention delivered during the third trimester of pregnancy for enhancing breastfeeding outcomes.

Method: The sample consisted of predominantly rural participants living in North Central Appalachia. Women were recruited through social media, local clinics, and word of mouth. Participants ($N = 81$) completed one in-person session during the third trimester of pregnancy and one follow-up phone call at one month postpartum. Participants were randomly assigned to either the MI intervention or a psychoeducation intervention focused on infant developmental milestones. Pre-post intervention outcome measures included feeding intentions, perceived behavioral control of breastfeeding, perceived importance of breastfeeding, infant feeding knowledge, breastfeeding attitudes and subjective norms, and knowledge of infant development. At one month postpartum, participants completed a phone interview which assessed breastfeeding initiation and current breastfeeding status.

Results: Directly following the intervention, there was a significant effect of the MI intervention on increasing breastfeeding attitudes among primiparous women only ($p < .05$). In addition, at one month postpartum, women in the MI group were more likely to report any current breastfeeding than women in the psychoeducation group, $\chi^2(1, N = 79) = 4.30, p = 0.040, \Phi = .233$. There were no between-group differences on intentions, perceived behavioral control, perceived importance, subjective norms, infant feeding knowledge, knowledge of infant development, likelihood of exclusive breastfeeding, total proportion of feedings that were breast milk, or plans for continued breastfeeding at one month postpartum.

Discussion: Results support the feasibility of a single-session, prenatal MI intervention. Preliminary findings demonstrate MI's effectiveness for increasing the likelihood of any breastfeeding at one month postpartum, and in enhancing breastfeeding attitudes among primiparous women. Future work may benefit from adding electronic communication to reinforce messages of MI interventions. Any future work should target populations facing breastfeeding inequities.

RACIAL/ETHNIC DIFFERENCES IN THE RELATIONSHIP BETWEEN STRESSFUL LIFE EVENTS AND QUALITY OF LIFE IN ADOLESCENTS

Gerald Eisman, B.A.¹, Yuzhu Yang, M.S.¹, Jan Wallander, PhD²¹University of California, Merced, Merced, CA; ²University of California, Merced, MERCED, CA

Stressful life events (SLE) impact health because they increase allostatic load and require adaptation. Adolescence is a developmental period that may be disproportionately affected by SLE. The accumulation of SLE has been associated with decreased health related quality of life (HRQOL) among adolescents. This study examined racial/ethnic and developmental differences in the relationship between SLE and HRQOL from pre- to early- to mid-adolescence. Data were from 4,824 participants in the Healthy PassagesTM project, a population-based survey of fifth, seventh, and tenth grade African- American, Latino/a, or White youth from metropolitan cities in the US. HRQOL was measured with PedsQL and SLE with items about family-related SLE (e.g., parent's death, separation, and divorce, family member's injury/illness, residential change, and new child in the household). An autoregressive model with cross-lagged effects revealed that the relationship between SLE and HRQOL was significant across pre-, early-, and mid-adolescence. Further, differences among racial/ethnic groups were significant such that Latino adolescents had a negative association from SLE in pre-adolescence to HRQOL in mid-adolescence. Racial/ethnic differences present in the relationship between SLE and HRQOL need to be considered in prevention efforts aimed at these racial/ethnic groups. For instance, Latino youth may need coping skills training that address negative delayed effects from SLE.

REDUCTION IN BMI Z-SCORE REFLECTS CHANGES IN BODY COMPOSITION IN OBESE CHILDREN

Bryce M. Abbey, PhD, Kate A. Heelan, PhD, R. Todd Bartee, PhD

University of Nebraska at Kearney, Kearney, NE

Childhood obesity continues to be a primary focus related to pediatric disease and health outcomes. BMI z-score changes commonly are used as an indicator of success in childhood obesity treatment programs with clinically meaningful risk factor reduction suggested by reducing BMI z-score by 0.10 or more with increased risk reduction with a BMI z-score reduction of ≥ 0.25 (Ford et al., 2010; Pollestad Kolsgaard et al., 2011). However, BMI z-score reductions do not account for independent changes in body composition.

PURPOSE: To examine the degree in which BMI z-score reductions reflect relative changes in body mass (%WT), body fat percentage (BF%), fat mass index (fat mass (kg)/(height (meters))² (FMI), and lean body mass index (lean body mass (kg)/(height (meters))² (LBMI) in obese children following a 12-week pediatric obesity treatment program.

METHODS: Participants included 47 children (43% boys; mean age = 10.1 ± 1.2 years) with BMI percentile above the 95th percentile (98.0 ± 1.4). Body mass, stature, BMI z-score, BF%, FMI and LBMI were measured at baseline and 12-week post-intervention using a digital scale and GE Lunar Prodigy DXA. BMI z-scores were categorized by clinical significant reductions post intervention ($< 0.10, 0.10 - 0.249, \geq 0.25$) and comparisons were made between body composition measures.

RESULTS: Twenty-one (45%) participants had a BMI z-score reduction ≥ 0.25 and 17 (36%) had a reduction between 0.10 - .249. Significant differences ($p < 0.05$) were found between each clinically meaningful BMI z-score reduction categories for %WT change $< 0.10 (0.19 \pm 2.85), \geq .10 (-3.33 \pm 2.17)$ and (-8.03 ± 3.76) , FMI change $< 0.10 (-0.24 \pm 0.92), \geq 0.10 (-1.34 \pm 0.73), \geq 0.25 (-2.10 \pm 1.06)$, and BF% change $< 0.10 (0.19 \pm 2.04)$ and $\geq 0.25 (-5.23 \pm 2.93)$. There were no significant differences for changes in LBMI across the changes in BMI z-score.

CONCLUSION: At the conclusion of a 12-week pediatric obesity treatment program, clinically meaningful changes in BMI z-score accurately accounted for changes in %WT, BF% and FMI in obese children suggesting BMI z-score reductions may be meaningful in interpreting body composition changes in obese children. Our data, although with a small sample, suggests that a BMI z-score reduction ≥ 0.10 equates to an approximate 3% reduction in body mass, an early literature suggestion to improve health risk in children (Ricchini et al., 1988).

A NOVEL ASSESSMENT FOR UNDERSTANDING THE PARENTAL NICU EXPERIENCE

Victoria A. Grunberg, M.S.¹, Pamela A. Geller, Ph.D.¹, Chavis Patterson, Ph.D.²
¹Drexel University, Philadelphia, PA; ²The Children's Hospital of Philadelphia; Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA

Up to 15% of parents in the U.S. have an infant admitted to a neonatal intensive care unit (NICU) each year. NICU infants are at increased risk for neurodevelopmental impairments and medical complications (Wilson-Costello et al., 2005). The ongoing medical complications of the child can impact financial, social, occupational, and recreational aspects of family life (Stephens et al., 2008). Among children, high levels of parental stress and depression have been associated with more behavior problems, poorer social skills, and reduced play with parents (Huhtala et al., 2012). Although infant health is critical for parental and child outcomes, it remains unclear which specific indices can be used to identify parents who may need additional psychosocial services.

The current study developed the first parental report of NICU infant health severity measure to determine how objective infant health indices can be used to identify parents at-risk for negative psychosocial sequelae. Parents ($N = 199$) whose children were discharged from the NICU six months to three years prior, and co-habiting with partner and child since discharge, were recruited via the internet. Most participants were Caucasian (81.91%) and biological mothers of the infant (91.45%). Average parental age was 31.75 years ($SD = 5.34$). Mean gestational age of infants at birth was 31.54 weeks ($SD = 4.64$) and mean birth weight was 1791.54 grams ($SD = 1000.82$). Fifty-four infants were diagnosed with an additional medical condition after discharge (27.4%) and 47 were diagnosed with a developmental disability (23.6%). A hierarchical cluster analysis was conducted to identify parents at low, medium, and high risk for increased stress and greater family burden. Five clusters were identified: cluster 1 ($N = 77$), parents at lowest risk (i.e., least severe infant health, moderate parental stress, low family burden); cluster 2 ($N = 68$), parents at moderate risk (i.e., moderately severe infant, moderate parental stress, moderate family burden); and clusters 3, 4, and 5 ($N = 8$), parents at highest risk (i.e., severely ill infants, high parental stress, high family burden). Follow-up independent t-tests revealed that clusters 1 and 2 differed on nearly all items of infant health. Psychometric analyses will also be reported. Findings highlight how this novel infant health measure can be used to identify which parents would benefit from additional psychosocial services during and following NICU hospitalization.

A TWO SIDED COIN: POSITIVE AND NEGATIVE SOCIAL INTERACTIONS AND HEALTH AMONG POSTPARTUM WOMEN

Orna Baron-Epel, PhD MPH¹, Ola Ali-Saleh, RN MPH², Michal Cohen-Dar, MD³

¹University of Haifa, Haifa, N/A, Israel; ²Ministry of Health, Haifa, N/A, Israel; ³Ministry of Health, Nazereth, HaZafon, Israel

Background: Studies suggest that social support is positively related to health of postpartum women. There are cultural traditions that are performed to support women after childbirth, however, in certain situations these traditions may cause negative social interactions and these may cause negative health outcomes. Maternal health after birth may be, in part, the result of the function of social environments in which the mother lives. Objectives: To measure if positive (social support) and negative interactions due to traditions in society, intended for helping the mother, predicts postpartum women's health.

Methods: Jewish ($N=203$) and Arab ($N=202$) women were interviewed one month and four months postpartum. Information regarding health problems, self reported health, social support, social networks, negative social interactions and socioeconomic measures were collected. Factors predicting health problems and self reported health four months after childbirth were identified using multi-variable regression models.

Results: In a linear multivariate regression model both positive social support (Beta -0.23, $p<0.0001$) and negative interactions between the woman and her social surroundings one month after childbirth (Beta 0.28 $p<0.0001$) predicted health problems independently four months after childbirth, after adjusting for perceptions of traditions, type of childbirth, ethnicity and education. When self reported health served as the dependent variable similar results were obtained in a logistic multivariable regression model. For social support the odds ratio was 1.8 (CI 1.30, 2.52) and for negative interactions the odds ratio was 0.53 (CI 0.38, 0.74). Positive social support seems to decrease health and negative interactions seem to improve health.

Conclusions: Traditions and customs intended to give support may have negative health outcomes by increasing exposure to negative social interactions. Health service providers should be aware of the woman's cultural background and consider the needs and preferences of the woman and help them obtain a supportive social environment.

CAREGIVER PERSPECTIVES ON GENE THERAPY FOR CHILDREN WITH SICKLE CELL DISEASE

Rebecca J. Rupff, BA, CCRP, Yvonne Carroll, RN, JD, Sara Lewis, MS, CGC, Jerlym Porter, PhD, MPH, Christy Matthews, MEd

St. Jude Children's Research Hospital, Memphis, TN

Background: Sickle cell disease (SCD) is a genetic blood disorder affecting approximately 100,000 Americans. Currently, the only cure for SCD is hematopoietic stem cell transplantation; available to only 14–19% of patients due to lack of suitable matched donors and access barriers. Gene therapy is a novel approach being tested and may cure SCD while circumventing the need for a matched donor.

Objectives: To examine perspectives of caregivers of youth with SCD on gene therapy and clinical trial participation.

Methods: Participants completed an anonymous 19-item survey after seeing a presentation during a SCD Education Day. The presentation covered information about current treatments and gene therapy. Caregivers who elected to participate were asked to rate the likelihood of allowing their child participate in a gene therapy study (1="Not likely at all" to 5="Absolutely yes") and indicate risks and benefits that would influence participation. Caregivers rated reasons that would influence their choice to allow their child to be in a gene therapy study (0=No, 1=Maybe, 2=Yes) and if they would be interested in participating in a gene therapy focus group.

Results: Surveys were completed by 37 caregivers (62% mothers, 19% fathers, 11% legal guardians, 8% grandparents) of patients with SCD (*M*_{age}=9.79 years, *SD* = 5.23, range=2–19; 68% female; 100% African American). Caregivers rated likelihood of allowing their child to participate in a gene therapy study before the presentation (*M*=3.68) and after (*M*=3.68). Highest rated risk factors included: Death (*N*=26, 74%) and Cancer (*N*=20, 57%). Highest rated benefits included: Cured of SCD (*N*=32, 91%), Better quality of life (*N*=25, 71%). Factors rated to most influence study participation were: Child's current health (*N*=30, 91%, *M*=1.70, *SD*=0.64), Child's health after gene therapy (*N*=30, 91%, *M*=1.52, *SD*=0.67). Factors with the least influence were: Religious beliefs (*N*=3, 9%, *M*=0.09, *SD*=0.29), Family's opinion (*N*=15, 46%, *M*=0.64, *SD*=0.78). Finally, the majority of caregivers endorsed interest in participating in a gene therapy focus group (*N*=32, 94%).

Conclusions: Results indicate that caregivers are interested and willing to learn more about gene therapy as a treatment option for their child with SCD. Future directions should tailor information about gene therapy to disseminate to families that address questions and concerns regarding the treatment and clinical trial participation.

COMPARING MINIMUM DIETARY DIVERSITY OVER TIME IN BANGLADESH: AN EXAMINATION OF THE 2011 AND 2014 DEMOGRAPHIC AND HEALTH SURVEY

Sarah Blackstone, PhD, MPH

James Madison University, Harrisonburg, VA

Improving infant and young child feeding practices is critical for improving growth and reducing child mortality and morbidity. This paper aims to compare predictors of minimum dietary diversity, an important indicator of adequate complementary feeding practices, in Bangladesh in 2011 and 2014. The 2011 and 2014 Bangladesh Demographic and Health Survey were used to examine predictors of minimum dietary diversity among 6–23 months. An additional analysis was conducted for the 18–23-month group, because a significant increase in meeting minimum dietary diversity recommendations was seen in this age group only. Factors found to be associated with practices were compared across time points. In 2011, minimum dietary diversity was 23.8% and increased to 28.8% in 2014. Among children 18–23 months, in 2011 minimum dietary diversity was 32.5% and increased to 42.8% in 2014. Consistent predictors of minimum dietary diversity among 6–23 months were education, exposure to media via newspaper, and infant age. In the 18–23-month age group, significant predictors in 2011 were wealth and decision making. In 2014, significant predictors were education and exposure to media. Important predictors included education, exposure to media, and infant age in the overall 6–23-month analysis. Demographic trends in Bangladesh indicated a significant increase in education and exposure to media between 2011 and 2014. As these were significant for minimum dietary diversity in 2014 overall and specifically in the 18–23-month group, they might be important targets of future interventions, specifically utilizing media channels and tailoring special strategies for women with low education and limited exposure to media.

GENETIC AND ENVIRONMENTAL CONTRIBUTIONS TO ADOLESCENT TELOMERE LENGTH IN A LOW-INCOME, AFRICAN AMERICAN SAMPLE

Wendy Kliever, PhD, Jo Robins, PhD

Virginia Commonwealth University, Richmond, VA

A recent meta-analysis documented a negative association between level of psychosocial stressors experienced during childhood and telomere length (Hanssen, Schutte, Malouff, & Epel, 2017). However, no study to date has assessed this association while also controlling for genetic contributions to telomere length, and few studies have examined the mechanisms by which psychosocial stressors affect shortened telomeres during childhood and adolescence. The present study addressed these gaps by examining the contribution of cumulative family risk to mean telomere length (mTL) in adolescents, after accounting for the contribution of biological mothers' mTL. Indicators of cardiometabolic risk were included in the model as potential explanatory variables. African American biological mother-adolescent dyads (*N* = 40) were recruited from low-income communities and participated in a home visit to complete study measures as well as overnight fasting, a blood draw, and analysis of cardiometabolic risk indicators. Adolescents (*M* age = 14.05 years, *SD* = 1.20; 57.5% female) completed measures of felt acceptance and a health screen; mothers (*M* age = 37.79 years, *SD* = 6.04) answered questions on demographics, family stressors, and health status. Trained staff took blood samples and measures of height, weight, waist circumference, and blood pressure in the home. A 5-item cumulative family risk measure was calculated from sociodemographic and psychosocial risk factors. Blood was analyzed for glucose, insulin, C-reactive protein, low-density lipoprotein, and high-density lipoprotein as well as mTL. Youth mTL was not associated with youth age or sex. Regression analysis predicting youth mTL in base pairs revealed a positive association with maternal mTL (standardized beta = .65, *p* < .001), a negative association with cumulative family risk (standardized beta = -.34, *p* < .05), and a marginal negative association with C-reactive protein (standardized beta = -.28, *p* < .10) but no other indicators of cardiometabolic risk. The overall model explained 42.4% of the variation in adolescent mTL. Overall it appears that in this sample of low-income minority youth, both genetic and environmental factors make independent contributions to adolescent mTL in expected directions. Because cytogenetic changes are potentially modifiable, interventions to decrease family risk or alter responses to risk may decrease chronic disease risk in the AA population.

MATERNAL KNOWLEDGE, ATTITUDE AND PRACTICE TOWARDS CHILD IMMUNIZATION: AN EXPLORATORY STUDY IN TAIWAN

Ting-Yi Wu, BEd.¹, Shu-Fang Shih, Ph.D.¹, Chen-Li Chen, Ph.D.²¹National Taiwan Normal University, Taipei, Taipei, Taiwan (Republic of China); ²Taipei City Hospital, Taipei, Taipei, Taiwan (Republic of China)

Previous studies have documented that parental health literacy, or caregivers' health literacy, have had a significant impact on child health outcomes. So far, only a limited amount of studies have investigated maternal childhood immunization literacy. This study was carried out among pregnant women attending the antenatal clinic in the Taipei City hospital. A qualitative approach was adopted. We conducted in-depth interviews with 15 pregnant women who are aged 20 years or older, and are able to read and speak Chinese. All information from the interviews has been saturated. We transcribed and reviewed the data, and then analyzed the data for thematic analysis. Our findings showed that most women were lacking in knowledge with regard to infant and child vaccines, as well as skills for managing the side-effects from vaccines, although they did show a positive attitude towards the importance of vaccines. In terms of interactive literacy, less than 50% of the women would discuss child vaccines with their partners, but only focusing on the time arrangement of taking their children for vaccinations. Most of them would search online for the information, especially the knowledge, but the sources were mainly from either a celebrity's Blog or by using keywords on Google, rather than from the government websites. Finally, women were less likely to consult health care professionals, instead, they searched for help from parents, friends, or information from websites. We suggested that future health education should use multi-component strategies to enhance the maternal child immunization literacy as well as to involve women's spouses in prenatal education.

PARENTING STYLES AND SUBSEQUENT EFFECTS ON CHILD INTERNALIZING BEHAVIORS: A STATISTICAL ANALYSIS

Tayler N. Turnquist, B.A.

Mercer University, Atlanta, GA

Throughout the media and the scientific community, there has been a long-standing question regarding what constitutes a good parent. Two prominent developmental psychologists, Diana Baumrind and Susie Lamborn, expanded their field by defining parental attributes and parenting styles. They conducted research on the significant influence parenting styles have on how children emotionally, behaviorally, and cognitively develop. Four specific parenting styles: Authoritative, Authoritarian, Permissive, and Neglectful were found to impact various aspects of childhood development and lifespan behaviors. The purpose of the current study was to determine the effect of the four parenting styles on internalizing behaviors in children. The study utilized data from the NICHD Study of Early Child Care and Youth Development (SECCYD) database, a longitudinal study spanning 17 years, beginning in 1991 and ending in 2007. With access to all four phases of the SECCYD, a latent growth curve and class analysis was used to examine change in child internalizing behaviors over time within the four parenting styles. Results of the latent growth analysis indicate a prominent change in individual internalizing behavior trajectories over time. Preliminary results of the latent class analysis support current research and the primary hypothesis of this study that clusters of internalizing behavior trajectories are attributed to a Permissive parenting style. The findings of this research will allow for possible interventions in order to establish more adaptive parenting techniques in order to combat potential maladaptive behaviors in children.

PARENTS IN THE BATTLE OF KIDS VS SODA

Michayla Stallings, HS, April Leshner, HS, Jack Burg, HS, Allison Kiefner-Burmeister, Ph.D.

The University of Findlay, Findlay, OH

Regular intake of sugar sweetened beverages (SSB) increases the risk of childhood obesity and other serious health issues. Both parent and child factors are important influences on child health (Tipton, 2014; Fitzgerald, Heary, Nixon, Kelly, 2010). In the present study, parent and child motivation and barriers to decreasing SSB intake were examined. We predicted that even in autonomy seeking pre-teens, the association between child factors (motivations and perceived barriers) and child SSB intake would be mediated by the same parent factors.

Participants were 41 seventh grade students (68% White, mean age 13.3(46)) from Northwest Ohio and their parents. All participants reported eating behaviors, psychological factors with regard to eating, and more specifically, their motivations and barriers to personal SSB intake.

Examined via regression analyses, parents' perceived barriers fully mediated the association between child perceived barriers and child SSB intake. Parent barriers and child barriers were related to each other ($r = .65, p < .001$) and child SSB intake before mediation (parent barriers, $b = -.64, t(27) = -4.30, p < .001$; child barriers, $b = -.40, t(38) = -2.70, p = .01$). The inclusion of parent barriers as a mediator reduced the relationship between child barriers and SSB intake to non-significance ($b = .02, t(27) = .08, p = .94$).

Parents' motivations fully mediated the association between child motivations and child SSB intake. Both parent motivation and child motivation were related to each other ($r = .65, p < .001$) and SSB intake before mediation (parent motivation, $b = -.42, t(27) = -2.40, p = .02$; child motivation, $b = -.54, t(38) = -4.00, p < .001$). The inclusion of parent motivation as a mediator reduced the relationship between child motivation and SSB intake to non-significance ($b = -.22, t(27) = -1.06, p = .30$).

Additionally, Pearson's correlations were used to explore whether specific parental feeding practices were associated with parent and child motivations and perceived barriers to SSB intake (CFPQ; Musher-Eizenman & Holub, 2008). Parent-reported feeding for emotion regulation, child nutrition education, and healthy environment promotion were all related to child barriers and/or motivations to reduce SSB intake (all $ps < .05$). Findings suggest children's and parents' psychological factors are both influential on SSB consumption, but that parental feeding factors are still of greater importance in this pre-teen age group.

PREDICTORS OF EXCLUSIVE BREASTFEEDING IN BANGLADESH: AN EXAMINATION OF THE 2007, 2011, AND 2014 DEMOGRAPHIC AND HEALTH SURVEYS

Sarah BLackstone, PhD, MPH

James Madison University, Harrisonburg, VA

Background: Exclusively breastfeeding (EBF) up to 6 months can significantly reduce child morbidity and mortality. In Bangladesh, rates of EBF are sub-optimal. The objective of this study was to explore predictors of EBF using data from 2007, 2011, and 2014, specifically to see if notable predictors have changed over time.

Methods: Data on mother/infants pairs with infants below 6 months were examined at the three time points. The EBF prevalence, changes in EBF since the previous survey, and determinants of EBF at each time were examined using t-tests, chi-squared, and multi-level multiple logistic regression to account for regional clustering.

Results: Prevalence of EBF was 42.5%, 65%, and 59.4%, respectively. Age of the child was significantly associated with EBF across all time points. Additionally, regional variations were present, with lowest rates of EBF in Barisal and Dhaka. The largest changes in EBF occurred in the 3–5 month age group. Predictors of EBF in this specific age group were similar to overall predictors (e.g. age of the child and region). Participation of the mother in household decisions was a significant predictor in 2014.

Conclusion: EBF prevalence in Bangladesh increased between 2007 and 2011, and then decreased between 2011 and 2014. The increase in 2011 may have been a result of the wide-spread initiatives to promote EBF in that time frame. Due to the unexplained decrease in EBF between 2011 and 2014, there is still a need for interventions such as peer counseling, antenatal education, and community awareness to promote EBF.

RISKY BEHAVIORS AND DEPRESSIVE SYMPTOMS IN CHRONICALLY ILL COLLEGE STUDENTS

Emma Roberts, Student, Julia Johnston, Student, Ali Brenman, Student, Anna Baker, PhD, Professor

Bucknell University, Lewisburg, PA

Background: Previous research has shown that having a chronic illness can serve as a protective factor against risk taking behaviors in adolescents. However, a growing body of literature suggests that chronically ill teens are engaging in these behaviors at equal, if not higher rates than their peers. This study explores whether depression mediates risk taking behavior in college students with and without chronic illness.

Methods: Data was collected using an online survey distributed to 565 undergraduate students (79% female, 72% Caucasian) with and without chronic illnesses. Of these students, 151 reported having a chronic illness and 414 were healthy. Students completed measures of depressive symptoms (PHQ-8) and risky behaviors as part of a larger study.

Results: Both groups in the sample reported moderate to severe levels of depression (healthy students $M = 16.00$, chronically ill students $M = 17.55$). Both groups in the sample reported rates of risk taking behavior comparable to those reported in previous research on college students. Researchers utilized regression analysis using Hayes' PROCESS analysis. There was no significant difference in risk taking behaviors. However, results indicated that the presence of chronic illness was a significant predictor of depressive symptoms $b = 1.74$, $SE = .62$, $p < .01$, and that depressive symptoms were a significant predictor of risky behaviors, $b = .1903$, $SE = .03$, $p < .001$. A bias-corrected bootstrap confidence interval for the indirect effect based on 5,000 bootstrap samples was entirely above zero (.1173, .6409). These results support the mediational hypothesis of a significant indirect effect of depressive symptoms on risk taking behavior. Data collection is ongoing to attain a larger sample of students with chronic illness.

Discussion: The data suggests that college students engage in equal amounts of risky behavior, regardless of illness status. The data showed high levels of depressive symptoms in both groups, though chronically ill college students had more depressive symptoms than their peers. Students with depression may be more likely to engage in risky behaviors. These findings demonstrate a need for increased mental screening and intervention for college students, particularly if they have a chronic illness. In addition, these risk-taking behaviors might negatively impact their treatment regimens and overall health outcomes.

RURAL CAREGIVER SUPPORT AND ENGAGEMENT WITH CHILD HEALTH BEHAVIORS IN THE HOME ENVIRONMENT: A QUALITATIVE STUDY

Maja Pedersen, M.S.

School of Public and Community Health Sciences / The University of Montana, Missoula, MT

Background: Obesity rates are disproportionately high among rural and Native American (NA) children. Health behaviors which contribute to child obesity are influenced by the obesogenic environment, including the considerable influence exerted by caregivers at home. Although current childhood obesity prevention programs recognize the importance of incorporating the caregiver as a central aspect of child behavior change, effectively engaging caregivers remains a crucial challenge, particularly among low-income and ethnic minority families. The purpose of this study was to learn how rural caregivers support and engage with their children's nutrition and physical activity (PA) behaviors at home.

Methods: Community-based methods were used to recruit 25 NA and non-NA caregivers with children living on a rural American Indian reservation to participate in focus groups or semi-structured interviews. Questions were designed to explore caregivers' habits, challenges, and opportunities for (1) supporting for their children's healthy eating and PA behaviors at home; and (2) engaging with their children in these behaviors. Questions were developed by community members and researchers trained in qualitative research methods. Duplicate content analysis, guided by a grounded theory approach, was performed to identify themes and develop a coding frame.

Results/Discussion: Over half of caregivers identified as NA, and over 60% reported being the main decision-maker in the household regarding food and PA. Caregivers identified themes around family strengths, barriers, and opportunities for improvement. Family strengths included behaviors reflecting a "whole family approach" for support and engagement, including role modeling, participation of all children in the family, and multi-cultural, multigenerational learning. Barriers included lack of resources, concern for child safety, and competing family priorities. Strategies for improvement included organized opportunities for caregiver-to-caregiver learning and support in the form of resources and education for promotion of healthy activities in the home.

Conclusion: Themes identified reflect distinct social and cultural strengths and challenges for NA and non-NA families living in rural areas. Results from this study may inform childhood obesity prevention programs seeking to effectively engage non-NA and NA rural caregivers in home-based child behavior change efforts.

TAKING STOCK OF DIETARY SUPPLEMENTS' HARMFUL EFFECTS ON GIRLS AND WOMEN: ANALYSIS OF 11 YEARS OF ADVERSE EVENTS

Flora Or, Doctor of Science¹, Yongjoo Kim, Sc.D., M.P.H., K.M.D., Ph.D.¹, Juliana Simms, Staff Assistant & HAA Receptionist², Bryn Austin, Professor¹¹Harvard T.H. Chan School of Public Health, Boston, MA; ²Harvard University, Cambridge, MA

Many dietary supplements target marketed especially to women have been found to be tainted with toxic ingredients. We examined the gender and age differences in adverse events reported to the U.S. Food and Drug Administration (FDA) involving dietary supplements consumed by children and young adults (ages 0–25 years) from January 2004 through April 2015. Based on brand names in the FDA database, we used descriptions on company websites, Amazon.com, or articles identified via Google search to categorize supplements in seven groupings: weight loss, colon cleanse, diuretic, muscle building, sexual function, vitamin, or other. We conducted multivariable logistic regression analyses cross-sectionally using gender and age as predictors and the respective supplement category as binary outcomes. Over the 136-month observation period, there were 2535 adverse events due to dietary supplements, 119 of which led to death. Approximately half of these adverse events affected girls and women aged 25 years or younger. Based on the reported adverse events (i.e., unique clinical symptom per person per report), the risks for adverse events and deaths associated with a supplement category varied by gender and age group. Within each age group, females were twice as likely to experience an adverse event related to dietary supplements sold for weight loss or vitamins ($p < 0.001$) and ten times as likely to experience an adverse event related to as supplements sold as diuretics ($p < 0.05$) as compared to males; whereas, males were more likely to experience an adverse event from dietary supplements sold for muscle building ($OR = 6.7$, $p < 0.001$) or sexual function ($OR = 4.3$, $p < 0.001$) than were females. Compared to females younger than 12 years old, 12–17-year-old females had lower risks for adverse events due to vitamins ($OR = 0.4$, $p < 0.001$) or the "other" supplement category ($OR = 0.7$, $p < 0.001$); however, 12–17 year-old females had higher risks for adverse events due to dietary supplements sold for weight loss ($OR = 2.9$, $p < 0.001$), colon cleanse ($OR = 2.5$, $p < 0.001$), diuretics ($OR = 3.2$, $p = 0.055$), muscle building ($OR = 2.3$, $p < 0.001$), and sexual function ($OR = 7.3$, $p < 0.05$). Given the heightened dangers as well as large gender and age disparities in adverse events due to dietary supplements, public health scrutiny of youth access, gendered-marketing, and sales of these products is warranted.

THE FRAGILE X BRAIN: A PET/MR CASE STUDY

Soujanya Gade, California¹, Soujanya Gade, BS², Bin Shen, California³, Jae Ho Jung, Ph.D.⁴, Byung Chul Lee, Ph.D.⁴, Sang Eun Kim, MD, PhD⁵, Lawrence Fung, California¹, Frederick Chin, California⁶

¹Stanford University, Palo Alto, CA; ²research assistant, Palo Alto, CA; ³Stanford University, Stanford, CA; ⁴Seoul National University Bundang Hospital, Department of Nuclea Medicine, Seongnam, Kyonggi-do, Republic of Korea; ⁵Seoul National University Bundang Hospital, Seongnam, Kyonggi-do, Republic of Korea; ⁶Stanford University, STANFORD, CA

Objective: Detail one of the first case reports of a 28-year-old adult male with a diagnosis of fragile X syndrome (FXS) utilizing Stanford's state-of-the-art hybrid PET/MR system.

Introduction/Background: Fragile X syndrome (FXS) is the result of a mutation on the FMR1 gene and is the leading heritable cause of cognitive disability that affects approximately 1 in 5000 individuals. Common behavioral characteristics of FXS include autistic-like features such as social anxiety, poor eye-contact and sensory issues. The cognitive phenotype identified in individuals with FXS can include learning disability, reduction in verbal skills, and deficits in visuo-spatial reasoning.

Methods: A comprehensive neuropsychology battery of assessments for cognitive function (Stanford-Binet Intelligent Scales), adaptive skills (Vineland-II) and autism spectrum symptoms (ADOS-2) were completed. Clinical-grade [¹⁸F] flumazenil was synthesized at Stanford. Following intravenous injection of [¹⁸F] flumazenil participant was scanned on a 3T time-of-flight (TOF) GE PET/MR system (Signa, GE Healthcare, Waukesha, WI). Dynamic PET images were analyzed using PMOD (PMOD v2.9, PMOD Inc, Zurich) and FSL was utilized to calculate fractional anisotropy (FA) from diffusion tensor images (DTI).

Results: Time activity curves were generated for 10 subcortical regions are shown in Figure 1. Fractional anisotropy (FA) values were observed in the hippocampus (0.42 ± 0.20) caudate (0.28 ± 0.22) and thalamus (0.29 ± 0.16). Representative 1H-MRS data on the GABA editing are shown in Figure 2.

Discussion/Conclusion: The current study encompasses a global report across multiple domains ranging from neurodevelopment to cognitive and behavioral measures. PET/MR data was used to report initial analyses for the first participant in this study. Future analyses will report group differences with a larger sample that includes age and IQ matched adults with idiopathic developmental delays as a comparison group.

Implications: Elucidating the underlying neurobiological differences in FXS be a critical step in developing targeted treatment that is currently unavailable due to the lack of knowledge about the emergence of the behavioral phenotype and their underlying neural substrates.

DIMENSIONS OF LIFESTYLE HEALTH-RELATED SELF-CONCEPT ASSOCIATED WITH WEIGHT IN A TYPE 2 DIABETES PREVENTION INTERVENTION

Jenifer Thomas, PhD¹, Bhibha M. Das, PhD, MPH², Lesley Lutes, Ph.D.³, Sarah Clinkenbeard, Student⁴, Colter J. Linford, Student¹, Tessa Woods, Student⁵

¹University of Wyoming, Laramie, WY; ²East Carolina University, Winterville, NC; ³University of British Columbia, Canada, Kelowna, BC, Canada; ⁴University of Wyoming, Loveland, CO; ⁵University of Wyoming School of Pharmacy, Laramie, WY

Behavior change and its maintenance is a complex process that is affected by context, behavior, setting, and mechanisms of change. Examination of psychosocial factors may provide insights into lifestyle intervention participation and, subsequently, desired health outcomes (i.e., weight loss, healthy eating, increased physical activity) as well as the maintenance of lifestyle change. Health-related self-concept (HRSC) indicates both positive (i.e., promote well-being) and negative (i.e., decrease adaptive health behavior) factors associated with health. The Lifestyle-HRSC assesses HRSC in the context of lifestyle change. The purpose of this study was to examine of how Lifestyle-HRSC is associated with desired outcomes of a T2DM prevention intervention. The Lifestyle-HRSC scale (79-items) was implemented at pre and post intervention within a type 2 diabetes prevention program. Dimensions of the Lifestyle-HRSC include nutrition, social support, avoiding diabetes, physical activity, problem solving, and challenges related to being healthy. Data were obtained from 69 participants; 47 who completed pre/post intervention assessment and 22 who did not complete post intervention assessment. Simple linear regressions were calculated to predict Lifestyle-HRSC dimensions based on weight and significant relationships were found. For individuals who completed pre/post intervention assessment: at pre intervention, higher weight indicated high agreement with risk-reducing nutrition scores ($F(1, 46) = 4.36, p = 0.04, R^2 = 0.09$). For individuals who did not complete post intervention assessment: at pre intervention, higher weight indicated low agreement with risk-reducing social support scores ($F(1, 21) = 6.39, p = 0.02, R^2 = 0.23$) and low agreement with risk-reducing physical activity scores ($F(1, 21) = 4.98, p = 0.04, R^2 = 0.19$). Pre intervention weight and post intervention weight did not predict any post intervention Lifestyle-HRSC dimension. Chronic disease prevention is an important public health concern and requires innovative approaches to prevention intervention delivery. Lifestyle-HRSC could enhance our understanding of adherence to and engagement in diabetes prevention programs. In addition, this scale may provide an innovative screening to distinguish among individuals who are or are not likely to follow-through with a prevention intervention.

EXAMINING UNMET BASIC NEEDS AND HEALTH STATUS AMONG MEDICAID BENEFICIARIES WITH TYPE 2 DIABETES

Amy McQueen, PhD¹, Erika Halsey, BA², Matthew Kreuter, PhD, MPH², Debra Haire-Joshu³¹Washington University School of Medicine, St. Louis, MO; ²Washington University in St. Louis, St. Louis, MO; ³Washington University, St. Louis, MO

Patients with type 2 diabetes with unmet basic needs (e.g., housing, utilities, transportation) have greater barriers to effective disease self-management. Unmet basic needs impede health behaviors that prevent negative health outcomes and costly healthcare utilization. Most research on unmet needs, however, has focused on single problems (i.e., food insecurity) and distal health-related outcomes (i.e., HbA1C).

To inform the final design of a future intervention to assess and address unmet basic needs, we conducted a pilot study to describe the unmet basic needs and healthcare gaps in adult Medicaid beneficiaries in Louisiana with type 2 diabetes, as well as participants' interest in patient navigation programs. Descriptive statistics and bivariate associations are reported.

Participants completed a cross-sectional survey by phone (n=95) or online (n=14). The sample was 67% female; mean age=50 (SD=10); 51% African American, 39% white. Education varied: 28% had less than high school, 37% high school, and 31% had additional training or degrees. Few worked for pay (20%) and 48% were disabled; 55% reported a household income <\$10,000. Participants reported unmet needs (M=3.2, SD=2.6) including difficulty paying for unexpected expenses (68%), necessities (31%), medical costs (24%), and utilities (23%). Other needs were for adequate food (18%), housing (7%), neighborhood safety (20%), reliable transportation (17%), phone and internet access (10% each), and personal safety (4%). Most had a regular doctor (90%) with M=9 (SD=17) visits in the past year, 51% had an ER visit, and 43% were hospitalized at least once. Participants reported M=9 (SD=11) physical and mental "unhealthy days" and days with activity limitations; M=12 (SD=12) days with poor sleep; and 70% reported fair/poor health. Participants reported their last A1C: <7.0 (25%), 7.1–8.0 (11%), ≥8.1 (25%) and don't know (36%).

Having greater unmet needs was associated (p<.001) with less frequent diabetes self-care activities (r=-.30), worse self-reported health (r=-.28), greater perceived stress (r=.41), diabetes distress (r=.35), attention (r=.29), cognitive functioning problems (r=.27), activity limitations (r=.34), hospitalizations (r=.29), and wanting a basic needs navigator (OR=1.52). Unmet needs were associated with worse mental health days (r=.32) and sleep (r=.30), but were not associated with poor physical health days, self-reported A1C, BMI, smoking status, doctor or ER visits.

Our findings support calls for systematic screening and navigation programs to be integrated within healthcare systems for patients with unmet basic needs. Our findings suggest that helping Medicaid beneficiaries meet these needs may lead to improvements in multiple health-related outcomes including reduced stress, better self-reported health and health behaviors, and fewer hospitalizations.

LIVING WITH TYPE 2 DIABETES: A SOCIAL COGNITIVE PERSPECTIVE ON ADHERENCE

Shannon L. Mihalko, PhD¹, Suzanne Danhauer, PhD², Beverly Levine, PhD², Jaimie C. Hunter, MPH, PhD², Julie K. Kirk, PharmD², Deanna Befus, PhD, RN², Heather Black, PhD³, Sally A. Shumaker, PhD²¹Wake Forest University, Winston Salem, NC; ²Wake Forest School of Medicine, Winston Salem, NC; ³Merck and Co., Inc., Kenilworth, NJ

Adherence to a medical regimen is a multifaceted concept. Given the complexity of the diabetes self-care regimen, it is not surprising that individuals with type 2 diabetes have difficulty adhering to self-care behaviors, including physical activity, dietary choices, blood glucose monitoring, and medication usage. Social cognitive theory (SCT) has been used as a framework for examining psychosocial factors associated with health behavior change and is a valuable tool for understanding adherence. Two basic cognitions underlie this theory: outcome expectations (OE) and self-efficacy cognitions (SE). Although SE has received the most attention in the literature, it is important to assess both constructs to more fully understand adherence in adults with type 2 diabetes. 'Living with Diabetes' (LWD) was a multi-methodological study designed to provide a deeper understanding of the factors influencing adherence to diabetes self-care behaviors. Study participants (n=108) averaged 56.6 years of age (SD=10.3), were majority female (58%), and included African Americans (48%) and Whites (52%). After measurement with validated instruments, ordinary least squares regression was used to assess the relationship between the outcomes of self-care health behaviors (diet, exercise, blood glucose monitoring, and medication adherence), and the independent variables of SE and OE while controlling for demographic variables (age, sex, race) and A1c levels in all models. In multivariable models including all the above predictors, SE was significantly and positively associated with both diet (p<.0001) and physical activity (p<.001). Both OE for testing blood glucose and SE were significantly associated with self-reported monitoring (p=.001 for both). Neither OE nor SE was significantly associated with medication usage. All associations were in the expected direction (i.e., higher OE and SE associated with more favorable outcomes). Discussion of the relations between adherence, SE and OE will incorporate motivational data derived from in-depth laddering interviews in the LWD study – a technique that provides insights into the patients' key values, and the behavioral strategies they use to attain these values. By better identifying the relationship between strategies and values, we hope to more fully understand why adults with type 2 diabetes vary in their ability to maintain optimal adherence and promote their health and well-being.

RACIAL DIFFERENCES IN DIABETES DIAGNOSIS AMONG WOMEN WITH HIGH STRESS: FINDINGS FROM THE SOUTH CAROLINA WOMEN'S SURVEY

Jennifer Mandelbaum, MPH¹, Spencer Moore, MPH, PhD¹, Monique Lyle, PhD², Alexander McLain, PhD³, Jason Stewart, PhD⁴, Susan Heiney, PhD, RN, FAAN⁵

¹University of South Carolina, Columbia, SC; ²Institute for Public Service and Policy Research, University of South Carolina, Columbia, SC; ³Department of Epidemiology and Biostatistics, University of South Carolina, Columbia, SC; ⁴Department of Biological Sciences, University of South Carolina, Columbia, SC; ⁵College of Nursing, University of South Carolina, Columbia, SC

Background: Racial and ethnic minorities are disproportionately burdened by type 2 diabetes, and these disparities may be more prevalent in the southeastern U.S. There is evidence that stress may be associated with diabetes risk, yet few studies have examined racial differences in the association between chronic stress and diabetes. The purpose of this study was to examine relationships among chronic stress, diabetes, and race in South Carolina women.

Methods: Data came from the South Carolina Women's Survey, an ongoing study of racially, socioeconomically, and geographically diverse women intended to examine society-to-cell influences on aging among women in South Carolina. A subsample of African-American and White women enrolled in the study (N=290) were included in analyses. Chronic and perceived stress was measured using a 19-item scale (Cronbach's alpha=.84), and responses were categorized into tertiles. Diabetes diagnosis was based on participants self-reporting that a health professional had told them they had diabetes, and that diagnosis was not during pregnancy. Data were analyzed using multiple logistic regression, controlling for age, income, and education.

Results: Participants were racially-diverse (65.2% White, 34.8% African-American) and ranged in age from 18 to 93 years (mean age=56.6). African-American women were significantly ($p<0.01$) more likely to be in the top stress tertile compared to White women (41.6% compared to 31.4%). Overall, 23.1% of the participants reported being diagnosed with non-gestational diabetes. African-Americans were significantly ($p=0.04$) more likely to have been diagnosed with diabetes (30.0%) than Whites (19.4%). After adjusting for sociodemographic characteristics, higher stress was associated with a positive diabetes diagnosis among all women (OR=2.35, $p=0.01$). Race moderated the association between chronic stress and diabetes such that in the highest stress tertile, African-American compared to White women were less likely to be diagnosed with diabetes (OR=0.25, $p=0.03$).

Conclusions: Overall, African-American women had higher stress levels and were more likely to have diabetes than their White counterparts. Higher stress was associated with diabetes among all women, but African-Americans with high stress were less likely to have diabetes than Whites. Future research might examine factors that may help to explain racial and ethnic differences in the impact of high stress on women's risk of diabetes.

A DIABETES SELF MANAGEMENT E-HEALTH BEHAVIORAL INTERVENTION: CERTIFIED DIABETES EDUCATORS PERCEPTIONS AND RATINGS

Joanne Duncan-Carnesciali, EdD, MSc, MS

New York University School of Medicine, New York, NY

PURPOSE: Thirty million people in the United States have diabetes according to 2017 diabetes statistics. As a consequence of its prevalence, Healthy People 2020 has as part of its national objective the goal of increasing the proportion of persons with diagnosed diabetes who receive formal diabetes education. Certified diabetes educators (CDE) are at the forefront of the delivery of diabetes self management education (DSME). However, there are only 20,000 CDEs nationally. To address this disparity between diabetes prevalence and the number of CDE nationally, this study evaluated certified diabetes educators (CDE), representative of diverse health professions, perceptions of an e-health intervention that utilized avatar-based technology. This study investigated the potential an e-health intervention, that is framed within a logic model and grounded in health behavioral theories, has in increasing access and thus reducing disparity to diabetes self-management education (DSME).

HYPOTHESIS: After watching the video covering the seven diabetes self-management behaviors, CDE® will rate the quality of the avatar video as high.

METHODS: Cross-sectional, survey-based design utilizing quantitative and qualitative paradigms. N = 198 CDE® participated in the evaluation. Participants were mostly female and represented an age range of 26–76 years. The profession representative of the sample was registered nurses.

ANALYSIS: *t*-tests, Pearson product moment correlations, backward stepwise regression, content/thematic analysis.

RESULTS: Age, ethnicity, Arab/Middle Eastern, Asian, and White/European descents were significant predictors of a high-quality rating of the video. Thematic and content analysis of the data revealed an overall positive perception of the video.

CONCLUSIONS: An e-health intervention grounded in evidenced-based health behavior theories has potential to increase access to DSME as evidenced in the ratings and perceptions of the video by CDE®.

BEHAVIORAL DIABETES PREVENTION IN AFRICAN AMERICAN AND HISPANIC US WOMEN: REVIEW AND GENDER ANALYSIS

Shakira L. Smith, MEd, Hsien-Chang Lin, PhD, Krisha Thiagarajah, PhD

Indiana University Bloomington, Bloomington, IN

Objectives: Behavioral, or lifestyle, interventions have been indicated as the successful gold standard approach for the prevention of diabetes in large-scale studies. Translational studies have attempted to adapt interventions such as the Diabetes Prevention Program for use in community settings. African American and Hispanic women in the US face disproportionate risk of developing diabetes, however, few translational studies have focused specifically on these groups. The objective of the current study is to systematically review such studies, and to assess gender as an influential component of prevention programming.

Method: A systematic literature review was conducted to identify randomized controlled trial or quasi-experimental intervention studies in the US with African American or Hispanic women with prediabetes or who are at-risk for developing diabetes. Studies were identified via the following databases from inception to June 2017: Academic Search Premier, Ageline, CINAHL, Global Health, Health Source, and Medline. A gender analysis was conducted using a novel feminist appraisal tool.

Results: Among the eight studies identified, five yielded statistically significant weight loss. One study indicated significant reduction of blood glucose. Five studies described intervention adaptations that were specific to women participants, and five studies consulted women in development of the intervention. No studies provided a definition or measure of gender, and only three made recommendations based on women's experiences.

Conclusion: Behavioral diabetes prevention with African American and Hispanic women is promising. Although these studies focus exclusively on women, the influence of gender on health disparity is not thoroughly considered. Keywords: diabetes prevention, African American, Hispanic, feminist

COMPREHENSIVE COGNITIVE TRAINING: A FEASIBILITY STUDY FOR PERSONS WITH TYPE 2 DIABETES

Cuevas Heather, PhD, RN, ACNS-BC¹, Alexa Stuijbergen, PhD, RN, FAAN², Sharon A. Brown, PhD, RN, FAAN², Catherine Ward, RN²¹The University of Texas at Austin, School of Nursing, Austin, TX; ²The University of Texas at Austin, Austin, TX

Background: People with type 2 diabetes (T2DM) are at risk for cognitive decline, with about 50% of older adults with T2DM becoming cognitively impaired. If the ability to use effective T2DM self-management activities is diminished by changes in cognitive function, then addressing the individual aspects of self-management (e.g. exercise and diet) may be less effective. Previous studies have attempted to assess the interactions of the psychological, physiological, and environmental factors that impact self-management, but few have addressed these factors as they relate to cognitive function.

Objective: The primary objective of this feasibility study was to determine whether a comprehensive cognitive function intervention implemented in a sample with T2DM would be useful in improving diabetes self-management.

Methods: Participants (n=19) enrolled in an 8-week intervention. The biweekly educational classes included: (1) information on T2DM self-management; (2) assessment of cognitive problems; (3) lifestyle changes to improve cognitive health; and (4) strategies to maximize cognitive function. Each participant was asked to use an online cognitive training program at home for a minimum of 45 minutes 3 times a week. Self-report measures of cognitive functioning (Multifactorial Memory Questionnaire; Barkley Deficits in Executive Function) and T2DM self management (Summary of Diabetes Self-Care Activities) were administered pre- and post-intervention.

Results: Executive function, but not memory, was significantly correlated with diet, exercise, and foot care (general diet $r = -.665, p < .01$; exercise $r = -.725, p < .01$; foot care $r = -.516, p < .05$). Post-intervention scores in all areas improved, but only diet, memory ability, and executive function improved significantly (diet $t(18) = -2.41, p < .05$; $t(18) = 5.54, p < .01$; executive function $t(18) = 3.11, p < .01$). All participants agreed that the intervention helped them improve their cognitive abilities and the computer activities kept their interest. All stated they would recommend the program to others.

Conclusions: To date there have been no other published studies using comprehensive cognitive training as an intervention in T2DM. While these results generally suggest that people with T2DM can improve their cognitive functioning after exposure to a cognitive training intervention, a randomized clinical trial using performance measures of cognitive function is needed to determine that changes observed here can be attributed to the program.

DEVELOPMENT OF A MODIFIED VERSION OF THE DIABETES FATALISM SCALE FOR USE IN ADULTS WITHOUT TYPE 2 DIABETES

Erin L. Merz, PhD, MPH, Emily Rose N. San Diego, BA

California State University, Dominguez Hills, Carson, CA

Fatalistic health beliefs have been linked with behaviors and outcomes in numerous domains including cancer screening, condom use, medication adherence, and blood sugar control, among others. The Diabetes Fatalism Scale (DFS; Egede & Ellis, 2010) was developed to assess diabetes fatalism, conceptualized as a multidimensional construct consisting of diabetes-related emotional distress (Despair), religious and spiritual coping (Hopelessness), and perceived self-efficacy (Powerlessness) in patients with Type 2 Diabetes. The current study aimed to adapt the DFS for use among non-clinical respondents for research on Type 2 Diabetes risk. Minor wording modifications were made to 10 of the 12 items (e.g., the word “my” removed from: “I believe God can completely cure my diabetes”). An ethnically diverse sample ($N = 345$) of adults aged 18 to 53 years without a prior diagnosis of diabetes filled out the modified scale and convergent validity measures. Confirmatory factor analysis was used to test a series of plausible models based on theoretical and empirical considerations. The 3-factor oblique model containing 11 items provided the best fit to the data ($S-B \chi^2 [41] = 95.09$, $CFI = .949$, $RMSEA = .062$, $SRMR = .049$). Factor loadings for each factor were good (Despair [4 items]: .46 - .89; Hopelessness [4 items] = .54 - .89; Powerlessness [3 items] = .59 - .75) and there was a significant interfactor correlation between Despair and Hopelessness ($r = .15$, $p = .022$). Internal consistency reliability was adequate for the subscales ($\alpha_s = .69 - .85$). Convergent validity analyses suggested that the subscales correlated in the expected directions with measures of mastery, general self-efficacy, stress, mental health, and health-related quality of life but were not significantly associated with self-reported diet or physical activity. These preliminary findings suggest that the modified DFS (DFS-Community) demonstrated good factorial validity and adequate convergent validity when conceptualized as 3 separate subscales assessing different facets of diabetes fatalism in respondents without diabetes. The measure is tentatively recommended for use, but potential relationships with intention to perform health behaviors should be evaluated in future research.

EFFICACY OF A POSITIVE PSYCHOLOGY INTERVENTION FOR TEENS WITH TYPE 1 DIABETES: CHECK IT 2.0

Morgan Lyttle, BA¹, Sarah S. Jaser, PhD², Emily R. Hamburger, MEd², Rodayne Williams, BA², Leena Choi, B.S., M.S., Ph.D.³, Samuel Nwosu, B.S. and M.S.⁴

¹Vanderbilt University Medical Center, Mt. Juliet, TN; ²Vanderbilt University Medical Center, Nashville, TN; ³VUMC, Nashville, TN; ⁴Vanderbilt University, Nashville, TN

Background: Teens with T1D are at high risk for poor glycemic control, increasing their risk of developing long-term health complications. Because the burden of treatment for T1D falls largely on the patient and family, interventions aimed at increasing adherence to treatment regimens are needed. Positive psychology interventions that aim to increase positive affect have been demonstrated to improve treatment compliance in adult populations. The current study aims to examine feasibility and preliminary efficacy of the latest iteration in a series of pilot studies, a text message delivered positive psychology intervention (Check It 2.0).

Methods: Participants ($n = 48$, age 13–17 years, 50% female, mean $A1c = 8.8\%$) were randomized to an Education (Edu) group or a Positive Affect (PA) group. Participants in the Edu group received educational materials on type 1 diabetes management. Those in the PA group also received a text-message based intervention that incorporated empirically-validated exercises to induce positive affect through self-affirmation, gratitude, parental affirmation, and small gifts. Average daily blood glucose monitoring (BGM) was obtained through 30 day glucometer downloads. $A1c$ was obtained from medical charts and adherence was measured using the Self-Care Inventory (SCI) and Parent Self-Care Inventory (PSCI). Diabetes-related family conflict was measured using the Revised Diabetes Family Conflict Scale (DFC).

Results: Teens' response to PA text messages was high, with an average response rate of 75.7% during the intervention, indicating the feasibility of the protocol. Due to the small sample size of this study, the statistical analyses performed did not reach significance. However, small to moderate effects were observed on several clinically relevant measures. In terms of adherence, parent-reported adherence (PSCI, $d=0.214$) and frequency of BGM ($d=0.386$) increased in the PA group compared to the Edu group. Diabetes-related conflict (as reported by teens) decreased in the PA group ($d=-0.467$). An overall improvement in glycemic control was observed in the PA group compared to the Edu group ($d=-0.283$). Interestingly, the decrease in $A1c$ was most noticeable in those within the middle tertile ($8.03 < x < 9.23\%$) of baseline $A1c$ ($d=-0.344$).

Discussion: In our sample, notable improvements to adherence, glycemic control and diabetes-related conflict indicate that positive affect interventions could be a promising avenue for improving chronic disease management in teens with T1D. Furthermore, the feasibility of a text-message based intervention was validated by high teen rates of engagement. The decrease in $A1c$ indicates that a text-message based PA intervention has promising effects for glycemic control, especially for those with baseline $A1c$ between 8–10%.

ENGAGING STAKEHOLDERS IN INTERVENTION DEVELOPMENT: THE D1 NOW STUDY TO PROMOTE SELF-MANAGEMENT IN YOUNG ADULTS WITH DIABETES

Molly Byrne, PhD¹, Lisa Hynes, PhD², Mary Clare O' Hara, MSc., BSc.³¹National University of Ireland Galway, Galway, Galway, Ireland; ²West Virginia University, Morgantown, WV; ³HSE Health and Wellbeing, Galway, Galway, Ireland

Background: Young adults with Type 1 Diabetes are at high risk of poor diabetes self-management and poor clinical outcomes. In this research, our aim was to develop an intervention to engage young adults in diabetes health services and improve diabetes-related outcomes. As part of intervention development, we aimed to (1) engage key stakeholders and (2) explore perceptions of barriers and facilitators to self-management among young adults with Type 1 Diabetes (T1D) using the COM-B (Capability, Opportunity, Motivation - Behaviour) Model of understanding behaviour.

Methods: A Young Adult Panel (8 diabetes service-users aged between 18–25 years living with T1D) was formed, which guided the research process and informed the development of interview topic guides to explore barriers and facilitators to self-management. Interviews were conducted with parents of young adults with T1D (n=10) and health service providers (n=15), and focus groups (n=3) were conducted with young adults, at 3 sites in Ireland (Galway, Belfast and Dublin). Thematic analysis was used to analyse the data using the framework of the COM-B model to identify and categorise the determinants of T1D self-management among young adults.

Findings: Diabetes education and regular, informal access to diabetes-related information was considered vital to capability to engage in diabetes self-management. However, self-management behaviour appeared to be determined by external physical and social factors such as access to a supportive diabetes team. External factors may directly drive self-management behaviour, for example through a stable daily routine, or influence motivation, for example through beliefs about capability to engage in self-management. Resources such as diabetes devices and peer networks enhanced self-management. Young adult's identity as a person living with T1D was an important determinant of self-management behaviour.

Discussion: Interventions should target environmental factors to positively influence capability and motivation to engage in T1D self-management among young adults.

HUMAN FACTORS DURING TRIAL OF A HYBRID CLOSED LOOP SYSTEM FOR TYPE 1 DIABETES MANAGEMENT

Rebecca N. Adams, PhD¹, Molly L. Tanenbaum, PhD¹, Sarah J. Hanes, N/A¹, Jodie M. Ambrosino, PhD², Trang T. Ly, MD¹, David M. Maahs, MD, PhD¹, Diana Naranjo, PhD¹, Natalie Walders-Abramson, PhD³, Stuart A. Weinzimer, MD⁴, Bruce A. Buckingham, MD¹, Korey K. Hood, PhD¹¹Stanford University School of Medicine, Palo Alto, CA; ²Yale University School of Medicine, New Haven, CT; ³Barbara Davis Center for Childhood Diabetes, University of Colorado, Aurora, CO; ⁴Yale University, New Haven, CT

Background: Hybrid closed loop (HCL) systems are designed to automate insulin delivery to improve type 1 diabetes (T1D) outcomes and reduce user burden and distress. The Medtronic MiniMed 670G, the first FDA approved HCL system, became available to consumers in early 2017. The system consists of continuous glucose monitoring (CGM), an insulin pump, and an algorithm to integrate them; thus, use of the system requires ongoing acceptance and use of both CGM and the insulin pump. In the current study, we explored the role of human factors in HCL system use. Specifically, we examined whether attitudes towards diabetes technology and management distress would: (1) change after using the system, and (2) predict system performance during the trial. We hypothesized that technology attitudes would become more positive, whereas management distress would decrease after trial on the HCL system. We also hypothesized that more positive pre-trial technology attitudes and less pre-trial management distress would be associated with better system performance (i.e., greater percent time within target glucose range), controlling for percent time in target range during the days prior to the HCL system trial.

Method: 14 adults and 15 adolescents with T1D (mean age=22.8 years, age range 15–38, 86% female, mean HbA1c %=8.0, mean diabetes duration=13.6 years) participated in a multisite clinical trial of a research version of the Medtronic 670G HCL system over 4–5 days in a semi-supervised outpatient setting. Users completed questionnaires assessing diabetes management burden and diabetes technology attitudes prior to beginning the HCL system and at the conclusion of the study. We conducted t-tests and general linear model analyses to test hypotheses.

Results: As expected, users' management distress decreased ($t(27)=2.7, p=0.01$) and their diabetes technology attitudes became more positive ($t(27)=-3.9, p=0.001$). Neither pre-trial technology attitudes or management distress were significant predictors of system performance; however, there was a trend towards greater pre-trial management distress predicting poorer system performance both during the day ($b=-0.35, p=0.11$) and night ($b=-0.41, p=0.05$).

Conclusions: Results suggest that HCL system technology is promising for enhancing diabetes technology attitudes and reducing management distress. Human factors, such as management distress, may negatively impact system performance and should be investigated in studies with larger samples.

IMPROVEMENT AND MAINTENANCE OF HEALTHY BLOOD GLUCOSE LEVELS IN PEOPLE WITH TYPE 1 DIABETES PAYING FOR ONE DROP | EXPERT COACHING

Lindsay Sears, PhD¹, Jeff Dachis, MA², Mark Heyman, PhD, CDE², Rachel Head, RD, CDE¹, Brian Huddleston, JD², David Rodbard, MD³, Chandra Osborn, PhD, MPH¹

¹Informed Data Systems Inc., New York, NY; ²Informed Data Systems, Inc, New York, NY; ³Biomedical Informatics Consultants, New York, NY

Objective: Over 1,500 mobile applications ‘apps’ assist with the management of diabetes, but only three of these apps offer live, in-app coaching support, and only two of these apps have been scientifically evaluated. One of these studies included people with type 1 diabetes (T1D), but did not report T1D-specific outcomes.

With the free One Drop | Mobile app on iOS or Android, people can log and track self-care/health data, get data-driven insights, set goals and monitor progress, and more. A paid subscription to One Drop | Experts offers in-app support and coaching from a Certified Diabetes Educator (CDE) a Bluetooth-connected meter and test strips. An independent company tested ‘Mobile’ with ‘Experts’ at no cost to users, and found people with type 2 diabetes and an A1c $\geq 7.5\%$ had a -90% lab A1c improvement at 3 months. There remains a need to evaluate the health outcomes of people with T1D and a real-time coach in an app.

Method: We queried One Drop’s database for people with T1D paying for an ‘Expert’ for at least 3 months. Among people with an average blood glucose (BG) ≥ 169 mg/dL (estimated A1c $\geq 7.5\%$) at start, three mixed repeated measures models assessed 1st- to 12th-week change in average BG, percentage of high BGs, and percentage of in-range BGs by coaching program (‘On Call’ vs. ‘On Track’). Unadjusted and adjusted logistic regression models tested the likelihood of a 12th-week average BG < 155 mg/dL (eA1c $\leq 7\%$) if 1st week average BG was < 155 mg/dL (eA1c $\leq 7\%$).

Result: The sample (N=196) was 53% male and diagnosed with T1D for 16.8 ± 12.6 years. People (n=98) with a 1st week average BG ≥ 169 mg/dL (eA1c $\geq 7.5\%$) had a -22.2 mg/dL lower average BG in week 12, $p < .001$, equivalent to -0.8% lower A1c. Average percentage of high BGs was -18.5% lower, and in-range BGs $+18\%$ higher, $p < .001$. There was no interaction by coaching program. People with a 1st week average BG < 155 mg/dL (eA1c $\leq 7\%$) had a higher likelihood (1.6 OR/1.7 AOR) of staying at BG < 155 mg/dL (eA1c $\leq 7\%$) in week 12.

Conclusion: Among people with T1D paying for a One Drop | Expert, average BG measured objectively improved among people with a high average BG at start, and a healthy level of BG was maintained among people with a low average BG at start. People paying for an in-app coach and meter with strips may be more motivated than someone not paying for these services. More studies should evaluate the impact of apps with coaching, especially within people with T1D.

MEASURING RISK PERCEPTIONS FOR DEVELOPING DIABETES IN A SAFETY-NET CLINIC POPULATION OF ENGLISH AND SPANISH SPEAKERS

Catherine Rochefort, MS¹, Austin S. Baldwin, PhD¹, Jasmin A. Tiro, PhD², Molly McGuire, MPH³, Michael E. Bowen, MD, MPH, MSCS⁴

¹Southern Methodist University, Dallas, TX; ²University of Texas Southwestern Medical Center, Dallas, TX; ³UT Southwestern Medical Center, Dallas, TX; ⁴University of Texas Southwestern Medical Center, Dallas, TX, Dallas, TX

Background: Individuals’ perceptions of illness risk are an important determinant of and motivator for changing health behaviors. The Risk Perception Survey – Developing Diabetes (RPS-DD) is a validated instrument measuring risk perceptions, worry, and perceived control of developing diabetes. However, its psychometric properties have not been evaluated in low education, high-risk populations attending safety-net clinics. Although one study has examined psychometrics of a Spanish version, multiple items for external locus of control were removed, leaving the scale’s psychometric structure an open question. This study examined whether the psychometric structure of the RPS-DD is similar across males and females and for English and Spanish speakers in this low education population at high risk for diabetes.

Methods: Adult patients in a safety-net health system participating in a diabetes screening study (N = 658) answered interviewer-administered diabetes risk items assessing internal locus of control (2 items), external locus of control (2 items), comparative risk (2 items), and worry (2 items) over the telephone in their preferred language (English: 42%, Spanish: 58%). All participants completed the RPS-DD prior to completing diabetes screening tests. We performed exploratory and confirmatory factor analyses using a randomly generated split sample to determine the subscales’ structure.

Results: Exploratory factor analyses suggested a four-factor solution, and confirmatory factor analyses supported it (RMSEA = 0.094, 95% CI: .069, .121, CFI = .903). The 2-group factorial invariance analyses indicated that the 4-factor structure did not vary between males and females ($p = .13$). However, the structure did vary between English and Spanish speakers ($\chi^2(8) = 40.59$, $p < .001$). Specifically, the item ‘I feel I have little control over risks to my health’ loaded more strongly for English speakers.

Conclusions: The structure of the perceived control subscale in the RPS-DD is slightly different in the English and Spanish versions. Future studies should continue to assess factorial equivalence of RPS-DD language translations to ensure patients’ interpretations and responses to scale items are comparable across languages.

PARENTAL INVOLVEMENT IN TYPE 1 DIABETES ACROSS EMERGING ADULTHOOD: IS IT BENEFICIAL AND FOR WHOM?

Cynthia A. Berg, Ph.D.¹, Deborah Wiebe, PhD, MPH², Eunjin Lee, Ph.D.³, Caitlin S. Kelly, MA¹, Jonathan Butner, Ph.D.¹, Daniel Mello, Doctoral Candidate⁴¹University of Utah, Salt Lake City, UT; ²University of California, Merced, Merced, CA; ³University of Utah, salt lake city, UT; ⁴University of California - Merced, Merced, CA

Parental involvement is beneficial for supporting the daily self-regulation of emotions, cognitions, and behaviors involved in managing type 1 diabetes across adolescence (Berg et al., in press), but little is known about what happens to parental involvement across emerging adulthood nor whether it may still be beneficial for diabetes management at this time. Individuals with poorer self-regulation capacities as assessed by executive function are at risk for poorer diabetes management, especially across the transition to emerging adulthood (Suchy et al., 2016, 2017). The study examined whether parental involvement during emerging adulthood may be especially beneficial for young adults with lower executive function across the high risk time of emerging adulthood. Two-hundred and three adults (*M age*=17.74 at baseline) were followed from their senior year of high school and annually for two additional years. Individuals completed measures of how knowledgeable their mothers and fathers were of their diabetes (knowing their blood sugar readings, how much insulin has been taken) as well as general behaviors (who their friends are, where they are at night), performance-based assessments of their executive functions (the DKEFS), and measures of adherence to the diabetes regimen; HbA1c was gathered from home test assay kits. Repeated measures ANOVAS indicated that participants reported significant declines in fathers' general knowledge (no significant declines in mothers' general knowledge), and in mothers' and fathers' diabetes-specific knowledge across each year of the study. Multi-level models with parental knowledge (both within-person and between-person effects) predicting adherence and HbA1c at each time point revealed that in general young adults who perceived that fathers and mothers were more knowledgeable about diabetes and about their lives in general reported better adherence. Within-person effects demonstrated that when parental knowledge was higher than one's average, adherence was also better. Mothers' general and diabetes-specific knowledge was associated with better glycemic control, but only for emerging adults who had poorer executive function ($p < .01$). The results suggest that continued involvement in diabetes management during emerging adulthood is beneficial for adherence and mothers' involvement may be helpful for young emerging adults who may need greater support due to lower self-regulation capacities.

PARTICIPANTS' BENEFITS AND BARRIERS TO IMPROVE DIABETES PROGRAMS IN APPALACHIAN COMMUNITIES

Samantha Shawley-Brzoska, MPH, Ranjita Misra, PhD, CHES, FASHA, Jonathan Stewart, MS, Brandon Lucke-Wold, PhD, John Spencer Ingels, MA, Sabena Thomas, MA

West Virginia University, Morgantown, WV

Introduction: The Diabetes Prevention and Management (DPM) program was implemented in twenty-two sessions over 12 months in two Appalachian churches, which was modeled after the evidence-based National Diabetes Prevention Program and modified to include diabetes management sessions using the American Association of Diabetes Educators Self-Care Behaviors framework (AADE7). Participants provided feedback on the benefits and barriers and suggested improvements of the community-based diabetes program.

Methods: Trained health coaches led culturally-tailored educational sessions and had weekly communication with participants to help them modify health-related behaviors. The benefits and barriers survey was implemented at mid-program and end of the program to examine participant satisfaction of the program; information was also collected on their health status and literacy level. The survey was one of the first to identify the benefits and barriers of a community-based diabetes prevention and management program in West Virginia.

Results: Program participants included adults with dysglycemia (pre-diabetes or had diabetes). Ninety-four adults completed the pre-screening (73% females, 54% with diabetes); 83 participants completed the benefits and barriers survey at 6-months and 68 completed both mid- and final-program assessments (completion rate of 82%). The majority of target audience did not perceive transportation and community location as barriers to participation. Additionally, a majority of participants did not perceive they had trouble remembering instructions provided in the program sessions. Additionally, program attendance and participation allowed the majority to change their lifestyles and were satisfied with the program.

Discussion: This survey was to understand the community's needs, benefits, and barriers while providing a novel way of identifying and overcoming perceived benefits and barriers unique to the Appalachian culture. These findings suggested minimal adjustments to the DPM program while providing insight on increasing program participation.

PILOT TESTING A CULTURALLY TAILORED DIABETES SELF-MANAGEMENT PROGRAM FOR CHINESE AMERICANS WITH TYPE 2 DIABETES

Bin Xie, PhD¹, Yawen Li, PhD², Wei-Chin Hwang, PhD³, Zhongzheng Niu, MPH⁴, Xiaomeng Lei, MPH¹, Ruizhi Yu, MPH¹, Yunsheng Ma, PhD, MD⁵¹Claremont Graduate University, Claremont, CA; ²San Diego State University, San Diego, CA; ³Claremont McKenna College, Claremont, CA; ⁴State University of New York at Buffalo, Buffalo, NY; ⁵University of Massachusetts School of Medicine, Worcester, MA

Background: Although progress has been made in improving the efficacy of Diabetes Self-Management Education (DSME) programs, there continues to be a dearth of research on culturally adapting evidence-based DSMEs for Chinese Americans (CA) with Type 2 diabetes. Through collaborative partnerships with two large community recreation centers and the AHMC hospital network in San Gabriel Valley, California, we developed and pilot tested a culturally tailored DSME program with mHealth technology integration, entitled Culturally Appropriate Strategies for Chinese Americans with Diabetes (CASCADe).

Methods: The CASCADe program utilized a combined theoretically driven and community-participatory approach to develop an evidence-based curricular program consisting of eight weekly sessions of health education and diabetes management. Topics covered include recognition of diabetes and its complications, risk factors, nutrition knowledge, dietary practices, exercise, behavioral self-monitoring, medication adherence, and stress management. In addition, the program includes 1) a home visit for training of monitoring devices use, WeChat app and acquiring family support, 2) a combined format of group class, games, food demonstration, group exercise, video and discussion, 3) WeChat follow-up on education tips, monitoring data summary, and group discussion. The monitoring system used a smartphone to coordinate cloud data transmission from a set of wireless devices to capture daily monitoring data on physical activity, body weight, blood pressure and blood glucose levels. WeChat app (a mobile platform of instant messaging widely used in Chinese population) was used to facilitate behavioral self-monitoring by providing daily messages related to diabetes education curriculum, weekly summary reports on monitoring data as well as reinforcement messages and group discussion on readings and monitoring results implication.

Results: The pre- and post-comparison among 8 participants showed a significant improvement on levels of HbA1c (7.28 vs. 7.68, $p=0.02$, with all except one participant having HbA1c reduction and 50% participants achieving >0.5 HbA1c reduction), self-efficacy (8.45 vs. 6.16, $p=0.04$), quality of life (2.68 vs. 1.92, $p=0.007$) and stress coping skills (3.90 vs. 3.09, $p=0.03$) at 3 months after baseline.

Conclusion: Our pilot study demonstrated the feasibility to implement our CASCADe program among CAs to improve diabetes self-management skills, and provides promising results to further test the efficacy in a larger randomized trial.

SENDING PATIENTS DIABETES SCREENING TEST RESULTS: CHANGES IN COMPARATIVE RISK AND WORRY AND INFORMATION SEEKING BEHAVIOR

Michael E. Bowen, MD, MPH, MSCS¹, Catherine Rochefort, MS², Jasmin A. Tiro, PhD³, Molly McGuire, MPH⁴, Austin S. Baldwin, PhD²¹University of Texas Southwestern Medical Center, Dallas, TX, Dallas, TX; ²Southern Methodist University, Dallas, TX; ³University of Texas Southwestern Medical Center, Dallas, TX; ⁴UT Southwestern Medical Center, Dallas, TX

Background: Diabetes screening is an opportunity for healthcare providers to discuss diabetes risk and prevention; however, the impact of receiving diabetes test results on patients' risk perceptions, worry, and information seeking behavior is unknown.

Methods: Patients in a safety-net health system were asked to participate in a longitudinal diabetes screening study. Study participants were 18–65, not currently pregnant, and included those with unknown glycemic status and no resulted screening test in the past two years. At enrollment, interviewers administered items on comparative risk (2 items) and worry (2 items) via telephone in English or Spanish, using a 4-point scale ranging from strongly agree to strongly disagree. Participants were then asked to complete diabetes screening at their safety-net clinic. Two weeks after mailing screening results, patients with normal or prediabetes results ($n = 302$) were contacted to complete a similar assessment of beliefs and behaviors since receiving the results. We assessed: (1) changes in comparative risk and worry; (2) whether changes differed by self-reported results or were associated with information seeking; and (3) whether test results were associated with information seeking ("Since receiving your test results, have you looked for information about diabetes or prediabetes from any source?"). Two-week survey response rate was 59% ($n = 179$).

Results: Most participants correctly reported their test result (96%). Change in comparative risk did not differ between those reporting a normal ($n = 107$) or prediabetes ($n = 72$) result, $F(1, 175) = .41, p = .52$. Patients with prediabetes had greater increases in worry ($M = 2.78$ to 3.02) than those with normal results ($M = 2.68$ to 2.67), $F(1, 176) = 4.20, p = .04, d = .31$. Neither changes in comparative risk nor worry predicted information seeking in either group ($ps \geq .10$). However, patients with prediabetes were more likely to report looking for diabetes-related information (49%) than those with normal results (31%), $\chi^2(1) = 5.77, \phi = .18, p = .02$.

Conclusions: Receiving a prediabetes test result was associated with increases in patient's worry about diabetes and looking for relevant information. These findings suggest that test results potentially prime patients to be receptive to education. Thus, health systems should use the diabetes screening process as an opportunity to engage patients in risk discussions and diabetes prevention interventions.

SLEEP HABITS AND SELF-MANAGEMENT IN TEENS WITH TYPE 1 DIABETES: A QUALITATIVE STUDY

Rodayne J. Williams, BA¹, Erin M. Bergner, MPH, MA¹, Emily R. Hamburger, MEd¹, Morgan Lyttle, BA², Angelia C. Davis, BS³, Sarah S. Jaser, PhD¹

¹Vanderbilt University Medical Center, Nashville, TN; ²Vanderbilt University Medical Center, Mt. Juliet, TN; ³Vanderbilt University Medical Center, Antioch, TN

Sleep has increasingly been identified as a modifiable risk factor for poor diabetes management and suboptimal glycemic control in teens with type 1 diabetes (T1D), but no qualitative studies have been conducted to explore barriers to obtaining good quality and sufficient sleep in this population. We conducted semi-structured interviews with 25 teens with T1D, ages 13–17 (mean age = 15.6 years; 52% female; mean HbA1c = 8.9%; 56% used insulin pumps). Interviews explored teens' sleep habits and barriers to sleep in relation to diabetes management. Interviews were transcribed and each was coded by two raters using Atlas.ti. Inter-rater reliability was 82%. Similar to teens in the general population, teens in our sample described several barriers to obtaining sufficient sleep, and 64% believed that they did not get adequate sleep. Common barriers reported included using electronics (e.g., cell phone, laptop, television) before bed (92%), homework or school-related activities, sports, and other external factors (e.g., siblings, pets, outside noise) that resulted in sleep delay and disruption. The majority of teens described differences between sleep on school days and weekend days/holidays, primarily describing staying up and sleeping in much later on the weekends. Teens also noted several associations between sleep and diabetes management. Teens complained that diabetes often interfered with sleep when waking to treat low blood glucose levels, or in response to alarms (20% of participants reported using a continuous glucose monitor). Teens also perceived that sleep habits had an impact on their diabetes management. For example, teens who slept more than the recommended 8–10 hours reported frequent missed blood glucose checks, especially on the weekends, disrupted meal schedules, and waking up with low blood glucose levels. In addition, teens who reported obtaining insufficient sleep (<8 hours/night) acknowledged consuming caffeine to stay awake, being less aware of their food choices, and forgetting to check their blood glucose levels at the appropriate intervals. Sleep disturbances are common in the T1D population, and the current study provided teens' perspectives on common barriers to obtaining sufficient sleep, as well as the links between sleep and diabetes management. Findings will inform a sleep-promoting intervention for teens with T1D.

SOCIAL SUPPORT PROFILES OF LATE ADOLESCENTS AND EMERGING ADULTS WITH TYPE 1 DIABETES

Natalie R. Troxel, PhD¹, Deborah Wiebe, PhD, MPH², Cynthia Berg, Ph.D.³

¹UC Merced, Davis, CA; ²University of California, Merced, Merced, CA; ³University of Utah, Salt Lake City, UT

Cluster and profile analyses have been used to a very limited degree in studying adolescents and emerging adults with Type 1 diabetes, despite the potential clinical importance of identifying subgroups and developmental trajectories within this population. Prior research has focused on identifying subgroups of glycemic control and illness coping, or examining longitudinal trajectories of glycemic control in relation to adolescents' self-control and parental monitoring. The present study used survey methods to examine whether there are discernible social-support profiles among late adolescents and emerging adults with type 1 diabetes, whether those profiles are stable across this period of development, and whether those profiles predict glycemic control, adherence, and depression. Late adolescents with type 1 diabetes were recruited during their senior year of high school (N = 247; 60% female; M = 17.8 years old). Participants completed surveys to measure perceived support and diabetes involvement from their doctor, mother, father, friends, and romantic partners, adherence, and depressive symptoms; a blood sample was provided to assay HbA1c. Participants repeated these measures annually for two subsequent years. At each of three time points, a two-cluster solution best fit the data, with group 1 representing "high social support" and group 2 representing "low-to-moderate social support." At each time point, high social support predicted better adherence (t1 = -7.71, t2 = -5.12, t3 = -5.55, all *ps* < .05) and less depression (t1 = 2.26, t2 = 2.16, t3 = 3.62, all *ps* < .05). At T2 only, high social support predicted lower A1c (t = 2.03, *p* < .05). Support was not consistent over time, however. Those with consistent support had lower A1c and marginally fewer depressive symptoms than those with inconsistent support. There was further evidence that those with consistently high support fared best on glycemic control, depression, and adherence at T3, as compared to those with inconsistent or consistently low support. Findings may identify those more at risk for poor diabetes management (low or inconsistent support) that may be targeted for intervention.

THE RELATIONSHIP BETWEEN ILLNESS IDENTITY AND PSYCHOLOGICAL AND DIABETES-SPECIFIC FUNCTIONING IN ADULTS WITH TYPE 2 DIABETES

Kaile M. Ross, MA, Christianne M. Biggane, N/A, Christina Rush, M.A., Kevin S. Masters, PhD

University of Colorado Denver, Denver, CO

Introduction: Many individuals with Type 2 Diabetes Mellitus (T2DM) struggle to adhere to prescribed treatment regimens. Illness identity (i.e., how individuals integrate diabetes into their identity) may influence treatment adherence; yet research on illness identity is limited. The Illness Identity Questionnaire (IIQ) is a recently developed questionnaire that assesses four dimensions of illness identity: Acceptance, Rejection, Enrichment, and Engulfment. The current study sought to determine how different dimensions of identity, measured by the IIQ, relate to psychological and diabetes-specific functioning in individuals with T2DM.

Methods: Adults with T2DM ($N = 282$) were recruited through an online service, Qualtrics, to complete the research survey. Structural equation modeling was used to assess how the IIQ dimensions relate to both psychological and diabetes-related functioning.

Results: Participants were on average 54 years old ($SD = 15.21$), and tended to be female (65.6%), Non-Hispanic (90.4%), and White (87.2%). The structural equation model results demonstrated that Acceptance was significantly associated with less depression ($\beta = -2.32, p < 0.05$), less diabetes distress ($\beta = -2.97, p < 0.01$), better life satisfaction ($\beta = 5.25, p < 0.001$) and better medication adherence ($\beta = -2.07, p < 0.05$). Enrichment was significantly associated with less depression ($\beta = -2.29, p < 0.05$), better life satisfaction ($\beta = 3.86, p < 0.001$), and better diabetes self-care ($\beta = 6.17, p < 0.001$). Rejection was significantly associated with worse depression ($\beta = 2.90, p < 0.001$), poorer diabetes self-care ($\beta = -2.52, p < 0.05$), and worse medication adherence ($\beta = 3.89, p < 0.001$). Engulfment was significantly associated with worse depression ($\beta = 6.42, p < 0.001$), worse life satisfaction ($\beta = -4.61, p < 0.001$), greater diabetes distress ($\beta = 14.76, p < 0.001$), and poor medication adherence ($\beta = 2.72, p < 0.01$).

Conclusions: The IIQ dimensions that were associated with the integration of illness with identity (i.e. Acceptance and Enrichment) were associated with positive psychological wellbeing and better diabetes self-care behaviors; whereas dimensions that reflect poorer identity integration (i.e., Rejection and Engulfment) were generally associated with poorer psychological wellbeing and poorer diabetes-specific functioning. The IIQ may be a useful clinical tool for understanding illness identity in adults with T2DM.

VIRTUAL ENVIRONMENTS PROVIDE THE FULL RANGE OF SUPPORT TO ADULTS LIVING WITH CHRONIC ILLNESS

Allison A. Lewinski, PhD, MPH, RN¹, Allison A. Vorderstrasse, DNSc, APRN², Ruth A. Anderson, RN, PhD³, Wei Pan, PhD⁴, Edwin B. Fisher, PhD⁵, Constance M. Johnson, PhD⁶

¹Durham Veterans Affairs Medical Center, Durham, NC; ²New York University, New York, NY; ³University of North Carolina Chapel Hill, Chapel Hill, NC; ⁴Duke University, Durham, NC; ⁵UNC Gillings School of Global Public Health, Chapel Hill, NC; ⁶The University of Texas Health Science Center at Houston, Houston, TX

Aims: Self-management interventions via immersive virtual environments (VEs) can facilitate support for those living with chronic illness. Yet, whether these Internet environments provide comprehensive support, and, if so, how, remain widely unknown. This study aimed to describe the characteristics of VE support from two perspectives: the aggregate support received by the individual, and the contributions of different VE components. In both cases, Cohen's four types of support (emotional, instrumental, informational, appraisal) served as an organizing framework.

Methods: This study was a secondary analysis that analyzed synchronous conversational data from a study that provided self-management education and support to individuals with type 2 diabetes (T2D) who interacted in a VE. The sample included individuals with T2D ($n = 20$) and diabetes educators/study investigators ($n = 4$). Diabetes educators led two education sessions and one support session per week for six months.

Results: • **Aggregate Support:** A total of 1170 support exchanges occurred in the education ($n = 723, 62%$) and the support ($n = 406, 34%$) sessions, or outside of session times ($n = 41, 4%$). In the aggregate, individuals received substantial informational support (535 or 46% of all exchanges), including information about food (149 or 28% of informational exchanges) and problem solving (85 or 16% of informational exchanges). Participants received substantial emotional support (377 or 32% of all exchanges) and appraisal support (217 or 19% of all exchanges). Under emotional support, exchanges addressed physical health (88 or 23% of emotional support exchanges) as well as distress (189 or 50% of emotional support exchanges), and enacting behaviors (100 or 27% of emotional support exchanges). Under appraisal support, exchanges provided affirmations in response to information seeking (32 or 15% of appraisal exchanges) or self-management behaviors (185 or 85% of appraisal support exchanges). In contrast, the VE provided little instrumental support (41 or 4% of all exchanges).

• **Contributions of VE Components:** When disaggregating by session type, educational sessions provided predominantly informational support (357 or 49% of 723 exchanges). In contrast, general support sessions provided predominantly emotional support (159 or 39% of 406 exchanges).

Conclusions: With the perhaps understandable exception of instrumental support, VEs may provide individuals a full range of informational, emotional and appraisal support. At the same time, their components are complementary. Educational sessions provide mostly informational support, while general support sessions provide mostly emotional support. With this versatility, then, VEs are able to contribute substantially to support for those with T2D and, very likely, other chronic illnesses.

VIVIENDO SALUDABLE: A COMMUNITY BASED PROGRAM TARGETING CLINICAL AND PSYCHOLOGICAL HEALTH IN HISPANIC WOMEN WITH PREDIABETES

Harsimran Singh, PhD¹, John Billimek, PhD², Beatriz Camacho, BA³, Ana Pimentel, MSW⁴, Joanna Gallo Moreno, RDN, CDE⁵, Rommy Andrea Renteros, BSc, MPH⁶, Rocio Valencia, LCSW⁷, Daniel Nadeau, MD⁸

¹Mary & Dick Allen Diabetes Center, Hoag Memorial Hospital Presbyterian, Ladera Ranch, CA; ²Health Policy Research Institute, Division of General Internal Medicine and Department of Family Medicine School of Medicine, University of California, Irvine, Irvine, CA; ³Melinda Hoag Smith Center for Healthy Living, Hoag Memorial Hospital Presbyterian, Newport Beach, CA; ⁴Mary & Dick Allen Diabetes Center, Hoag Memorial Hospital Presbyterian, Huntington Beach, CA; ⁵Mary & Dick Allen Diabetes Center, Hoag Memorial Hospital Presbyterian, Santa Ana, CA; ⁶Public Health Sciences, University of California, Irvine, Irvine, CA; ⁷Melinda Hoag Smith Center for Healthy Living, Hoag Hospital, Newport Beach, California, Newport Beach, CA; ⁸Mary & Dick Allen Diabetes Center, Hoag Hospital, Newport Beach, California, Newport Beach, CA

About 38% of Hispanics have prediabetes and are at an increased risk for developing type 2 diabetes. Culturally competent and sustainable interventions are needed to equip this population with specific lifestyle and psychosocial skills for healthier outcomes. The Viviendo Saludable (VS) program was developed as a 23-week intervention with 12 group sessions (90 minutes each) held every other week. Sessions focused on nutrition, physical activity, and psychological health. Each session was followed by a weekly maintenance phone call to encourage participants to continue with their lifestyle changes. Preliminary efficacy of VS was evaluated in a non-randomized, prospective trial of 34 Hispanic women with prediabetes. Participants were consented and recruited from a community health center and were unaware of their prediabetes status before the study. Prediabetes was determined based on HbA1c (glycated haemoglobin) and fasting glucose values. Participants were evaluated on clinical and psychosocial variables at baseline and post intervention. The majority of participants were married (n=23), employed (n=18), and had no health insurance (n=19). Only 18 (of 34) participants had completed high school or received any further education. The majority (n=20) reported an annual household income of <\$20,000 and indicated concerns with food security (n=19). Adherence to VS sessions was high (80–100%). Pre-post comparisons with Bonferroni correction highlighted significant reductions in BMI (31.7 vs 29.3, p <0.001), body weight (165.8 vs 158.2, p <0.001), waist circumference (38.8 vs 36.3, p <0.001), and HbA1c (5.8 vs 5.6, p <0.001). The majority of participants (n=20) did not have prediabetes at post assessment. Significant improvements were also observed in psychological well-being (15.3 vs 19.5, p <0.001), physical health status (44.5 vs 51.7, p <0.001), and mental health status (46.7 vs 53.4, p <0.001). Exit interviews revealed that instruction around nutrition and psychological health was valued the most by participants. Participants also reported introducing significant lifestyle changes for their family members based on the VS sessions. For program sustainability, 4 women were selected to be trained as promotoras for a future roll out. Findings emphasize the importance of addressing both psychological and clinical health while developing diabetes interventions for underserved communities so that they feel appropriately empowered to achieve healthier outcomes.

GLUCOPILOT: A DATA-POWERED PERSONALIZED NUTRITION DECISION SUPPORT SYSTEM FOR DIABETES SELF-MANAGEMENT

Marissa Burgermaster, PhD¹, Arlene Smaldone, PhD, RN², Patricia Davidson, DCN, RD³, Kate Gardner Burt, PhD, RD⁴, Daniel J. Feller⁵, Jung Hoon. Son, MD⁵, Lena Mamykina, PhD⁵

¹Columbia University, Maplewood, NJ; ²Columbia School of Nursing, New York, NY; ³West Chester University, West Chester, PA; ⁴Lehman College, Bronx, NY; ⁵Columbia University, New York, NY

Diabetes education guidelines recommend that individualized dietary self-management plans be developed for those with type 2 diabetes (T2D). Data generated by diet self-monitoring technologies present an opportunity for data-powered, personalized diet recommendations. Despite the increasing availability of self-monitoring data to improve dietary management of T2D, few solutions have been identified for leveraging these data to provide personalized dietary recommendations in order to improve dietary management of T2D. The goal of this research was to develop and evaluate a suggestion system, GluCopilot, which generates data-powered personalized T2D dietary recommendations.

We used process coding to qualitatively analyze data from 10 registered dietitian (RD) interviews to identify how RDs utilize records of patients' meals and blood glucose levels to generate recommendations to reduce post-meal glucose excursions. Next, we developed a decision tree model to sequentially order themes from the process coding, representing the RDs' counseling process. Two RDs assessed the model's face validity, clinical appropriateness, and utility. We then developed a task-specific ontology of classes and attributes from process coding themes and, using R, programmed a series of functions to transform meal data into personalized patient goals. Using 30-days of meal photos and associated macronutrient data, we compared GluCopilot recommendations to those made by two experienced certified diabetes educators (CDEs) using (1) CDE-generated recommendations and (2) CDE selections from a closed set of recommendations (i.e., eat more/maintain/eat less of specific macronutrients).

Thirty-six process codes and seven themes were identified. Two RDs found the decision tree to be face valid and clinically appropriate with potential for use in clinical practice. GluCopilot was 69% and 83% consistent with CDE-generated and 44% and 67% consistent with the closed-set gold standards.

Although the comparison of GluCopilot to the CDE-generated recommendations was promising, GluCopilot was less consistent with CDEs' choice of closed set recommendations. This raises important questions about whether human experts or computer algorithms are better suited to discerning signals from large patient-generated datasets. The data used here represent patients with few glucose excursions. We plan to evaluate GluCopilot with data from more diverse patients with T2D. As clinicians see the utility of using patient-generated data in personalizing care, GluCopilot represents a first step towards extending the reach of self-monitoring data by synthesizing it with clinical knowledge in a dietary decision support tool.

AN ENVIRONMENTAL SCAN & REVIEW OF ORAL HEALTH PROMOTION APPS: OPPORTUNITIES FOR FUTURE INTERVENTION DEVELOPMENT

Paula R. Blasi, MPH¹, Tooka Zokaie, MPH Candidate, BS², Sheryl Catz, PhD³, Jennifer B. McClure, PhD¹¹Kaiser Permanente Washington Health Research Institute, Seattle, WA; ²University of California Davis, El Dorado Hills, CA; ³UC Davis, Sacramento, CA

Most U.S. adults own a smartphone, making mobile applications (apps) promising tools for promoting healthy behaviors. As a result, there has been an explosion of consumer-facing health promotion apps in recent years. Much is known about apps addressing popular health issues like smoking, diet, and physical activity, but almost nothing is known about the availability or quality of apps to promote better oral health care. Oral disease (e.g., cavities, gum disease, oral cancer) affects millions of Americans annually, resulting in unnecessary pain and suffering and costing the U.S. ~\$120 billion per year. Thus, we sought to better understand the landscape of consumer-focused oral health promotion apps to inform the need for future intervention development. We conducted an environmental scan of apps available in the Apple iTunes and Google Play stores from June-August 2017. We identified all apps that were designed for adult consumers (i.e., we excluded educational apps for dental providers or children). For each app identified we assessed the source, platform, cost, content, and any cited theoretical or empirical basis for the content. Thirty-six apps were identified (9 for iOS, 11 for Android devices, and 16 for either platform). Most (n=31) were free. The producers/sponsors ranged from app developers (n=14) to insurers (n=4) and dental care providers (n=4). Most apps (n=25) were designed for the general public, but the rest targeted specific audiences such as dental insurance plan members (n=4) or dental clinic patients (n=3). Content was heterogeneous. Many, but not all, included some form of oral health education (n=16). Other common features included oral hygiene tracking and reminders (n=9) and various features designed to facilitate seeing a dentist (n=9). Only 8 apps mentioned tobacco use as an oral health risk factor and only 3 cited an evidence base for their information. None cited any theoretical basis for their content. In short, relatively little attention has been focused on developing or disseminating mobile health (mHealth) tools to improve adult oral health care, and existing programs do not appear to have a strong theoretical or empirical basis for their content. As such, an important opportunity exists to develop theoretically and empirically-grounded oral health promotion programs delivered via self-help apps. Such programs could help reduce the burden of common oral diseases in this country.

CO-DESIGNING WITH YOUTH TO DEVELOP A WEB-BASED INTERACTIVE NUTRITION COMIC TO DECREASE CHILDHOOD OBESITY RISK

May May Leung, PhD, RDN¹, Katrina F. Mateo, MPH², Eman Abbas, BS³, Sandra Verdaguier, BS, MS¹¹Hunter College, City University of New York, New York, NY; ²CUNY Hunter College / CUNY School of Public Health, New York, NY; ³Primary: Hunter College, City University of New York, Woodside, NY

Background: A user-centered design approach aims to engage the intended audience throughout development of tools to increase their acceptability and potential effectiveness. While m-Health tools have potential to reach and engage culturally diverse populations, there is limited literature on youth involvement in design and development. We aim to: 1) Describe participatory processes for engaging minority youth in the development of a web-based interactive nutrition comic, 2) Summarize development process findings, and 3) Describe lessons learned through the co-designing process.

Methods: African-American(AA)/Black and Latino youth ages 9 to 12 years (n=37; 54% female; 62% AA/Black, 57% Hispanic) residing in low-income neighborhoods of New York City participated in focus groups and interviews. In Summer 2016, formative research was conducted to identify perceived healthy dietary behaviors, assess technology use, and identify preferred comic storylines and characters. In Fall 2016, finalization of comic story content occurred. In Winter 2017, design thinking approaches (card sorting and sketching) were used to elicit website wireframe feedback. In Spring and Summer 2017, usability testing was conducted with online tool prototypes using a *think-aloud* protocol.

Results: Formative research found that youth believed important health behaviors included increasing fruit/vegetable intake and limiting sugar intake, utilized apps to primarily play games, preferred comics to include action, adventure and fantasy elements, and suggested the main character be a brave teenager who overcame struggles. From these data, the intervention's targeted behaviors were selected and a comic storyline and character profiles were developed and tested. Overall, youth responded positively to the storyline and character personas, and suggested scenarios to make the story more relatable. While assessing website components and design, youth preferred not to receive messages from parents and wanted more details about characters. Tool changes from usability testing included adding a navigation guide and improving graphic designs. Specific comic text was edited to enhance literacy. Lessons learned included testing in pairs led to more meaningful data and a modified *think-aloud* approach was needed.

Conclusion: Engaging youth during development resulted in a tablet-optimized tool to deliver a culturally-tailored interactive nutrition comic. This innovative, technology-enhanced tool will be tested using a two-group pilot randomized study, with the goal of reducing childhood obesity risk in minority, low-income youth.

CREATING A DIGITAL ADVISORY BOARD FOR A LARGE COHORT STUDY

Mona AuYoung, PhD, MS, MPH¹, Gayle Simon, MPH¹, Anna Andersen, MA¹, Donna Spruijt-Metz, MFA, PhD², Camille Nebeker, Ed.D, M.S.,³¹Scripps Translational Science Institute, La Jolla, CA; ²University of Southern California, Los Angeles, CA; ³UC San Diego, La Jolla, CA

Community advisory boards have been an important part of community-based research, especially for research on populations that are vulnerable and/or under-represented. There is increasing emphasis on the recruitment of more diverse populations for research to more accurately represent the general population, especially in large cohort studies. However, for large cohort studies to represent populations that are diverse (in terms of race/ethnicity, geography, and other characteristics), there are inherent challenges such as time and location. A digital advisory board may be a more feasible way to incorporate the voices of community members, especially with ever-increasing numbers of the general population gaining access to the internet and also using social media platforms. Using an innovative method that combines traditional features of the community advisory board and key strategies from studies on online communities and social networks, this paper will describe the process for forming a digital advisory board for a large cohort study and early lessons learned.

DETECTING REAL TIME EPISODIC OVEREATING FOR JUST IN TIME INTERVENTIONS

Nabil Alshurafa, PhD¹, Rawan Alharbi, PhD¹, Angela F. Pfammatter, PhD², Bonnie Spring, PhD¹

¹Northwestern University, Chicago, IL; ²Northwestern University Feinberg School of Medicine, Chicago, IL

Obesity, caused primarily by overeating relative to need, is a preventable chronic disease that exacts staggering healthcare costs. Obesity treatment would benefit from an accurate, passive, and timely measure of problematic eating. Current methods assess overeating by comparing overall intake to daily caloric need, a day level measurement. Defining and measuring problematic overeating episodically (per meal/snack) in real-time would allow researchers to test timely interventions to prevent overeating. In the BeYourself study, we followed 30 participants with and without obesity. Dietitians performed 24-hour dietary recall for two-weeks. We operationalize overeating episodically in a manner that is personalized based on the individual's caloric intake distribution, each meal validated by a dietitian. Participants also responded to event-triggered prompts to generate contextual features that surround eating such as whether they felt they overate (subjective overeating). Our operationalized definition of overeating, defined as a meal that exceeds 1 z-score (85.1% percentile) threshold of participants personalized caloric intake distribution (meaning larger than normal meals typically consumed by the participant) correlated with participant subjective overeating response. Fast food and empty-calorie foods like candy and popcorn consistently correlated with episodic overeating. Personalized predictors of overeating episodes existed for each individual and included one participant's overeating that correlated with alcohol consumption during meals. Operationalizing overeating episodically, detecting it objectively and passively (without participant input and burden), learning to predict it, and intervening in a timely manner that adapts to an individual's unique problematic overeating profile, would be foundational to personalized behavioral medicine for obesity.

DEVELOPING AN ONLINE TOOL TO SUPPORT HEALTHY FEEDING BEHAVIORS AMONG URBAN MINORITY PARENTS OF PREADOLESCENTS

Katrina F. Mateo, MPH¹, Sandra Verdaguer, BS, MS², Eman Abbas, BS³, May May Leung, PhD, RDN²

¹CUNY Hunter College / CUNY School of Public Health, New York, NY; ²Hunter College, City University of New York, New York, NY; ³Primary: Hunter College, City University of New York, Woodside, NY

Background: While children transitioning into adolescence (ages 9 to 12) are gaining autonomy and developing decision-making skills, parents still play a significant role in fostering their child's dietary behaviors. As part of the development of a technology-enhanced intervention to promote healthy eating among urban minority preadolescents, research was conducted to develop a parent-focused health promotion tool to support positive feeding behaviors.

Methods: Twenty-four parents (42% African-American/Black, 63% Latino, 96% female) from a New York City community organization participated in focus groups and interviews (with/without child). Formative research was conducted to identify barriers and facilitators to healthy eating/feeding behaviors, and characterize technology use (Summer 2016). Findings informed design of an online tool, which was iteratively developed and assessed using qualitative, co-design, and *think-aloud* approaches to confirm/finalize content (Fall 2016), assess the website wireframe (Winter 2016), and conduct usability testing (Spring-Summer 2017). Sessions were conducted in English or Spanish. Session notes and audio-recordings were reviewed throughout development to design and improve prototypes.

Results: Formative research identified barriers including having picky eaters, limited time/energy to cook meals, and cost. Important feeding behaviors included offering a variety of fruits/vegetables to their child. Suggestions for an online health tool included quick recipes, healthy tips, clear tool navigation, and the use of pictures and visuals. When finalizing the tool wireframe and content, parents preferred a variety of motivational healthy feeding tips that encouraged positive interaction with their child, local family-oriented community events, and a simple, colorful layout with minimal clicking to access links/information. During usability testing, parents responded positively to the content (healthy feeding tips, recipes, coupon, and free community event) and clean layout, especially the use of bright color schemes and easy navigation. Suggestions included incorporating more fruit/vegetable images and action words ("click here") to draw attention to coupon/event links.

Conclusions: Engaging parents throughout development resulted in a web-based, mobile-friendly health promotion tool. It will be tested as part of a larger technology-enhanced intervention using a two-group pilot randomized study, with the aim of reducing childhood obesity risk.

DEVELOPMENT AND TESTING OF A MOBILE-BASED INTERVENTION TO REDUCE HEALTH RISK BEHAVIOURS IN PEOPLE WITH MENTAL HEALTH PROBLEMS

Louise Thornton, PhD¹, Frances Kay-Lambkin, PhD², Bree Tebbutt, BPsych³, Tanya Hanstock, DPsych³, Amanda L. Baker, PhD³, Katrina Champion, PhD⁴

¹University of New South Wales, Randwick, New South Wales, Australia; ²The University of Newcastle, Newcastle, New South Wales, Australia; ³The University of Newcastle, Callaghan, New South Wales, Australia; ⁴UNSW Sydney, Sydney, New South Wales, Australia

Background: Substance use and other health risk behaviours (e.g. poor diet and physical inactivity) are much more common among people with mental health problems. Smoking, alcohol misuse, physical inactivity and poor diet are also consistently identified as the top four behavioural risk factors associated with chronic disease such as cardio-vascular disease (CVD) which are responsible for more deaths in this population than suicide. However, due to time constraints, lack of awareness, training and resources, mental health services often confine their services to mental health issues therefore, neglecting these types of health risk behaviours. This presentation describes the development and initial evaluation of the first mobile-based intervention to target multiple key health risk behaviours (smoking, alcohol misuse, poor diet and physical inactivity) for people with mental health problems called MyHealthPA.

Methods: The development of MyHealthPA occurred in four stages: 1) reviewing and addressing the literature; 2) a scoping survey with end-users (n = 251); 3) program development; and 4) pilot testing with young people with and without a previous diagnosis of a mental illness (n = 28).

Results and Conclusions: Overall, MyHealthPA represents an innovative approach to substance use, diet and exercise and chronic disease risk reduction among people with mental health problems. It appears that MyHealthPA is acceptable, easy to use, potentially effective and potentially easy to integrate into existing clinical and public health practice.

DISPARITIES IN MOBILE PHONE USE AMONG DIVERSE PATIENTS WITH TYPE 2 DIABETES

Lyndsay A. Nelson, PhD¹, Lauren M. LeSturgeon, MPH¹, Ken A. Wallston, PhD², Erin M. Bergner, MPH, MA¹, Lindsay S. Mayberry, PhD¹

¹Vanderbilt University Medical Center, Nashville, TN; ²Vanderbilt University, Nashville, TN

In the past decade, there has been a surge in the development of mHealth interventions to support self-management of chronic diseases, including type 2 diabetes (T2D). Across many trials, interventions using phone calls, text messaging, and apps to deliver diabetes education have significantly improved patients' self-care and glycemic control. Despite the promise of mHealth to improve health outcomes, understanding the ways in which patients use their phones has implications for who can ultimately benefit. We used baseline data from a text messaging intervention for diabetes self-care promotion to examine how mobile phone owners with T2D used their phones and examined associations between patient characteristics and mobile phone use.

We recruited adults with T2D from primary care clinics who owned a mobile phone with text messaging capability. Participants completed a survey asking about demographics (i.e., age, gender, race, education, income), their health literacy (Brief Health Literacy Screen), numeracy (Subjective Numeracy Scale), and mobile phone use. We examined descriptive statistics and used non-parametric tests of differences to examine associations between patient characteristics and use of texting, smartphones, and apps. We report all associations where $p < .05$.

Participants (N=409) were 55.9 ± 9.8 years old; 54% female; 39% African American; 43% had \leq a high school degree, and 46% had annual incomes or send text messages (2%) because they had reached their monthly limit. Participants who were non-White and had less education, lower income, lower health literacy, and lower numeracy were less likely to use texting to communicate. The majority of participants (82%) owned a smartphone; however, among smartphone owners, less than half (47%) had ever used a health app. Older participants were less likely to own a smartphone. In addition, participants with less education, lower income, lower health literacy and lower numeracy were less likely to own a smartphone and to have ever used a health app.

We found disparities in mobile phone use and smartphone ownership among disadvantaged groups with T2D who also tend to experience worse health outcomes. Despite the potential reach of mHealth interventions to engage patients in their health care and improve health outcomes, neglecting these differences in the design and deployment of mHealth programs may widen health disparities.

ENERGY BALANCE MODELS & BITE GOALS TO MAXIMIZE ADHERENCE TO WEIGHT LOSS TREATMENT: THE BITES PILOT STUDY

Carly M. Goldstein, PhD¹, Diana Thomas, Ph.D.², Adam Hoover, PhD³, Dale S. Bond, PhD⁴, J. Graham Thomas, PhD⁵¹The Miriam Hospital/The Alpert Medical School of Brown University, Providence, RI; ²United States Military Academy, Randolph, NJ; ³Clemson University, Clemson, SC; ⁴The Miriam Hospital/Brown Alpert Medical School Weight Control and Diabetes Research Center, Providence, RI; ⁵Brown University School of Medicine & The Miriam Hospital, Providence, RI**Background:** Online behavioral weight loss (OBWL) treatment can be effective but often produces less weight loss than in-person treatment, likely due in part to insufficient adherence to the prescribed caloric restriction. Technology to convey and support adherence may improve outcomes by helping users understand how non-adherence results in insufficient weight loss or by supporting caloric restriction at mealtime.**Methods:** Adults with BMI 27–45 kg/m² (83.3% women, mean±SD age 49.8 ± 8.9, BMI 38.4 ± 11.4) were randomized to 12 weeks of OBWL alone (N=9), OBWL plus energy balance modeling (OBWL+EBM, N=7) that involved weekly feedback in the form of a graph depicting their actual and a range of their expected weight loss based on their personalized physiological parameters, or these two interventions plus the provision of the wrist-worn Bite Counter device (OBWL+EBM+BC, N=8) that was used to set a EBM-based within-meal bite goal with alarm after two consecutive weeks of lower than expected weight loss per the EBM. All 24 participants were weighed weekly at the clinic for 24 weeks and the EBM and BC interventions were continued during weeks 13–24. Participants were assessed at baseline, 3-, and 6-months.**Results:** The experimental interventions were administered successfully. Study completion rates were 44.4% in OBWL, 74.4% in OBWL+EBM, and 62.5% in BWL+EBM+BC (p=.53). Failure to complete was most often attributed to dislike of weekly weigh-ins, of which 67.4% were attended across groups. In intent-to-treat analysis with zero weight loss imputed for missing data, mean±SD weight loss (kg) was 4.0 ± 5.0 in OBWL, 4.6 ± 5.1 in OBWL+EBM, and 5.3 ± 3.7 in OBWL+EBM+BC at 12-weeks (p=.85) and 3.7 ± 4.4 in OBWL, 5.9 ± 7.6 in OBWL+EBM, and 6.3 ± 4.7 in OBWL+EBM+BC at 24-weeks (p=.58). The BC was used 120.5 ± 46.1 (71.7%) of the 168 days it was instructed to be used per participant.**Conclusion:** EBM and BC were feasible for administration but acceptability of the interventions was low due to the requirement for weekly clinic weigh-ins. Though not statistically significant in this small sample, the larger mean weight losses achieved via these interventions warrant further investigation in an adequately-powered clinical trial without clinic weigh-ins. EBM and BC may support weight loss in middle-aged adults with excess weight who are also engaging in a structured, empirically-based weight loss program.

ENGAGING USERS IN THE MHEALTH DESIGN PROCESS - OVERWEIGHT/OBESE WOMEN'S PREFERENCES FOR A PRECONCEPTIONAL HEALTH INTERVENTION

Frank T. Matera, MHS¹, Joshua M. Smyth, PhD², Mark E. Feinberg, PhD¹, Marianne Hillemeier, PhD², Danielle Symons. Downs, BA, MA, PHD¹¹The Pennsylvania State University, University Park, PA; ²Pennsylvania State University, University Park, PA

The prevalence of maternal perinatal obesity is increasing, posing health risks for both mother and child. The Strong Healthy Women (SHW) intervention is an evidence-based intervention to reduce adverse perinatal risk factors and improve women's preconceptional health. As designed, however, the program is delivered in face-to-face sessions and is thus resource- and time-intensive. Mobile health (mHealth) technologies afford an opportunity to expand SHW reach while reducing burden and cost. Our prior research suggests preconceptional women are accepting of using smartphones for behavior change, yet few studies have engaged them in the design of a targeted mHealth intervention.

Objective: To evaluate women's preferences for receiving SHW content via smartphone to enhance the design of SMART SHW, a redeveloped version of the intervention that utilizes smartphones to enhance program delivery.**Methods:** Semi-structured focus group interviews were conducted with overweight/obese (M BMI= 31.4) preconceptional community women (N= 40). Participants were presented with all SHW components across four content areas (physical activity, nutrition, stress, weight management) and provided preferences for program elements viewed as acceptable to convert to mobile. Thematic analysis was used to analyze interview data. Separately, a scientific team conducted an iterative review of the data to determine which aspects of SHW were feasible to modify for delivery via smartphone.**Results:** Women preferred to receive SHW communications, surveys, and educational materials on their smartphones via texting, mobile websites, and a SMART SHW app; MyFitnessPal and a pedometer were preferred methods for tracking nutrition and activity. Salient mHealth design themes were using online videos to supplement the curriculum, providing popups as reminders, and presenting on-screen information in a concise format. The scientific team incorporated 87% of participant preferences in designing the final prototype.**Conclusion:** Smartphone devices can reduce implementation burden and enhance the reach of face-to-face behavioral interventions. Engaging target users (overweight/obese preconceptional women in this case) in the mHealth redesign process, particularly through semi-structured focus groups, is a feasible and useful approach. By leveraging user preferences this method guides the development of an intervention framework that is highly acceptable to the target participants.

EVALUATION OF THE IMPACT OF A DIGITAL HEALTH PLATFORM ON ASTHMA SELF-MANAGEMENT

Kelly Henderson, MPH¹, Meredith Barrett, PhD², Melissa Williams, RT³¹Propeller Health, Berkeley, CA; ²Propeller Health, San Francisco, CA; ³Propeller Health, Indiana, IN

Louisville ranks in the top 20 most challenging places to live with asthma in the US. Public and private stakeholders established an innovative community program using a digital health platform to help improve the asthma burden. The objective of this project was to evaluate motivations for participation in the program and to assess if a digital health platform contributes to improved asthma self-management. Residents with asthma in Louisville enrolled in the program and recorded their medication use with a wireless, GPS-enabled sensor, which passively collected the date, time, and location of inhaler use. Participants received access to a digital health platform including smartphone and web-based applications that provided information about their medication use trends, asthma control, education, and personalized support for 12 months. Participants received electronic surveys at program start and completion that evaluated their motivation for participating, health goals, understanding of their asthma, and learnings as a result of the program. A subset of participants responded to both surveys (n=57). The top three reasons for joining the program were to improve asthma control, learn about asthma triggers, and support a community program. Respondents cited a number of health goals, including feeling more in control of their asthma, having fewer asthma attacks, and missing fewer days of work or school. Respondents reported improved knowledge about their condition: 86% reported that they now understand their asthma either “very well” or “well,” 58% reported that they can always tell when their asthma is getting worse, and 35% reported that they know what triggers their asthma attacks. Respondents reported progress on their goals including knowing more about their triggers (63%), having fewer attacks (60%), feeling more in control of their asthma (60%), and feeling more confident taking their medication on time (42%). Fifty-six percent of respondents reported talking with their provider about the information from the digital platform. Use of a digital health platform successfully led to improvements in asthma self-management. Participants improved their understanding of their asthma, achieved asthma health goals, and initiated conversations with their healthcare provider. More work is needed to understand mechanisms of improvement and to identify ways to scale the platform to meet the needs of diverse participants.

FEASIBILITY AND ACCEPTABILITY OF A PHARMACIST-LED MOBILE APPROACH TO IMPROVING HYPERTENSION MANAGEMENT

Lorraine Buis, PhD¹, Dana N. Roberson, BS², Shivang Danak, MD¹, Reema Kadri, MLIS¹, Nicole G. Rockey, PharmD³, Melissa Plegue, MA¹, Hae Mi Choe, PharmD⁴, Caroline R. Richardson, MD¹¹University of Michigan, Ann Arbor, MI; ²University of Michigan, Geneva, FL; ³Michigan Medicine, Saline, MI; ⁴Michigan Medicine, Ann Arbor, MI

Hypertension (HTN) affects about 78 million Americans and adds significant cost to our healthcare system, making it an important public health issue. Overall, only about 50% of patients with HTN achieve adequate blood pressure control. Clinical pharmacists embedded in primary care settings are becoming increasingly common, and have been shown to be a valuable strategy for managing HTN. Mobile health (mHealth) is increasingly touted as the future of medicine, and has tremendous potential to support pharmacist HTN management, yet evidence supporting its use is not well documented. The goal of this pilot study was to establish the feasibility of a clinical pharmacist-led mHealth intervention in primary care patients with uncontrolled HTN. We conducted a one-group 12-week pre-/post- pilot study of BPTrack, a pharmacist-led mobile intervention that supports patient home blood pressure monitoring, medication adherence, and communication with a clinical pharmacist who is managing patient HTN. Clinical pharmacists were able to easily view participant data via a clinical app and use this data in their ongoing HTN management efforts. Participants in this study were recruited from a primary care setting and were between the ages of 18–65 years, had been diagnosed with HTN, were taking at least one antihypertension medication, and had uncontrolled HTN (SBP > 140 mmHg and/or DBP > 90 mmHg on repeat measurements as documented in the medical record). We collected baseline and 12-week follow up data from 13 individuals (mean SBP=137.6 mmHg, SD=11.4 mmHg; mean DBP=88.2 mmHg, SD=7.2 mmHg). Preliminary data from this pilot indicate that BPTrack participants had significantly lower SBP and DBP at 12-week follow up compared to baseline (mean change SBP = -6.62 mmHg, t(12)=2.72, p=.02; mean change DBP = -5.65 mmHg, t(12)=4.13, p=.001). Moreover, the use of BPTrack was acceptable to participants, with the majority of participants agreeing / strongly agreeing that they would recommend it to others (100.0%), liked knowing someone was watching their BP in between visits with their primary care physician (100.0%), were satisfied with the program (92.3%), and felt the program was beneficial to their overall health (92.3%). Preliminary results from this pilot suggest that our mobile approach to supporting clinical pharmacist management of HTN may be a feasible and acceptable approach for use within primary care settings.

IDENTIFYING MECHANISMS OF ACTION IN A MOBILE SMOKING CESSATION APP: A QUALITATIVE APPROACH

Christian J. Cerrada, BS¹, Sheila Yu, MPH¹, Ana Francisco, MSW, MPH¹, Jonathan Castaneda, B.A.², Eunice Hong, BS³, William Fang, N/A⁴, Jimi Huh, PhD¹

¹University of Southern California, Los Angeles, CA; ²Keck School of Preventive Medicine, Pico Rivera, CA; ³University of Southern California, Fullerton, CA; ⁴University of Southern California, Temple City, CA

Introduction: Although the role of qualitative research has been emphasized in understanding how users interact with digital interventions, such research is sparse for smoking cessation apps. In particular, more research is needed on the processes through which apps influence cessation (Mechanisms of Action, MoAs). The present study seeks to elucidate perceived MoAs for a just-in-time (JIT) momentary lapse avoidance intervention, MyQuit USC (MQU). MQU is a highly personalized quit app that delivers tailored reminders for implementation intentions (II) to avoid lapse during user-specified “high risk” smoking hours.

Methods: Korean American young adult smokers (18–25 yo) participated in semi-structured interviews (~30–60 mins) upon using MQU for 4 weeks. We report on the experiences of a subset of these participants (n=20; 16 M, 4 F; target N=60). A preliminary code list was created inductively using open codes derived from the first 10 interviews and then compared with constructs described in the Theoretical Domains Framework. New codes were created as additional MoAs emerged in the remaining interviews. Thematic analysis was performed using Atlas.ti 7.5. The authors refined codes iteratively and discussed emergent themes.

Results: Three major themes emerged and provide insight for MoAs in achieving lapse avoidance: 1) Behavioral Regulation, which refers to strategies used to avoid lapses, e.g. staying indoors. Although we designed MQU to facilitate behavioral regulation via II reminders delivered JIT, participants frequently described examples of behavioral regulation beyond their planned IIs, e.g., not buying packs; 2) Change in Motivation for Cessation, which was often described in relation to greater awareness of one’s smoking frequency or quit progress; and 3) External Factors Unrelated to MQU, such as being too busy to smoke and spending time with family. We also noted abstinence self-efficacy as an important factor; those with higher levels of abstinence self-efficacy tended to describe MoAs unrelated to MQU and negative experiences with the app.

Conclusions: Qualitative data from an ongoing investigation provides a rich account of users’ perspectives while using MQU during a quit attempt. Participants described a range of MoAs for lapse avoidance, a sizable portion of which were not part of our intended intervention or were unrelated to MQU. Our findings highlight the specific app features that facilitated lapse avoidance and potential user characteristics that may have influenced prominent MoAs throughout a cessation attempt. Future work will elucidate additional MoAs and triangulate findings with log data and EMA reports.

IMPLEMENTING TEXT MESSAGING TO ENHANCE DELIVERY OF THE DIABETES PREVENTION PROGRAM IN A DEVELOPING NATION

Frank T. Materia, MHS¹, Joshua M. Smyth, PhD², Thandi Rose. Puoane, Dr PH³, Kathy Goggin, PhD⁴, Lungiswa P. Tsolekile, BSc (Dietetics), MPH⁵, Ken Resnicow, PhD⁶, Taylor Haddad, B.S. (May ‘19)¹, Sarah Schlachter, M.Ed.⁷, Delwyn Catley, PhD⁸

¹The Pennsylvania State University, University Park, PA; ²Pennsylvania State University, University Park, PA; ³University of the Western Cape, Bellville, Western Cape, South Africa; ⁴Children’s Mercy Hospital; University of Missouri - Kansas City, Kansas City, MO; ⁵University of the Western Cape, Cape Town, Western Cape, South Africa; ⁶University of Michigan, Ann Arbor, MI; ⁷Children’s Mercy Kansas City, Kansas City, MO; ⁸Children’s Mercy Hospital, Kansas City, MO

There is great promise in leveraging mobile technology to enhance global health intervention efforts, particularly given the rising prevalence of lifestyle related disease in developing countries. South Africa (SA) has increasing rates of diabetes mellitus (DM) and cardiovascular disease (CVD), and many communities face disparities in access to care. Previous work in SA demonstrates the potential utility of text messaging for expanding intervention reach and increasing participant adherence, as ~90% of adults own a mobile phone. Yet, evidence is scant regarding how to develop and implement text messaging systems to supplement interventions in the developing world. The Diabetes Prevention Program (DPP) is an empirically supported approach for reducing chronic disease risk, and our team is currently adapting the program for delivery in SA. One goal of this work is to implement a mHealth component of text messaging to enhance the program curriculum and increase intervention reach in resource poor SA communities. Messaging is designed to reinforce session content, enhance motivation, planning, self-efficacy, and provide positive affirmation to participants. To develop content-reinforcing messages, we reviewed the seventeen-session curriculum and existing literature to identify nine overarching content domains: physical activity; healthy eating; tracking; shopping/cooking; reducing barriers; stress; mental health; social support; maintenance. Messages (N= 336) were stratified by content domain, message type, and DPP session. We developed two independent message banks: session-specific messages sent between program meetings, and generic texts (i.e., not tied to session content) that can be sent as general support (e.g., motivational enhancement) or when program meetings are delayed (e.g., holidays). After iterative development and refinement, messages were reviewed by SA community advisory board members for cultural appropriateness and translated to the Xhosa language. A system implementation logic model was established that specifies delivery frequency and timing. Custom text messaging technology (e.g., web-based management platform) was developed for implementing the system and integrated with a third-party SA company to gain access to SA cellular networks. In addition to establishing the feasibility and contributions of this approach, we also present lessons learned and extractable principles that may be of use for other mHealth projects in similar contexts.

IS THERE A MINIMUM SELF-MONITORING FREQUENCY FOR EFFECTIVE WEIGHT LOSS?

Gregg Khodorov, MBA¹, Lu Hu, PhD², Jinchun Zhang, Master³, Huilin Li, Ph.D.⁴, Mary Ann Sevick, New York⁵

¹Rutgers Robert Wood Johnson Medical School, Piscataway, NJ; ²NYU School of Medicine, New York, NY; ³New York University, New York City, NY; ⁴NYU, New York, NY; ⁵New York University School of Medicine, New York, NY

Background: Self-monitoring of diet and physical activity is the cornerstone for weight loss interventions; a consistent decline in adherence to self-monitoring over time is well documented. To date, there is a gap in the literature on minimum self-monitoring frequency required for effective weight loss.

Purpose: To determine the minimum effective frequency (MEF) of self-monitoring of diet and exercise in individuals with type 2 diabetes and concurrent chronic kidney disease. MEF was defined as the optimal threshold adherence to self-monitoring at which effective weight loss was achieved.

Methods: This study was a secondary analysis of data collected from an ongoing randomized clinical trial, the *Healthy Hearts and Kidneys (HHK) Study* (R01-DK100492). Data from 35 HHK Study participants enrolled in 2 of the 4 study arms were analyzed: (1) MONITORING: mobile self-monitoring of diet and physical activity via MyNetDiary™ iPad application, (n=17), and (2) COMBINED: MONITORING + Social Cognitive Theory-based behavioral counseling, (n=18). Fourteen-week cumulative percentages of days with activities logged for exercise (>0 kilocalories recorded) and for diet (>1 meal recorded) were examined.

Logistic regression was used to check the association between each self-monitoring variable (exercise/diet) and effective weight loss, which we defined as the median weight loss in the cohort. The area under the receiver operating characteristic curve (AUC) was used to evaluate the predictability of each self-monitoring variable (exercise/diet) for effective weight loss. The optimal cutoff was the value with the highest sensitivity and specificity.

Results: 3-month median weight loss for the two groups was 2.22%, which was used to define effective weight loss (=1 if >2.22%; =0 if <=2.22%). Exercise logging was significantly positively associated with effective weight loss (p value=0.018) after adjusting for age, gender, treatment group, employment, financial need, and marital status. The AUC for predicting effective weight loss based on exercise logging was 0.675, and the optimal cutoff on exercise logging was 70.56% (sensitivity = 0.941, specificity = 0.444). No significant result was found for meal logging.

Conclusions: Daily exercise logging can be used to predict effective weight loss. This MEF of 70.56% daily exercise logging for 3 months could inform adherence strategies for patients enrolled in weight loss programs that employ mobile self-monitoring.

OUTCOMES OF A NATIONAL PHARMACY-LED DIGITAL HEALTH PROGRAM WITH BIOMETRIC TRACKING AND GOAL SETTING TO ACHIEVE WEIGHT LOSS

Tanya Singh, MPH¹, Michael S. Taitel, PhD¹, Gregory Orr, MBA², Michael C. Sokol, MD, MS³, Renae Smith-Ray, PhD⁴

¹Walgreen Co., Deerfield, IL; ²Walgreen Co., Bellevue, WA; ³WebMD Health Services, Basking Ridge, NJ; ⁴Walgreen Co., Deerfield, IL

Background: More than one third of U.S. adults are obese¹. A loss of 5% of body weight can result in positive clinical outcomes including the management of chronic disease². Digital health applications can be used to aid in weight loss and maintenance.

Objective: To describe the impact of a pharmacy-led digital health program on weight loss and to examine the association between engagement in wellness goals and weight loss outcomes.

Methods: We assessed weight loss among users of a digital health program, Your Digital Health Advisor (YDHA). Participants started a weight loss goal and recorded at least five YDHA entries, at least two of which were weight entries within a 2–12 month period. YDHA is a part of Walgreens nation-wide Balanced Rewards for healthy choices (R) program which provides small financial incentives for the achievement of health goals. The goals are self-selected and allow the user to track their progress. The program is offered at no cost online and as a mobile phone application. ANOVA and logistic regression models were used to study the relationship between goal engagement (exercise, nutrition, or stress) and loss of $\geq 5\%$ baseline weight.

Results: Participants (n=9,403) had a mean age of 42.69, median baseline weight of 181 pounds, and were mostly female (88.11%). Most participants recorded weight loss; 29.72% lost at least 10 pounds and 30.59% lost $\geq 5\%$ of their baseline weight. Nearly a third of participants achieved their weight loss goal (31.53%) and over half (55.27%) achieved at least one wellness goal (exercise, nutrition, stress). Those who lost $\geq 5\%$ of baseline weight recorded 31.03 more wellness goal entries than those who lost < 5% of baseline weight (p < .0001). After controlling for covariates, participants who achieved at least one goal had 1.35 (95% CI 1.22–1.48) greater odds of losing $\geq 5\%$ of baseline weight compared to those who did not achieve any goals. The exercise goal was most utilized; those who achieved this goal had a 1.15 (95% CI 1.04–1.27) increased odds of losing $\geq 5\%$ of baseline weight.

Conclusions: Nearly one third of users tracking weight in a national pharmacy-led digital health program achieved clinically significant weight loss. Engagement and achievement of wellness goals was associated with an increased odds of losing $\geq 5\%$ of baseline weight. Digital health programs such as YDHA play a significant role in helping participants track and maintain their weight goals.

SMOKERS' ENGAGEMENT IN A HEALTHY EATING TEXT MESSAGING PROGRAM AND DUAL PARTICIPATION IN A SMOKING CESSATION PROGRAM

Kisha Coa, PhD, MPH¹, Laura Vercammen, MPH², Kara P. Wiseman, MPH, PhD³, Dannielle Kelley, PhD, MPH⁴, Tessa Heydinger, BS⁵, Amy Sanders, Masters - Communications - Texas A&M University¹, Erik Augustson, Ph.D., M.P.H.⁶

¹ICF, Rockville, MD; ²ICF International, Washington, DC; ³National Cancer Institute, Bethesda, MD; ⁴National Cancer Institute, ROCKVILLE, MD; ⁵ICF, Coronado, CA; ⁶National Cancer Institute, Rockville, MD

Background: Smokers trying to quit often cite weight gain as a barrier to quitting. To address this concern, the National Cancer Institute Smokefree.gov initiative provides resources to help smokers manage their weight during a quit attempt. One of these resources is HealthyYouTXT (HYTXT), a six-week text messaging program that provides tips, and supports users in trying to eat healthier.

Purpose: This study assessed baseline characteristics and engagement among HYTXT users, comparing those who were also enrolled in SmokefreeTXT (SFTXT), a separate six-week smoking cessation text messaging program, to those who were not. Engagement outcomes for HYTXT users participating in the SFTXT program were also explored.

Methods: Baseline smoking status is assessed in both programs. We conducted descriptive analyses to characterize users and used multivariate regression models to identify predictors of HYTXT engagement.

Results: Between October 2016 and July 2017, 437 users enrolled in HYTXT. HYTXT users were predominately female (86.3%) and a mean age of 41 years. Most users were current or former smokers (current - trying to quit: 44.1%; current smokers – not actively trying to quit: 20.2%; former smokers: 20.2%). Approximately half of users completed the program. Users who dropped out before program completion spent an average of 13.3 days in HYTXT. Forty-three percent of HYTXT users were also enrolled in SFTXT. These HYTXT users were more likely to be female and to report currently trying to quit smoking than users not enrolled in SFTXT. In multivariate analysis, there were no significant differences in days in program or dropout rates by smoking status or SFTXT enrollment.

Of the HYTXT users participating in SFTXT, 42.3% reset their quit date at least once to restart the cessation program after facing a setback (i.e., slip, relapse), and 60.3% completed the SFTXT program. Both these percentages are higher than the average for SFTXT users overall.

Conclusion: These analyses indicate that a sizeable proportion of individuals enrolled in the HYTXT were also enrolled in SFTXT. Data revealed that those smokers enrolled in both text programs had higher engagement in SFTXT than is usually seen for SFTXT, although significant differences were not seen in HYTXT program completion. These findings highlight the importance of weight concerns for many smokers and reveal the potential that integrating messaging from both programs could have on treatment outcomes.

TEMPORAL ASSOCIATIONS BETWEEN COMMUNICATION, MOOD, AND RELATIONSHIP SATISFACTION: AN ECOLOGICAL MOMENTARY ASSESSMENT STUDY

Shelby Langer, PhD¹, Michael Todd, PhD¹, John Burns, PhD², Niall Bolger, Ph.D.³, Jonathan B. Bricker, PhD⁴, Joan M. Romano, Ph.D.⁵, Karen Syrjala, PhD⁴, Francis Keefe, PhD⁶, Timothy J. Strauman, PhD⁷, Neeta L. Ghosh, MA, MPH⁴, Blair Puleo, BA⁶, Ashley K. Randall, PhD⁸, Rachel Hagan, N/A¹, Laura Porter, PhD⁶

¹Arizona State University, Phoenix, AZ; ²Rush University Medical Center, Chicago, IL; ³Columbia University, New York, NY; ⁴Fred Hutchinson Cancer Research Center, Seattle, WA; ⁵University of Washington, Seattle, WA; ⁶Duke University Medical Center, Durham, NC; ⁷Duke University, Durham, NC; ⁸Arizona State University, Tempe, AZ

Few studies have examined relationship communication (disclosure, responsiveness) among adult samples in naturalistic, day-to-day settings. We examined lagged (afternoon to evening) associations between communication with one's partner and a) negative affect and b) relationship satisfaction (RELSAT) using ecological momentary data collected via a smartphone application – in preparation for a larger project focused on couples coping with cancer. Constructs were assessed using items from standard questionnaires: 2 items from the Protective Buffering scale (protective buffering), 4 items from the Emotional Disclosure Scale (enacted disclosure, perceived partner disclosure, enacted holding back, and perceived partner holding back), 6 items to assess responsiveness (to what extent did you support/ understand/ criticize your partner) and perceived partner responsiveness (to what extent did your partner support/ understand/ criticize you), 9 items from the POMS (negative affect), and 1 item from the Dyadic Adjustment Scale (RELSAT, evening only). Adults (N = 29; M age = 36.5; 86% female; 90% Caucasian and 7% Hispanic) in a married or cohabiting partnered relationship ≥ 1 year in length recruited from researchmatch.org received 2 smartphone prompts per day for 14 days, one in the afternoon and one in the evening. Of 756 prompts sent, 606 (80%) were responded to. Multilevel regression models yielded consistent findings for within-person lagged associations. Afternoon protective buffering predicted greater evening negative affect, $b = 0.128$, $p = .03$. Afternoon disclosure (both enacted and perceived, $bs = 0.159$ and 0.226) and responsiveness (both enacted and perceived, $bs = 0.347$ and 0.199) predicted greater evening RELSAT, $ps < .05$. Cross-lagged models predicting evening communication from afternoon negative affect and afternoon communication from the previous evening's RELSAT were not statistically significant ($p > .05$), bolstering the notion that communication precedes affect and RELSAT but not vice versa. Findings provide ecologically valid support for the critical role of communication in daily functioning and offer implications for the delivery of couple-based communication interventions designed to optimize emotional and relationship wellbeing.

USER FEEDBACK ON THREE DIFFERENT MOBILE DIET TRACKING METHODS USED IN BEHAVIORAL WEIGHT LOSS INTERVENTIONS

Caroline G. Dunn, MS, RD¹, Gabrielle Turner-McGrievy, PhD, MS, RD², Destiny Byrd, N/A², Alycia Boutte, MPH², Eric Muth, PhD², Adam Hoover, PhD², Sara Wilcox, PhD²

¹USC, Columbia, SC; ²University of South Carolina, Columbia, SC; ³Clemson, Clemson, SC; ⁴Clemson University, Clemson, SC

Background: Dietary self-monitoring (DSM) is associated with increased weight loss in behavioral interventions. Traditional methods of DSM, such as food diaries and calorie counting, can be burdensome. Mobile apps and devices may offer more convenient methods of DSM, but little is understood about users' perception and satisfaction with these novel apps/devices. The purpose of this study was to assess user satisfaction with and feedback about three methods of mobile DSM from two mobile weight loss interventions.

Method: Overweight and obese adults (n=125; mean BMI=34.6 ± 5.6 kg/m²) from two different randomized controlled weight loss interventions (2SMART, DIETm) were randomized to one of three diet tracking conditions: a wearable Bite Counter device (Bite), standard DSM app, FatSecret (App), or photo meal tracking app, MealLogger (Photo). Participants received twice weekly behavioral weight loss podcasts and tracked their diet with the assigned technology. At 6 weeks, 100 participants (Bite, n=31; App, n=48; Photo, n=21) completed a survey measuring satisfaction with their device and provided feedback using a 7-point Likert-type scale. Survey questions assessed ease of use, novelty, ease of regular engagement, ease of understanding feedback, likeability, and attribution of device to weight loss. ANOVA with Tukey's post hoc analysis were used to evaluate differences between devices.

Results: Bite participants were more likely to agree that their device was novel (P<0.001), but also more difficult to use (P=0.03) compared to participants using the standard DSM app. Bite and Photo participants reported that they forgot to regularly use their device more than the App group (P<0.001). There were no significant differences among the three groups for likeability, difficulty in understanding feedback, or attribution of device to weight loss (all P's >0.05).

Conclusion: Mobile technology to encourage DSM presents promise in increasing user engagement and ease of use. More research should be done to understand associations between user satisfaction and rates of DSM, and features of mobile technology that can increase engagement. Early interventions to prompt user engagement and offering choices or combinations of DSM methods to provide users with options should be considered to increase DSM and weight loss.

WHO VOLUNTEERS TO PROVIDE ONLINE PEER MENTAL HEALTH SUPPORT, AND WHY? LESSONS FROM THE 7 CUPS OF TEA LISTENER COMMUNITY

Rachel Kornfield, MA¹, Arlen C. Moller, PhD²

¹University of Wisconsin, Chicago, IL; ²Illinois Institute of Technology, Chicago, IL

Rationale. Little is known about why individuals voluntarily provide online social support to others. To study this question, we collected survey data from volunteer Listeners on the *7 Cups of Tea* (7cups) platform, a community of >220,000 Listeners who help over 1.3 million people per month. Listeners complete an online active listening course before connecting anonymously with members for one-on-one chats. By learning about the motivations and characteristics of Listeners, we hope to provide insights relevant to recruiting, retaining, and motivating volunteers on this and similar platforms.

Methods. New listeners received emailed survey invitations from 7cups administrators during a 5 month period (March to September, 2017). 250 answered at least 1 question (analyzed here), and 193 completed the survey.

Results. 74% were women, 22% were men, and 4% had another gender identity or did not disclose. The median age was 23 years old. **Motives.** Participants completed the Volunteer Function Inventory, a 30-item scale characterizing 6 motivations for volunteering using a 5-point Likert scale (1=not at all to 5=extremely). Listeners reported greatest motivation from altruistic values (M=4, SD=0.84), followed by understanding (M=3.63, SD=0.91), self-enhancement (M=3.00, SD=1.12), self-protection (M=2.90, SD=0.84), career (M=2.33, SD=1.11), and social (M=1.89, SD=0.91). Despite being a weaker motivation, self-protection was most strongly associated with having completed more chats as a listener (r=0.34, p<0.001) and being listened to (r=0.23, p=0.001). Self-enhancement motivations were likewise associated with having completed more chats as a listener (r=.27, p<0.001) and being listened to (r=0.20, p<0.01). **Issue preferences.** 7cups allows Listeners to customize their profiles by selecting preferred issues about which to listen. We asked participants to report which of 33 issues they had personally experienced (past or current), and about which (if any) they preferred to listen. Participants reported a mean of 7.0 current issues (SD=5.5) and 8.1 in the past (SD=5.2). Rates of psychological distress were highest, with 83% of Listener respondents reporting ever struggling with anxiety, 79% with loneliness, and 77% with depression. The majority (73.4%) reported a preference for listening to individuals with particular issues. Respondents preferred listening to others with their own issue 50% of the time for current issues and 32% for past issues.

Discussion. Altruism was the strongest motive for Listening, but ego-centric motives (i.e., self-protection and self-enhancement) were associated with frequency of volunteering. Many 7cups Listeners reported psychosocial issues in their own lives, and often preferred to listen to others facing the same issues. This insight could be leveraged to optimize volunteer recruitment and retention on 7cups and similar peer support platforms.

ALCOHOL USE AND DEPRESSION OVER TIME IN A NATIONAL COHORT OF HIV+ LATINO/A AND NON-LATINO WHITE PATIENTS IN HIV CARE

Catherine Rivas, B.S. Candidate¹, John A. Saucedo, PhD, MSc², Nadra E. Lisha, PhD³, Tor Neilands, BA; PhD², Katerina Christopoulos, MD, MPH³, William C. Mathews, MD, MSPH⁴, Julie Levison, MD⁵, Ann Dennis, MD⁶, Mallory Johnson, PhD²

¹Summer HIV/AIDS Research Program (SHARP), San Francisco Department of Public Health, Berkeley, CA; ²University of California, San Francisco, San Francisco, CA; ³UCSF, San Francisco, CA; ⁴UCSD Department of Medicine, San Diego, CA; ⁵Mass General Hospital/Harvard Medical School, Boston, MA; ⁶University of North Carolina at Chapel Hill, Chapel Hill, NC

Background: Nearly 1 in 3 people living with HIV (PLWH) report hazardous alcohol use or meet criteria for a mood disorder, primarily major depressive disorder. However, we know less about how alcohol use and depressive symptomatology change over time in PLWH regularly seen in HIV care, especially for Latino/as. The objective of this study was to model the trajectories of alcohol use and depressive symptoms between HIV+ Latino/a and non-Latino/a White patients.

Methods: Patients were enrolled in the Center for AIDS Research (CFAR) Network of Integrated Clinical Systems (CNICS) study, a cohort of PLWH receiving care at seven university-affiliated HIV care clinics across the U.S. CNICS participants typically complete a patient reported outcome survey at primary care visits every 4–6 months. Using data from 2007 to 2013, we examined depressive symptoms via the PHQ-9, hazardous alcohol use via the AUDIT, and controlled for demographics (sex, viral load, race/ethnicity, and age). We analyzed survey data in six-month intervals for 30 months (five time points). We performed a latent growth curve model using Mplus V8, adjusting for missing data using the full information maximum likelihood method.

Results: Model fit indices suggested that the models fit the data well (RMSEA <.05, CFI>.98 and SRMR=.02). In 3088 patient observations (27% Latino/a), the intercept factor mean for depression ($b=3.98$, $p<.001$) and the slope factor for depression ($b = -.43$, $p<.01$) were statistically significant, indicating that the severity of depression decreased over 30 months. Depression intercept scores were positively associated with alcohol use intercept and slope ($r=.40$ & $.04$, $ps<.05$), suggesting that higher depression scores at baseline were positively associated with greater alcohol use at baseline, and increased alcohol use over time. Lastly, Latino/as and non-Latino White patients did not differ in baseline depression or alcohol use scores, or their growth over time.

Conclusion: Among PLWH in routine HIV care, depressive symptoms were indicative of increased alcohol use at baseline and over time. However, being seen regularly in HIV care was associated with decreases in depression. We also did not find differences in outcomes between Latino/a and non-Latino White patients, despite the evidence elsewhere for ongoing HIV-related health disparities. We speculate this could be due to a potentially high level of acculturation among this group of Latino/as. To fully optimize HIV treatment and improve the quality of life of PLWH, we must continue to solve the challenges of mental health and substance use.

BEHAVIORAL DISENGAGEMENT MODERATES THE RELATIONSHIP BETWEEN INTERNET SEXUAL SAFETY KNOWLEDGE AND SEXUAL RISK IN HIV+ MSM

Matthew C. Sullivan, B.A., Dean G. Cruess, Ph.D., Lauren Straunge, M.A., Kaylee B. Crockett, Ph.D., Jaime E. Blackmon, M.A., Moira O. Kalichman, M.A., Tamar Grebler, MA, Chauncey Cherry, MA, Seth Kalichman, Ph.D.

University of Connecticut, Storrs, CT

Because many HIV-positive men who have sex with men (MSM) seek sexual partners online, an understanding of the factors that influence risky sexual behavior in this population is needed to inform HIV prevention strategies. In the present study, we examined the relationship between sexual health knowledge and risky sexual behavior in a sample of 127 MSM with HIV who reported using the Internet to meet sex partners (mean age=44.4; 42.5% non-White). In particular, we examined trait coping strategies as moderators of the health information—sexual risk behavior relationship using the COPE (Carver et al., 1997). Participants' knowledge of safe online partner-seeking behavior was assessed with items such as, "Can finding out the HIV status of potential partners met online have health benefits?" Self-reported sexual risk behavior was defined as the number of times a participant reported condomless anal intercourse with HIV serodiscordant (HIV/unknown status) male partners. Overall, 55.1% of participants endorsed at least one instance of this sexual risk behavior. To examine factors associated with sexual risk behavior, negative binomial regression was applied. As hypothesized, greater knowledge of online HIV safety behavior was associated with fewer acts of condomless anal intercourse with negative/unknown status partners ($B= -.271$, 95% CI [-.535, -.007], $p=0.044$). This relationship was moderated by trait disengagement coping ($B= .141$, 95% CI [-.040, -.005], $p=0.011$), such that the negative relationship between sexual health knowledge and sexual risk behavior was not observed in individuals who reported high levels of behavioral disengagement. These effects held when controlling for participants' reported depression (CES-D; Radloff, 1977) and education levels. Neither sexual health knowledge nor behavioral disengagement were associated with rates of condom-protected sex with either serodiscordant or seroconcordant male partners. These results support the notion that information regarding Internet sexual safety is an important determinant of sexual risk behavior. Moreover, these results underscore the insufficiency of information alone; efforts to promote effective coping skills may be particularly important for MSM living with HIV who seek partners online.

EXPERIENCED STIGMA AND TOBACCO USE AMONG PEOPLE LIVING WITH HIV: THE MEDIATING ROLE OF AVOIDANCE COPING

Kaylee Burnham, Crockett, PhD, Bulent Turan, PhD

University of Alabama at Birmingham, Birmingham, AL

Background: People living with HIV (PLWH) face a greater burden of stigma and discrimination related to HIV. In addition, HIV stigma intersects with other forms of stigma related to sexual orientation and race. These chronic stressors may be associated with negative health behaviors, such as tobacco use. PLWH have approximately double the rate of tobacco use compared to the general population. Smoking can have particularly negative consequences in the context of HIV and lead to comorbidities (e.g., opportunistic respiratory infections, COPD, lung cancer). Understanding the unique risk factors for tobacco use among PLWH can help improve smoking prevention and cessation programs.

Purpose: The purpose of the current study was to explore the psychosocial context of tobacco use in PLWH, examining avoidance coping as a mediator in the relationship between experienced stigma and tobacco use. Three different types of stigma were assessed including HIV stigma, sexual orientation stigma, and race-related stigma.

Methods: Participants included 203 PLWH recruited from an HIV primary care clinic in Birmingham, AL. Participants responded to parallel items assessing their experiences of stigma related to their HIV status, sexual orientation, and race. They also reported their likelihood of engaging in avoidance coping strategies in response to stress (e.g., “I try to forget the whole thing.”). Current tobacco use was assessed at their clinic visit.

Results: Approximately 24% of the present sample reported current tobacco use. All three forms of stigma were associated with avoidance coping. Three separate mediation models adjusting for demographic variables and the other forms of stigma were evaluated. The indirect effect of HIV-related stigma on likelihood of tobacco use through avoidance coping was significant when controlling for the effects of sexual orientation stigma and race-related stigma.

Conclusions: These findings suggest avoidance coping serves as a mechanism for the association between experienced stigma and tobacco use. HIV stigma was associated with tobacco use through avoidance coping, even when controlling for other forms of stigma PLWH may experience. Future research may uncover if this effect on tobacco use remained because HIV stigma is the most salient form of discrimination PLWH face, and if the relationship between HIV stigma and smoking risk remains over time. Given the disproportionate rate of smoking in PLWH, behavioral scientists and interventionists may extend their reach by including content specific to coping with experiences of stigma in individuals' communities to smoking prevention and cessation programs targeting PLWH.

HIV MEDICATION-ALCOHOL INTERACTION BELIEFS AND MEDICATION NONADHERENCE AMONG HIV + HEAVY DRINKING MEN WHO HAVE SEX WITH MEN.

Anthony Surace, MA¹, David W. Pantalone, Ph.D.², Kenneth H. Mayer, M.D.³, Peter Monti, PhD¹, Christopher W. Kahler, Ph.D.¹¹Brown University School of Public Health, Providence, RI; ²University of Massachusetts, Boston, Boston, MA; ³Fenway Health Institute, Boston, MA

Rationale: Alcohol use is associated with low adherence to antiretroviral therapy (ART) for people living with HIV, which can result in poor viral suppression. Thus, it is crucial to examine what factors influence the association between alcohol use and ART adherence. Research indicates that beliefs regarding whether alcohol reduces ART effectiveness may influence ART nonadherence in general and specifically, nonadherence when drinking. Such research should be expanded upon to a wider range of populations and treatment settings.

Objective: The purpose of this study was to examine beliefs in reduced ART effectiveness when drinking, skipping ART when drinking, and overall ART adherence in a sample of heavy drinking HIV+ men who have sex with men (MSM).

Methods: Data were derived from a subsample of heavy drinking HIV+ MSM who participated in randomized clinical trial testing an intervention to reduce alcohol use (N=180) and completed survey items on ART-alcohol interaction beliefs at the initial study visit (n=69) or 12-month (n=110) follow-up.

Results: Approximately 28% and 35% of participants reported believing that ARTs were less effective with alcohol at baseline and 12-month follow-up, respectively. Those endorsing ART-alcohol interaction beliefs, compared to those who did not, did not report significantly more missed ART days or drinks consumed, but did report significantly worse depression. Those who reported intentionally skipping/stopping taking ART when drinking had poorer overall ART adherence at baseline (n=13, 19%), this relationship approached significance (t=3.37, d=1.24, p=.05). Those who endorsed ART-interaction beliefs, compared to those who did not, reported significantly more alcohol related problems at baseline (t=2.52, d=.77, p

Conclusions: Consistent with prior research about a quarter of our sample endorsed beliefs about reduced ART-effectiveness when drinking. The association between ART beliefs and adherence approached significance, and the association between ART beliefs, depression, and alcohol related problems was significant. This suggests ART beliefs and problematic alcohol use play a role in adherence for HIV+ MSM, but more research is needed to understand how these factors interact in this population.

INSIGHTS FROM THE TWITTERVERSE: A STUDY OF WHAT TWITTER USERS SAY, AND FROM WHERE THEY SAY IT, ABOUT PREP FOR HIV PREVENTION

Jessica L. Maksut, MA¹, Michael F. Tynes, B.S.², Daniel Snyder, M.Eng.³, Kate Dibble, M.A.⁴

¹University of Connecticut, Storrs Mansfield, CT; ²Fordham University, Stamford, CT; ³Yale University, Manchester, CT; ⁴University of Connecticut, Storrs, CT

Background: Data from social media (e.g., Twitter) may be used to study the public's conversations about HIV prevention tools (e.g., pre-exposure prophylaxis (PrEP), or Truvada®). Truvada®, a HIV medication approved by the U.S. FDA to be used as PrEP in 2012, is a highly effective HIV prevention strategy for individuals at risk for HIV. Despite its demonstrated efficacy in clinical trials, PrEP implementation has been, and continues to be, challenging.

PrEP stigma -- or being stigmatized by others for using PrEP -- is a key barrier to PrEP uptake, adherence, and persistence. Studies show that peers who believe that PrEP will lead to increased sexual risk behavior and providers who are unwilling or hesitant to prescribe PrEP are key deterrents to individuals' use of PrEP. While PrEP stigma has demonstrated a negative impact on PrEP use, little is known about the prevalence of negativity toward PrEP and whether it varies by location.

Method: We sought to determine the prevalence and the content of Twitter conversations about PrEP in each U.S. state. We also examined whether there were associations between prevalence and content of geolocated PrEP tweets and state-level HIV prevalence rate.

Results: A total of $N=415$ geolocated tweets were collected using Twitter's Advanced Programming Interface (API) June-December 2017. The API collects tweets containing user-specified key words (e.g., PrEP, Truvada). We then used AIDSVu to determine most recent (2015) state-level HIV prevalence rate and IBM's Watson to code each tweet for sentiment and presence of fear, disgust, and joy toward PrEP.

Forty-four states (including D.C.) had \geq one tweet about PrEP. The states with the most tweets were D.C. ($n=79$ tweets, 19.03%), California ($n=76$, 18.31%), and New York ($n=49$, 11.81%). We found that tweet prevalence was positively associated with that state's HIV prevalence rate ($r = .593, p < .001$).

Sentiment toward PrEP was most positive in Washington state ($M=0.815$), Oregon ($M=.784$), and Maryland ($M=.648$), and most negative in Kentucky ($M=0.064$), North Carolina ($M=0.017$), and Nevada ($M=0.036$). Tweets' PrEP sentiment was negatively associated with state HIV prevalence ($r = -.186, p = .004$). The presence of the emotion *fear* in tweets was positively associated with state HIV prevalence ($r = .160, p = .013$), while the presence of the emotion *joy* was negatively associated with state HIV prevalence ($r = -.139, p = .030$). The association between the presence of the emotion *disgust* and state HIV prevalence was trending toward significance ($r = .119, p = .064$).

Conclusions: Eliminating PrEP stigma will require a multi-faceted approach wherein there is a ramping up of public education and marketing campaigns, both in face-to-face and social media formats. Areas with high HIV prevalence but where PrEP sentiment is relatively negative must be our first priority for these efforts.

INTERSECTIONALITY OF FACTORS ASSOCIATED WITH HIV RISK BEHAVIORS AMONG FORMERLY INCARCERATED BLACK DRUG OFFENDERS

Rahma Mkuu, MPH, CPH¹, Tawandra Rowell-Cunsolo, PhD², Francisco A. Montiel Ishino, MPH, BS, CPH³, Zachary Jackson⁴, Idethia Shevon. Harvey, DrPH⁵

¹Texas A&M University, Collge Station, TX; ²Columbia University, New York, NY; ³Texas A&M University, Transdisciplinary Center for Health Equity Research, Bryan, TX; ⁴Texas A&M University, Bryan, TX; ⁵Texas A & M University, College Station, TX

Purpose: In the United States, Black Americans are vastly overrepresented among individuals incarcerated for drug-related offences and account for the highest proportion of those with HIV. Post-incarceration, they reportedly engage in high risk behaviors, further complicating efforts to **successfully** transition to the community. The purpose of this study was to examine syndemic relationships that influence HIV risk behaviors among formerly incarcerated Black drug offenders.

Methods: Surveys and qualitative in-depth interviews ($N = 30$) were conducted with Black Americans charged with drug-related offenses and recently released (< 1 year) from prisons in the New York City area. Descriptive analysis was conducted on demographic characteristics. Qualitative data were coded and analyzed using Qualitative Comparative Analysis (QCA). QCA allowed for the exploration of causal contribution regarding different risk factors that lead to the engagement of high-risk sex.

Results: The majority of the participants were male (83%), experienced homelessness post-release (83%), never married (77%), identified as heterosexual (67%), and on parole or probation (60%). Among the participants, 23% were employed full-time, 43% used illicit drugs since release, 40% reported using alcohol or drugs before or during sex, 60% reported not using a condom during their last intercourse. Majority reported ever being physically attacked (80%) or experiencing emotional abuse (70%). QCA analysis revealed that syndemic relationships occurred between drug use, condomless sex, homelessness, underemployment and experienced violence.

Conclusion: Our results support findings of syndemic relationships between substance abuse, violence and HIV risk behaviors. In addition to risk behaviors associated with increasing vulnerability to HIV infection, participants in our study experienced stigma due to their criminal justice background that resulted in social marginalization and poverty. Formerly incarcerated Black drug offenders experience inter-correlated challenges after release from prison, thus multidisciplinary research approaches for HIV prevention programs that are multisectorial are needed to address broader social integration concerns.

NECESSITY AND CONCERNS BELIEFS AND HIV MEDICATION ADHERENCE: A SYSTEMATIC REVIEW

Luke Mitzel, M.S., Peter Vanable, Ph.D.

Syracuse University, Syracuse, NY

Background: Adherence to antiretroviral medication regimens is crucial to reducing HIV transmission rates and extending longevity among people living with HIV. Adherence-promoting interventions often focus on fostering the self-regulatory skills necessary to overcome barriers to adherence. However, missed doses also occur when patients make a conscious decision not to take their medication. Past research confirms that beliefs about medication necessity (perceived need for the benefits of a medication) and medication concerns (evaluation of the perceived negative consequences of a medication) play an important role in determining medication-taking behaviors across a variety of chronic illnesses, including HIV. However, there has not been a focused review of the literature on associations of necessity and concerns beliefs to HIV medication adherence. Accordingly, we conducted a systematic review of the HIV literature to identify (a) effect sizes for associations of necessity and concerns to adherence, (b) factors that may influence these associations, and (c) methodological strengths and weaknesses of the current research base.

Methods: A total of 22 studies were included in the review that examined associations of necessity and concerns to HIV medication adherence based on the Necessity-Concerns Framework.

Results: Both necessity and concerns beliefs showed small, clinically significant effects on adherence. Provider perceptions emerged as a contextual influence directly associated with necessity and concerns and indirectly associated with adherence. Five studies provided initial evidence that the necessity-concerns differential, a simple indicator of the relative standing of necessity to concerns, may better explain adherence variability than independent analysis of either belief.

Conclusions: Overall, necessity and concerns demonstrated clinically significant associations to adherence among people with HIV. Future work can advance this literature by testing models based on the Necessity-Concerns Framework, improving measurement of adherence and medication beliefs, and assessing changes in beliefs and adherence over time.

NEUROPSYCHOLOGICAL FUNCTION IN HIV CLADE C INFECTED AND UNINFECTED INDIVIDUALS IN NORTHERN INDIA

Deborah L. Jones, PhD, MEd¹, Lissa Mandell, BS¹, Kristopher L. L. Arheart, EdD², Suat Babayigit, MEd¹, Manju Mohanty, PhD³, Anchal Sharma, M.A. PSYCHOLOGY³, Deepika Aggarwal, Ph. D.³, Aman Sharma, MD³, Sameer Vyas, MD, DM⁴, Vivek Gupta, MD³, Niranjan Khandelwal, MD³, Stephen M. Weiss, PhD, MPH¹, Varan Govind, PhD², Mahendra Kumar, PhD¹

¹University of Miami Miller School of Medicine, Miami, FL; ²University of Miami, Miami, FL; ³Postgraduate Institute of Medical Education and Research (PGIMER), Chandigarh, Chandigarh, India; ⁴Postgraduate Institute of Medical Education and Research (PGIMER), Chandigarh, Chandigarh, India

Objectives: India has 2.1 million people living with HIV Clade C. Previous studies of Clade B have identified cognitive decrement in early HIV infection, and poor functioning is linked with poor adherence to treatment. The impact of HIV Clade C on cognitive functioning has been understudied, and most cognitive assessment of those not on antiretroviral medication has been limited to Clade B. This preliminary study compared neuropsychological functioning between untreated HIV Clade C infected and uninfected individuals.

Methods: Participants (N=47) were men and women aged 22–44 years old in Northern India recruited from a large, public teaching hospital. Eligible participants had no history of major head injury, chronic or neurological illness, or addiction.

Results: Participant demographics did not differ by serostatus; 57% HIV positive, median age 28 (IQR 25–36), and 55% male. HIV infected participants had lower education ($p=0.009$) and income ($p=0.001$); CD4 count median 315 (range 60–876); participants were asymptomatic but reported lower self-perceived motor/sensory functioning ($p=.007$). Comparing those previously ($n=5$, 2012–2014) and newly diagnosed ($n=22$, 2016–2017) with HIV, those newly diagnosed were younger ($p=0.045$). HIV infected and uninfected participants did not differ on self-perceived memory, cognition and linguistic performance (all $p>.09$). HIV infected participants displayed poorer cognitive functioning and had lower scores on delayed recall/recognition ($p=0.005$), processing speed ($p=0.008$), and word/color STROOP tasks ($p=0.008$). Demographic variables and cognitive functioning were associated: age with processing speed ($r_s=-0.50$, $p_r_s=0.30$, $p=0.040$); education with processing speed ($r_s=0.71$, $p_r_s=0.59$, p

Conclusions: Preliminary results suggest that in this sample, decrements in cognitive performance may be attributable to HIV Clade C when contrasted with HIV uninfected individuals, while HIV patients may be unaware of such decrements. Findings have important implications for clinical intervention in newly diagnosed Clade C patients due to the potential impact of cognitive functioning on adherence.

Study funded by NIH/NINDS R01NS094043.

PRE-EXPOSURE PROPHYLAXIS TO PREVENT HIV TRANSMISSION FOR SERODISCORDANT COUPLES: PERSPECTIVES OF PEOPLE LIVING WITH HIV

Jacklyn Babowitch, M.S., Alan Sheinfil, B.S., Jeremy Ramos, B.S., Peter Venable, Ph.D., Shannon Sweeney, Ph.D.

Syracuse University, Syracuse, NY

Pre-Exposure Prophylaxis (PrEP) for HIV-negative partners and antiretroviral therapy (ART) for infected partners can virtually eliminate HIV transmission risk for serodiscordant couples. Most efforts to promote PrEP uptake have focused on the HIV-negative partner's perspective with little consideration of the HIV-positive partner's attitudes and beliefs about PrEP. The current study provides descriptive data on attitudes towards PrEP among people living with HIV and examines the association of PrEP attitudes to risky health behaviors (i.e., <95% ART adherence and any instances of condomless sex). Participants ($N = 214$; M age = 46.5; 62% male) received information about the efficacy of PrEP and were asked to "imagine that you are in a relationship with a partner who is HIV-negative." Participants then responded to a questionnaire that assessed their attitudes towards PrEP. Despite the fact that 57% of the sample had not previously heard of PrEP, 81% reported that they would want their HIV-negative partner to be on PrEP. The majority of participants agreed that they would also facilitate PrEP uptake by talking to their partner (86%) and healthcare provider (72%) about starting their partner on PrEP and helping their partner to remember to take the medication daily (85%). Individuals also indicated that PrEP would make them feel more protected from transmitting HIV (79%) and a minority (38%) reported that they would use condoms less consistently if their partner was on PrEP. While positive attitudes about PrEP did not vary as a function of ART adherence, participants who reported recent condomless sex expressed greater interest in having their partner take PrEP, $t = -3.18$, $p = .002$, greater willingness to discuss PrEP with a healthcare provider, $t = -2.34$, $p = .02$, and greater perceived protection from HIV transmission with PrEP, $t = -2.07$, $p = .04$. Those with a history of sexual risk also indicated that they would continue to use condoms less consistently compared to participants reporting no recent unprotected sex, $t = -4.92$, $p < .001$. Overall, findings confirm greater interest in PrEP among HIV-positive partners with elevated sexual risk histories. Future research should consider how the implementation of PrEP may include HIV-positive sex partners to promote PrEP uptake and adherence, as well in interventions targeting behavioral risks (i.e., condomless sex) that may reduce the long-term effectiveness of PrEP.

TECHNOLOGY FOR ENGAGEMENT AND MANAGEMENT OF HEALTH (TEAMH) TO IMPROVE MEDICATION ADHERENCE FOR PERSONS WITH HIV: A PILOT STUDY.

Paola DiMarzio, PhD, MPH¹, Sheneiza Moore, N/A², Barbara Martens, MA³, Oonagh Dowling, PhD⁴, Joseph McGowan, MD⁵, Rebecca M. Schwartz, PhD⁶

¹Department of Medicine, Zucker School of Medicine, at Hofstra/Northwell, Manhasset, NY; ²Zucker School of Medicine at Hofstra/Northwell, Roosevelt, NY; ³Department of Medicine, Northwell Health, Manhasset, NY; ⁴Department of Anesthesiology, Zucker School of Medicine at Hofstra/Northwell, Queens, NY; ⁵Department of Medicine, Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY; ⁶Department of Occupational Medicine, Epidemiology and Prevention, Northwell Health; Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY

Background: Medication adherence issues remain a major barrier in the management of patients living with HIV/AIDS (PLWH).

Methods: This mixed-method pilot study evaluates the feasibility of a smartphone application and web-based medication adherence program, *Technology for Engagement And Management of Health (TEAMH)*, and its potential to impact patient adherence. TEAMH is an application designed to help manage the key aspects of patient care at home enabling users to: 1) track adherence to medications; 2) track medical appointments; and 3) to interact via a secure two-way messaging system between the patient and clinician (health coordinator). We held one focus group with all study participants at the end of the study period facilitated by an experienced qualitative researcher. Medication adherence measurements were based on reports generated by the TEAMH app which recorded overall medication compliance of patients enrolled in the pilot study. Adherence was calculated based on average of the number of pills reported to have been actually taken divided by the number of pill prescribed pills prescribed over the course of the number of functional days of app use. A system usability scale questionnaire, adapted from the mHIMMS App Usability work group, was administered to all patient participants and the health educator at the end of the one-month study period.

Results: Nine patients completed the study with 92% medication adherence. On average, these patients were 51.9 (SD 12.1) years old, 66% (n=6) were female, 34% (n=3) were White/non-Hispanic, 11% (n=1) were White/Hispanic and 33% (n=3) were Black/non-Hispanic. The average rate of medication adherence at the end of the study was 92% ranging from 78–100% adherence. Of total doses taken, 64% of medications were taken on time, 9% were missed and 27% were postponed by a mean of 11 (SD +/-7.7) minutes from the scheduled time. As part of the focus group, patient participants (n=9) were asked about the intervention feasibility and acceptability, and they were encouraged to discuss any barriers to using the technology that they encountered during the study period. Overall, the focus group indicated that participants were satisfied with the app and found it easy to use. They felt that it would be extremely beneficial for all patients, especially those struggling with ART adherence or who have to manage complicated medication regimens.

Conclusions: Data collected in this study demonstrated that TEAMH not only aided with medication adherence but was overall well received by the participants in the study. This pilot represented a first step toward the development of technology for engagement and adherence to treatment for PLWH. In addition, our TEAMH technology has the potential to be effective for use with other chronically ill patient populations.

THE USE OF A THERAPEUTIC INTERVIEWING AND IMAGE RE-SCRIPTING TO CATALYZE RESILIENCE IN AN INDIVIDUAL WITH HIV, A CASE STUDY.

Alexander Young, M.A. LPC

Our Lady of the Lake University, San Antonio, TX

Resilience is known to be a significant attribute in the prevention of further psychological distress caused by trauma (Bonanno, 2005); however, there is a scarcity of qualitative research on how resilience interplays with patients who suffer from chronic health conditions (Cal, Sa, Glustak, & Santiago, 2015; Gooding, Hurst, Johnson, & Tarrier, 2012). The purpose of this instrumental case study is to understand resilience factors augmented by image rescripting-- the technique of bringing an image into verbal depiction, which is then rescripted in a strengths-based paradigm with an individual with HIV (Kirkham, Smith, & Havsteen-Franklin, 2015). I recruited a participant using referral sampling from personal sources and intensity sampling. Therapeutic intervention took place using image rescripting in a strengths-based therapeutic interview session. During the process of rescripting, the client identified personal systemic resilience elements. These systemic elements using a post-traumatic growth lens suggest that this participant has adapted to HIV over time. The participant was successful in integrating positive illusion into the construction of the self. Further, he externalized his HIV into a personified element of his systemic resilience network. I found that empowerment through the act of "doing" is prominent throughout this study, which suggests that individuals with HIV may benefit from active action in the form of "doing hope" or "doing empowerment" (Flaskas, 2007). This study contributes to the growing body of literature on HIV interventions, as well as provides evidence for the use of strengths-based therapeutic interviews in conjunction with image rescripting to catalyze resilience.

ASSESSING SUICIDAL IDEATION: THE ROLE OF ALCOHOL/SUBSTANCE USE DISORDERS AND CIGARETTE USE AMONG HIV+ INDIVIDUALS

Melanie R. Roys, M.S., C.A.G.S.¹, MacKenzie R. Peltier, PhD², Kasia S. Plesky, MA¹, Ryan Cummins, B.S.¹, Amy Copeland, PhD³, Glenn N. Jones, PhD⁴

¹Louisiana State University, Baton Rouge, LA; ²Yale University School of Medicine, New Haven, CT; ³Louisiana State University Department of Psychology, Baton Rouge, LA; ⁴LSU Health - Baton Rouge, Baton Rouge, LA

Objective: Substance use disorders (SUD), including alcohol use disorders (AUD), as well as cigarette use, are associated with an elevated risk for suicidal ideation (SI). It is often thought that depressive symptoms mediate this relationship; however, SI may occur without the presence of these symptoms. Exploring this relationship is especially prudent among HIV+ individuals, as they smoke and use substances at a higher rate. Additionally, HIV+ individuals endorse increased rates of depression and are three times more likely to attempt suicide compared to the general population. The present study sought to explore the relationship between substance use, including cigarettes, SI and depression among patients entering treatment in a medical clinic for HIV. It was hypothesized that patients with an AUD, SUD, or daily cigarette use would be more likely to endorse SI than non-substance using counterparts, even when controlling for depression.

Methods: Participants (n= 1,292) were primarily male (58.8%), African American (90%) patients entering treatment at an HIV clinic. AUD, SUD, depression, and SI status were assessed using the M.I.N.I. International Neuropsychiatric Interview. Daily cigarette use was assessed via self-report. A logistic regression was utilized to explore the relationships between substance use, SI, and depression.

Results: Daily cigarette use was reported by 42% of participants, and 18.2% reported symptoms of a current AUD or SUD. A total of 33.2% reported symptoms consistent with a current depressive disorder. Depression increased the odds of endorsing current SI (Odds Ratio 6.88, 95% CI, 4.75 – 9.96). As hypothesized, participants endorsing symptoms consistent with AUD and/or SUD were 1.60 times (95% Confidence Interval, 1.06 – 2.13) more likely to endorse SI, even when controlling for depression. Those endorsing daily cigarette use also demonstrated a higher likelihood (OR 1.49, 95% CI, 1.04 – 2.13) of endorsing SI, when controlling for depression.

Conclusion: Findings suggest that even when accounting for depression symptoms, AUD, SUD, and daily cigarette use are predictors of SI in a population seeking treatment for HIV. Results emphasize the need to not only screen for SI in patients with depression, but to also screen individuals with AUD, SUD, or daily cigarette use.

CORRELATES OF DUAL PROTECTION STRATEGY USE AMONG SOUTH AFRICAN ADOLESCENT GIRLS: A REVIEW AND CRITIQUE OF THE LITERATURE

Jennifer L. Brown, PhD¹, Rachel E. Schafer, N/A², Nicole Gause, M.A.³, Lochner Marais, Ph.D.⁴, Carla Sharp, Ph.D.⁵, Jessica Sales, PhD⁶¹University of Cincinnati College of Medicine, Cincinnati, OH; ²Kenyon College, CINCINNATI, OH; ³University of Cincinnati, Cincinnati, OH; ⁴University of the Free State, Bloemfontein, Free State, South Africa; ⁵University of Houston, Houston, TX; ⁶Rollins School of Public Health, Emory University, Atlanta, GA

Background: Globally, South African (SA) adolescent girls experience some of the highest rates of both unintended pregnancies and STI/HIV. One-third of SA adolescent girls will be pregnant by age 20 and SA accounts for one-third of all new HIV infections among young women worldwide. To inform culturally-tailored interventions to reduce both unintended pregnancies and STI/HIV, there is a need to understand factors associated with the use of dual protection strategies (use of methods to prevent both pregnancy and STI/HIV) among SA adolescent girls.

Purpose: The purpose was to conduct a review and critique of studies examining correlates of condom, contraceptive, and dual protection use among SA adolescent girls.

Methods: Studies were included in the review if they met the following criteria: (a) the sample was comprised predominantly of SA adolescent girls between 15 to 24 years of age; and (b) the study reported on correlates of condom use, contraceptive use, and/or dual protection use. Searches of electronic databases were conducted with combinations of relevant search terms to identify studies included in the review. The review included 25 studies published between 2003 and 2016.

Results: The majority of studies utilized a cross-sectional design (72%) examining individual-level constructs (e.g., age, condom use self-efficacy) as key correlates. Condoms were the most frequently endorsed method used, with use of other contraceptive methods varying across studies, and dual protection infrequently endorsed (e.g., 7.5% among sexually active sample). Findings were mixed regarding correlates associated with condom, contraception, and/or dual protection use; however, strategy use often differed by sociodemographic variables (e.g., age, educational status), current relationship characteristics, and previous sexual behaviors (e.g., age at first sex).

Conclusions: There was a limited number of studies examining dual protection strategy use with the majority focusing exclusively on condom use. Individual-level factors (e.g., sociodemographic characteristics, HIV serostatus, etc.) were typically examined as correlates of condom, contraception, and/or dual protection use. While studies of individual-level factors facilitate understanding of personal decision making processes, there is a need to examine the broader cultural context that may influence SA adolescent girls' use of dual protection strategies to inform future multi-level intervention efforts.

INTERSECTING STIGMA: RACIAL DISCRIMINATION AND GAY REJECTION SENSITIVITY PREDICT MENTAL HEALTH AND SEXUAL RISK IN GBM OF COLOR

Devin English, PhD¹, H. Jonathon Rendina, PhD, MPH², Jeffrey T. Parsons, PhD²¹Center for HIV Educational Studies & Training (CHEST), Hunter College, City University of New York, New York, NY; ²Hunter College of the City University of New York (CUNY), New York, NY

Introduction: Although the CDC has identified social discrimination as a key risk factor causing gay and bisexual men (GBM) of color to have the highest rates of seroconversion, AIDS classifications, and deaths caused by HIV, there has been relatively little research examining how the constellation of social stigma facing these men affects their HIV risk. Minority stress and intersectionality theories together suggest that experiences associated with the intersection of multiple social identities, such as sexual orientation and race, can lead to negative mental health outcomes and, in turn, sexual risk. Thus, the present study investigates whether racial discrimination and gay-related rejection sensitivity individually and intersectionally predict sexual risk among GBM of color through their association with emotion dysregulation and negative mental health symptoms.

Methods: Participants were a community sample of 235 Latino, Black, and Multiracial GBM. We administered the Gay-Related Rejection Sensitivity Scale, the race version of the Everyday Discrimination Scale, and the Difficulties with Emotion Regulation Scale at baseline evaluation, the Brief Symptom Inventory at 6 months, and the Hypersexual Disorder Screening Inventory and Decisional Balance for Sex without Condoms scale at 12 months. We ran mediational structural equation models within *Mplus* 7.4 and tested mediational pathways using the Model Indirect command.

Results: Ninety seven percent of the sample reported non-zero gay-related rejection sensitivity and 85% of the sample reported experiencing racial discrimination. Racial discrimination ($\beta=.21, p<.01$), gay-related rejection sensitivity ($\beta=.17, p<.01$), and the interaction between them ($\beta=.16, p<.01$) significantly predicted emotion dysregulation. Simple slopes analyses showed that emotion dysregulation significantly increased at higher levels of both racial discrimination and gay-related rejection sensitivity. Emotion dysregulation ($\beta=.40, p<.01$) positively predicted later mental health symptoms which, in turn, predicted higher perceived benefits of condomless sex ($\beta=.28, p<.01$) and hypersexuality ($\beta=.40, p<.01$). There were significant indirect pathways from racial discrimination, gay-related rejection sensitivity, and the interaction term through emotion regulation and mental health to the two sexual risk outcomes.

Conclusion: This study indicates that the experience of both racial discrimination and gay-rejection sensitivity interact to put GBM of color at unique risk of emotion regulation difficulties, negative mental health symptoms and, in turn, risky sexual behavior. These results suggest that care providers and researchers must pursue comprehensive and intersectional intervention approaches to address the constellation of social stressors experienced by GBM of color.

LONGITUDINAL EFFECTS OF SYNDEMICS ON CONDOMLESS SEX WITH HIV-UNINFECTED PARTNERS AMONG SEXUAL MINORITY MEN LIVING WITH HIV

Audrey Harkness, Ph.D.¹, Sierra A. Bainter, Ph.D.², Conall O’Cleirigh, Ph.D.³, Christopher Albright, B.S.¹, Kenneth Mayer, M.D.⁴, Steven Safren, Ph.D., A.B.P.P.²

¹University of Miami, Miami, FL; ²University of Miami, Coral Gables, FL; ³Massachusetts General Hospital, Boston, MA; ⁴The Fenway Institute, Boston, MA

Background. The relationship between syndemics, or co-occurring psychosocial problems associated with HIV sexual risk behaviors and HIV acquisition has been widely documented among HIV-negative sexual minority men. Comparatively, few studies have examined the link between syndemics and sexual health behaviors among those living with HIV. Men who have sex with men (MSM) remain the largest risk group for HIV in the U.S. Extending the work on syndemics to HIV-positive sexual minority men can inform the development of evidence-based secondary prevention programs, which may reduce HIV transmission.

Methods. This study was a one-year (5-time points) longitudinal analysis of the cumulative effects of syndemics on engaging in condomless anal sex (CAS) with HIV-uninfected partners among 390 HIV-positive MSM who participated in one of two prior secondary prevention trials. Participants were assessed for childhood sexual abuse, post-traumatic stress disorder, anxiety disorders, depression, alcohol abuse, and polysubstance/stimulant use. The number of psychosocial problems for which participants met criteria was used to compute their longitudinal syndemics scores (continuous, 0 – 6). Bivariate logistic regressions assessed co-occurrence among each of the psychosocial concerns. We employed multi-level modeling (SAS 9.4, PROC GLIMMIX) with participants’ syndemics scores at each time point as a longitudinal predictor of CAS with uninfected partners (binary). Control variables included time, intervention (or control) assignment, and their interaction.

Results. Bivariate logistic regression analyses with each individual syndemic condition regressed on the others showed seven significant associations ($p < .05$) and four approaching significance ($p < .10$). Multilevel modeling revealed that the number of syndemics for which participants met criteria over time significantly predicted CAS with uninfected partners, such that for each additional syndemic condition, participants had 1.41 increased odds of CAS (95% CI [1.16, 1.70], $p = 0.0004$).

Conclusions. This is the first study to the authors’ knowledge to show the longitudinal association between psychosocial syndemics and sexual risk among sexual minority men living with HIV. The findings highlight the importance of addressing co-occurring psychosocial concerns when developing and implementing secondary prevention and sexual health promotion programs for sexual minority men living with HIV.

PREDICTING SEXUAL BEHAVIORS AMONG HOMELESS YOUNG ADULTS USING ECOLOGICAL MOMENTARY ASSESSMENT: RESULTS OF PROJECT YOUTH EMA

Diane Santa Maria, DrPH, MSN, RN, PHNA-BC¹, Nikhil Padhye, PhD¹, Yijiong Yang, MHA/PhD candidate-Health Economics², Kathryn Gallardo, MSW³, Michael Businelle, PhD⁴

¹University of Texas Health Science Center Houston, Houston, TX; ²University of Texas Health Science Center School of Nursing/School of Public Health, Houston, TX; ³University of Texas School of Public Health, Houston, TX; ⁴University of Oklahoma Health Sciences Center, Oklahoma City, OK

Introduction: Homeless youth continue to be disproportionately affected by HIV compared to their housed peers with prevalence rates as high as 13%. Yet, HIV prevention in this high-risk population has only been marginally effective.

Objective: The aim of this study was to determine whether EMA data can be used to develop a predictive model of sexual risk among homeless youth.

Methods: Homeless youth 18–24 years old were recruited from a drop-in center in Houston, TX between August, 2015 and May, 2016. All participants received a study-issued smartphone that prompted brief Ecological Momentary Assessments (EMAs) 5 times a day for 21 days. EMA items assessed near real-time sexual behaviors, cognitions, stress, affect, environmental factors, and environmental circumstances.

Results: Participants (N=66) were predominantly male (64%) and Black (66%) with a median age of 20 years old. The mean number of EMAs completed by each participant was 45 observations (i.e., 13 daily and 33.6 random EMAs). Of the 70% of participants who were sexually active during the study, condomless sex was reported in 102 incidences or 75% of sexual intercourse incidences. In total, 38 (58%) participants reported engaging in any high risk sexual behaviors within the data collection period including condomless sex (53%), having multiple sexual partners on the same day (26%), trading sex (16%), or sharing needles for injecting drugs (3%). Of those, 71% had engaged in more than one of the risk behaviors during the study. The predictive model was based on observations from 66 subjects over 811 days and included 137 cases of sexual intercourse and included sexual orientation, race, mental health, drug use, and sexual urge as predictors in the parsimonious GLMM selected on the basis of the Akaike information criterion (AIC). Youth who were LGBT, youth of color, or who had a mental illness had higher odds of sexual activity. For within subject factors, the estimated odds ratios were notable for same day drug use (OR = 2.17, $p < .001$) and sexual urge (OR = 1.44, $p < 0.01$). Performance of the risk estimator was satisfactory, as indicated by the value of 0.834 for the area under the ROC curve.

Conclusions: Real-time EMA data can be used to predict sexual intercourse among a sample of high risk, predominately unsheltered homeless youth. Sexual urge and drug use account for increased odds of engaging in sexual activity on any given day. Just-in-time interventions targeting sexual urge and drug use may help address high rates of HIV risk behaviors among this homeless youth

PREDICTORS OF PREP ADHERENCE AMONG A LARGE NATIONAL SAMPLE OF GAY, BISEXUAL, AND MEN WHO HAVE SEX WITH MEN

Thomas H.F. Whitfield, MA¹, Jeffrey T. Parsons, PhD², H. Jonathon Rendina, PhD, MPH², Jeffrey T. Hietikko, PhD²¹The Graduate Center, CUNY, New York, NY; ²Hunter College of the City University of New York (CUNY), New York, NY

Background: Pre-exposure prophylaxis (PrEP) is currently the most effective biomedical HIV prevention method available. Although the USFDA has approved PrEP for daily use among at-risk individuals, research has shown that adherence to 4 or more doses per week is the minimally effective dosing for the prevention of transmission. There has been competing evidence published on levels of adherence to PrEP, and one issue may be how adherence is captured. As such, we sought to provide further examination of the issue, examining both overall frequency of non-adherence and non-adherence for 4 or more days in a row.

Methods: Utilizing advertisements on a popular sexual networking app and a social networking website, we recruited 11,032 gay, bisexual, and men who have sex with men (GBMSM) to complete an online survey about sexual behavior, substance use, and PrEP. To examine predictors of frequency of missed doses we utilized a negative binomial regression; to examine missing 4 or more doses in a row, we utilized a binary logistic regression. In both models we included age, race, income, education, years on PrEP, any club drug use, any condomless anal sex with male casual partners (CAS), and AUDIT score.

Results: Significant predictors of frequency of missed doses in the last 3 months included income under 30K (ARR=1.76, $p=0.001$), club drug use in the last 3 months (ARR=1.26, $p=0.003$), and any engagement in condomless anal sex (CAS) acts with casual male partners (ARR=1.29, $p=0.004$). Significant predictors of the odds of missing 4 or more doses in a row in the last 30 days included younger in age (AOR=0.97, $p=0.003$) and having an income under 30K (AOR=1.88, $p=0.001$).

Conclusions: We found differences between predictors of individual's frequency of missed doses and missing 4 or more doses in a row; although there were many group differences in overall levels of adherence, few predictors emerged of missing sub-threshold levels of adherence that may undermine PrEP's effectiveness. Club drug use was significant for frequency of non-adherence but not those that missed 4 or more doses in a row, whereas alcohol use was not significant for either group. Post initiation can be costly (e.g. quarterly STI and HIV testing, prescription refills) and these findings suggest that interventions are needed to help HIV at-risk lower income individuals maintain a PrEP prescription.

PREP KNOWLEDGE AND USE AMONG MEN WHO HAVE SEX WITH MEN IN A SMALL METROPOLITAN REGION OF THE SOUTHEASTERN US

James A. Griffin, Ph.D., Elizabeth D. Eldridge, Ph.D., Megan M. Loew, M.S., Lara M. Stepleman, Ph.D.

Augusta University, Augusta, GA

Background. Men who have sex with men (MSM) continue to be at high risk of acquiring HIV, particularly those living in Southern US states. Pre-exposure prophylaxis (PrEP), an antiretroviral HIV prevention treatment, was approved by the US Food and Drug Administration in 2012. PrEP has become increasingly popular, although knowledge of this prevention strategy varies widely across communities.

Methods. The present survey study examined PrEP knowledge and use in a sample of 164 mostly White (70%), gay-identified (84%), HIV-negative (84%) adult MSM ($M_{age} = 36.16$, $SD = 13.97$) living in the Central Savannah River Area (CSRA) of the South.

Results. Results revealed that approximately one-fifth of the sample (19.5%) had never heard of PrEP, with approximately one-third (32.9%) reporting they are very familiar with PrEP. Approximately one-fifth of the sample (19.7%) had spoken to a healthcare provider about PrEP, with a slightly lower percentage (16.8%) reporting that a healthcare provider discussed PrEP with them. Just under one in ten MSM (9.1%) had previously taken PrEP. Factors associated with knowledge of PrEP include higher levels of education ($r = .22$, $p < .01$), gay identification ($r = .22$, $p < .01$), HIV-positive status ($r = .22$, $p < .01$), and history of healthcare provider discrimination ($r = .16$, $p < .05$). MSM of color were more than three times more likely than White MSM to have used PrEP (17% versus 4.7%; $\chi^2 = 5.55$, $p < .05$).

Conclusion. Although PrEP familiarity is high among MSM in this region, rates of discussion with healthcare providers and PrEP use remain low. Increased PrEP awareness and provision of appropriate and competent healthcare to MSM by providers is needed in order to effectively address the ongoing HIV epidemic among Southern MSM.

PSYCHOSOCIAL STRESSORS AND CD4 COUNT AMONG HIV-POSITIVE OLDER ADULTS: SUPPORT FOR A BIOPSYCHOSOCIAL MODEL OF HIV STIGMA & HEALTH

H. Jonathon Rendina, PhD, MPH¹, Laurel Weaver, MA², Jonathan López Matos, MA², Brett M. Millar, PhD³, Jeffrey T. Parsons, PhD⁴¹Hunter College of the City University of New York (CUNY), New York, NY;²Graduate Center of the City University of New York (CUNY), New York, NY;³Graduate Center CUNY, New York, NY; ⁴Hunter College - CUNY, New York, NY

Background: Available evidence suggests a link between psychosocial wellbeing, adherence, and immune function. For example, depression has been strongly linked to inflammatory processes and this has been shown among individuals with chronic illnesses such as HIV. We sought to explore how a range of psychosocial issues might influence immune health among older adults with HIV adjusting for known differences in adherence and virologic failure

Method: We enrolled 120 substance-using older adults, and utilized a multivariable linear regression predicting log CD4 cell count with depression, loneliness, social support, HIV stigma, alcohol use problems, and drug use problems, adjusting for gender, race, income, age, years since HIV diagnosis, medication adherence, and undetectable viral load.

Results: The sample was two-thirds male ($n = 81$, 67.5%) and the majority were people of color ($n = 111$, 92.5%). The average age was 54.6 ($SD = 4.1$) and participants had been living with HIV for an average of 17.1 years ($SD = 6.9$). In the adjusted multivariable models, we found that HIV stigma was the only significant psychosocial predictor of CD4 count ($\beta = -0.27$, $p = 0.02$)—depression, loneliness, social support, alcohol use problems, and drug use problems were all non-significant.

Conclusions: In adjusted models, HIV stigma was the only psychosocial condition to show a statistically significant association with CD4 count, such that increased levels of stigma were associated with decreased CD4 count (i.e., poorer immune health). This was true even after adjusting for factors such as medication adherence and undetectable viral load. This study provides evidence that HIV stigma is a critical psychosocial factor influencing the immune health of HIV-positive older adults. Interventions with this population should focus on reducing stigma. Future research should examine the interrelation among these psychosocial conditions and how they may interact in their association with health.

PSYCHOSOCIAL SYNDEMICS AMONG HIV-POSITIVE PEOPLE WHO INJECT DRUGS IN RUSSIA

Eileen V. Pitpitan, PhD¹, Karsten Lunze, MD, MPH, DrPH², Debbie M. Cheng, ScD³, Elena Blokhina, MD, PhD⁴, Dmitry Lioznov, Head, Department of Infectious Diseases/MD, PhD⁵, Natalia Gnatienko, MPH⁶, Emily Quinn, M.A.³, Evgeny Krupitsky, MD, PhD, Professor⁷, Anita Raj, PhD, MS⁸, Jeffrey H. Samet, MD, MA, MPH⁹¹University of California San Diego, La Jolla, CA; ²Boston Medical Center,Boston, MA; ³Boston University School of Public Health, Boston, MA; ⁴First

Pavlov State Medical University of St.Petersburg, Saint-Petersburg, N/A, Russia;

⁵First Pavlov State Medical University, St. Petersburg, N/A, Russia; ⁶Boston

Medical Center/Clinical Addiction Research and Education (CARE) Unit,

Boston, MA; ⁷St.-Petersburg Bekhterev Reserach Psychoneurological Institute,St.-Petersburg, Saint Petersburg City, Russia; ⁸UC San Diego, San Diego, CA;⁹Boston University School of Medicine, Boston, MA

Background: Psychosocial problems including substance use, violence, and depression co-occur and form a “syndemic” among key at-risk populations for HIV. Research on the syndemic framework has shown that individuals with a higher syndemic load, or a greater number of problems, are more likely to engage in risky sex. Most of the extant evidence has been found among men who have sex with men, HIV-negative, and U.S. populations with a focus on behavioral outcomes. Much less research has examined syndemic load among HIV-positive populations and clinical outcomes, especially among non-U.S. populations. The HIV epidemic in Russia is expanding, greatly affecting people who inject drugs (PWID), and would benefit from examination on this topic in this context.

Purpose: Our primary aim was to test whether syndemic load (i.e., sum of psychosocial problems) is associated with lower CD4 count (primary outcome), more HIV symptoms, lower perceived access to care and health literacy among HIV-positive PWID in Russia.

Method: This analysis examined data at the 6-month interview from the LINC RCT testing an intervention to improve HIV care outcomes among HIV-positive PWID in Russia. Participants completed measures of sociodemographics, syndemic problems (depressive symptoms, experience with violence, alcohol, and drug use), and other variables via face-to-face interviews with trained research staff. CD4 count testing occurred at baseline.

Results: Among 230 study participants, multivariable linear regression analyses showed that after controlling for sociodemographic covariates (age, gender, education, resource stability), there was a non-significant pattern such that compared to PWID with 0 or 1 problems ($N=61$, Adj. mean CD4 = 471.7), those with 2 ($N=66$, Adj. Mean = 415.8, $p=0.20$), 3 ($N=52$, Adj. Mean = 385.0, $p = 0.07$), or 4 problems had lower CD4 counts ($N=51$, Adj. Mean = 382.4, $p = 0.08$). A statistically significant association was found between higher syndemic loads (3 or 4) and more HIV symptoms. Depression and drug use also appeared to be associated with HIV symptoms. Syndemic load was not significantly associated with perceived access to care or health literacy.

Conclusion: Findings demonstrate the association between syndemic load and physical health among HIV-positive PWID in Russia, and extends prior findings that HIV prevention and care interventions with key populations should be multi-faceted to address multiple psychosocial problems.

PSYCHOSOCIAL SYNDemics AND BARRIERS TO HIV CARE AMONG OUT-OF-CARE HIV-POSITIVE INDIVIDUALS IN TIJUANA, MEXICO

Eileen V. Pitpitan, PhD, Laramie R. Smith, Ph.D.

University of California San Diego, La Jolla, CA

Background: An understanding of the barriers to HIV care among HIV-positive marginalized and hard-to-reach populations is necessary to achieve the promises of “Treatment as Prevention.” Psychosocial problems including substance use, childhood sexual abuse, and depression co-occur and form a “syndemic” among key at-risk populations for HIV. Whereas a great deal of evidence has shown that syndemic load (number of psychosocial problems) is associated with higher risk behavior among HIV-negative populations, less is known about the role of syndemics in barriers to care among people living with HIV. In Tijuana, Mexico, the HIV epidemic is concentrated among female sex workers (FSW), people who inject drugs (PWID), and men who have sex with men (MSM). Previous research has shown that members of these populations in this region are not linked to or retained in HIV care and very few are virally suppressed.

Purpose: The aims of the current study are to examine syndemic psychosocial problems among out-of-care HIV-positive FSW, PWID, and MSM in Tijuana, and to test whether syndemic load is associated with barriers to HIV care. We hypothesized that participants with higher syndemic load would report a greater number of barriers to HIV care.

Method: Out-of-care HIV-positive FSW, PWID, and MSM in Tijuana, Mexico ($n=54$) completed a survey assessing sociodemographics, syndemic problems (depression, recent drug use, hazardous alcohol use, childhood abuse, and recent experiences with violence victimization), and barriers to HIV care.

Results: Multivariable linear regression analyses showed that after controlling for sociodemographic covariates (age, housing instability, food insecurity), syndemic load was a significant and positive predictor of barriers to HIV care ($B = 0.59$, $t = 2.11$, $p = 0.04$). Syndemic load was specifically associated with reporting not having transportation to HIV care ($OR = 1.90$, $p = 0.02$), being unable to pay for travel to HIV care ($OR = 2.79$, $p =$

Conclusion: Members of key HIV-positive populations (FSW, PWID, MSM) in Tijuana, Mexico who experience more psychosocial problems report more barriers to care. Primary barriers may have to do with transportation and internalized stigma or depression. Interventions to improve linkage to and retention in HIV care with these populations should focus on addressing these barriers.

REACHING THE COMMUNITY: HIV RISK AMONG AFRICAN AMERICAN CHURCH AND COMMUNITY MEMBERS

Alexandria Bauer, MA¹, Jannette Berkley-Patton, PhD, MA, BSEE², Kelsey Christensen, MA³, Carole Bowe-Thompson, BS⁴, Nia Johnson, BA⁵, Sheila Lister, B.S.⁴

¹University of Missouri-Kansas City, Raytown, MO; ²University of Missouri-Kansas City, School of Medicine, Kansas City, MO; ³University of Missouri-Kansas City, Kansas City, MO; ⁴University of Missouri-Kansas City, Kansas City, MO; ⁵University of Missouri Kansas City, Kansas City, MO

Background: The rate of new HIV infections among African Americans (AAs) is eight times that of Non-Hispanic Whites. AAs report more frequent church attendance than any other racial/ethnic group, and faith-based HIV prevention interventions have demonstrated potential among AA church members and community members who use church outreach ministries (e.g., food pantry, daycare, counseling). However, few studies have examined whether AAs community members who use church outreach services are a greater risk for HIV compared to AA church members.

Methods: The current study examined HIV risk behaviors (e.g., sexual activity, drug use, correctional system history) using baseline data from Taking it to the Pews (TIPS), a faith-based HIV/STD screening and education intervention. Participants were recruited from 14 AA churches in the Kansas City metropolitan area. Binary logistic regression was used to examine participants' engagement in 10 HIV risk behaviors within their lifetime and over the past 12 months.

Results: Among church ($n = 1,021$, 68%) and community members ($n = 479$, 32%), participants were primarily female (68%) and had an average age of 43 ($SD = 13$). Preliminary analyses indicated associations between nine of the ten behaviors at both lifetime and over the past 12 months. In their lifetimes, community members were at greater risk than church members for injecting street drugs ($OR = 3.4$, $p < .001$), sharing needles ($OR = 4.4$, $p = .001$), having been to alcohol or drug treatment ($OR = 2.5$, $p < .001$), having been homeless ($OR = 2.14$, $p < .001$), having been in the correctional system ($OR = 2.5$, $p < .001$), having sex while high on drugs or alcohol ($OR = 1.37$, $p = .008$), and having sex with someone who has been in prison ($OR = 1.4$, $p = .01$) or injects drugs ($OR = 2.4$, $p < .001$) or a man who has sex with men ($OR = 2.2$, $p = .02$). These findings also held over the past 12 months, with the exception of having sex with a man who has sex with men. Community members were also at greater risk for being the victim of domestic violence or abuse over the last 12 months ($OR = 1.8$, $p < .001$).

Conclusions: Findings indicate that AA community members who used church outreach services were more likely to endorse risk behaviors (e.g., drug use, homelessness) and therefore, may be at greater risk for HIV than AA church members. By tapping existing church outreach networks, faith-based HIV prevention interventions may have the potential to increase their reach. Furthermore, HIV prevention programs implemented in church settings should consider targeted recruitment of AA community members who use outreach ministries, in order to more effectively focus HIV prevention efforts for members of the AA community who may be at greater risk for HIV.

REDUCING UNDIAGNOSED HIV INFECTIONS: UNDERSTANDING GENDER DIFFERENCES IN HIV TEST BEHAVIOR OF YOUNG AFRICAN AMERICAN ADULTS

Melanie Moore, M.S.¹, Faye Z. Belgrave, Ph.D.²¹Virginia Commonwealth University, Raleigh, NC; ²Virginia Commonwealth University, Richmond, VA

PURPOSE/OBJECTIVES: Over 50% of young adult ages 18–24 who are HIV positive, are unaware they are infected with HIV. African Americans represent the racial/ethnic with the highest burden of HIV, accounting for 45% of HIV infections in the United States. Despite these statistics, little research has been dedicated to understanding factors that increase the likelihood of HIV testing among Black/African American young adults. Getting tested for HIV is the only way to know one's status. The primary aim of this study was to examine gender differences in predictors of past HIV test behavior in this population.

PARTICIPANTS/METHOD: Data from (n = 142) young adults participating in an evidenced-based safer sex behavioral intervention were collected. Participants self-identified as Black/African American, and most were between the ages of 18 and 26. They completed a questionnaire with measures of sexual behaviors, HIV testing attitudes, and HIV test behaviors, among other measures. A series of chi-square tests of associations and independent samples t-test were performed to assess gender differences in past HIV testing, HIV test attitudes, HIV knowledge, HIV test behavior, and HIV risk behaviors. Following these tests, multivariate regressions examined the relation between both HIV test attitudes and knowledge of where to get tested, with having previously been tested for HIV.

RESULTS: Overall, 58% percent had been previously tested for HIV. Predictors of past HIV testing differed by gender. Negative attitudes about HIV testing were associated with a significantly lower likelihood of past HIV testing among men, but not this was not a significant predictor of past HIV testing among women. Knowledge of where to get tested was significantly associated with a greater likelihood of past HIV testing among women, but not among men. There were significant differences between groups on number of sexual partners and HIV testing attitudes, such that men reported a significantly higher number of sexual partners in the past 3 months and more negative HIV testing attitudes compared to women. There were no significant differences between groups in recent engagement in unprotected sex, knowledge of where to go to talk to a health professional about HIV/STDs, or past HIV test behavior.

CONCLUSIONS: Understanding gender differences in predictors of HIV testing can provide important information about barriers/motivators to get tested for HIV. This information can be utilized to improve the effectiveness of HIV prevention efforts/strategies aiming to increase HIV testing among Black young adults. Findings from this study may be relevant to infectious disease clinicians and health care providers, HIV test counselors, and HIV behavioral interventionists working to increase rates of HIV testing among young Black/African American adults.

RESULTS OF A RCT OF SOCIAL MEDIA (WECHAT) BASED INTERVENTION TO IMPROVE MEDICATION ADHERENCE IN PEOPLE LIVING WITH HIV/AIDS

Y. Alicia Hong, Ph.D.¹, Yan Guo, Ph.D.²¹Texas A&M University, College Station, TX; ²Sun Yet-sen University, Guangzhou, N/A, China (People's Republic)

OBJECTIVE: Adherence to medication adherence is critical to optimal disease management and quality of life for people living with HIV/AIDS (PLWHA). Effective interventions that can reach a large number of PLWHA in a cost-effective manner is urgently needed, especially in developing countries such as China where healthcare resources are limited. This study reports the results from a pilot mHealth intervention aimed to improve medication adherence and quality of life among PLWHA in China.

METHODS: Based on formative research, we developed an intervention program on WeChat, a popular Chinese social media mobile app with more than 900 million active users. A sample of 62 PLWHA was recruited from the infectious Department for HIV/AIDS treatment of a large hospital in South China. Participants were randomly assigned to intervention or control group. The intervention group (n=31) received information and reminders on medication adherence, physical exercise reminders, and HIV-related information three times a week on WeChat for 3 months. The control group (n=31) received nutrition information at the same frequency on WeChat.

RESULTS: Three months after the intervention, 86% (n=53) of the participants completed a follow-up survey. The mean age the participants was 28 years, 90% were male. Many of the participants were young men who have sex with men (MSM). The key outcomes of medication adherence and quality life did not improve significantly in the either groups; no statistically significant difference existed in the pre-post differences between intervention group and control group either. The minimal efficacy might be due to the small sample size and high ceiling effect of the primary outcomes (>90% in the baseline). We conducted qualitative interviews with the participants for their comments on the current intervention and recommendations for revision. The critiques included high-level interest in nutrition for PLWHA in control group and low-level interest in HIV-related information in the intervention group. Most participants had subscribed many WeChat accounts and did not read all the messages we sent.

CONCLUSIONS: The current study represents one of the first WeChat-based interventions for PLWHA, and it had a low level of efficacy. Future mHealth interventions need to identify the true needs of the target population and develop culturally appropriate programs delivered via user-preferred channels.

THE IMPACT OF GENERAL STRESS AND HIV-RELATED STRESS ON DEPRESSION AND ANXIETY AMONG HIV-POSITIVE GAY AND BISEXUAL MEN

Jonathan López Matos, MA¹, Jeffrey T. Parsons, PhD², H. Jonathon Rendina, PhD, MPH²¹Graduate Center of the City University of New York (CUNY), New York, NY; ²Hunter College of the City University of New York (CUNY), New York, NY

Background: General life stress and HIV-related stress have been independently associated with negative mental health outcomes, including anxiety and depression. For HIV-positive gay and bisexual men (GBM), these two forms of stress may have concurrent effects that independently exacerbate symptoms of anxiety and depression. The present study sought to simultaneously examine the impact of general and HIV-related stress on depression and anxiety in a sample of HIV-positive GBM.

Methods: Data were taken from a sample of 85 HIV-positive GBM from New York City. The Perceived Stress Scale (PSS) was used to measure general life stressors and the HIV/AIDS Stress Scale (HASS) was used to measure HIV-specific stressors. Anxiety and Depression were assessed using the Overall Anxiety Severity & Impairment Scale and the Overall Depression Severity & Impairment Scale.

Results: Average age was 39.1 years ($SD=10.4$), the majority of the sample identified as men of color (41.2% Black, 27.1% Latino, 20.0% White, 11.8% Other), 27.5% had a college degree or more, 88.2% were employed, 35.3% made more than \$30,000 a year, and 28.2% were in a relationship; the sample had been living with HIV for an average of 11.4 years. In bivariate analysis, PSS showed positive correlations with HASS ($r=.59, p<.01$), anxiety ($r=.71, p<.01$) and depression ($r=.69, p<.01$); HASS was significantly correlated with anxiety ($r=.61, p<.01$) and depression ($r=.46, p<.01$). After adjusting for sociodemographic differences and one another, PSS ($\beta=.52, p<.001$) and HASS ($\beta=.25, p<.05$) were both independently associated with overall anxiety. PSS was also associated to overall depression ($\beta=.65, p<.001$), but HASS did not maintain a significant independent association with depression ($\beta=-.03, p=.79$).

Conclusions: These findings support an association between two sources of stress and negative mental health outcomes among HIV-positive GBM. Further, these findings support the hypothesis that simultaneous sources of stress and different types of stressors may have unique impacts on mental health, with both general and HIV-specific stressors independently impacting symptoms of anxiety. Interventions targeting stress reduction as a means to improve mental health outcomes may need to consider incorporating specific techniques for dealing with HIV-related stigma.

THE ROLE OF INFORMATION AVOIDANCE IN CONTEMPORANEOUS HIV TESTING DECISION MAKING

Devon M. Price, M.S.¹, Juan Carlos Loubriel, N/A², Jacquetta Brooks, MSW, LGSW², Seth Kalichman, PhD³¹University of Connecticut, Manchester, CT; ²Whitman Walker Health, Washington D.C, DC; ³University of Connecticut, Storrs, CT

HIV testing is treated as the first step towards HIV prevention. However, there are significant psychological barriers to testing uptake. Even with improved HIV testing technology that can deliver accurate results in a matter of minutes, 1 in 8 people living with HIV are still unaware of their positive status (CDC, 2015). Washington, D.C. is one of the areas hardest hit by HIV in the United States, with rates of prevalence higher than some developing countries. In D.C., approximately 2.5% of the population is living with HIV, which exceeds UNAIDS' definition of a "generalized" epidemic (D.C Department of Health, 2014). With the HIV testing gap still a pressing issue, we sought to pinpoint psychosocial factors that might affect testing.

This study examined a four psychosocial factor model of HIV testing decisions among DC residents at risk for HIV. Three of the psychosocial factors, HIV stigma, HIV treatment optimism, and HIV infectiousness beliefs, have been well documented in the literature on HIV testing. However, the fourth psychosocial factor, the tendency to avoid threatening information, has received less attention in relation to HIV testing. The present study investigated how these factors impact contemporaneous HIV testing behaviors in a diverse sample of at-risk DC residents.

Surveys were collected from 130 at-risk DC residents during mobile HIV testing events held during the months of August 2016-December 2016. Participants were asked if they would like to take an HIV test. Those who refused the HIV test were immediately asked if they would like to take the survey for a \$5 Starbucks gift card. Participants who turned down the HIV test, reported being sexually active, and had not been tested in the last 4 months were retained for analyses. This group was compared to those who accepted the HIV test and then took the survey upon receiving a negative result.

A multivariate logistic regression predicting HIV testing group (turned down testing, accepted testing) revealed that the only significant psychosocial predictor of accepting an HIV test was information avoidance. Interestingly, those who reported greater information avoidance tendencies were more likely to accept HIV testing when offered, OR 1.15, 95% CI [1.03–1.28].

Overall, our results indicate that an important mechanism has been missing from the study of psychosocial barriers to HIV-testing. Information avoidance predicts HIV-testing behavior above and beyond the psychosocial factors that have previously been considered the primary deterrents of testing. However, our results indicated the opposite effects than what we predicted. Further examination of information avoidance and how it functions in relation to HIV testing decisions is warranted for understanding why at-risk populations choose not to test for HIV and which psychological mechanisms should be targeted for intervention.

TRANSGENDER WOMEN'S ALCOHOL USE AND HIV HIGH-RISK BEHAVIORS IN THE DOMINICAN REPUBLIC

Kristine Ria Hearld, PhD¹, Henna Budhwani, PhD, MPH¹, Rosa Mayra Rodriguez-Lauzurique, MSc², Robert A. Paulino Ramirez, MD, HIVS, DTM&H²¹University of Alabama at Birmingham, Birmingham, AL; ²Universidad Iberoamericana, Santo Domingo, Distrito Nacional, Dominican Republic

Background: Studies on alcohol use in transgender populations, particularly those in global resource-limited settings are scarce. This is particularly alarming, since alcohol use may be both a facilitator of HIV risk behaviors and a coping mechanism used after the engagement in such activities. Thus, we examined the relationships between high-risk sexual practices and alcohol use in a national sample of transgender women from the Dominican Republic.

Methods: Data for this study was from the 2015 Dominican Republic Transgender Health Needs Study (THNS), collected by Centro de Orientación e Investigación Integral (COIN), and funded by the National Council for HIV and AIDS (CONAVIHSIDA) representing the Dominican Republic Ministry of Health. As recommended by the Joint United Nations Programme on HIV/AIDS (UNAIDS), this study leveraged the PLACE method of data collection. Bivariate analysis examined differences between routine alcohol users and abstainers (n=291). Multivariate analyses reported odds ratios with alcohol use during sexual activity as the outcome (n=245).

Results: About half of respondents (49.5%) had sex under the influence of alcohol in the last 30 days, and 37.1% reported income from sex work. Bivariate tests found significant differences between alcohol users and abstainers. Sex workers (defined as reporting primary or secondary income through sex work), respondents who engaged in high risk sexual behaviors, those who used condoms less frequently, and respondents reporting higher numbers of sexual partners were all more likely to consume alcohol regularly as compared to their peers (p

Conclusions: Significant knowledge gaps persist in the behaviors of transgender women in resource-limited settings, especially in the Spanish speaking Caribbean. Although cross-sectional data cannot offer causal inferences, the associations between alcohol use and sex work in the transgender women from our national sample is particularly alarming, since alcohol consumption has been well-documented as an associate of engagement in high-risk for HIV sexual behaviors. Furthermore, transgender women are stigmatized in the Dominican Republic, potentially limiting their work opportunities. Anti-discrimination laws to exist that protect workers, but those policies are not consistently enforced potentially forcing transgender women to seek work in alternative settings. Further research on if alcohol enables the entry into sex work, if it reduces psychosocial effects of being a sex worker, or both is necessary to develop culturally appropriate, effective harm-reduction strategies for transgender women in the Dominican Republic.

BARRIERS AND FACILITATORS OF IMPLEMENTING PEER SUPPORT IN VHA PRIMARY CARE-MENTAL HEALTH INTEGRATION SETTINGS

Robyn L. Shepardson, PhD

VA Center for Integrated Healthcare, Syracuse, NY

In the Veterans Health Administration (VHA), over 1,100 Peer Support Specialists (PSS) promote recovery-oriented care. Peer support was historically delivered in VHA specialty mental health, but is now being piloted in Primary Care-Mental Health Integration (PC-MHI) settings. Research has shown the importance of consulting with key stakeholders when implementing peer support in new settings. Therefore, we conducted a qualitative study to identify barriers and facilitators to implementation of peer support in VHA PC-MHI. We conducted semi-structured interviews with 25 stakeholders (56% female): 7 PSS, 6 PC providers, 6 PC-MHI providers, and 6 PSS supervisors. Data were analyzed via conventional content analysis with inductive coding. Two authors independently coded all responses (kappas .62-.75) and resolved discrepancies through consensus. The most common barriers were: program functioning (educating staff about peer support, establishing workflow/referral processes), administrative support (lack of: funding, office space, training, appropriate supervision, local autonomy), role clarity (guidance on PSS role/scope of practice), and stakeholder buy-in (patients, PC staff, leadership). Key facilitators of initializing and maintaining peer support were similar, with administrative support (logistical resources; local autonomy; funding, clinical supervision, training, professional development, and peer networks for PSS) as a central focus. Program functioning (staff education, workflow/referral processes, tailoring program to local needs, feedback loops) and team cohesion (support/respect for PSS, open communication, PSS in team meetings) were also identified as important. Stakeholder buy-in, which could be obtained via staff education, shadowing, testimonials, demonstrating immediate impact, was most important initially. Access and visibility of PSS (to PC staff and patients) and evidence of success (improved patient outcomes) were additional unique initial and maintenance supports, respectively. For leadership support, stakeholder buy-in and administrative support (funding, communication, supervision, local autonomy) were most discussed. These findings can help inform future implementation of peer support in VHA PC-MHI settings. Specifically, local leadership and staff should collaborate to delineate the PSS role, establish workflows, ensure PSS inclusion in teams, and obtain staff buy-in to facilitate successful implementation. Administrative support spanning logistical, financial, and supervisory resources is essential for both establishing and maintaining programs.

DEFINING INTEGRATED BEHAVIORAL HEALTH CORE PRINCIPLES AND TASKS IN PRIMARY CARE

Kari A. Stephens, PhD¹, Constance van Eeghen, DrPH, MHSA, MBA², Matt Martin, PhD, LMFT³, Jessica Clifton, PhD², Elizabeth Witwer, MPH¹, Rodger S. Kessler, N/A⁴

¹University of Washington, Seattle, WA; ²University of Vermont, Burlington, VT; ³Arizona State University, Phoenix, AZ; ⁴Doctor of Behavioral Health, Arizona State University, Phoenix, AZ

Introduction: Different models of integrated behavioral health have been studied and utilized across primary care practices, but no unifying set of integrated behavioral health (IBH) elements in primary care (PC) exists to guide implementation, dissemination, and measurement. PC needs these elements defined to build and refine IBH in practice.

Objective: We convened a national panel of IBH leading experts to define the core principles and tasks of IBH.

Methods: A small group of nine integrated behavioral health national experts evaluated an initial set of IBH core elements (i.e., principles and tasks), drawing from several well documented models. A REDCap survey was used to empirically and qualitatively evaluate each core principle and task with 31 national stakeholders. Results from the survey were then used to guide a focus group of 23 national stakeholders to refine task definitions to ensure each task uniquely described IBH.

Results: Seven core IBH principles were defined with 2–9 affiliated core tasks, for a total of 34 tasks. Survey responses ($N = 31$, 84% response rate) resulted in high endorsement of all the tasks with rating options that included 1 = strongly no to 4 = strongly yes ($M = 3.42\text{--}3.50/4.00$, $SD = 0.70\text{--}0.92$), with 35% of the tasks endorsed by 100% of the respondents and a low occurrence of non-endorsements (3–14% of respondents across 65% of the tasks). A pervasive theme included the need to separate tasks related to good primary care from good IBH primary care and drove the focus group activity. The five final IBH principles included patient-centric care, treatment to target, use evidence-based behavioral treatments, population-based care, and conducting efficient team care.

Discussion: Overall, strong expert consensus guided the definition of IBH core principles and tasks, with some dissent among members particularly with “treat to target” tasks. While the tasks have not been tested in real practice settings, the Integrated Behavioral Health Primary Care pragmatic trial team is planning to adapt them to the intervention and metrics. Initial crosswalks are showing good concordance with the Practice Integration Profile survey and NCQA Patient-Centered Medical Home and Behavioral Health Distinction core competencies, demonstrating promise for refining metrics for IBH as well. Our IBH principles and tasks can be used to promote IBH dissemination, quality measurement, and value based payment models.

PEER SUPPORT FOR DIABETES SELF-MANAGEMENT IN SHANGHAI COMMUNITY HEALTH CENTERS

Patrick Y. Tang, MPH¹, Yuexing Liu, PhD², Muchieh M. Coufal, MA, MPH³, Chun Cai, MsC, MPH⁴, Edwin B. Fisher, PhD¹, Weiping Jia, MD, PhD²

¹UNC Gillings School of Global Public Health, Chapel Hill, NC; ²Shanghai Sixth People's Hospital, Shanghai, Shanghai, China (People's Republic); ³Asian Center for Health Education, Plano, TX; ⁴Shanghai Municipal Commission of Health and Family Planning, Shanghai, Shanghai, China (People's Republic)

Background: Substantial research shows that peer support is effective in diabetes management, but integrating peer support into primary care continues to be a challenge. The Shanghai Integration Model (SIM) coordinates primary care in Community Health Centers (CHCs) with hospital-based specialty care. A key component of this healthcare transformation is the deployment of volunteer peer coaches to promote patient engagement in integrated care and daily self management. This presentation reports on the development and initial implementation of a CHC-based peer coaching program for adults with type 2 diabetes in Shanghai.

Method: Structured interviews with 15 CHC staff and patients with diabetes prior to implementation and a focus group with CHC staff members 2 months into the intervention provided insights into implementation progress and challenges. Using a stepped wedge study design, 10 CHCs were randomized into 3 cohorts with a 6-month delay in implementation.

Results: CHC staff and patients with diabetes recognized that peer support could contribute to the following needs for diabetes care in CHCs, including: 1) promoting self management behaviors, 2) improving knowledge about medication use and healthy diet, 3) reducing psychosocial and diabetes distress, 4) sustaining physical activity, and 5) reducing barriers to insulin initiation and treatment adherence. The formative evaluation informed the development of a program plan that includes: 1) regular, theme-based group meetings led by staff or co-led with peer coaches, 2) individual follow-ups by telephone, home visits, and WeChat, and 3) neighborhood-based group activities. In February 2017, 66 coaches and 25 staff from 10 CHCs received the initial training. In the following month, the CHCs recruited a total of 1192 patients with diabetes and 4 CHCs in the first cohort commenced the program. Ongoing technical assistance for CHC staff is provided through monthly conference calls and social media (WeChat) discussions. After 5 months, the 4 sites had held an average of 3.5 group sessions. Following a second training in August 2017, 3 additional CHCs commenced program implementation. One CHC withdrew from the project.

Discussion: Group and individual peer coaching through CHCs is proving to be feasible in “real world” settings of Shanghai's CHCs. Peer coaches are highly motivated to work with patients in the community and serve as mentors and inspirations to new coaches. In CHCs that have allocated additional staff time to the project, group activities have been organized on a regular basis and peer coaches are empowered to work closely with patients on specific diabetes self management goals. These initial success stories provide a model for successful implementation in later cohorts and wider dissemination to CHCs across Shanghai.

UNDERSTANDING AND OVERCOMING BARRIERS TO IMPLEMENTATION OF PEER SUPPORT MODELS IN PRIMARY CARE

Susan J. Andreae, PhD, MPH¹, Lynn Andreae, MPH¹, Quinetra Gathers, MPH¹, Monika Safford, MD², Andrea L. Cherrington, MD, MPH³¹University of Alabama at Birmingham, Birmingham, AL; ²Weill Cornell Medicine, New York, NY; ³UAB School of Medicine, Birmingham, AL

The potential benefits of peer support for diabetes and other chronic illnesses are well described in the literature. However, numerous challenges exist related to the operationalization and implementation of peer support in primary care. In this presentation, we discuss barriers to implementation based on experience with two separate projects. In the first project, an urban safety net clinic is partnered with a local non-profit providing community health worker services to deliver peer support to patients with diabetes. The project aims to promote ambulatory care and reduce acute care utilization; multiple emergency room visits and hospitalizations with high risk for readmission trigger referral for community health worker (CHW) services. The second project is an ongoing four-arm randomized controlled trial to improve blood pressure control in the rural south; two arms include peer coaching as part of the intervention. Rural primary care clinics are recruited and randomized into one of the four arms. For those randomized to a peer coaching arm, trained peer coaches work with eligible patients to provide support for self-management of uncontrolled hypertension. We conducted qualitative interviews with primary care providers and focus groups with CHWs. Providers saw the value of CHW services, especially provision of peer support and education beyond the walls of the clinic; they had concerns about CHW limitations and overstepping scope of work, integration with the health care team, and cost. CHWs, all employed by community based organizations outside the clinic, did not feel comfortable interfacing with the clinic staff and had varied comfort levels with technology-based tools to interface with the care team. Strategies to overcome these barriers included increased PCP education regarding CHW services, building discussion groups with practice champions into CHW training, and identifying sustainable sources of funding. We present lessons learned from each project as well as strategies to overcome barriers and enhance program sustainability.

10:00 AM-11:00 AM

BHOP FIRST STOP: MAKING PRIMARY CARE THE “FIRST STOP” FOR MENTAL HEALTH CARE IN THE USAF

Mario G. Nicolas, Ph.D.¹, William C. Isler, Ph.D.², Hla Y. Myint, MBBS, DT-M&H, MCTM, PhD³¹Chenega Corp. (Contractor for Air Force Medical Operations Agency), San Antonio, TX; ²Air Force Medical Operations Agency, San Antonio, TX; ³Decypher (Contractor for Air Force Medical Operations Agency), San Antonio, TX

Background: A pilot study conducted at three USAF military treatment facilities (MTFs) from fiscal year (FY) 2014 to FY 2015 examined the effects of shifting the access point for mental health care from the base mental health clinics (MHCs) to the primary care behavioral health clinic (referred to as Behavioral Health Optimization Program or “BHOP” in the USAF). Pilot study results indicated that the BHOP service at pilot study sites experienced close to a 50% (48.9%) increase in the number of unique patients, and close to 56% (55.7%) increase in the number of patient encounters, compared to FY 2014 numbers. Additionally, MHCs at pilot study sites experienced nearly a 15% (14.8%) decrease in the number of unique patients, and nearly a 12% (11.8%) decrease in patient encounters, compared to FY 2014 numbers. Data from 2016 and 2017 indicated a continuation of promising results.

Objectives: Given the promising results across the pilot sites, one of the aims of this project was to examine the impact of the “First Stop” initiative for behavioral health services. An additional goal was to examine changes in BHOP and MHC utilization (number of unique patients seen, number of patient-encounters) prior to, and since, the pilot study.

Methods: We polled leaders of our Air Force Mental Health Clinics to get an idea of how many MTFs have begun taking steps to implement “First Stop.” We also reviewed annual data from FY 2014 – FY 2017 to examine the number of unique patients seen, and number of patient encounters, in the MHC and BHOP service across the three pilot sites.

Results: A poll of Air Force MHC leaders revealed that about 40% of MTFs have begun implementing “First Stop” at least to a limited degree. Across the three pilot sites, annual data revealed a 1.8 times increase in unique patients seen in BHOP, a 2.04 times increase in patient encounters seen in BHOP, and a 1.13 times decrease in the number of unique patients seen in MHCs since FY 2014. The average number of encounters per patient remained stable in BHOP but increased in pilot study MHCs since 2014.

Conclusions: Results suggest that increased efforts are being made across the USAF to make primary care the “First Stop” for behavioral health services. At the three sites examined during the initial pilot study findings also indicate higher utilization of BHOP services, and a decrease in the number of patients seen in MHCs. Findings also suggest that MHC patients are seen for more sessions than prior to the pilot study. This latter finding is consistent with expectations, since one goal of the First Stop initiative is to manage low acuity patients in primary care and to vector higher acuity patients requiring a higher level of care to the specialty mental health clinics.

PRIMARY CARE PHYSICIANS' CONFIDENCE IN AND DELIVERY OF HEALTH BEHAVIOR CHANGE INTERVENTIONS

Stephanie Hooker, PhD, MPH, Michelle Sherman, PhD LP ABPP

University of Minnesota Medical School, Minneapolis, MN

Objectives: About one-third of the variance in health outcomes is attributable to modifiable healthy lifestyle behaviors, such as physical activity, eating habits, sleep, medication adherence, smoking cessation, and alcohol reduction. Primary care physicians (PCPs) are uniquely positioned to address health behavior change (HBC). However, little is known about PCPs' confidence in helping patients modify their behavior nor the specific strategies physicians employ to do so. This study aims to examine HBC techniques PCPs use with their patients.

Method: Family medicine resident and faculty physicians ($N = 28$; 64% female; 56% residents) completed an online survey regarding the frequency of use, confidence in, and perceived efficacy of HBC interventions for 6 behaviors (physical activity, eating habits, sleep, medication adherence, smoking cessation, and alcohol reduction). Qualitative questions assessed use of specific HBC techniques and barriers to administering interventions. Techniques were coded using Abraham and Michie's (2008) behavior change taxonomy.

Results: Of the six behavior domains, PCPs reported they offered HBC interventions most commonly for smoking cessation and least frequently for alcohol use. PCPs had moderate confidence in their ability to deliver HBC interventions (M_s across domains range from 4.6 – 6.0 /10, very confident); PCPs perceived their interventions to have low to moderate efficacy with their patients ($M_s = 3.8 – 5.6$ /10, very effective). PCPs felt least confident discussing alcohol use reduction and most confident encouraging patients to increase physical activity. With the exception of alcohol use, the most commonly used behavior change strategy for all behaviors was providing instruction. Other common strategies were teaching patients to use prompts or cues, motivational interviewing, providing resources/referrals, and prompting specific goal setting. Insufficient time in visits was the most oft cited barrier to implementing HBC strategies, followed by perceived low motivation among patients, and provider uncertainty about how to help patients make changes.

Conclusion: PCPs seem to lack confidence in their ability to deliver HBC interventions and tend to employ a commonly used approach among physicians of telling patients what to do. To maximize the impact of PCPs' efforts in short visits, PCPs need to learn brief, evidence-based HBC interventions. Future directions include gathering more data from a larger sample of PCPs and integrating education and user-friendly resources regarding HBC intervention strategies into family medicine residency curricula.

A CASE EXAMPLE OF COGNITIVE-BEHAVIORAL THERAPY FOR TINNITUS IN A PATIENT CENTERED MEDICAL HOME (PCMH)

Chelsea Wiener, B.S., M.S.¹, Cerissa L. Blaney, PhD¹, Jeffrey Cassisi, Ph.D., Clinical Health Psychologist¹, Virgil L. Dawson, Jr., MD²¹University of Central Florida, Orlando, FL; ²University of Central Florida College of Medicine, Orlando, FL

Tinnitus is a common and sometimes severely debilitating condition that may significantly impair a patient's quality of life. It has been estimated that over 25% of Americans over the age of 20 have experienced tinnitus within the past year, and that approximately 7% of Americans experience tinnitus daily. Of those experiencing tinnitus, approximately 30% report it to be a notable problem in their lives. Hearing difficulties, sleep problems, concentration difficulties, and anxiety are among commonly reported associated concerns. To address the psychosocial impact of burdensome tinnitus, psychosocial interventions such as cognitive-behavioral therapy (CBT) are often recommended in conjunction with medical assessment and treatment (e.g., hearing aids). Given the prevalence of the condition and psychosocial impact, behavioral health treatment in a Patient Centered Medical Home (PCMH) may serve as an accessible resource for patients in need. Thus far, evaluated CBT interventions have largely been group-focused, with treatment often delivered over the course of eight or more sessions. The presented case of illustrates that brief (4-session) CBT treatment, consistent with a population health approach, can be effective in reducing patient symptoms. Overall Tinnitus Handicap Inventory (THI) score decreased from a 48 ("moderate impairment") at baseline to a 20 ("mild impairment") at discharge. Overall Tinnitus Functional Index (TFI) score decreased from a 40 ("moderate problem") during first administration to a 9.6 ("not a problem") at discharge. Implications for expanding access to care for patients with this burdensome condition and reducing medical costs are discussed.

A CLIMATE FOR EVIDENCE-BASED PRACTICE IN THE PATIENT-CENTERED MEDICAL HOME

Marisa Sklar, PhD¹, Justin M. Nash, PhD², Roberta E. Goldman, MA, PhD³, Gregory Aarons, PhD¹, Charles Eaton, MD, MS³¹University of California San Diego, La Jolla, CA; ²University of Connecticut, Storrs, CT; ³Alpert Medical School of Brown University, Pawtucket, RI

Background: The patient centered medical home (PCMH) integrated primary care model is an important component of healthcare transformation in the United States. Although there is hope the PCMH service delivery model can facilitate the provision of higher quality healthcare, the extent to which organizational climate within the PCMH supports the implementation of evidence based practices (EBPs) is unknown. With the ever increasing efforts to reform our health system, including transforming primary care practices into PCMHs, identifying and addressing factors associated with the implementation of EBPs within the PCMH are crucial for improving the health and healthcare of the United States.

Specific Aims & Design: The purpose of this mixed-methods study was to assess EBP implementation climate (i.e., the extent to which organizational members perceive that the adoption of EBPs is expected, supported, and rewarded) and attitudes about EBPs in the PCMH. The quantitative assessment procedure was based on existing procedures for assessing organizational climate and tailored to meet the unique characteristics of the PCMH. Additionally, qualitative methods were used to uncover how the PCMH practices function.

Results: Staff and physicians from two PCMHs, the Memorial Hospital of Rhode Island Family Care Center (FCC), NCQA Level 3 PCMH, and Internal Medicine Clinic (IMC), NCQA Level 2 PCMH, were asked to participate in this study. Results from analysis of variance suggested differences between FCC (n = 39) and IMC (n = 21) staff and physicians with regard to attitudes toward EBPs, and implementation climate. In addition to reporting significantly more positive attitudes toward EBPs overall ($x\text{-bar}_{\text{FCC}} = 3.05$, $x\text{-bar}_{\text{IMC}} = 2.76$; $F(1,59) = 4.79$, $p = .033$), FCC staff and physicians reported significantly greater willingness to adopt EBPs if required ($x\text{-bar}_{\text{FCC}} = 3.07$, $x\text{-bar}_{\text{IMC}} = 2.50$; $F(1,58) = 5.48$, $p = .023$), and if the EBP was appealing ($x\text{-bar}_{\text{FCC}} = 3.41$, $x\text{-bar}_{\text{IMC}} = 2.94$; $F(1,57) = 4.84$, $p = .032$), compared to IMC staff and physicians. Additionally, FCC staff and physicians reported significantly greater educational support for EBPs than IMC staff and physicians ($x\text{-bar}_{\text{FCC}} = 2.96$, $x\text{-bar}_{\text{IMC}} = 2.48$; $F(1,58) = 4.10$, $p = .048$). Analysis of in-depth interviews elucidated themes regarding attitudes toward EBPs, as well as facilitators and barriers to EBP. While the majority of physicians reported valuing EBPs, lack of time, disjointed coordination of services, complexity of patients' presenting health concerns, and patient choice were commonly discussed as barriers to EBP.

Discussion: Understanding factors that facilitate EBP implementation within the PCMH is becoming increasingly important given widespread adoption of the PCMH model. Limitations to this study will be reviewed. Recommendations for sustainable implementation of EBP in the PCMH will be presented.

ANALYSIS OF AN INNOVATIVE CURRICULUM IN INTEGRATED PRIMARY CARE: ASSESSMENT OF STUDENT INTEREST AND COMPETENCY

Mark Stillman, PhD, Vincent Fitch, MS

Mercer University College of Health Professions, Atlanta, GA

The American Psychological Association Society for Health Psychology's Committee on Integrated Primary Care (IPC) developed an innovative course, *Integrated Primary Care Psychology: An Introductory Curriculum*, for use by graduate programs or training sites to enhance psychologists' roles in transforming health care. The curriculum includes Foundation Modules (4) and Topic Modules (11). The finalized curriculum was first taught to students in the Health Psychology II course at Mercer University's Clinical Medical Psychology doctoral program during the spring 2017 semester. The study intended to examine whether exposure to the curriculum would result in significant changes in student interest level and attitudes toward IPC, and student's actual and perceived competency levels in IPC both within themselves and against a control group.

Participants in the experimental and control group completed self-perceived competency and interest measures prior to the course. These competencies include science, systems, professionalism, relationships, application, and education. Interest in the field was obtained across multiple domains focused on interest in the specialty of IPC psychology.

Groups also completed module quizzes assessing objective competence that included Introduction to IPC; Across the Continuum: Psychology's Role in PC; PC Patients: Who Are they and How Can Psychologists be Helpful?; and IPC Interventions. Measures were given prior to teaching the modules and after they were finished. Quizzes were given weekly and corresponded to the materials related above.

Results indicate significant changes between pre and post assessment of the experimental group along with significant differences between experimental and control groups. Students enrolled in the course presented with significantly higher overall interest rates after completion of training when compared to pre-assessment measures. As well, subjective self-competency was significantly higher at post-assessment than pre-intervention. When comparing groups, students in the IPC course showed significantly higher overall interest after completion of training when compared to non-IPC control measures.

Access to the IPC curriculum increased interest rates and competency of those in the class. The course led to overall higher interest when compared to the non-IPC control group. Continued use of this curriculum is warranted to engage future professionals and improve competency of the primary care setting.

ASSOCIATION BETWEEN HEART RATE VARIABILITY AND PSYCHOLOGICAL OUTCOMES IN GASTROESOPHAGEAL REFLUX DISEASE

Livia Guadagnoli, MS¹, Tiffany Taft, PsyD¹, Katherine Ritter, BS¹, John Pandolfino, MD, MSCI¹, Laurie Keefer, PhD²¹Northwestern University Feinberg School of Medicine, Chicago, IL; ²Department of Gastroenterology, The Mount Sinai Hospital, New York, NY

Background: Autonomic nervous system arousal has a direct impact on the brain-gut axis and can perpetuate symptoms in individuals with gastroesophageal reflux disease (GERD). Heart rate variability (HRV) is a method of characterizing autonomic functioning, with increased HRV positively correlated with one's ability to adapt to and recover from distressing situations. Our aim was to evaluate HRV in GERD, its relationships with psychological drivers of symptom experience (e.g. esophageal hypervigilance), and the influence of deep breathing on HRV. We hypothesized individuals with increased HRV would report decreased hypervigilance and psychological distress, and deep breathing would increase HRV.

Methods: Participants were adults ages 18–65 with a confirmed diagnosis of GERD who presented to a university-based outpatient gastroenterology practice for esophageal motility testing. Eligible participants completed questionnaires related to symptom severity, hypervigilance, somatization, and psychological distress. Next, participants engaged in a 5-minute baseline HRV recording while at rest and a 1-minute HRV recording while completing a standardized deep breathing exercise (6 breaths/minute). HRV was analyzed using the following time-domain methods: standard deviation of all NN intervals (SDNN) and root mean square of successive differences (RMSSD). 15 GERD patients [mean(SD) age = 38.1(13.30)yrs, 60% male] participated. Spearman's correlations evaluated relationships between baseline HRV and clinical variables. A Wilcoxon signed-rank test examined differences in HRV at baseline and during deep breathing.

Results: Although not significant due to small sample size, there were several small to moderate correlations of interest. RMSSD, a reflection of vagal tone, was moderately associated with decreased hypervigilance ($r_s = -0.31$, $p = .25$). SDNN, a marker of overall HRV, was negatively correlated with subjective distress ($r_s = -0.23$, $p = .41$) and positively correlated with anxiety ($r_s = 0.26$, $p = 0.34$). In addition, there was a significant difference in SDNN between baseline ($M=67.67$, $SD=40.18$) and deep breathing recordings ($M=100.05$, $SD=17.74$); $Z = -2.10$, $p = 0.03$.

Conclusion: GERD patients with increased vagal tone report decreased hypervigilance towards esophageal symptoms. Interestingly, higher overall HRV is associated with decreased distress at the time of HRV recording, but increased anxiety. Finally, short-term deep breathing has immediate positive effects on overall HRV.

BRIEF PSYCHOLOGICAL INTERVENTIONS FOR ANXIETY IN ADULT PRIMARY CARE PATIENTS: A REVIEW AND RECOMMENDATIONS FOR FUTURE RESEARCH

Robyn L. Shepardson, PhD¹, Laura J. Buchholz, PhD², Risa B. Weisberg, PhD³, Jennifer S. Funderburk, PhD¹¹VA Center for Integrated Healthcare, Syracuse, NY; ²University of Tampa, Tampa, FL; ³Boston VA Healthcare System, Boston, MA

Anxiety symptoms are prevalent in primary care, yet treatment rates are low. The integration of behavioral health providers into primary care via the Primary Care Behavioral Health (PCBH) model offers a promising way to improve treatment options by adding a team member with the necessary skillset to deliver evidence-based, psychological (i.e., non-pharmacological) interventions for anxiety. We conducted a narrative review (1990–2016) of psychological interventions ($k = 44$) for DSM-5 anxiety disorders applied within adult primary care settings to update the literature and evaluate the fit of existing interventions with the PCBH model. The majority of studies were randomized controlled trials (RCTs; 70.5%) conducted in the United Kingdom (52.3%) or United States (27.3%). Samples were predominantly White, though 61.4% of studies did not report participants' race and/or ethnicity. The most common inclusion criterion was a primary diagnosis of anxiety or an anxiety-related disorder (54.5%). Most interventions utilized cognitive-behavioral therapy (68.2%) and were delivered individually, face-to-face (52.3%). Other common formats were face-to-face group (20.5%) and self-help (20.5%). Although the PCBH model calls for brief, time-limited treatment (e.g., up to six 15–30 minute sessions per episode), only 31.2% of interventions were offered in ≤ 6 sessions, and only 13.6% were offered in sessions typically lasting ≤ 30 minutes. Overall, 65.9% of interventions (58.6% of RCTs, 91.7% of pre-post) were effective in reducing anxiety symptoms, and 77.8% maintained the gains at follow-up. Of studies also examining depression outcomes, 62.5% (65.0% of RCTs) were effective in reducing depressive symptoms. Overall, the results support the growing consensus in the literature that anxiety can be effectively treated in the primary care setting. Although it is encouraging that most interventions significantly reduced anxiety, their longer formats (i.e., number and duration of sessions) and narrow symptom targets (most commonly threshold generalized anxiety disorder and/or panic disorder) make translation into practice difficult. Methodological limitations of the research included homogenous samples, failure to report key procedural details, pre-post designs, and restrictive eligibility criteria. We discuss clinical implications and offer recommendations to guide future research to improve the likelihood of successful translation of anxiety interventions into clinical practice.

DEMOGRAPHICS, HEALTH LITERACY AND FOOD SECURITY OF PRIMARY CARE PATIENTS IN SOUTH LOUISIANA

Caitlin J. Creel, BS, Lauren D. Tran, BS, Paula R. Brantley, PhD, Amanda R. Phillips-Savoy, MD, D. Jeffrey Mohr, MD, Brian L. Gamborg, MD, Mary T. Coleman, MD, PhD

LSUHSC School of Medicine, New Orleans, LA

The LSU Primary Care Research Organization (LSU-PRO) is a primary care research network recently established to help facilitate research and scholarly activities among six university affiliated family medicine clinics across the southern region of Louisiana. In order to initiate collaborative data collection and describe the patient population, an exploratory demographic study was conducted utilizing purposive sampling of 30 patients per full-time practitioner. In addition to standard demographic, medical and psychosocial history information, sampled patients were administered the Rapid Estimate of Adult Literacy in Medicine-Revised (REALM-R; Bass, 2003) and the U.S. Household Food Security Survey Module (USDA, 2012). To date, data have been collected from 292 participants at five of the six clinic sites. Results indicate that the sample is older ($M = 62.75$ years, $SD = 18.97$, range: 1–104), 54.9% white, 39.6% African American, 27.6% on Medicare, 27.2% on Medicaid, and 21.6% uninsured. 67.2% live in HRSA-designated medically underserved and/or rural (37.5%) areas. 60.4% have at least two chronic diseases, with the highest prevalence for hypertension (55.6%), hyperlipidemia (25.9%), Type 2 diabetes mellitus (20.8%), and anxiety (11.9%). 59.7% are overweight or obese, and 28.7% are current smokers. REALM-R scores indicate that 49.4% are at risk for low health literacy, and 37.4% have marginal, low or very low food security. Health literacy and food security scores were positively correlated among the urban, but not the rural participants ($N = 143$, $r = .20$, $p \leq .02$), and multinomial logistic regression analyses indicated that the combination of high BMI and low health literacy scores significantly predicted low food security scores among the urban participants [$\chi^2(33, N = 119) = 54.46$; $p \leq .01$], accounting for between 37% and 42% of the variance (Cox & Snell's $R^2 = .367$; Nagelkerke's $R^2 = .416$). Future directions include developing primary care based interventions for obesity and hypertension within the context of low health literacy and low food security environments.

DEVELOPMENT AND IMPLEMENTATION OF A PSYCHOLOGY-BASED CHRONIC PELVIC PAIN CURRICULUM FOR OB-GYN RESIDENTS

Fabiana Araujo, PhD¹, Hoda Abou-ziab, PsyD¹, Griselda Gutierrez, MD¹, Paul Arns, PhD², Astrid Reina, PhD¹

¹Harbor-UCLA Medical Center, Torrance, CA; ²Los Angeles County Dept. of Mental Health, Los Angeles, CA

Chronic Pelvic Pain (CPP) is among the most common issues in gynecology clinics and many of CPP patients present with comorbid psychological problems (Howard, 2000). Despite its high incidence, there seems to be a significant knowledge gaps about CPP among medical providers. Deficient understanding of CPP issues can lead to physicians' frustration, negative attitude, and possibly avoidance of addressing their patients' CPP issues, ultimately affecting the quality of care provided (Cheong & Stones, 2007; Denny & Mann, 2008). Thus, this project targeted the development of an educational program with Ob-Gyn residents aiming a) to increase understanding the differences between functional and structural CPP; b) to expand comprehension of CPP's most common psychological aspects; and c) to increase awareness of their own attitude towards this population.

Individual interviews with Ob/Gyn attendings and residents supported the existence of negative attitude towards CPP patients and limited understanding of psychological factors associated with this condition. Then, a multidisciplinary lecture was provided to 13 Ob/Gyn residents primarily aiming the three goals aforementioned.

A questionnaire assessing resident attitude and perception about CPP (Witzeman & Kopfman, 2014) was administered prior to starting the lecture and 45 days after. Data suggested reduction of negative attitude towards CPP patient as well as in their perception of the prevalence of CPP. In contrast, residents reported increase in their perception of lack of time to see CPP patients. No change was noticed in residents' empathy, knowledge of pain medication, influence of mentor attitude, confidence in current knowledge, and desire to increase knowledge about CPP. Feedback provided during individual interviews indicated their appreciation for learning how to convey information about psychological aspects of CPP to their patients, without dismissing their somatic symptoms. Some of them also acknowledged increased compassion and awareness of their own negative attitude towards their patients and expressed commitment to keep that in mind when providing care. Regarding time available to see CPP patients, several residents shared that after better understanding how these patients think and react emotionally, they would like to have more time to properly address their patients' needs. Finally, residents expressed their openness for additional training on the non-medical aspects of the treatment of CPP.

GROUP MEDICAL VISITS: INNOVATIVE APPROACH TO IMPROVING HEALTH CARE VALUE FOR SELECT CONDITIONS

Jordan Thomas, BA¹, Shayna Cunningham, PhD¹, Kelly Flanagan, MPH², Jennifer L. Snow, MSc³, Jessica Lewis, LMFT, MPhil¹, Jeannette Ickovics, PhD¹

¹Yale School of Public Health, New Haven, CT; ²Yale School of Public Health, Boston, MA; ³Planned Parenthood Federation of America, Brooklyn, NY

RATIONALE: Innovations in care delivery are essential to address the growing burden of chronic disease and health expenditures. We assessed evidence of effectiveness of group healthcare models, involving shared medical visits among patients diagnosed with the same disease (e.g., diabetes, hypertension) or those who experience similar changes in their healthcare needs (e.g., pregnancy, aging), to improve health outcomes across the life course (pediatrics to geriatrics).

METHODS: We systematically reviewed randomized controlled trials designed to compare group versus individual medical care on health outcomes and service utilization. Studies were identified through the PubMed electronic database (through December 2016) and the reference lists of these articles and previously published reviews.

RESULTS: Forty-three articles met inclusion criteria for analysis. Studies focused on patients with diabetes (n=28), women receiving prenatal care (n=7), and patients with other chronic diseases and health conditions (e.g., asthma, hearing disability, cancer) (n=9). Seventy-four percent (n=32) of studies demonstrated significantly improved biophysical outcomes and/or care utilization (e.g., fewer emergency department visits, more preventative screenings) for patients who received group care compared to traditional individual care across health care conditions. Among articles that included financial analyses, most demonstrated cost savings for group care compared to individual care (80%, 4 of 5 studies).

IMPLICATIONS: Despite heterogeneity in populations, conditions and outcomes, group care models offer an approach to meet “the triple aim”: enhance health care quality, improve health outcomes and reduce costs. Implications for the transformation of health services delivery include organizational restructuring (i.e., dedication of hospital space to group care) and financing systems reform (i.e., alternative reimbursement models for provision of group care).

INTEGRATING BEHAVIORAL HEALTH SERVICES IN THE EMERGENCY DEPARTMENT: A NEW MODEL OF INTEGRATED PATIENT CARE

Rachel Davis-Martin, PhD¹, Niranchana Vallirajan, MBBS¹, Colette Houssan, MPH²

¹University of Massachusetts Medical School, Worcester, MA; ²University of Massachusetts Medical School - Department of Emergency Medicine, Worcester, MA

Integrating behavioral health services in primary care settings has become standard best practices in many medical centers. Unfortunately, disadvantaged populations including minorities, immigrants, people without health insurance, and low income households comprise underserved populations that currently rely disproportionately upon Emergency Departments (ED) for primary care. Among these populations, a large percentage of patients have unrecognized behavioral health treatment needs. Patients with untreated behavioral health issues are more likely to be admitted to the hospital and repeatedly rely on ED services, creating a significant burden on healthcare systems with high economic costs. With an estimated 130 million patients visiting the ED annually, ED-originated behavioral health intervention efforts have the potential for considerable impact on public health by promoting change in these high risk and hard to reach populations.

Traditionally, behavioral health interventions in EDs have focused solely on substance use (ie, tobacco, alcohol, illicit drug use) using screening, brief intervention, and referral to treatment (SBIRT) as the approach. While SBIRT has been established as a gold standard for alcohol use, it has its limitations and pitfalls: screening can be time consuming, physicians lack specialized behavioral health training, and patient engagement in follow-up treatment plans is underwhelming. These drawbacks are particularly salient in the ED, where the focus is on acute medical care rather than chronic condition management. To address these limitations, we have integrated a behavioral health service (BHS) in the ED and enhanced SBIRT.

The BHS utilizes computer adaptive screening to limit assessment time while increasing understanding of the patient’s behavioral health needs. Screening results are integrated into the electronic health record to enable behavioral health-related communication between physicians and patients. BHS health coaches provide brief interventions for a multitude of behavioral health focuses (mental health, stress management, suicidality, sleep, chronic pain, medication adherence, etc.) to ultimately change poor health habits that result in ED utilization; use mobile applications to further care beyond the ED visit; conduct follow-up calls to increase engagement in post-ED behavioral health treatments; and communicate with patients’ primary care providers to improve continuity of care. This integrated approach provides a new model of care aimed at improving healthcare outcomes and reducing healthcare costs.

MEASURING PRACTICE VARIATION IN INTEGRATED PRIMARY CARE: VALIDATION OF THE PPAQ-2

Gregory P. Beehler, PhD, MA¹, Jennifer S. Funderburk, PhD², Kyle Possemato, Ph.D.³, Paul King, PhD⁴, John Maddoux, PhD⁵, Wade R. Goldstein, M.A.¹, Michael Wade, MS⁶

¹VA Western New York Healthcare System, Buffalo, NY; ²VA Center for Integrated Healthcare, Syracuse, NY; ³Syracuse Veterans Affairs Medical Center, Syracuse, NY; ⁴VA Center for Integrated Healthcare, Buffalo, NY; ⁵Harry S Truman Veterans Memorial Hospital, Columbia, MO; ⁶Syracuse VAMC, Syracuse, NY

Improving model fidelity is one way to optimize patient experiences and clinical outcomes in integrated primary care. A crucial first step in this process is to assess practice variation in a systematic manner. The Primary Care Behavioral Health Provider Adherence Questionnaire (PPAQ) was originally designed to assess behavioral health provider fidelity to the Primary Care Behavioral Health model. However, the original PPAQ did not reflect practices that are unique to other common models in integrated care settings, such as collaborative care management (CCM). To expand the PPAQ, an item pool was developed based on a literature review that identified critical components of CCM. Four CCM content experts, including clinicians and researchers, provided multiple rounds of review to ensure a high degree of content validity. The resulting PPAQ-2 was then administered via anonymous web-based survey to integrated care providers (n=253) from diverse practice settings (i.e., Veterans Affairs, academic centers, and community organizations). Confirmatory factor analysis was conducted for each of the two PPAQ-2 scales (PCBH and CM) to assess the theorized factor structure. Results for both PPAQ-2 scales yielded adequate model fit measures following the removal of seven items. All retained items had significant (i.e., $p < .05$) and meaningful (i.e., $> .300$) factor loadings. The PCBH scale consisted of five practice domains: clinical interventions, practice management, referral management, collaboration with the primary care team, and prohibited behaviors. The CCM scale also consisted of five practice domains: patient identification, providing self-management support, supervision/care coordination, measurement-based care, and panel management. Composite reliabilities of the 10 practice domains ranged from acceptable (.719; patient identification) to excellent (.941; measurement-based care). Average fidelity scores within domains were highest for providing self-management support and lowest for panel management. Study results indicated that the PPAQ-2 is a psychometrically sound measure that can identify practice variation across models of integrated care by examining provider adherence. The PPAQ-2 can be used to advance integration 1) through future decomposition studies that identify provider behaviors which best predict patient and program outcomes, and 2) by focusing implementation support initiatives to reduce unwanted variation and promote high fidelity practice.

OPPORTUNITIES TO TREAT TOBACCO USE IN VA: PREVALENCE OF TOBACCO USERS UTILIZING MENTAL HEALTH SERVICES

Julie Gass, PhD¹, Jennifer S. Funderburk, PhD², John Acker, M.S.³

¹VHAWNY Center for Integrated Healthcare, Buffalo, NY; ²VA Center for Integrated Healthcare, Syracuse, NY; ³Syracuse VA Medical Center, Syracuse, NY

Among individuals with mental health (MH) conditions, cigarette smoking is common and a majority of smokers do not seek tobacco cessation-specific treatments. As such, providers in MH clinics have begun investigating strategies to embed tobacco cessation services into routine clinical practice such as at MH appointments and integrated primary care mental health (PCMH) appointments. The extent and rate of which tobacco users are utilizing these different services is not fully known - understanding utilization patterns of smokers within a large healthcare system can guide research and clinical efforts by highlighting the need for and ideal placement of tobacco use interventions. The objectives of this presentation are to: (1) examine tobacco users' MH service utilization (PCMH, MH, both) in VAs within one geographic region to determine need for embedded tobacco services; and (2) assess the proportion of encounters in which tobacco is being addressed in above clinics. A data pull of medical records of VAs across the Northeast region conducted during a 12-month period in 2014. Data included patient demographics, tobacco use status, encounter type (PCMH and MH) and three diagnoses associated with each encounter. Data from 108,926 mostly white (92.8%), mostly male (91.2%) veterans (average age 57.5) were used. 30.7% were tobacco users; 38.6% of tobacco users and 22.1% of nonusers utilized MH services. Among tobacco users, 4% used PCMH services; 26.9% used specialty MH services; and 7.5% utilized both. There were 443,241 MH encounters in this region in this one-year period; of those, tobacco use was a coded diagnosis at only 1.3%. Overall, these findings suggest that tobacco users are high utilizers of MH services compared to nonusers, and in particular utilize MH clinics more so than PCMH clinics. Tobacco is infrequently coded as a diagnosis at any given encounter, suggesting that it is not prioritized in MH clinics. This presentation will increase awareness of tobacco use prevalence in a vulnerable MH population and encourage researchers and clinicians to consider tobacco and integrate its treatment and research into daily practice. We will also discuss interrelationships between tobacco and other MH diagnoses, examine how patient demographics relate to service utilization, and describe implementation strategies for tobacco interventions that can be embedded within other MH treatments.

VETERANS' PRESENTING CONCERNS IN PRIMARY CARE MENTAL HEALTH SERVICES DIFFER BY GENDER

Paul King, PhD¹, Gregory P. Beehler, PhD, MA², Laura J. Buchholz, Ph. D.³, Emily M. Johnson, PhD⁴, Laura Wray, PhD⁵

¹VA Center for Integrated Healthcare, Buffalo, NY; ²VA Western New York Healthcare System, Buffalo, NY; ³The University of Tampa, Tampa, FL; ⁴VA Center for Integrated Healthcare, Syracuse, NY; ⁵VA Center for Integrated Healthcare, Buffalo, ND

Department of Veterans Affairs (VA) Primary Care Mental Health Integration (PCMHI) programs are designed to improve the detection and management of behavioral health concerns in primary care. PCMHI services are population-based, emphasizing functional assessment and problem-focused interventions to restore functioning. While administrative data suggest that depression, anxiety, PTSD, and alcohol misuse are the most common diagnoses recorded in PCMHI, little is known about the nature and breadth of functional complaints (e.g., physical limitations, interpersonal concerns) reported by patients. This presentation will summarize the results of a postal survey of Veterans' functional concerns and priorities for PCMHI. Data were obtained from 281 Veterans who received PCMHI care in a northeastern region during VA fiscal year 2016. Survey items focused on 24 biopsychosocial domains. Items queried whether participants experienced specific functional concerns in the past year, if they had previously addressed those concerns with a PCMHI provider, or if they would consider addressing those concerns in the future. An additional item asked participants to rank their top three priorities for future treatment. Participants were primarily Caucasian (76%) males (87%; age M[SD]=58.9[13.1] years. Most reported significant problems with sleep (83%), motivation (80%), stress management (75%), and pain (71%) in the past year. Relative to men, women more frequently endorsed relationship (70% vs. 50%, $\chi^2(1)=3.871$, $p=.049$) and family stress (82% vs. 56%, $\chi^2(1)=6.385$, $p=.041$), feeling unsupported (70% vs. 39%, $\chi^2(1)=9.909$, $p=.002$), changes in appetite (71% vs. 45%, $\chi^2(1)=7.617$, $p=.006$), and general difficulty managing stress (94% vs. 72%, $\chi^2(1)=7.650$, $p=.006$). Overall, problems with sleep, stress, motivation, concentration, pain, and anger were identified as the issues that patients previously addressed in PCMHI (64–78%). Compared to men, however, women were more likely to endorse having addressed interpersonal concerns in PCMHI, such as feeling unsupported (69% vs. 38%, $\chi^2(1)=9.171$, $p=.002$), and experiencing relationship stress (89% vs. 53%, $\chi^2(1)=11.946$, $p=.001$) and family stress (89% vs. 60%, $\chi^2(1)=8.788$, $p=.003$). Participants' top priorities for future treatment included addressing anger, stress, low energy, sleep, and concentration. Discussion will focus on biopsychosocial assessment to capture functional concerns and best match PCMHI services to patient needs.

FINANCIAL MANAGEMENT SUPPORT FOR SSA BENEFICIARIES: LOOKING BEYOND THE PAYEE

Annie Harper, PhD

Yale University, new haven, CT

Research objective: People receiving benefits from the Social Security Administration (SSA) who struggle to manage their money may be assigned a representative payee (payee henceforth), who receives the beneficiary's income and ensures that their basic needs are met. While having a payee can have a positive effect on beneficiary health and well-being, there is a shortage of people willing to be payees, and many who would benefit from the support are resistant to entirely relinquish control of their finances. There is no support available for SSA beneficiaries who face financial difficulties but are not considered incapable.

This study used qualitative methods to explore the potential for providing more flexible financial management support to SSA beneficiaries with mental illness, which would reduce the burden on the payee mechanism and offer support to a larger group of people. In addition to conducting focus groups and individual interviews with people with experience of having a payee, or serving as one, we conducted a review of the financial services environment exploring potential products and services which could support more flexible support for SSA beneficiaries. This included interviews with financial services and legal professionals and experts.

Principal Findings: The payee mechanism provides valuable support to some people with mental illness, without which they would struggle to meet their basic needs, but it can also create tension in relationships, cause frustration for those with a payee, and burden those serving as payee. In some cases the financial difficulties that people face which have caused them to be recommended or assigned a payee stem from their poverty and lack of access to appropriate financial services and products rather than their mental illness per se. There are a number of innovative financial services and products available which could enable some people currently assigned a payee to take more control over their finances, although some of these services and product would require adaptation to ensure their suitability for this specific population.

Providers of mental health services should be made aware of financial management support mechanisms, including available financial services and products, which may help some clients to retain control of their own finances and improve their financial situations. Additionally, the financial services industry should accommodate the specific needs of people with mental illness in developing products that minimize negative effects and maximize the potential for people to safely retain control of their own finances.

A SYSTEMATIC REVIEW ON INTERVENTIONS FOR HEALTH ANXIETY IN THE CONTEXT OF CHRONIC ILLNESS: AN UPDATE FROM 2014 TO 2017.

Danielle Petricone-Westwood, B.A.¹, Georden Jones, B.A.¹, Brittany Mutsaers, B.Sc.¹, Caroline Seguin Leclair, B.Sc.¹, Nicole Rutkowski, B.A.¹, Christina Tomei, Ph.D., C. Psych. (supervised practice)¹, Fatima Imsirovic¹, Andreas Dinkel, Ph.D.², Sophie Lebel, Ph.D., C. Psych.¹

¹University of Ottawa, Ottawa, ON, Canada; ²Technische Universität München, Munich, Bayern, Germany

Purpose. Individuals living with chronic illnesses often experience concerns about their symptoms or illness returning or progressing, known as health anxiety (HA). While some interventions have been designed to treat HA within specific illnesses, it remains unclear which interventions may be effective across chronic illnesses. This study is an update on a systematic review of literature on interventions that may influence HA in chronic illnesses.

Method. Relevant studies were identified through PsycINFO, PubMed, CINAHL, Web of Science, and SCOPUS, from January 1996 to October 2014. After filtering based on inclusion and exclusion criteria, 24 articles remained. An updated search of articles dated November 2014 to October 2017 was performed using the previously established search terms. The same inclusion and exclusion criteria were applied.

Results. Several new interventions were identified in this update (n=31), bringing the final total number to 55. The study designs included: randomized control trials (n=21); single-arm observational studies (n=3); pilot studies (n=5); and quasi-experimental trials (n=2). The HA construct was a primary outcome in less than half of the studies (n=13). Diseases studied included cancer (n=14), Parkinson's disease (PD, n=7), diabetes (n=6), cardiac illness (n=3), and seizure (n=1). The types of interventions included psychotherapies (n=13); medical interventions (n=10); exercise and training (n=5); rehabilitation (n=2); and education (n=1). Consistent with previous findings, exercise interventions were mostly conducted in PD and significantly reduced HA. Psychotherapeutic interventions were effective in reducing HA in cancer (n=10 significant reduction; n=1 no significant change) and some components of HA in cardiac samples (n=1). Medical interventions in diabetes had mixed results (n=3 effective in reducing HA; n=2 no reduction), and in seizure reduced HA (n=1). Medical interventions investigated in cancer and in cardiac illness yielded little influence on HA.

Conclusions. The update of this review suggest that while the number of studies has doubled, findings are consistent with previous research. Most interventions are tested only in specific illnesses (i.e. exercise in PD, psychotherapy in cancer and cardiac illnesses, medical interventions for glucose in diabetes). Efforts to examine the mechanisms of action on reducing HA may be beneficial, and possibility of cross-disease interventions has yet to be investigated.

“THEY ARE NOT ALONE, WE ARE NOT ALONE”: CULTURALLY BASED PEER SUPPORT FOR HIGH-RISK POPULATIONS

Megan S. Evans, MS¹, Patrick Y. Tang, MPH¹, Cherie Castellano, MA, CSW, LPC², Edwin B. Fisher, PhD¹

¹UNC Gillings School of Global Public Health, Chapel Hill, NC; ²Rutgers University Behavioral Health Care National Call Center, Piscataway, NJ

Providing ongoing peer support to high-risk populations is a promising approach to address significant public health/mental health problems such as suicide, avoidable hospitalizations, substance abuse, homelessness, domestic violence, and caregiver burden. Rutgers University Behavioral Health Care provides 24/7 telephone peer support for high-risk groups including police, veterans, first responders, child protection workers, caregivers of those with dementia, and mothers of children with special needs. Services are culturally based in that clients are paired with peer supporters based on shared social roles—e.g., veteran, police officer, caregiver—rather than clinical features or diagnoses. Sampling from these services, 10 qualitative in-depth interviews were conducted with peer supporters. Interviews were recorded, transcribed, and analyzed using qualitative thematic analysis. Key results included the importance of culturally based shared social roles to the effectiveness of the peer support relationships. Shared or similar personal experiences and lived knowledge of the unique cultures of these populations were identified as facilitating rapport and strengthening the peer support relationship. Confidentiality was recognized as key in fostering the connection between the caller and the peer supporter. As a guide to their work, peer supporters noted the importance of all four components of a model of reciprocal peer support: 1) connection and pure presence (rapport building); 2) information gathering and risk assessment; 3) case management and goal setting; and 4) promoting resilience, affirmation, and praise. The simple act of being there was identified as an important aspect of peer support relationships as callers are reminded that they are not alone in their struggles. Peer supporters also noted rapid and well-organized access to licensed clinicians and close supervision as important, especially in crisis situations. They also emphasized the importance of intentional ongoing follow-up with callers. Difficult aspects of being a peer supporter included bringing the job home and taking on clients' problems, while positive effects included being able to use their experiences to help others and give back to their communities. In summary, peer supporters identify organization of support around shared social roles, a comprehensive model for providing support, supervision, and back-up as key features of their work with high-risk groups.

COMPARING CONSTRUCTS OF PROBLEM SOLVING IN THE PREDICTION OF SUICIDAL IDEATION

Alexandra P. Woods, MS¹, Alexa M. Hays, MS², Christine M. Nezu, PhD, ABPP², Arthur M. Nezu, PhD, ABPP, DHL³¹Drexel University, Bronx, NY; ²Drexel University, Philadelphia, PA; ³Drexel University, Philadelphia, PA

Introduction: Deficits in problem solving have emerged as a potentially important and modifiable risk factor for suicide. One body of research has defined problem solving as a major component of executive functioning assessed by neuropsychological proxy measures. Another body of research has focused on *social* problem solving, which involves one's beliefs and emotional reactions to stressful problems that occur in real life. The current study aims to build a bridge between these two areas of research by comparing the relative contributions of neuropsychological measures of problem solving and social problem solving in the prediction of suicidal ideation.

Methods: Participants were students at Drexel University who were 18–29 years of age and able to speak English. Recruitment was conducted through Sona, an online participant management software. Study measures included a demographics survey; two traditional neuropsychological measures of problem solving: the Iowa Gambling Task (IGT) and the Tower of London (TOL); a measure of real-life problem solving: the Social Problem-Solving Inventory-Revised: Short Form (SPSI-R:S); and the Beck Scale for Suicide Ideation (BSS). An evidence-based suicide risk assessment and safety planning protocol was completed for students who endorsed suicidal thoughts. A debriefing statement and list of counseling and emergency resources were provided to all participants.

Results: The final sample included 192 students, the majority of whom were female (66.7%) and either Asian (43.2%) or White (39.6%), with a mean age of 20.4 years. Hierarchical linear regression was used to assess the ability of neuropsychological measures (IGT and TOL) and social problem solving (SPSI-R:S) to predict suicidal ideation (BSS) after controlling for significant covariates. Sex, sexual orientation, tobacco/drug use, and English as a first language were entered at Step 1, explaining 34.6% of the variance in suicidal ideation. After the entry of the IGT, TOL, and SPSI-R:S at Step 2, the total variance explained by the model as a whole was 49.2%, $F(7,184) = 8.40, p < .001$. In the final model, only sexual orientation, tobacco/drug use, first language, and the SPSI-R:S were statistically significant, with social problem solving making the greatest unique contribution to the prediction of suicidal ideation, ($\beta = -.36, p < .001$).

Discussion: These results suggest that social problem solving is an important construct to assess for suicide risk. Problem-Solving Therapy, which aims to improve social problem solving, may be an efficacious intervention in the reduction of suicidal thoughts.

CORRELATES OF PSYCHOLOGICAL EATING BEHAVIOURS IN EARLY PSYCHOSIS INDIVIDUALS.

Ahmed-Jerome Romain, PhD¹, Antony D. Karelis², Amal Abdel-Baki³¹University of Montreal Hospital Research Centre (CRCHUM), Montreal, PQ, Canada; ²Universite du Quebec à Montreal, Montreal, PQ, Canada; ³University of Montreal Hospital Research Centre, Montreal, PQ, Canada

In early psychosis individuals (EPI), the initiation of antipsychotic medication, mostly those of second-generation, was found to drastically increase weight even over the short period of time. While it has been suggested that the atypical medication can increase appetite, few research examined the correlated of psychological eating behaviours in EPI.

Objective: to analyze the correlates of psychological eating behaviours with anthropometric, metabolic, psychiatric/functional outcomes in EPI.

Methods: 29 EPI (18 men; mean age: 25.67 ± 2.95 ; mean BMI: $31.50 \pm 6.91 \text{ kg/m}^2$) whose primary diagnostic was schizophrenia or schizophrenia spectrum disorders (52%) referred to a physical activity program were included in the present study. They completed the three-factor eating questionnaire assessing cognitive dietary restraint (CR; eating restraint to loose weight), uncontrolled eating (UE) and feeling of hunger (FH). Body composition was evaluated with an anthropometric scale. Metabolic outcomes were measured with blood samples. Psychiatric/functional outcomes were assessed after interview with a research assistant.

Results: Regarding anthropometric outcomes, only flexible CR was correlated to lifetime highest weight reached ($r = 0.54, p = 0.004$), but also to waist circumference ($r = 0.52, p = 0.002$), BMI ($r = 0.47, p = 0.01$), and systolic ($r = 0.48, p = 0.01$). UE was highly correlated with FH ($r = 0.62, p$

Discussion: These results showed that psychological eating behaviour may have a role in the development of weight gain since associations were found with several anthropometric outcomes but also with fasting glucose. Consequently, more investigation is needed on the role of psychological eating behaviour.

DESCRIPTIVE DATA OF PATIENTS WITH SUICIDAL IDEATION PRESENTING TO AN EMERGENCY ROOM; WHO ARE THEY AND WHAT OCCURS POST ADMISSION?

Mariel P. Clapp¹, Lindsey Jenkins, MA², Heather Kruse, Ph.D.³¹University of Kansas Health System, Lee's Summit, MO; ²University of Kansas Health System, Westwood, KS; ³University of Kansas Health System, Kansas City, KS

Introduction: Suicide is the tenth leading cause of death in the United States. As such, it is important for healthcare providers to be aware of risk factors associated with suicidality and to provide appropriate follow-up treatment. Therefore, the purpose of this project was: 1) to examine demographic features of individuals who endorsed suicidal ideation (SI) within an emergency room department (ED), and 2) to assess the follow-up interventions provided for these patients.

Methods: Participants were 4,578 individuals who presented to the ED at the University of Kansas Health System (KU) between April – June 2017. Data were extracted from the electronic medical records. Upon admittance, each patient was screened for depression and SI. Participants who screened positive were asked follow-up questions to determine risk level.

Results: Of the total sample, 144 individuals endorsed depression (3.15%) and 148 endorsed SI (3.23%). Of individuals who endorsed SI, 51% were male, and ages ranged from 12 – 94, with a mean age of 37.77. Most (59.7%) were prescribed psychotropic medications; however, it was unclear whether these individuals were taking these medications at the time of their admittance. Half (50.3%) had a history of substance abuse and 46.3% were current tobacco users.

Of patients who endorsed SI, 96 (64.4%) reported a specific plan to harm themselves, 75 (50.3%) indicated that the plan was accessible, and 75 (50.3%) described a plan that was lethal.

Most (60.4%) received follow up treatment at KU post-ED visit. The majority (39.6%) were discharged from ED, while 37.6% were directly admitted to the KU psychiatric unit, and 23.5% were transferred to other inpatient psychiatric facilities. Most (61.7%) had not been to an ED or been hospitalized for mental health issues at KU prior to their visit. In the 3-month span, 12.8% were admitted to the ED more than once (up to 7 separate visits).

Conclusion: Analysis of descriptive data offers valuable insight for recognizing and providing care for those with SI. Most individuals who endorsed SI received follow-up care within the KU system; however, due to capacity restrictions, some were referred to outside medical facilities. This may result in gaps in care. A small portion of the sample repeatedly cycled through the ED for psychiatric care in a short period of time. Further analysis as to these patients' needs is necessary to address their concerns and diminish overutilization of the healthcare system.

DEVELOPING AN INTEGRATED SELF-MANAGEMENT INTERVENTION FOR TEENS WITH POLYCYSTIC OVARY SYNDROME: FOCUS GROUP FINDINGS

Cara C. Young, PhD, RN, FNP-C¹, Maria C. Monge, MD², Atami O Sagna, MPH, RN¹, Lynn Rew, EdD, RN, AHN-BC¹, Kelly Pretorius, MPH, MSN, PNP-A/C & P/C, RN¹, Alexis Shroyer, BSN Student¹¹The University of Texas at Austin, School of Nursing, Austin, TX; ²The University of Texas at Austin, Dell Medical School, Austin, TX

Polycystic ovary syndrome (PCOS) is the most common female endocrine disorder, affecting 6%-18% of reproductive-age women. Increasingly diagnosed during the challenging development period of adolescence, adolescent and young adult women with PCOS face significant challenges to feminine identity and body image that adversely impact their psychological well-being and health related quality of life. Despite the high prevalence of mental health concerns within this population, current clinical practice guidelines for PCOS focus on healthy lifestyle modifications and medication adherence but fail to include strategies for addressing mental health promotion or prevention. Our research team is developing an integrated self-management intervention specifically designed for adolescents with PCOS. The results presented in this abstract report findings from the first of a series of focus groups with adolescents with PCOS (N=7, ages 15–18) and a separate focus group with their parents (N=7, 5=moms; 2=dads) aimed at informing the development of the intervention. Ryan and Sawin's Individual and Family Self-Management Theory was used as the framework for discussion guide development and explored individual- and family-level context, processes, and proximal outcomes related to self-management. Transcripts from audio recorded focus groups were coded and analyzed for themes. Primary themes that emerged from both groups were (1) information seeking, (2) accepting the diagnosis, (3) adapting (both physically and emotionally) to the diagnosis, (4) the importance of family support, (5) bullying and discrimination due to physical manifestations of PCOS. Navigating the healthcare system emerged as a theme from the parent group. One parent eloquently stated, "And you have two worries, you have the clinical worries...But also, you have the visible effects, right? You have the overweight, you have – at that age, physical appearance is very important for them, right? They are teenagers. They are looking at other girls and comparing themselves with other girls." The similar themes that emerged between the two groups suggest that we incorporate a family-level component to the integrated self-management intervention. Additional focus groups will provide feedback on existing educational resources as well as prototype of the final intervention once developed.

EXAMINATION OF DISCLOSURE AFTER ADVERSE CHILDBIRTH

Burklee Bradley, BA student, Meghan Sharp, M.A., Christyn Dolbier, Ph.D.
East Carolina University, Greenville, NC

Introduction: Childbirth can be an adverse experience for some women that contributes to postpartum psychological distress. Disclosure (communication of personally relevant information, thoughts, and feelings) of a negative experience may affect distress. Disclosure has demonstrated associations with improved psychological adjustment following adverse experiences in other populations, such as decreased posttraumatic stress disorder (PTSD) symptoms. Little research has examined disclosure in the context of adverse childbirth and postpartum adjustment. The purpose of this study was to identify 1) the proportion of women who disclosed their adverse childbirth, 2) characteristics of this disclosure, and 3) the relationship between disclosure and characteristics of disclosure and PTSD symptoms.

Method: Women who were at least 18 years of age, residing in the United States, able to read/write in English, and the biological mother of a living child resulting from an adverse childbirth in the year prior to study participation ($N=166$) were recruited from social media for an online survey. Sample characteristics: Majority Caucasian (86%), married (77%), college-educated (57%), employed (53%), private/employer insurance (67%). The survey assessed disclosure methods, targets, and content, reasons for and for not disclosing, and PTSD.

Results: 81% of participants reported that they disclosed their adverse childbirth experience.

Methods: talking in person (92%) or via phone (49%), writing an online message post (67%), or texting (58%). Targets: romantic partner (89%), family member (82%), close friend (79%). Content: description of experience (98%), feelings (77%) and thoughts (72%) related to the adverse childbirth. Reasons for disclosure and non-disclosure are being explored through qualitative data analysis. Women who disclosed reported significantly lower severity of PTSD symptoms ($M=24.93$) compared to those who did not ($M=36.56$), $t(89)=2.09$, $p=.04$. Of those who disclosed, women whose disclosure content included feelings reported significantly lower severity of PTSD symptoms ($M=22.04$) compared to those who did not disclose feelings ($M=32.60$), $t(71)=1.99$, $p=.05$.

Conclusions: A high proportion of women reported that they disclosed their adverse childbirth experience. The disclosure rate identified here is similar to other types of adverse experiences, such as sexual assault. Participants most often disclosed in person to individuals with whom they had close, personal relationships. Disclosure was related to fewer PTSD symptoms, with disclosure of feelings being most important. This information can be used to develop optimal treatment strategies for women after an adverse childbirth experience.

HEALTHCARE DISPARITY AND MENTAL HEALTH STIGMA

Ashley Sansone, M.A. Psychology, Penny Koontz, PsyD, Brittany Canady, PhD, April Fugett, PhD

Marshall University, Huntington, WV

Diabetes mellitus occurs two to three times more often in those with severe mental illness (De Hert, et al., 2011); however, they receive less routine medical care to monitor diabetes (Frayne, Halanych, & Miller, 2005). Intervention for diabetes mellitus often involves behavioral changes like diet and exercise initiation (Shultz, Sprague, Branen, & Lambeth, 2010). Physicians are encouraged to discuss behavioral recommendations; however, they do not consistently do so due to lack of time and patient noncompliance (Kushner, 1995). Providers may hold bias against patients with mental illness and believe that they are less likely to understand and be adherent to behavioral change. Limited research examines physicians' willingness to conduct such interventions with patients with severe mental illness in comparison to patients without severe mental illness. This study examines the effect of patient diagnosis and gender on physician willingness to discuss dietary and exercise interventions. We also examine the relationship between physician willingness to refer to behavioral specialists and stigma predictor variables. Participants were physicians recruited at primary health care centers in West Virginia.

Participants were given case vignettes of a patient who is exhibiting symptoms of diabetes mellitus during a wellness visit. Mental health diagnosis (schizophrenia, no diagnosis) and gender were manipulated and were counter-balanced. The participants were asked about willingness to address health behaviors with the patient. The Perceived Devaluation and Discrimination Scale (PDD), which measures the endorsement of items indicative of stigmatizing attitudes toward individuals with mental illness (Vauth et al., 2007) and the MICA-4, which assesses health care professionals' attitudes about psychiatry and patients with mental illness (Gabbidon et al., 2013), were administered.

Preliminary analyses of the current data support differences in physicians' willingness to conduct dietary counseling with patients diagnosed with severe mental illness and patients without severe mental illness. Stigma was found to be a predictor of low willingness to address health behaviors with patients with severe mental illness. This study provides valuable information about physicians' willingness to address health behaviors, which can be used to both add to the limited research and increase awareness of barriers patients with severe mental illness face when seeking healthcare.

MEDIATING EFFECT OF INSULIN ON IMPACT OF STUNTING ON CHILD NEURODEVELOPMENT IN A COHORT OF RURAL INDIAN CHILDREN.

Andre Portella, MD PhD¹, Neha Gupta², Patricia P. Silveira, MD, PhD³, Narendra Arora, MD, MMSc²

¹McGill Centre for the Convergence of Health and Economics (MCCHE), Montreal, PQ, Canada; ²INCLIN Trust International, New Delhi, Delhi, India; ³McGill University, Montreal, PQ, Canada

Stunting is highly prevalent in low and middle-income countries bringing severe implications to health, such as altered endocrine function and poorer neurocognitive development. Increasing evidence also suggests that insulin influences several aspects of cognition and behavior, affecting working memory, impulsivity, and executive functions. In this study, we aimed at investigating the complex interplay between insulin metabolism, undernutrition, and neurodevelopment in a population where stunting is highly prevalent. This is a cohort study implemented in North India, involving three different blocks of the Palwal district. The study included children from 6 to 12 yo, to which were applied a comprehensive battery of cognitive tests (General IQ: Porteus Maze test; Semantic interference: Stroop test; Learned Vocabulary; Phonemic Fluency; Short-term Memory: N-Back; Visual Attention: Color Trails Test; Reward sensitivity: Delay of gratification and Cognitive flexibility: Wisconsin Card Scoring Test(WCST)). Insulin was measured after an overnight fasting. Height was standardized for age and sex using WHO Growth Standards, and standardized height (STDH) was used as a proxy for stunting or chronic undernutrition. Linear regression was conducted using STDH or insulin as independent factors and neurocognition tests were the outcomes. Co-variables for the linear regression models were maternal height (to control for genetic effects), child age (for scores non-normalized to age-raw scores), and socioeconomic status (SES). Mediation analysis was performed using PROCESS macro for SPSS. Statistical significance was set at $p \leq 0.05$. There was a positive correlation between STDH and fasting insulin. Insulin was positively correlated to Phonemic Fluency, N-Back, and Color Trails scores, negatively associated to Color-Word Stroop Test, but non-statistically associated with both IQ (Porteus) and perseverative errors in the WCST. STDH was positively associated with IQ, Phonemic Fluency, N-Back, and Color Trails, but non significantly associated with Color-Word Stroop and perseverative errors on the WCST. Delay of Gratifications was not associated with both STDH and Insulin. Follow-up analysis of mediation for Phonemic Fluency, N-back, and Color-Trails test showed that insulin mediated the effect of height on Phonemic Fluency (normality test $p=0.0179$), N-Back (normality test $p=0.006$) and Color Trails (normality test $p=0.0137$). We found a combined protective effect of STDH and insulin levels on many, but not all cognitive measurements, and showed that insulin mediates this relationship for constructs related to learning, short-term memory and visual attention.

METAMEMORY AND SELF-REGULATION IN HEALTHY ADULTS OVER AGE 50

Maria Quinones, PhD, Kathi Heffner, PhD

University of Rochester Medical Center, Rochester, NY

Self-knowledge about memory, termed metamemory, is more predictive of anxiety about memory and memory complaints than actual memory capacity. This suggests that metamemory may contribute to self-regulation of well-being as we cognitively age. We examined whether metamemory domains were associated with other psychophysiological markers of individuals' capacity for self-regulation, including actual memory capacity, high frequency heart rate variability (HF-HRV) at rest and in response to cognitive tasks, and emotion regulation. Healthy adults, aged 50 and older ($n=118$), completed the Metamemory in Adulthood questionnaire. Memory capacity was assessed using the Auditory Verbal Learning Test (AVLT) and the Auditory Consonant Task (ACT), a challenging cognitive task. High frequency-heart rate variability (HF-HRV) at rest and in response to the ACT served as an index of physiological self-regulatory capacity. Less negative affect (NA) response to the cognitive tasks indexed emotion regulation and was measured by the Positive and Negative Affect Schedule. Linear regression analyses showed that greater perceived stability of memory capacity over time, but not overall current memory capacity, was associated with better performance on the AVLT immediate ($B = .06, p = .04$) and delayed recall ($B = .06, p = .04$), and on the ACT ($B = .23, p < .01$). Perceptions of greater memory stability ($B = -.06, p = .02$), memory capacity ($B = -.15, p < .01$), and lower memory anxiety ($B = .12, p < .01$) were associated with lower NA response to the cognitive tasks. Memory stability was also associated with greater HF-HRV during ACT ($B = .01, p = .04$). When exploring potential confounders, memory stability ($B = -.01, p < .01$), memory capacity ($B = -.02, p < .01$), and lower memory anxiety ($B = .02, p < .01$), were each associated with lower depressive symptoms from the Geriatric Depression Scale (GDS). After controlling for GDS score, stability no longer was associated with NA response ($p > 0.05$), but all other associations remained significant. In conclusion, perceptions of stability in memory capacity over time were more strongly associated with actual memory capacity and better physiological self-regulation than one's perception of current memory capacity. In contrast, associations between metamemory and emotion regulation may reflect more depressed mood or anxiety, suggesting implications for interpreting clinical presentation of memory complaints. Overall, metamemory domains may be useful for understanding well-being in later life.

PERCEPTIONS OF SAFETY AND SUPPORT AMONG HIGH SCHOOL FOOTBALL PLAYERS UTILIZING A HELMET IMPACT DETECTION SYSTEM

Christopher Snyder, M.D.¹, Kailey Snyder, MS², Danae Dinkel, PhD³, Adam Rosen, PhD⁴¹University of Nebraska Medical Center, omaha, NE; ²University of Nebraska Omaha School of Health & Kinesiology, omaha, NE; ³University of Nebraska Omaha School of Health & Kinesiology, Omaha, NE; ⁴University of Nebraska at Omaha, omaha, NE

Background: Concussions are common in high school football athletes and can have severe short and long-term health consequences. New football helmets furnished with accelerometers to detect rate and location of impact have recently emerged for football programs aimed at providing advanced information to sports medicine professionals and coaches. The use of these helmets offers the ability to rapidly and objectively assess concussions on the sideline. However, minimal research has explored athlete's perceptions of the use of these helmets in regard to their safety and feelings of support from coaches and administrators.

Purpose: The purpose of this study was to determine high school football players' perceptions of safety and support following a season of use of a Helmet Impact Detection System.

Methods: 118 high school football players from a large parochial school completed an electronic 29-item cross-sectional survey to obtain demographic information and safety perceptions at the end of a football season. Participants wore Riddell InSite Helmets (Riddell, Inc. Elyria, OH) the entire football season prior to the survey. Descriptive statistics were computed utilizing SPSS software.

Results: When asked to rate the degree to which they agreed that their coaches cared about their safety while playing football, 77.1% of players strongly agreed that their coaches cared. When asked if their administration cared about their safety 67.9% reported strongly agreeing. The players were also asked to rate the degree to which they felt the concussion helmets helped keep them safe, 71.3% of students strongly agreed and 23.2% somewhat agreed. When asked if they agreed or disagreed that they felt safer than opposing teams that did not wear the helmets only 48% of players strongly agreed. When asked if they played harder or more confidently due to the helmets 58% of players strongly agreed. Finally, 17% of players agreed that they would not play football if it were not for the helmets.

Conclusion: These findings suggest the use of instrumented helmets may encourage athletes' feeling supported by coaches/administrators and their perceptions of safety which could impact their decision to engage in football. However, more research is needed to determine if these feelings of safety translate to a change in rates of concussions compared to players with traditional helmets.

SEDENTARY LIFESTYLE AND THE RISK OF DEPRESSION IN PATIENTS WITH ACUTE CORONARY SYNDROMES

Yidan Zhu¹, James A. Blumenthal, PhD, ABPP², Chuan Shi³, Ronghuan Jiang⁴, Anushka Patel⁵, Aihua Zhang⁶, Xin Yu³, Runlin Gao⁷, Yangfeng Wu⁸¹Department of Psychiatry and Behavioral Sciences, Duke University Medical Center; Department of Epidemiology and Biostatistics, School of Public Health, Peking University, Durham, NC; ²Department of Psychiatry and Behavioral Sciences, Duke University Medical Center, Durham, NC; ³Peking University Sixth Hospital, Beijing, Beijing, China (People's Republic); ⁴Department of Psychiatry, Chinese PLA (People's Liberation Army) Medical School, Beijing, Beijing, China (People's Republic); ⁵The George Institute for Global Health, University of Sydney, Sydney, New South Wales, Australia; ⁶The George Institute for Global Health at Peking University Health Science Center (PUHSC), Beijing, Beijing, China (People's Republic); ⁷The Department of Cardiology, Fuwai Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, Beijing, China (People's Republic); ⁸Peking University Clinical Research Institute, Beijing, Beijing, China (People's Republic)

Although there is good evidence that sedentary behavior is associated with poor health outcomes in healthy persons and patients with cardiovascular disease, the mental health consequences of sedentary behavior have not been widely studied. We conducted a cross-sectional analysis to examine the relationship of self-reported sedentary behavior and depression in a sample of 4043 hospitalized men and women with acute coronary syndrome (ACS) in China. Depression was assessed with the Patient Health Questionnaire-9 (PHQ-9) and, in a subset of 1209 patients, by the Beck Depression Inventory-II (BDI-II). Sedentary behavior was assessed by a 1-item self-report instrument. Results revealed that greater sedentary behavior was associated with higher levels of depressive symptoms measured by both the PHQ-9 ($P < 0.001$) and BDI-II ($P < 0.001$). Compared with patients who reported that they were seldom sedentary, patients who reported that they were frequently sedentary were 4.4 times (OR 4.4, 95% CI: 2.70–7.29) more likely to be clinically depressed (i.e., PHQ-9 scores ≥ 10) after adjusting for demographic factors, lifestyle behaviors, clinical characteristics and in-hospital treatments. Importantly, greater sedentary behavior was related to higher levels of depression in Chinese patients with ACS, independent of physical activity. These findings suggest that strategies to reduce sedentary behavior may reduce risk for depression and potentially improve medical outcomes.

THE EFFECT OF NONDIRECTIVE SUPPORT ON ANXIETY AND DEPRESSION IN PEOPLE WITH CHRONIC HEALTH PROBLEMS

Megan S. Evans, MS, Edwin B. Fisher, PhD

UNC Gillings School of Global Public Health, Chapel Hill, NC

Research has consistently documented the positive effects of social support on physical and mental wellbeing. However, social relationships are often characterized by both positive and negative qualities, and may also lead to dissatisfaction, stress, and maladaptive coping. The ways in which social support is perceived and delivered can influence the extent to which it is helpful. An important distinction in this is nondirective versus directive support. Prescribing “correct” choices and taking over responsibility characterizes directive support, while nondirective support is accepting of recipients’ wishes and is generally cooperative. To assess the effect of these types of support on anxiety and depression in people with a chronic condition, a survey regarding health behaviors, social support, anxiety and depression was distributed via email to students and staff of the University of North Carolina-Chapel Hill. Among the 83 respondents, the number of chronic conditions ranged from 1 to 5 but was unrelated to anxiety or depression in this sample. Age (range 18–78, $M=42.02$) was associated with both anxiety and depression and so was controlled for in all analyses. 78% reported receiving support in managing their chronic health condition from a family member or friend and 74% from a medical professional. 22% met criteria for borderline anxiety and 19% for clinical anxiety, as well as 11% for borderline depression and 5% for clinical depression. Nondirective support from family and friends was associated with lower anxiety ($r = -.42, p = .001$) and depression ($r = -.27, p = .046$). From medical professionals, nondirective support was also associated with lower anxiety ($r = -.29, p = .027$). These correlations were strongly moderated by the number of chronic conditions. For the 45 (54.2%) with 1 chronic condition, the relationships of nondirective support provided by family or friends were greater for both anxiety ($r = -.46$ vs. $-.42$) and depression ($r = -.35$ vs. $-.27$) but were not significant for those with 2 or more chronic conditions. In contrast, the relationship between anxiety and nondirective support from medical professionals was heightened among those with 2 or more chronic conditions ($r = -.57$ vs. $-.29$) but non-significant among those with just 1 chronic condition. Thus, nondirective support from both family/friends and medical professionals is related to both anxiety and depression but the nature of these relationships is influenced by such contextual factors as the number of chronic conditions.

TRANSCRANIAL MAGNETIC STIMULATION (TMS) IN SLEEP QUALITY AMONG PATIENTS WITH MAJOR DEPRESSIVE DISORDER (MDD)

Daniel R. Schaffer, B.S. Psychology¹, Samantha Nason, B.S. Psychology², Serina Neumann, Ph.D. Clinical Psychology and Behavioral Medicine¹¹Eastern Virginia Medical School; Virginia Consortium Program for Clinical Psychology, Norfolk, VA; ²Eastern Virginia Medical School, Suffolk, VA

The purpose of this study was to examine the treatment efficacy of Transcranial Magnetic Stimulation (TMS) in improving sleep quality among patients diagnosed with depressive disorders. TMS is an FDA approved treatment method for treating depressive disorders. Severe sleep disturbances, such as insomnia and hypersomnia, are often comorbid with depressive disorders. This study utilized a registry database of patients seeking TMS treatment for primary diagnoses of major depressive disorder (MDD) at the EVMS TMS Treatment Clinic ($N = 44$). Patients in the clinic undergo 1 hour of TMS treatment every day for six weeks, followed by a three-week taper period. Sleep was assessed with 3 measures: the Pittsburg Sleep Quality Index (PSQI), the Epworth Sleepiness Scale (ESS), and question 16 of the Beck Depression Inventory II (BDI-II). According to analyses, TMS is able to produce statistically and clinically significant improvements in sleep quality among depressed patients, as measured by the PSQI, with $F(1.70, 71.53) = 5.79, p = .004; \eta^2 = .121$, and question 16 of the BDI-II, with $F(1.66, 71.33) = 28.14, p < .001; \eta^2 = .396$; the ESS did not show significant changes across treatment, with $F(2, 84) = 2.72, p = .072; \eta^2 = .061$. Further analyses suggested that sleep improvements occur during the first 2 weeks of treatment. No significant changes were noted between week-two and the end of treatment showing sleep quality to be stabilized. Sleep quality appears to improve as a function of treating depressive symptoms, as sleep quality improvements were accounted for by the improvement in depressive symptoms.

USING QUALITATIVE METHODS TO DEVELOP A DYADIC INTERVENTION FOR PATIENTS WITH STROKE AND THEIR CAREGIVERS

Jessica McCurley, M.S., M.P.H.¹, Christopher Funes, M.S.², Emily Zale, Ph.D.¹, Michelle Jacobo, Ph.D.¹, Jamie Jacobs, Ph.D.¹, Ann Lin, B.S.², Danielle Salgueiro, R.N.², Tara Tehan, R.N.², Jonathan Rosand, M.D., M.Sc.², Ana-Maria Vranceanu, Ph.D.¹

¹Massachusetts General Hospital/Harvard Medical School, Boston, MA; ²Massachusetts General Hospital, Boston, MA

Stroke is the leading cause of death and disability among U.S. adults. Despite advances in neurological critical care that have improved physical outcomes of stroke, chronic emotional distress (e.g., depression, anxiety, post-traumatic stress), remains prevalent and interdependent between stroke patients and family caregivers. We aimed to develop an intervention to prevent chronic emotional distress in patient-caregiver dyads using qualitative methods. We conducted semi-structured interviews (N = 24) with patient-caregiver dyads and focus groups (N = 2) with nurses in a Neuroscience Intensive Care Unit (NICU) to gather multiple perspectives on the stressors and needs of SPs and CGs at risk for chronic psychiatric distress. Interviews were audio-recorded, transcribed, and coded using NVivo 8 software. Two independent raters conducted coding and resolved discrepancies. Patients were adult stroke survivors aged 28–86 years. Caregivers were spouses (50%), children (41%) and other family members (9%). The most salient challenges and impacts of stroke reported by dyads were uncertainty about future health, fear of recurrent strokes, negative emotions (e.g., sadness, anxiety), and role changes at home post-stroke. Patients and nurses agreed that skills such as mindfulness/staying in the present, problem solving, practicing gratitude/optimism, engaging in hobbies and self-care activities, and developing a supportive team of family, friends, and medical staff are beneficial to optimize recovery. Suggestions for content of a future intervention by dyads and nurses included education about emotional changes post-stroke, managing anxiety and worry, and improving communication between patients, caregivers, and medical staff. The major potential barrier to intervention delivery cited by dyads and nurses was time burden. Using this information, we developed the Recovering Together program, a 6 session (2 in-person during hospitalization, 4 at home via secure live video) dyadic skills intervention mapped directly onto themes identified through qualitative analyses. Recovering Together is the first dyadic intervention aimed to prevent chronic emotional distress in stroke patient-caregiver dyads. It includes active emotion regulation strategies such as mindfulness, problem solving, practicing gratitude, adjusting to sequelae and role changes, interpersonal communication among dyads and the medical team, and an innovative delivery format to increase feasibility and reduce time burden.

A MEDIATION ANALYSIS OF SELF-ESTEEM, STRESS AND RESILIENCE IN LESBIANS AND GAY MEN OVER 50

Bunyong Dejanipont, N/A¹, Mark Vosvick, Ph.D.²

¹University of North Texas, DENTON, TX; ²University of North Texas, Denton, TX

The minority stress model (Meyer, 2003) argues that the sexual minority experience adds stressors due to a person's minority status. Stress related to stigmatization and discrimination of sexual and gender minorities may explain the disproportionate number of mental health problems found among sexual minorities (Meyer, 2003) including substance use, suicidal ideation, psychiatric conditions and low self-esteem (Bos et al., 2008). Resilience is a well-established protective factor against these mental health issues (Davydov et al., 2010) and is thought to be receptive to clinical manipulation to improve mental health (Kobau et al., 2011). While the number of studies about self-esteem have increased, few examine self-esteem in relation to stress and resilience among older sexual minorities. Thus, the aim of our study is to examine whether resilience (CD-RISC) mediates the relationship between perceived stress (PSS) and self-esteem (RSES) in lesbians and gay men over 50 (LG+50).

We recruited participants ($n = 100$) from the Dallas/Fort Worth metropolitan area who were at least 50 years old and identified as lesbians or gay men. To test for mediation, we first examined the direct path relationship (c) between perceived stress and self-esteem by regressing perceived stress on self-esteem ($\beta = -.64, p < .001$). We then examined the indirect relationship between perceived stress and self-esteem via resilience. For path a, we regressed perceived stress on resilience ($\beta = -.57, p < .001$). Lastly, for path b and c', we regressed resilience and perceived stress on self-esteem ($\beta = .32, p = .001, \beta = -.45, p < .001$, respectively). The results of the regression analyses suggest a partial mediation. To test for the mediating effect, we ran the Sobel (1982) test and found it to be significant ($z = -3.11, p < .001$). The results suggest that the "true" relationship between perceived stress and self-esteem is mediated by resilience with resilience significantly reducing the strength of the relationship. Our findings highlight the important role of resilience, which may improve self-esteem among LG+50 with high perceived stress. Therefore, clinical interventions aimed at enhancing resilience may help older sexual minorities who experience stress improve self-esteem and subsequently mental health.

“I NEEDED A REASON TO BE ACCOUNTABLE”: DEPRESSED PREGNANT WOMEN’S PERCEPTIONS OF MOTIVATION FOR SYMPTOM SELF-MANAGEMENT

Patricia Kinser, PhD, WHNP-BC, RN¹, Nastassya Russell, BS¹, Christine Aubry, N/A¹, Amy Rider, RN²

¹Virginia Commonwealth University School of Nursing, Richmond, VA; ²VCU School of Nursing, Richmond, VA

Background: It is estimated that up to 20% of women experience perinatal depression which can lead to many negative sequelae for the mother, child, and family. Physical activity (PA) has been proven to be an effective treatment modality for depressive symptoms, but individuals with depression often have reduced self-regulation and self-efficacy that ultimately decreases their involvement in PA and their ability to self-manage their symptoms. There is therefore a great need to further understand what motivates pregnant women with depressive symptoms to self-manage their symptoms.

Purpose: The purpose of this study is to understand the experience of pregnant women with depressive symptoms who participated in an intervention ($n=41$) that involved mindful group physical activity. The intervention was encouraged by a nurse-led motivational interview and subsequent weekly check-ins to support the participant’s involvement in symptom management.

Methods: Semi-structured interviews were performed at a postpartum visit with open-ended questions about participants’ symptom experience, the intervention, and use of self-management skills during pregnancy and during the postpartum period. A descriptive, phenomenological data analysis lens was used to analyze the data. The themes that arose were used to construct a coherent picture of participants’ general experiences with the intervention and with motivation.

Results: The following themes arose in qualitative analysis: (1) participants were most motivated to join the study after personally recognizing a need for self-care and/or receiving a provider recommendation about facing their depressive symptoms; (2) weekly check-ins provided a sense of accountability, serving as a motivator for continued participation; (3) participant motivation was reinforced by positive experiences of a safe space and shared experiences with other participants.

Conclusions/Implications: It is important to understand women’s personal experiences with this mindful physical activity intervention in order to determine key factors involved in helping pregnant women self-manage their depressive symptoms. Analysis of the data from the postpartum interviews reveal that a sense of safety among fellow participants and a sense of accountability to the overall study were important motivators for engaging in the intervention. Further, clinicians should recognize the important role they play in helping pregnant women feel motivated to engage in self-care. The themes identified in this study will be used in future studies to guide intervention refinement and to enhance translatability of non-pharmacologic low-cost self-management interventions for pregnant women with depressive symptoms.

AGGRESSION & DEPRESSION: RESILIENCE AS A MODERATOR IN OLDER GAY MEN AND LESBIANS

Tosha Griggs, B.S.¹, Mark Vosvick, Ph.D., Texas²

¹University of North Texas, Lake Dallas, TX; ²University of North Texas, Denton, TX

Aggression & Depression: Resilience as a Moderator in Older Gay Men and Lesbians

Older gay men and lesbians (LG) are at risk for depression due to sexual minority stress (Fredriksen-Goldsen et al., 2013). When compared to sexual majority men, gay men report higher rates of depression (Cochran & Mays, 2000). Furthermore, single LG may be at an increased risk for depression (Kuyper & Fokkema, 2010). Aggression in older LG may be associated with negative mental health outcomes, relationship issues and may be more prevalent in gay men than lesbians (Suls & Bunde, 2005). However, anger may foster resilience if expressed in a manner that motivates positive action towards a greater purpose (Russell & Richards, 2003). Through a minority stress (Meyer, 2003) lens, we hypothesize aggression and being single are positively associated with depression. Resilience is negatively associated with depression. Aggression, resilience and being single account for a significant proportion of variance in depression and resilience moderates the relationship between aggression and depression. There is a significant difference between older LG aggression, resilience and depression scores. After IRB approval, we recruited and obtained informed consent from 50 gay men and 50 lesbians in DFW. Participants (Mage=59.0, SD=6.5) self-identified as 68% European American, 17% African American and 15% other. A hierarchical regression analysis ($F[8, 91]=10.62, p<.001$) revealed that in addition to aggression ($\beta=.32, p<.001$) and resilience ($\beta=-.24, p<.05$), being single ($\beta=.36, p<.05$) and income $<30,000$ ($\beta=.22, p<.05$) were significant predictors, accounting for 44% of variance in depression ($\text{adj}R^2=.44, p<.001$). Furthermore, the interaction effect was statistically significant, $\Delta R^2=.19, F \text{ change}=37.14, p<.001$, resilience moderates the relationship between aggression and depression. Our independent sample t-test indicated a significant difference ($t[98]=-2.14, p<.05$), between resilience scores for gay men ($M=1.80, SD=.29$) and lesbians ($M=1.91, SD=.08$) and depression scores ($t=3.39, p<.001$) for gay men ($M=1.96, SD=.28$) and lesbians ($M=1.78, SD=.23$). Depression is associated with a decrease in physical and cognitive function and an increased risk of mortality (Blazer, 2003), therapeutic priorities should address gender differences and focus on coping strategies that promote healthy aggression and depressive symptom management.

COGNITIVE APPRAISAL BIASES IN DEPRESSION AND POSTTRAUMATIC STRESS

Camilla Champion, BS, Joe Tomaka, Ph.D.

New Mexico State University, Las Cruces, NM

Cognitive appraisal theory suggests that appraisals of events determine emotional, physiological, and behavioral reactions to them (Lazarus, 1991). Likewise, theories of depression and post-traumatic stress (PTS) suggest that these conditions affect or bias how individuals appraise everyday situations. To date, however, few studies have examined such associations directly and none has examined cognitive appraisal bias across multiple life contexts. Accordingly, we examined how depression and PTS symptoms related to cognitive appraisals in a large sample ($N=737$) of municipal firefighters and using a novel measure of cognitive appraisal that assesses appraisal across multiple life domains. Specifically, the Appraisal of Challenge and Threat Scale (Tomaka et al., 2012) assess cognitive appraisal of threat (vs. challenge) across multiple every day, potentially stressful, situations clustered within six life domains including conflict situations, unexpected events, public speaking, social situations, financial stressors, and transportation. Firefighters completed the ACTS along with the civilian version of the Posttraumatic Stress Checklist (PCL-C; Weathers et al. 1993), and the Zung Self-Rating Depression Scale (Zung, 1965) as part of participation in a larger study. We first categorized individuals as making high (Threat) or low (Challenge) stress appraisal across the six stress domains and then used MANOVA to examine how such appraisals related to PTS and depression symptoms. MANOVA showed depression and PTS symptoms to be strongly associated with the tendency to appraise life events as threatening vs. challenging (both $p < .01$). Supplemental regression analyses examined similarities and differences between depression and PTS symptoms across the life domains. Although both were associated with threat appraisals in social situations (both $p < .01$), depression was also related to threat appraisal of financial situations ($p = .01$) and conflict situations ($p = .02$), whereas PTS related more strongly to conflict situations ($p = .03$) and was unrelated to appraisal of financial situations (ns). Neither condition related to appraisals in the transportation domain. Overall, the results suggest that depression and PTS symptoms are strongly related to threat appraisal in some, but not all, life domains. They also show that the two conditions share similarities and differences in life domains that trigger threat appraisals.

CO-OCCURRENCE OF DISORDERED EATING BEHAVIOR AND OTHER HEALTH-COMPROMISING BEHAVIORS IN U.S. COLLEGE STUDENTS

Marley Hornewer, N/A¹, Nancy Jao, M.S.², Brian Hitsman, PhD², Christina Ciecierski, PhD³¹Northwestern University, Chicago, IL; ²Northwestern University Feinberg School of Medicine, Chicago, IL; ³Northeastern Illinois University, Chicago, IL

Background: Eating disorders in young adults are associated with other mental health problems and health compromising behavior. Less is known about disordered eating behavior (DEB) in college students. The purpose of this study is to examine the extent to which students who report DEB symptoms also engage in other health compromising behavior.

Methods: The National College Health Assessment (American College Health Association) was administered in the spring of 2015 to 93,034 students from 108 universities/colleges. Only undergraduates ($N=73,727$; 68% women, 35% racial minorities, 13% Hispanic) were included in this study. DEB was defined by report of vomiting or taking laxatives to lose weight and/or taking diet pills to lose weight in the past month. Logistic regression analysis was used to evaluate the association between DEB and the following health behaviors: any tobacco use (cigarettes, cigars, hookah, smokeless tobacco) or any illicit drug use (marijuana, cocaine, methamphetamine) in the past month; ≥ 1 alcohol binge drinking episodes (≥ 5 drinks/sitting) in the past 2 weeks; and sleep problems (e.g., extremely hard time falling asleep) ≥ 3 days in the past week. Separate analyses were conducted for each behavior. Covariates included age, race, ethnicity, gender, sexual orientation, and any diagnosis/treatment of a mental health disorder in the past 12 months.

Results: DEB was reported by 5.7% ($N=4,219$) of students, with 33% of these reporting laxatives only, 51% reporting diet pills only, and 16% reporting use of both laxatives and diet pills. Only 14.2% of students with DEB reported diagnosis/treatment for eating disorder (anorexia, bulimia) in the last 12 months. The prevalence of the health compromising behaviors was as follows: tobacco use 18.3%, alcohol binge drinking 33.1%, illicit drug use 18.8%, and sleep disturbance 72.1%. There were significant associations between DEB and all 4 health compromising behaviors ($ps < .001$). Students who endorsed DEB had a significantly higher odds of tobacco use (OR=2.1, 95% CI=1.9–2.2), illicit drug use (OR=1.7, 95% CI=1.6–1.9), alcohol binge drinking (OR=2.1, 95% CI=1.9–2.2), and sleep problems (OR=1.8, 95% CI=1.6–1.9).

Conclusions: In this sample of U.S. college students, DEB was associated with increased rates of health compromising behavior. Findings highlight the potential importance of the identification of DEB as a strategy for targeting of campus-based mental health and health promotion intervention.

DO AS I SAY, NOT AS I DO: REPORTED PHYSICAL ACTIVITY OF MENTAL HEALTH PRACTITIONERS AND THEIR EXERCISE REFERRAL PRACTICES

Hamish Fibbins, Bachelor of Exercise Physiology, AEP¹, Louise Czosnek, NA², Robert Stanton, PhD³, Kade Davison, PhD⁴, Oscar P. Lederman, Bachelor of Exercise Physiology⁵, Rachel Morell, AEP, B.ExPhys⁶, Philip B. Ward, BMedSc, PhD⁷, Simon Rosenbaum, PhD⁸

¹South Eastern Sydney Local Health District, Sydney, New South Wales, Australia; ²Exercise & Sports Science Australia / Australian Catholic University, Mulgrave, Victoria, Australia; ³Central Queensland University, Rockhampton, Queensland, Australia; ⁴University of South Australia, Adelaide, South Australia, Australia; ⁵NSW Health, Sydney, New South Wales, Australia; ⁶UNSW, Bondi Junction, New South Wales, Australia; ⁷UNSW Sydney, Liverpool BC, New South Wales, Australia; ⁸UNSW Sydney, Sydney, New South Wales, Australia

Background: Physical activity can significantly improve physical health and clinical symptoms across a range of mental disorders. Accredited Exercise Physiologists (AEPs) are ideally-placed to lead physical activity interventions for people with mental illness, but referral rates to AEPs are low. Encouraging mental health professionals to actively refer to AEPs may lead to significant physical and mental health benefits for people with mental illness.

Methods: A cross-sectional paper-based survey was conducted at the 2017 Royal Australian and New Zealand College of Psychiatrists conference, to investigate delegates' knowledge and attitudes towards physical health monitoring for people with mental illness, self-reported physical activity, and to determine their understanding of the role of AEPs within mental health settings. Additionally, a subgroup of delegates underwent assessment of cardiorespiratory fitness (sub-maximal cycle ergometer test) and functional capacity (handgrip dynamometry).

Results: In total, 73 delegates completed questionnaires and 24 underwent fitness assessment. Delegates demonstrated a high level of knowledge regarding the general associations between physical activity and cardiovascular disease (CVD) risk. Furthermore they had good understanding of the higher incidence of sedentary time for people with mental illness and the associated increased CVD risk. Delegates were less knowledgeable of the role of AEPs within mental health settings and 42 (58%) had never referred a person with a mental illness to an AEP. Forty-six participants (63%) did not meet the Australian recommended guidelines for physical activity. No association between self-reported physical activity or measures of fitness and referrals to AEPs was evident.

Conclusion: Consistent with previous studies, referral rates to AEPs are low. Promoting physical activity participation for mental health professionals, coupled with professional development on the important role AEPs play in the multidisciplinary treatment of mental health consumers is vital to promote better physical and mental health outcomes for this vulnerable group.

DOES THE END JUSTIFY THE MEANS? THE PSYCHOLOGICAL COSTS OF STUDENT LOANS

Mario Weick, PhD

University of Kent, Canterbury, England, United Kingdom

Introduction: There is an increasing unease about the potential negative consequences of graduates accumulating large debts, in excess of \$1 trillion in the US alone. However, economic considerations, such as the impact on individuals' ability to access mortgages and other financial products, or the failure to repay debts, dominate current debates. We know that debts can have a detrimental impact on individuals' psychological well-being, but it remains contested whether this also applies to debts accumulated via student loans. Participation in higher education is thought to reduce economic inequality and as such may offset the negative effects of graduate debts.

Methods: An analysis of cross-sectional data derived from the UK Household Longitudinal Study. A total of 7792 adults (4511 female) aged 21 to 35 ($M=28.63$, $SD=4.29$) fulfilled the inclusion criteria; 47.2% had a higher education qualification (incl. HE diploma), 18.5% had debts from a student loan, and 39.3% had other unsecured (i.e., non-mortgage) debts. Measures of psychological well-being and mental functioning served as outcome variables (SF-12, Short-Form 12 Health Survey, and GHQ, General Health Questionnaire).

Results: Controlling for age, gender, and income, debts from student loans correlated negatively with measures of psychological well-being and mental functioning. The detrimental effect of student loans was similar in magnitude as the negative effect of other types of unsecured (i.e., non-mortgage) debt. Of note, student loans negated the otherwise positive effects of participation in higher education on individuals' psychological well-being and mental functioning.

Conclusions: Student loans and unsecured debt have a similar negative impact on graduates' psychological well-being and mental functioning. From the point of view of mental health, the end (graduate employment) may not justify the means (student loans) that enable individuals to participate in higher education.

EATING DISORDER RECOVERY: A SYSTEMATIC REVIEW OF QUALITATIVE RESEARCH EXAMINING CLIENTS' AND CLINICIANS' PERSPECTIVES

Nadia Jafari, Clinical Health Psychology, M.A.

University of North Carolina at Charlotte, Charlotte, NC

Despite decades of research, eating disorder recovery continues to be poorly understood empirically (Bardone-Cone et al., 2010). Past studies have mainly focused on eating disorder behaviors (e.g., purging, binge eating) as outcomes for recovery and have not considered an integration of cognitive symptoms, quality of life, and the functional state of the patient ("Recovery", 2008). Moreover, there may be meaningful distinctions between patients' experiences of ED recovery and medical and health professionals' definitions of ED recovery. Qualitative data may contribute unique understandings of definitions and experiences of ED recovery from both clinician and patient perspectives. The aims of this review are 1) to provide a brief overview of ED types and treatment approaches, 2) to review the conceptualization, measurement, and assessment of eating disorders, 3) to highlight the need for a comprehensive definition of ED recovery driven by the integration of patient and provider perspectives to guide subsequent research and treatment models, and lastly, 4) to perform a systematic review of the qualitative literature exploring clients' experiences of recovery from an eating disorder (ED) and clinicians' perspectives on the recovery process. Six distinct themes emerged from the analysis: (1) social support, (2) psychological factors related to recovery (3) importance of professional support/intervention, (4) turning points to recovery, (5) characteristics and definitions of recovery, and (6) environmental factors related to recovery. Implications for conceptualization of ED recovery, design and focus of aftercare treatments, and future directions are discussed.

EXPLORING THE PSYCHOMETRIC PROPERTIES OF THE CESD-10 AND ITS PRACTICALITY IN DETECTING DEPRESSIVE SYMPTOMATOLOGY IN LMICS

Caryl James, PhD¹, Marvin Powell, N/A², Azizi Seixas, PhD, MS, MA³, Andre Bateman, MSc (Clinical Psychology)⁴, Karl Peltzer, Professor⁵, Karl Peltzer, PhD⁶, Supa Pengpid, Dr.PH⁷

¹The University of the West Indies, Mona, Kingston ⁶, Kingston, Jamaica; ²George Mason University, Centreville, VA; ³NYU Langone Health, New York, NY; ⁴The University of the West Indies, Kingston, Kingston, Jamaica; ⁵HSRC, Pretoria, Gauteng, South Africa; ⁶HSRC, Pretoria, N/A, South Africa; ⁷Mahidol University, Salaya, Puthamonthon, Nakhon Pathom, Thailand

Background: The CESD-10 is known for its good psychometric properties in detecting depressive symptoms; however some researchers question its applicability across various settings. This study explored the factor structure of the CESD-10 in low-and-middle-income countries (LMICs).

Methods: This cross-sectional survey consisted of 16,723 university students across 27 low-and-middle-income countries that completed self-report instruments assessing socio-demographic information and depressive symptoms using the CESD-10. Data analysis included: exploratory factor analysis (EFA), along with the χ^2 goodness-of-fit statistics, root mean square error of approximation (RMSEA) and comparative fit index (CFI).

Results: We found that the two-factor model (depressive affect and positive affect) was the best fit for this population and accounted for 52% of the total observed variance with an internal consistency of $\alpha = .77$ for the depressive affect items and $\alpha = .57$ for positive affect items. While all the countries had acceptable factor loadings ($\lambda > .40$) the scores varied across these two dimensions. Lastly, we found that on average there was a gender difference where females scored higher on the depressive affect domain ($M = 6.65$, $SD = 4.63$; $M = 6.39$, $SD = 4.76$) and males scored higher on the positive affect domain ($M = 2.60$, $SD = 1.81$; $M = 2.38$, $SD = 1.71$).

Limitations: A clinical sample, along with other measures of depression would have been ideal for comparison.

Conclusion: The two-factor model seems most ideal for LMICs with cross-cultural variability, however responses to the items loading onto the positive affect factor should be interpreted with caution.

FORMATIVE EVALUATION OF AN ASSISTED OUTPATIENT TREATMENT PROGRAM IN NM

Joe Tomaka, Ph.D.¹, Christine Spurny, MPH¹, Brenna Bandstra, BS², Elizabeth Olivares, MPH¹, Jamie Michael, BS³

¹New Mexico State University, Las Cruces, NM; ²Crimson Research., Las Cruces, NM; ³Dona Ana County HHS, Las Cruces, NM

We describe the planning, implementation, and formative evaluation of the Doña Ana County Assisted Outpatient Treatment (AOT) program in Southern New Mexico. AOT involves petitioning local courts to order individuals to enter and remain in treatment within the community (SAMHSA, 2017). AOT facilitates the delivery of community-based outpatient mental health treatment services to individuals with SMI. Primary goals include providing access to treatment and related services, assisting patients to function in the local community, and prevention of relapse or deterioration that leads to harm to self or others or a need for hospitalization. New Mexico SB 113 provides the legal statute that guides the Dona Ana AOT program. The Dona Ana AOT program is unique because it the county is host to a large immigrant and multi-cultural population and its mix of urban, semi-urban, and rural communities including colonias.

Eligible individuals include adults 18 or older who have been hospitalized, incarcerated, or detained two or more times in the last 48 months, or who have engaged in violent acts or threats as a result of non-compliance with mental health treatment. The evaluation includes data from direct observation and participation in program planning and implementation, client surveys/interviews, and qualitative interviews with key stakeholders (e.g., case managers, program administrator, clinicians, attorneys, treatment guardians/family members, and the County's 3rd Judicial District Court Judge. The first AOT client was court ordered May 12, 2017, and as of August 8, 2017, 15 individuals are receiving treatment under AOT. Early success has included a multidisciplinary approach to ensure that participants have access to medication, community-based group and individual psychiatric treatment, rehabilitation, transportation, enrollment in public assistance programs and supplemental shelter. Barriers have included, gaps in communication among partnering agencies, misinterpretation of the scope of the grant funds and of SB 113, data sharing from real or perceived HIPAA regulations, housing, treatment team staffing, and re-hospitalizations following court orders.

Overall, it is expected that the formative evaluation will identify the strengths and weaknesses of the Doña Ana AOT program, guide its future development, and serve as a preliminary guide for upcoming AOT intervention sites.

HEART RATE VARIABILITY BIOFEEDBACK: IMPLICATIONS FOR COGNITIVE AND PSYCHIATRIC EFFECTS IN OLDER ADULTS

Dylan Jester, B.S.¹, Ellen Rozek, Ph.D.², Ryan McKelley, Ph.D., LP, HSP²¹School of Aging Studies, University of South Florida, Tampa, FL; ²University of Wisconsin - La Crosse, La Crosse, WI

Objectives: Two decades of heart rate variability (HRV) biofeedback research have focused on adolescent and adult populations with a variety of symptoms and conditions at the exclusion of older adults. This study explores HRV biofeedback as a novel treatment to decrease anxiety and depressive symptoms in older adults, while simultaneously improving cognitive functioning.

Methods: Participants enrolled in a three-week intervention that included six 30-minute biofeedback sessions. Diaphragmatic breathing techniques and guided muscle relaxation skills were administered during the interventions for participants to achieve coherence. Neuropsychological and psychiatric measures were administered before and after the intervention.

Results: Overall, the intervention was a significant predictor of changes in psychiatric symptoms and cognition with a large effect size. Univariate analyses revealed large effect size decreases in depression ($p < .001$), state anxiety ($p = .007$), and trait anxiety ($p = .002$). A large effect size increase in attentional skills as measured by the Trail Making Test - Part A was seen ($p = .005$). A medium-to-large effect size was witnessed in the task-switching and mental-rule holding skills needed for the Trail Making Test - Part B, but a borderline p-value was found ($p = .05$).

Conclusion: This study suggests that older adults may benefit from HRV biofeedback interventions much like the younger populations that have been studied for decades. Depression, anxiety, and attentional skills were positively affected. Several participants reported improved sleep quality and stress management. Future studies should corroborate these findings.

PREDICTION OF TREATMENT RESPONSE TO EXERCISE IN ADULTS WITH MAJOR DEPRESSIVE DISORDER

Christopher J. Brush, B.S.¹, Peter J. Ehmann, B.A.², Brandon L. Alderman, Ph.D.³¹Rutgers, The State University of New Jersey, Somerset, NJ; ²Rutgers, The State University of New Jersey, Long Valley, NJ; ³Rutgers, The State University of New Jersey, Hightstown, NJ

Major depressive disorder (MDD) is a debilitating mental health condition that poses a significant burden to society. Despite the well-established antidepressant benefits of available behavioral treatments, such as aerobic exercise, approximately one-half of all clinically diagnosed individuals fail to remit. Thus, it is critical to assess heterogeneity in treatment response in order to advance individually-tailored prescriptions for MDD. Combining individual patient-level characteristics with neurophysiological measures may help to characterize treatment response at various levels of analysis, and ultimately improve treatment success and remission rates.

Purpose: To identify and characterize behavioral, clinical and neurophysiological markers associated with treatment response to an 8-week exercise program among individuals diagnosed with MDD.

Methods: Young adults ($n=32$; 16 responders) aged 18–25 years currently experiencing a major depressive episode completed neurophysiological (event-related potential [ERP]) and cardiorespiratory fitness assessments before and after an 8-week moderate-intensity aerobic exercise training program. Treatment response was defined as a $\geq 50\%$ reduction in depressive symptoms at post-intervention. Cognitive control (N2, ERN) and reward-related (RewP) ERP components were elicited by a flanker task and simple guessing task, respectively.

Results: At baseline, treatment responders reported higher depressive severity ($p < .05$, $ES = 0.96$) and exhibited lower aerobic fitness ($p < .05$, $ES = 0.13$) relative to nonresponders. Nonresponders exhibited marginally increased changes in aerobic fitness, which was not observed among responders. Changes in cognitive control from pre-to-post intervention emerged ($p < .05$, $ES = 0.33$), such that increased N2 amplitude was observed for responders relative to nonresponders. Interestingly, baseline reward sensitivity as a predictor of treatment response approached significance, such that responders had a larger RewP ($3.9 \pm 3.6 \mu V$) relative to nonresponders ($2.2 \pm 3.4 \mu V$).

Conclusion: These results suggest that there may be a set of moderators and mediators that can be used to help identify specific individuals with MDD who may or may not benefit from exercise. Similar to studies using typical antidepressants (Trivedi et al., 2016), these findings suggest important behavioral, clinical, and biological factors that may predict treatment response to behavioral interventions such as aerobic exercise.

PREGNANCY-SPECIFIC DISTRESS, BUT NOT DEPRESSIVE SYMPTOMS, IS ASSOCIATED WITH EXCLUSIVE BREASTFEEDING STATUS.

Kristin J. Horsley, B.A., Blaine Ditto, Ph.D., Deborah Da Costa, PhD

McGill University, Montreal, PQ, Canada

Background: Exclusive breastfeeding (EBF) is recommended for the first 6-months of life and has significant benefits for both infant and mother. Despite this recommendation, most women discontinue breastfeeding or supplement with formula within the first 6-weeks. While postpartum depression and other psychosocial factors play a role, how prenatal psychological factors influence EBF duration remains unclear.

Aim: To investigate the association between pregnancy-specific distress and depressive symptoms assessed in each trimester of pregnancy and EBF status early in the postpartum period.

Methods: Data were available for approximately 400 women with singleton pregnancies from an ongoing longitudinal study conducted in Montreal, QC, Canada. Sociodemographic information, pregnancy characteristics, and psychosocial factors were assessed through online questionnaires in each trimester of pregnancy and at approximately 6–9 weeks postpartum ($M=7.27$, $SD=1.92$). The Prenatal Distress Questionnaire-Revised (PDQ-R) and the Edinburgh Postnatal Depression Scale (EPDS) were used to assess pregnancy-specific distress and depressive symptoms, respectively. EBF status was determined by a postpartum self-report item that asked mothers to indicate the age their infant was first fed formula.

Results: The sample was primarily White, well-educated women who were pregnant with their first child. Approximately 50% ($n=223$) reported EBF at postpartum follow-up. After accounting for the influence of age, ethnicity, education, pre-pregnancy BMI, and parity, greater pregnancy-specific distress in the first ($OR = 0.94$, 95% $CI=0.91-0.99$) and third ($OR = 0.95$, 95% $CI=0.91-0.99$) trimester was associated with a significant reduction in odds of EBF. Prenatal depressive symptoms were not associated with EBF.

Conclusion: Results of these analyses contribute to our understanding of how prenatal psychological factors impact EBF and add to a growing literature that has identified pregnancy-specific distress as a unique construct associated with maternal and infant health outcomes. Our findings suggest that worries and concerns specific to the pregnancy period (e.g., concerns about birth and baby, physical symptoms, and relationships) may be particularly important to consider when designing antenatal interventions to improve EBF duration.

PROSPECTIVE PREDICTION OF DEPRESSIVE SYMPTOMS IN UVEAL MELANOMA PATIENTS

James MacDonald, B.A.¹, Alexandra Miller-Jorge, M.A.², Tara McCannel, M.D., Ph.D.³, Tammy Beran, Ph.D.², Annette L. Stanton, Ph.D.²

¹University of California, Los Angeles, Los Angeles, CA; ²Department of Psychology, University of California, Los Angeles, Los Angeles, CA; ³Department of Ophthalmology, Stein and Doheny Eye Institutes, University of California, Los Angeles, Los Angeles, CA

Background: Diagnosis with uveal melanoma (UM), a rare cancer, presents potential vision loss and life threat. This prospective, longitudinal study interrogated the predictive utility of pre-diagnosis objective and subjective visual impairment, as well as optimism and neuroticism on depressive symptoms in a sample of individuals undergoing diagnostic biopsy for UM.

Method: Adults ($N=299$) completed questionnaires before diagnostic biopsy for UM (T0) and 1 week (T1), 3 months (T2), and 12 months (T3) post-diagnosis. Patients subsequently received a cancer ($n=107$) or non-malignant ($n=192$) diagnosis. Measures were: CES-D (depressive symptoms), MOOD-V (subjective vision), logMAR (visual acuity), LOT-R (optimism), and NEO (neuroticism). Subgroup comparisons of depressive symptoms tested the hypothesis that the cancer subgroup would exhibit more depressive symptoms than the non-cancer subgroup following diagnosis. Multiple linear regressions tested the predictive utility of independent variables. Age and gender were entered as covariates into each regression, and T0 CESD was controlled in T1, T2, and T3 models.

Results: Patients diagnosed with cancer had significantly worse objective ($F=4.45, p<.05$) and subjective ($F=14.08, p<.001$) vision at T0 and higher depressive symptoms than non-cancer patients at T1 ($F=12.94, p<.001$). Diagnosis (after T0; $b=2.83, p<.01$) and T0 optimism ($b=-.31, p<.05$) were associated with T0 depressive symptoms, and neuroticism moderated an association of subjective vision with depressive symptoms at T0 ($b=.11, p<.01$); subjective vision significantly predicted higher depressive symptoms at mean ($b=.11, p<.01$) and high ($b=.18, p<.001$) levels of neuroticism, but not at low levels of neuroticism ($b=.03, p>.05$). T0 neuroticism ($b=3.36, p<.01$) and diagnosis ($b=3.38, p<.01$) significantly predicted depressive symptoms at T1. At T2, an effect of visual acuity on the outcome was moderated by neuroticism ($b=-.18, p<.05$), but simple slopes were not significant. At T3, T0 subjective vision predicted the outcome ($b=-.13, p<.05$) as did the diagnosis x neuroticism interaction ($b=-7.78, p<.01$); higher neuroticism predicted higher depressive symptoms in non-cancer patients ($b=4.63, p<.01$) but not cancer patients ($b=-3.13, p>.05$).

Conclusion: Pre-diagnosis personality and vision variables significantly predicted depressive symptoms across one year after UM diagnosis. Even prior to UM diagnosis, factors that potentially confer risk for depressive symptoms can be identified.

PSYCHOMETRIC PROPERTIES OF THE CHINESE SELF-COMPASSION SCALE AND ITS SHORT-FORM: INSIGHTS ON PATHWAYS TO MENTAL WELL-BEING

Adrian Wan, PhD Candidate¹, Ted C. T. Fong, MPhil², Rainbow T. H. Ho, Prof³¹The University of Hong Kong, Hong Kong, N/A, Hong Kong; ²Centre on Behavioral health, Hong Kong, N/A, Hong Kong; ³Centre on Behavioral Health, The University of Hong Kong, Hong Kong, N/A, Hong Kong

Background: Self-compassion is receiving increasing research attention. There is lack of consensus on a paucity of psychometrically robust measures of self-compassion. The only self-report measurement of self-compassion is the Self-Compassion Scale developed by Neff (2003). Existing validation studies showed diverged opinions on its psychometric structure. Neff (2003) proposed a 6-factor structure with a composite score; while López et al. (2015) proposed a two-factor model, formed by the positively and negative formulated items respectively. The current study examines the factor structure, reliability, and construct validity of the SCS and its short-form in a community sample.

Methods: Two independent samples of 455 and 292 Chinese adults were recruited via convenience sampling. In addition to the Chinese SCS, the first sample completed a battery of mental health measures. Factor structure of the SCS and SCS-SF were evaluated using confirmatory factor analyses. Convergent and divergent validity of the SCS were examined via the relationships of the SCS factors with covariates and mental health measures in a path analysis.

Results: The 6-factor correlated model and the 6-factor model with 2 higher-order factors provided adequate fit to the SCS and cross-validated well in an independent sample. The two higher-order factors of the positively formulated “Self-Compassionate Behaviors” and the negatively formulated “Self-Uncompassionate Behaviors” showed good internal consistency and test-retest reliability. The factor “Self-Compassionate Behaviors” significantly predicted hope, perspective taking, empathic concern, and positive affect while the “Self-Uncompassionate Behaviors” factor significantly predicted personal distress, anxiety, depression, general health problems, and negative affect. For the SCS-SF, the 2-factor correlated model but not the 1-factor model was found to provide a good fit in terms of model fit and parsimony.

Conclusion: This is the first study to assess the factor structure of the Self-Compassion Scale in the non-Western world, utilizing a non-clinical community sample. The present study suggested a two second-order factor structure for the Self-Compassion and its short-form. The structure with the best fit was comprised of the six first-order factors, and two second-order factors of “Self-Compassionate Behaviors” and “Self -Uncompassionate Behaviors”, with distinct pattern of correlations with other psychological measures. The findings were consistent with evidence in neuroscience suggesting that the default threat-defense system and the self-soothing system are two separate systems in mood regulation. Such differentiation would allow the SCS to be adopted as both an assessment of strengths and vulnerabilities to well-being.

RACIAL DIFFERENCES IN THE ROLE OF RELIGION AND SPIRITUALITY ON DECISIONS TO USE BEHAVIORAL HEALTH TREATMENT

Erlanger Turner, PhD, Yadira Gamez, N/A

University of Houston-Downtown, Houston, TX

Individuals from racial and ethnic groups often use behavioral health (BH) treatments less frequently than European Americans. One possible explanation for this lack of seeking BH treatment is due to cultural factors such as religious beliefs. Researchers have deduced that for the African American community, religious leaders often serve as first responders to mental health issues and spirituality impacts treatment seeking among the Latino populations (e.g., Neighbors et al., 1998; Oppenheimer et al., 2004; Payne, 2009).

The purpose of the current study was to examine the role of religion and spirituality on decisions to seek BH treatment across ethnic groups (i.e., African American, European American, and Latinos). Participants were 112 young adults who self-identified as Black, White, or Latino. The sample included 75% female, 62% Latino, 23% Black, and 12% White. 89% were single and 63% self-identified as Christian (5% did not believe in religious affiliation). Ages ranged from 18 to 55 years old. The mean age was 22.60 (SD = 6.45). Participants completed the following measures: *Demographic Information Questionnaire*, developed for the present study, the Duke Religion Index (Koenig, Parkerson, & Meador, 1997), and the Spiritual Meaning Scale (SMS; Mascaro, Rosen, & Morey, 2004).

Results indicated that participants decisions differed based on their spirituality and religious practices [$F(2,107) = 4.95, p = .009, R^2 = .086$]. Specifically, strong spiritual beliefs was a significant predictor of not seeking behavioral health treatment [$t(107) = -2.73, p = .007, \beta = -.018, SE = .007$]. Furthermore, racial differences were noted in spirituality and religious practices among Black, White, and Latino college students. The main effect was significant [$F(2,108) = 3.52, p = 0.008, \eta_p^2 = .061$]. However, univariate analyses indicated a significant effect for religious practices [$F(2,109) = 6.25, p = 0.003, \eta_p^2 = .103$] and *not* spirituality [$F(2,109) = 2.50, p = 0.086, \eta_p^2 = .04$]. The data indicated that Black participants reported the strongest spiritual beliefs and engaging in more religious practices than the other racial groups. Furthermore, no differences in religious practices were found between Latino and White participants. Our study found that difference exist in spiritual beliefs and religious practices across ethnic groups. It appears that these variable may partially explain disparities in behavioral health treatment. Specifically, participants who reported stronger spiritual beliefs were less likely to seek behavioral health treatment. Implications and future directions for behavioral health providers will be discussed.

THE EFFECTS OF SEXUAL ORIENTATION OUTNESS ON DEPRESSION, ALCOHOL, AND MARIJUANA USE AMONG LESBIAN AND BISEXUAL WOMEN

Stephanie Finneran, MA¹, Devon M. Price, M.S.², Redd Driver, BA¹, Seth Kalichman, PhD¹¹University of Connecticut, Storrs, CT; ²University of Connecticut, Manchester, CT

Previous research has shown that bisexual women have poorer health outcomes than lesbian women, including anxiety, depression, and substance use. Additionally, the health benefits of sexual orientation disclosure have previously appeared robust. Theories such as Meyer's (2003) minority stress model offer an explanatory framework for the positive outcomes observed in sexual orientation disclosure. However, the majority of past studies have combined lesbian, gay, and bisexual (LGB) participants instead of examining differences across subgroups. It is unclear whether the positive benefits of sexual orientation outness generalize to the entire LGB community.

The present study examined differences between the role of sexual orientation disclosure on alcohol use, marijuana use, and depression among lesbian and bisexual women at a Gay Pride festival in 2015. The Outness Inventory (OI, Mohr & Fassinger, 2000) was used to assess the degree of openness about one's sexual orientation to others, such as friends, coworkers, and healthcare providers. A shortened subscale of the Center for Epidemiologic Studies Depression Scale (CES-D) was used to measure depression (Radloff, 1977). To assess past year substance use, participants were asked how often they had consumed marijuana and were given the AUDIT-C (Kush et al., 1998) to assess alcohol consumption.

After controlling for demographics, bisexual women had higher marijuana use than lesbian women, $F(1,120) = 6.85, p = .01$, which was consistent with past research. Interestingly, outness was not a significant predictor of marijuana use and did not interact with sexual orientation, $ps > .15$. Alcohol use was marginally predicted by outness, in that more outness led to higher rates of alcohol consumption, $F(1,122) = 3.0, p = .08$. Sexual orientation did not predict alcohol consumption, $p = .3$. Lastly, sexual orientation interacted with outness to predict depression levels: lesbians who were more out had significantly lower levels of depression, but bisexual women did not show this pattern, $F(2,122) = 4.35, p < .001$. This finding suggests that the previously robust finding on the positive benefits of outness could be limited to specific groups or specific health outcomes. Future research needs to address the unique experiences of bisexual women instead of combining these groups. Additionally, bisexual mental health should be a major focus for future research on prevention and intervention efforts within the LGB community.

THE MULTI-FACETED EFFECTS OF ACCEPTANCE-BASED BEHAVIORAL TREATMENT ON WEIGHT, DEPRESSION, EMOTIONAL EATING & QUALITY OF LIFE

Danielle M. Moskow, B.S.¹, Stephanie Manasse, PhD², Meghan Butryn, Ph.D.², Evan Forman, Ph.D.²¹Drexel WELL Center, Merion Station, PA; ²Drexel University, Philadelphia, PA

Introduction: Acceptance-based behavioral treatment (ABT) for obesity shows promise for improving weight loss compared to standard behavioral treatment (SBT). Given ABT's aim to promote adherence to behavioral changes for weight loss, it is possible that ABT could also have a positive impact on other components that often coexist with obesity. As such, we examined the effect of ABT on depression, emotional eating, and quality of life, when controlling for weight loss.

Methods: Participants ($n = 190$) were randomized to 25 sessions of ABT or SBT over 1 year. Weight and self-reports of depression, emotional eating, and quality of life were assessed at baseline, mid-treatment (6 months), post-treatment (12 months) and 1 year follow up (24 months).

Results: Relative to SBT, participants in ABT showed greater reductions in emotional eating ($p = 0.03$) and quality of life ($p = 0.04$). When controlling for weight loss, participants who received ABT showed higher results in quality of life than those who had SBT ($p = 0.02$). Those who received ABT did not show significantly reduced depression scores than those who received SBT.

Conclusions: These results may indicate that in addition to weight loss, ABT also impacts emotional eating and quality of life. It may be the case that ABT helps improve emotional eating and quality of life in those who are obese and desire to lose weight. Therefore, it would be worthwhile to further investigate the benefits of ABT above and beyond weight loss in obese populations.

UNDERSTANDING THE IMPACT OF ALEXITHYMIA ON ORGAN TRANSPLANT CANDIDATES' QUALITY OF LIFE AND THE ROLE OF DEPRESSION

Camilla W. Nonterah, PhD¹, Wendy Balliet, PhD², Ryan J. Marek, Ph.D.³, Jeff Borckardt, Ph.D.²¹University of Richmond, Richmond, VA; ²Medical University of South Carolina, Charleston, SC; ³University of Houston - Clear Lake, Houston, TX

Solid organ transplant candidates who display alexithymia, a cognitive and affective deficit in an individual's ability to experience and identify emotions, also report psychological distress, lower quality of life (QOL) and noncompliance with medical recommendations. This study sought to examine the mediating role of depression on the relationship between alexithymia and QOL. The study also compared two measures of depression; the Brief Symptom Inventory-18 (BSI-18) and the depression dimension of the abbreviated Minnesota Multiphasic Personality Inventory-2 (MMPI-2) for identifying the relationship between depression and QOL. Using a sample of 707 patients who sought a pre-transplant psychosocial evaluation for liver, kidney, heart and lung transplant, findings revealed that depression partially mediated the relationship between alexithymia and QOL. This relationship was evident for psychological QOL with both the BSI-18 and MMPI-2 but differed for physical QOL, with depression measured by the BSI-18 as the only significant mediator of the relationship between alexithymia and physical QOL. These results indicate that transplant candidates with higher levels of alexithymia who report poor QOL may be depressed. Implications for the utility of using BSI-18 or the MMPI-2 for assessing depressive symptoms among patients under consideration for solid organ transplant are discussed.

USING ITEM RESPONSE THEORY TO ASSESS PSYCHOMETRIC PROPERTIES OF THE FIVE FACET MINDFULNESS QUESTIONNAIRE IN A DIVERSE SAMPLE.

Nathaniel Y. Lu, MA¹, Ronald Hays, PhD², Amanda Shallcross, ND, MPH³

¹Columbia University, Bayside, NY; ²UCLA: Health Policy and Management, Los Angeles, CA; ³NYU Langone: Department of Population Health, New York, NY

Objective. Increasing evidence indicates that mindfulness is associated with improved well-being among individuals with psychological disorders and chronic diseases. The widespread interest in mindfulness emphasizes the need for psychometrically sound mindfulness measures. The Five Facet Mindfulness Questionnaire (FFMQ) is a widely used self-report measure of trait mindfulness. However, extant psychometric evaluations of the FFMQ have been conducted in primarily White respondents and have relied exclusively on classical test theory methods. Item response theory (IRT) approaches are recommended for the refinement and development of instruments that measure psychological functioning and have not been reported for the FFMQ. To address these limitations, we administered the FFMQ to a diverse sample and analyzed the data using IRT methods.

Methods. This study evaluates the reliability and validity of the FFMQ in a racially and ethnically heterogeneous sample ($n = 240$) using IRT methodology. The sample was pooled across two studies and included an online sample (Sample 1) and baseline data from participants in an intervention study (Sample 2). Results did not differ when analyzing studies separately. The pooled sample was: 51.3% non-Hispanic White; 27.5% non-Hispanic Black, 7.6% Hispanic, and 13.6% Other.

Results. Reliabilities were ≥ 0.82 for the 5 sub-scales: observing (0.82), nonreactivity (0.82), acting with awareness (0.90), nonjudging (0.91), and describing (0.93). Classical test theory (simple-summed scoring) and IRT scores estimated using the graded response model correlated 0.98 to 0.99 with one another. Product-moment correlations among IRT scores for the 5 sub-scales ranged from 0.10 to 0.39, indicating substantial unique variance. IRT scores were also similarly correlated with outcomes when compared with simple summed scoring. The FFMQ scales correlated significantly with depression, rumination, perceived stress, emotional intelligence, and emotion regulation reappraisal.

Conclusions. This study provides support for the reliability and validity of the FFMQ in a racially and ethnically heterogeneous sample. This study also suggests that classical test theory scores for the FFMQ are similar to IRT scores. Future studies with larger sample sizes are needed to replicate these findings and to compare performance of the FFMQ using IRT methods within unique racial and ethnic groups. This is a particularly important area of exploration given divergent operationalizations of mindfulness across the literature, which may be influenced by sociocultural contexts.

AGE AND EMOTION DYSREGULATION DISTINGUISH RESPONSIVENESS TO NEGATIVE MOOD INDUCTION PROCEDURES

Laura Aylward, M.S.¹, Kristin Schneider, Ph.D.², McKenzie Bourque, B.S.³, Jessica Oleski, MA⁴, Sherry Pagoto, PhD⁴

¹Rosalind Franklin University of Medicine and Science, Chicago, IL; ²Rosalind Franklin University of Medicine & Science, North Chicago, IL; ³Rosalind Franklin University of Medicine and Science, Lake Bluff, IL; ⁴University of Connecticut, Storrs, CT

Background: Though mood induction procedures (MIP) are a common way to study emotion and behavior in psychological research, we know little about factors associated with non-response to MIP. Identifying the characteristics that differentiate non-responders from responders may illustrate how inadvertently excluding non-responders introduces threats to external validity. Though research suggests that older adults are more effective at emotion regulation than younger adults, the impact of age and emotion regulation on response to MIP is unknown. This secondary data analysis aimed to explore whether responders and non-responders differ on demographic variables and emotional regulation.

Methods: Participants ($N=110$; 68% female, 18–63 years old) were recruited for an emotional eating study that required responsiveness to anger and anxiety mood inductions (i.e., at least a 4-point increase on the Profile of Mood States subscale for anxiety or anger, depending on the mood induction) as part of the eligibility criteria. During the screening session, participants underwent anxiety and anger MIP; nearly half ($n=49$) of the initially eligible participants were deemed ineligible solely due to non-response to the anxiety or anger MIP. Age, sex, ethnicity, body mass index category (lean, obese), and the emotion dysregulation subscale of the Eating Disorder Inventory-3 were examined for responders and non-responders. The sample size varied for the non-responders due to missing data, and separate analyses were conducted per variable.

Results: Non-responders ($M=43.24$, $SD=11.58$) were significantly older than responders ($M=34.61$, $SD=11.37$), $t(97)=3.65$, $p<.001$, $M_{\text{difference}}=8.63$, 95% bias-corrected and accelerated CI [4.54, 13.19]. Non-responders ($M=1.62$, $SD=1.39$) also scored significantly lower on emotion dysregulation compared to the responders ($M=3.02$, $SD=3.48$), $F(1, 49.75)=5.35$, $p=.025$. No other variables differentiated non-responders and responders.

Discussion: Participants who failed to respond to either the anxiety or anger MIP were significantly older and reported more effective emotional regulation compared to MIP responders. MIP studies may underrepresent people effective in emotion regulation, which limits the variance of emotion regulation abilities and generalizability of findings in MIP studies. Since only one type of MIP was utilized in the study, future research should examine age and emotion regulation differences between responders and non-responders in various forms of anxiety and anger MIP.

BASELINE RESEARCH LITERACY IS LOW AMONG YOUNG ADULTS IN A BEHAVIORAL RANDOMIZED TRIAL

Michaela Kiernan, PhD¹, Marily Oppezzo, PhD¹, Ken Resnicow, PhD², Gwen Alexander, PhD³

¹Stanford University School of Medicine, Stanford, CA; ²University of Michigan, Ann Arbor, MI; ³Henry Ford Health System, Detroit, MI

Background: Participants' research literacy is essential for engagement in clinical trials, but rarely assessed. In our prior work, only two-thirds of adults in a Mechanical Turk online sample correctly answered a knowledge question about how study dropouts distort study conclusions, $n=174$, 67% (CI 59%-74%). To date, it is unknown whether this surprisingly low knowledge level generalizes to actual clinical trial participants.

Objective: We assessed participants' baseline knowledge about the impact of dropouts on study conclusions as well as four other key constructs among 1662 young adults (21–30 years old) enrolled in MENU Gen Y, an online behavioral intervention randomized trial to improve fruit and vegetable intake.

Methods: In the trial's baseline survey, knowledge was assessed with a single-item question describing a hypothetical scenario, and four constructs (perceived value of retention, trust of the research organization, perceived value of study outcome, and perceived value of keeping commitments) were assessed with 5-point scales from 1–5 with response options (not at all, a little bit, moderately, quite a bit, extremely). Almost 69% were women, 79% were from a White racial/ethnic background, and 56% had a bachelor's degree or higher.

Results: Only 61% (CI 58%-63%) of trial participants correctly answered how study dropouts affect study conclusions. Participants rated perceived values highly, including for retention (importance of filling out the trial's follow-up surveys), $M=4.1$ (CI 4.1–4.2); trust in the research organization, $M=4.0$ (CI 3.9–4.0); value for study outcome (importance of eating more fruits and vegetables), $M=4.1$ (CI 4.0–4.1), and keeping commitments, $M=4.4$ (CI 4.4–4.4). Post-hoc analyses revealed racial/ethnic and educational disparities in knowledge, but not perceived values. Participants from a White background correctly answered the knowledge question more than those from racial/ethnic backgrounds other than White, 64% (CI 62%-67%) vs 47% (CI 42%-53%). Participants with a bachelor's degree or higher correctly answered more than those without a bachelor's degree, 66% (CI 63%-69%) vs 54% (CI 50%-58%).

Conclusions: Only a little over half of young adults in an online behavioral randomized clinical trial correctly answered a knowledge question about research literacy. Future studies should experimentally test innovative strategies to improve research literacy, especially to reduce racial/ethnic and educational disparities.

CHARACTERIZING EMPLOYMENT OF COLORECTAL CANCER SURVIVORS USING ELECTRONIC MEDICAL RECORDS

Alexandra Varga, MPH¹, Inga Gruss, PhD¹, Ginger Hanson, PhD, MS², Debra Ritzwoller, PhD³, Carmit McMullen, PhD¹, Andrew Sterrett⁴, Cathy Bradley, PhD⁵, Matthew P. Banegas, PhD, MPH¹

¹Kaiser Permanente Center for Health Research, Portland, OR; ²Johns Hopkins University Baltimore, MD, Baltimore, MD; ³Institute for Health Research, Kaiser Permanente Colorado, Denver, CO; ⁴Institute for Health Research, Denver, CO; ⁵Colorado School of Public Health, Aurora, CO

Background: Assessing changes to employment following cancer diagnosis is imperative, as cancer survivors may experience treatment-related outcomes that can impede return to work. However, collection of employment information is not required by health systems, thus data may be sparse. We describe an approach to using multiple sources of electronic health record (EHR)-based data to characterize CRC survivors' employment status and industry.

Methods: We obtained data from adults aged 18–70, enrolled in one of two health systems, and diagnosed with colorectal cancer (CRC) between 2010–2014 ($n=1107$). A mixed-methods approach was used to categorize EHR data from multiple sources into employment status and industry. Employment status was available via the EHR as: full-time, part-time, self-employed, not employed, full-time student, part-time student, retired, on active military duty, and unknown. For employment industry, we employed a multi-pronged approach using data on: (1) health plan subscriber status (primary vs. dependent); (2) health plan group (e.g., employer or organization that provides health coverage); (3) North American Industry Classification System (NAICS) codes; and (4) Standard Industrial Classification (SIC) codes. For primary subscribers, health plan group was mapped to NAICS codes and categorized into one of twenty employment industry sectors. SIC codes were converted to NAICS codes using a crosswalk from census.gov. For dependents, we used data from three open-text EHR fields with information on employment and occupation history. A qualitative analyst assessed the open-text data and categorized it into industry (using NAICS-based industry sectors). Descriptive statistics were used to characterize the demographic, employment, and cancer characteristics of CRC survivors.

Results: Among CRC survivors, 78% were primary subscribers and 22% were dependents. We characterized employment status for 56% of primary subscribers and 66% of dependents, as well as employment industry for 50% of primary subscribers' and 31% of dependents. Overall, 31% were employed, with the most common industries being public administration, finance/insurance, and educational services.

Conclusion: Leveraging existing EHR-based data to identify employment characteristics is essential for developing studies to assess employment outcomes among cancer survivors. Our results underscore the lack of existing employment data and describe a method to use EHR-based employment data in research.

COMPARING THE EFFECTIVENESS OF FOOD CRAVING INDUCTION TECHNIQUES: ARE GIFS BEST?

Leila Azarbad, Ph.D., Jaclyn Keeney, M.S.

North Central College, Naperville, IL

A food craving is described as an intense desire to consume a particular food or drink. Food cravings are quite common, with the vast majority of adults experiencing them regularly. Regular or intense food cravings can lead to overeating, in turn interfering with weight loss efforts. In order to better understand ways to reduce food cravings, a reliable method of inducing food cravings in the laboratory is first needed. To date, common craving induction techniques have utilized writing, imagery, or exposure to static images of food. Though studies have examined the utility of these techniques independently, few studies have directly compared the effectiveness of these techniques. Additionally, no studies to date have examined the utility of food-related Graphics Interchange Format (GIFs), an image in motion that has become widely used in social media, in inducing cravings. This study aimed to: 1) directly compare the effectiveness of four different craving induction techniques (Imagery, Writing, Static Image, GIF Image), and 2) to explore whether exposure to food GIFs successfully induce food cravings. Participants consisted of 75 undergraduates who completed the General Food Craving Questionnaire - State Version (G-FCQ-S; Nijs et al., 2006) prior to undergoing one of four craving induction techniques for five minutes: the Writing group wrote about a time that they ate their favorite food, the Imagery group imagined the last time they ate their favorite food, the Static image group viewed a slideshow of 36 static images of commonly craved foods, and the GIF image group viewed a slideshow of the same 36 images but in GIF format. Afterward, participants' cravings were again measured. A repeated measures ANOVA found that participants across all four conditions reported increases in cravings following the induction, $F(1, 69) = 26.289, p < .01$. The full scale craving score did not differ significantly across the four groups ($p > .05$). However, there were significant differences between groups in the Hunger subscale of the G-FCQ-S, $F(1, 71) = 17.460, p < .01$. A Bonferroni post-hoc test indicated that the Static Image and GIF Image groups reported higher levels of hunger compared to the Imagery group, p 's $< .05$. These findings suggest that while all of the tested craving induction techniques were equally effective in inducing cravings overall, viewing static and GIF images of food may have a stronger effect in stimulating hunger in participants.

DIAGNOSTIC PREDICTIONS OF HEART-FOCUSED ANXIETY: A LATENT PROFILE ANALYSIS OF THE CARDIAC ANXIETY QUESTIONNAIRE

Anna-Leigh Powell, M.S.¹, Craig Marker, Ph.D.², Cheryl Carmin, Ph.D.³

¹Mercer University, Atlanta, GA; ²Mercer University College of Health Professions, Atlanta, GA; ³Ohio State University Wexner Medical Center, Columbus, OH

The Cardiac Anxiety Questionnaire (CAQ) was developed to assess heart focused anxiety (HFA), a construct characterized by the distinct fear of cardiac related sensations. The 18-item measure is a reliable and valid instrument for the assessment of HFA in chest pain of cardiac and non-cardiac origins with similar levels of distress observed in both samples (Eifert, 2000).

Chest pain in the absence of cardiac pathology, referred to in the literature as non-cardiac chest pain (NCCP), results in recurrent healthcare utilization posing a financial burden on hospital systems (Mourad et al., 2013). Several empirical studies have demonstrated distinct differences between the groups, including higher levels of attention to heart related sensations among NCCP (Carmin et al., 2003). Such findings provide support for the perpetuating role of HFA and co-occurring interoceptive sensitivity in the maintenance of NCCP.

Regarding CAQ comparisons of NCCP and cardiac chest pain, less is known about the discriminative properties of the measure, or the ability to predict whether the symptoms are occurring in the absence of organic cardiac pathology. Given the function of HFA in NCCP, it is hypothesized that item profiles can be utilized to facilitate diagnostic predictions. The current study applied latent profile analysis to CAQ responses of 658 participants undergoing electron beam tomography scanning. Cardiac chest pain was defined by coronary artery calcium (CAC) levels, a marker for coronary heart disease.

A two-profile model to test the hypothesized connection between high HFA and NCCP was analyzed. Profile 2 demonstrated higher averages of all CAQ items and is considered the high HFA profile. Profiles were then compared to the imaging results to test the predictive properties of the classifications. 178 of the 419 patients in Profile 1 had normal CAC levels (sensitivity of 60%). 79 of the 239 patients in Profile 2, the profile hypothesized to coincide with NCCP, had abnormal CAC scans (specificity of 31%).

The current analysis did not evidence strong diagnostic predictive ability between groups based on total CAQ latent profiles. The literature has supported a four-factor structure of the CAQ. These factors will be considered, in the next step, as latent indicators to improve specificity and increase utility of the CAQ as a screening instrument in chest pain populations. Future analyses will also include cardiac risk factors to explore low risk, high HFA profiles.

DOES LEVEL OF SPECIFICITY IMPACT MEASURES OF MOTIVATION TO COMPLY? A RANDOMIZED CONTROLLED TRIAL

Paul Branscum, PhD, RD¹, Valerie Senkowski, M.S.²¹Miami University, Oxford, OH; ²Miami University, Hamilton, OH

The Theory of Planned Behavior is a popular value-expectancy model in social and behavioral health. Motivation to comply, one of the theory's constructs, has been not been well operationalized and measured in the past, and to date, there has been no assessment of whether level of specificity impacts the evaluation of the construct. Purpose of this study was to evaluate motivation to comply measurements across 4 domains (from general to TACT-behavior specific) and evaluate the potential impact the differences have on injunctive norm belief strength when identifying determinants of generalized injunctive norms. Students (n=234) attending a large southwestern university completed a TPB survey related to sleep and physical activity, and for each behavior, intentions, generalized injunctive norms, injunctive normative belief strength, and a motivation to comply was evaluated. Participants were randomized to one of four domains that measured motivation to comply [general domain (n=58); Health domain (n=60); Behavioral domain (n=56); TACT domain (n=60)]. Results from this study showed that for generalized injunctive norms, the expectancy-only-based determinants were significantly better correlated for a majority of cases (10 of 12 physical activity referents and 5 of 12 sleep referents), compared to the value-expectancy measurement approach. Across both behaviors, motivation to comply measurements did not appear to be impacted by changing the level of specificity. Referents for sleep and physical activity were mostly significant, but the effects were small to medium. Future researchers should consider dropping these measures to reduce respondent burden, or find alternative ways of measuring these constructs.

EXAMINING ANXIETY AND FEAR RESPONSES DURING EXPOSURE TO A DIGITAL BLOOD DRAW PARADIGM

Stephen Spivey¹, Sarah Atkinson¹, Danielle Hill¹, Allison Cvangros¹, Ala'a Abu-Spetani¹, Corey Shum¹, Zane Ballard, BS², Deanna D. Rumble, PhD¹, Allison Jones, PhD¹, Christopher R. France, Ph.D.³, Zina Trost, PhD⁴¹University of Alabama at Birmingham, Birmingham, AL; ²The University of Alabama at Birmingham, Birmingham, AL; ³Department of Psychology, Ohio University, Athens, OH; ⁴University of Alabama Birmingham, Birmingham, AL

Fear of blood and needles comprise central barriers to blood donation and blood draws within healthcare settings. Considerable evidence suggests that in-vivo exposure to feared experiences such as blood draws is among the most effective means of intervention for those with blood and needle phobia. A previous proof-of-concept study provided initial validation of a digital blood-draw paradigm as a potential platform for graded-exposure treatment for people with blood and needle fear. The paradigm derives from the "rubber arm" phenomenon and pairs footage of a human arm undergoing a blood draw with tactile stimuli delivered to the participant's own arm, thus generating a sense of "ownership" of the digital arm. Although significant changes in physiological arousal have been noted in response to the paradigm, studies have not yet examined the pattern of fear/anxiety responses or extinction of such responses over the course of the exposure sequence. Understanding such patterns of response is important to further validate the utility of the paradigm as a means to facilitate exposure. As part of the current study, healthy college students received two successive inductions of the digital blood draw paradigm. Participants completed a standard measure of state anxiety, as well as measures assessing fear of blood and needles and elements of blood donation experience. Participants also rated their current fear and anxiety prior to and following each exposure sequence. Finally, participants were prompted to rate fear and anxiety at successive phases of the blood draw sequence. In line with previous studies, manipulation checks indicated that the digital arm paradigm successfully produced a realistic illusion that blood was being drawn from the participant's own arm. Repeated-measures analyses indicated that, over the course of a single blood draw simulation, participants' fear and anxiety were most elevated during introduction of the needle and subsequent blood draw ($p < .05$). Across successive exposure sequences, participants showed a pattern of progressively declining anxiety and fear ratings ($p < .01$). Finally, measures specific to fear of blood and needle stimuli, rather than general measures of anxiety, were associated with fear and anxiety ratings both within and across the exposure sequence. The current results provide further support for the digital blood donation paradigm and suggest avenues for future inquiry and application.

MEDIATIONAL INFLUENCE OF SIGNIFICANT OTHERS ON COLLEGE-AGED STUDENTS' DISTRACTED DRIVING BEHAVIORS

Neha Trivedi, Maryland¹, Kenneth Beck, Maryland²¹University of Maryland at College Park, Adelphi, MD; ²University of Maryland at College Park, College Park, MD

Introduction: Texting while driving is prevalent among college-aged students despite distracted driving laws. Social Norms Theory suggests that individual behaviors are influenced often times by perceptions of how their social groups act. Proximal sources of social influence, such as significant others (S.O.) may be more likely to effect college-aged students. We investigated whether perceived S.O. texting behaviors mediate perceived risk of texting while driving and past month texting while driving behaviors among college-aged students.

Method: A total of 861 undergraduates at a large, suburban, East Coast University in the Washington, D.C., metropolitan area participated in an anonymous web-based survey that measured their driving behaviors, perceptions, and questions about their social network and its influence on their driving. Our analysis included 835 undergraduates, who were licensed drivers and usually drove a car or other motor vehicle. We examined the influence of perceived risk of texting while driving on texting while driving in the past month, and whether seeing ones S.O. texting while driving mediated this effect. The sample was analyzed in two groups: low-risk drivers and high-risk drivers. Low-risk drivers never received a traffic citation nor got into a crash. High-risk drivers had ever received traffic citation or got into a crash. A series of logistic regressions were conducted to test the mediation effect, adjusting for gender and race/ethnicity. Sobel Tests were conducted to evaluate the indirect effect.

Results: Results showed that the influence of S.O. partially mediated the effect of perceived risk of texting while driving on past month texting while driving. Sobel tests for participants who were low-risk drivers showed that the effect of texting while driving in the past month was mediated by the influence of S.O. ($t=2.24$, $p < 0.05$). Participants who were high risk drivers were also partially mediated by perceived influence of their S.O. ($t=2.03$, $p < 0.05$).

Conclusions: We found that perception of S.O. texting while driving partially mediated the effect between perceived risk of texting and driving and past month texting and driving behaviors among both low-risk and high-risk college-aged drivers. These findings bolster the limited research on the importance of proximal sources of social influence. These findings suggest prevention efforts focus on proximal social networks of college-aged students as opposed to distal social influences when targeting young adults distracted driving behaviors, and intervention strategies be tailored towards texting while driving.

QUALITATIVE ANALYSIS OF OUR VOICE DISCOVERY TOOL DATA USING NVIVO TO CAPTURE RESIDENTS' PERCEPTIONS OF LOCAL WALKABILITY

Sawa Keymeulen, N/A¹, Janet Chen, N/A¹, Ann Banchoff, MSW, MPH², Sandra J. Winter, PhD, MHA³, Abby C. King, PhD²

¹Stanford Prevention Research Center, Stanford, CA; ²Stanford Prevention Research Center, Palo Alto, CA; ³Stanford University School of Medicine, Palo Alto, CA

Marginalized communities typically have limited access to places that facilitate walking and other physical activities that can reduce chronic disease risk. One emerging approach to fostering more walkable neighborhoods is to empower residents themselves to collect relevant data and build consensus with local decision makers around realistic environment and policy changes that can promote walkability. In one multi-site project, residents used a mobile application (The Discovery Tool) to systematically capture audio narratives depicting aspects of their neighborhood that facilitated or hindered walkability. As the residents used their data to drive community improvements, the Discovery Tool research team has used the data to better understand US regional differences in walkability. We describe the application of NVivo, a qualitative data software program, to analyze 28 Discovery Tool neighborhood walks that involved 57 young to middle-aged adult participants from 7 different US cities. Together, participants collected 129 geocoded audio narratives using the application. NVivo was used to code the data using three levels of analyses: location, facilitator/barrier, and walkability. The NVivo software facilitates display of useful visualizations of the auditory data that helped clarify which factors most contributed to, or detracted from, walkability in different locales, including: hierarchy charts, word frequencies, word clouds, word trees captured from the audio narratives, and visual distributions of neighborhood features identified from the different regions. Future work will aim to optimize the process of using the Discovery Tool application and NVivo to more fully understand the qualitative data collected by residents. This type of visually compelling data analysis can help community leaders and researchers better understand local resident health issues and perspectives, and the best methods for summarizing and communicating them.

ATTRITION IN LONGITUDINAL RESEARCH WITH FITBITS

Briana McCoy, M.A.¹, Christina Lawrence, M.A.², Jamie E. Humphrey, Associates in Psychology¹, Stephanie Spaulding, N/A³, Brittany Canady, PhD¹

¹Marshall University, Huntington, WV; ²Marshall University, Barboursville, WV; ³Marshall University, Hurricane, WV

Introduction: Exercise is widely known to have extensive health benefits, but it is difficult for researchers to obtain longitudinal biometric measurements of activity. Fitbits are a good indicator of physical activity which could potentially aid health care professionals in better assessment of patients' needs (Diaz, et.al., 2015). Fitbit and the web-based tracking that accompanies its use are preferred and lead to a greater increase in physical activity compared to standard pedometers (Cadmus-Bertram, Marcus, Patterson, Parker, & Morey, 2015). However, despite incentives and reminders, attrition in studies has been high (e.g., Hartman, et. al., 2016). The current study investigates reasons for attrition in the context of a longitudinal study using Fitbits.

Method: Fitbits were provided to nineteen female college students for a nine-month study of health behaviors in which they were asked to wear the Fitbit at least 5 days per week. Participants were entered into a drawing for a \$25 Amazon Gift Card as an incentive for completion of the study. Fitbit data was monitored weekly, and participants were contacted if they did not sync their Fitbit to inquire about their continued engagement in the study. Participants were interviewed at the end of the study regarding difficulties in completion of the study or their reasons for withdrawing.

Results: Of the initial 19 participants, 10 maintained engagement in the study to completion. Selective attrition for more physically active participants was evaluated using a Mann-Whitney U test. Results indicate a significant difference in the average biweekly step count of people who completed the study compared to those that withdrew ($U = 901, p = .026$) such that participants who were less physically active were more likely to withdraw. Participants' qualitative responses reveal that difficulties were largely due to trouble syncing and remembering to charge or wear the Fitbit. Further, many participants cited no problems using their device consistently, perhaps reflecting a lack of awareness of their behavior.

Conclusion: This study shows that technical difficulties, remembering to use the device, and engagement in exercise impact participation in studies involving longitudinal Fitbit use. The sample size of this study limits the conclusions which can be drawn but does provide initial exploration of the topic. Future research should consider how to better prompt continued participation and earlier resolve technical concerns.

CONFIRMATORY FACTOR ANALYSIS OF THE EATING DISORDER EXAMINATION QUESTIONNAIRE IN VEGANS AND OMNIVORES

Sydney Heiss, BA, James Boswell, Ph.D., Julia M. Hormes, Ph.D.

University at Albany, SUNY, Albany, NY

Introduction. The Eating Disorder Examination Questionnaire (EDE-Q) has been shown to be a valid and reliable measure of eating-related pathology; however, the original four-factor structure has been proven difficult to replicate in diverse samples of respondents. The main purpose of this study was to compare goodness-of-fit of five alternative models of the EDE-Q in a sample of vegans recruited from the community (i.e., individuals refraining from all animal products, $n = 395$; mean age = 31.72 ± 12.63 ; 82% female) and undergraduate omnivores (i.e., individuals not restricting intake of animal products, $n = 207$; mean age = 18.86 ± 1.96 ; 62.7% female).

Methods. Participants completed the EDE-Q, along with a battery of self-report measures. Demographics were compared in a series of ANOVA and chi-square. Confirmatory factor analysis was used to compare fit indices of the original four-factor model of the EDE-Q, along with three-, two-, full one-, and brief one-factor models.

Results. Groups did not differ in BMI ($p > .05$). Vegans were more likely to be older, White, female, and scored lower on the restraint subscale of the EDE-Q (all $p < .05$), which is in line with past work. Internal consistency ranged from .83 to .94 in omnivores and .81 to .94 in vegans. Error terms were high, and across samples subscales were all highly correlated. The brief one-factor model was the closest to being acceptable in omnivores [$\chi^2(df) = 134.71(20)$; $p < .001$; RMSEA = .17; GFI = .87; AGFI = .77; NNFI = .87; SRMR = .04; CFI = .91], but did not perform as well in vegans [$\chi^2(df) = 486.40(20)$; $p < .001$; RMSEA = .27; GFI = .77; AGFI = .59; NNFI = .73; SRMR = .06; CFI = .91]. The four-factor model was the next best fit in both omnivores [$\chi^2(df) = 806.49(202)$; $p < .001$; RMSEA = .12; GFI = .71; AGFI = .64; NNFI = .77; SRMR = .08; CFI = .80] and vegans [$\chi^2(df) = 1389.37(202)$; $p < .001$; RMSEA = .14; GFI = .72; AGFI = .66; NNFI = .74; SRMR = .08; CFI = .77], though a Haywood case was observed in both samples and therefore the results were rendered uninterpretable. The three-, two- and full one-factor model were all far from providing adequate fit to the data.

Discussion. Our data confirm difficulties in replicating the proposed factor structure of the EDE-Q, including in vegan respondents. More research is therefore needed to determine the suitability of the EDE-Q for quantifying eating behaviors in those abstaining from animal products.

EXPLORING GENDER EXPRESSION MEASUREMENT AMONG GENDER MINORITIES

Jennifer Glick, PhD¹, Miranda Pollock, MPH², Katherine Theall, PhD³

¹Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; ²Tulane University School of Public Health, New Orleans, LA; ³Tulane School of Public Health and Tropical Medicine, New Orleans, LA

Background: While best practices for gender identity data collection are beginning to emerge, little has been done to capture gender expression. Gender expression- how one expresses their gender identity through appearance and behavior- is an important construct for better understanding gender minority experiences, especially related to discrimination and health correlates. Discrimination is often based on outward appearances, and is linked to health-seeking behavior, access and quality of care. This study explores gender expression among gender minority individuals in an effort to build a measurable conceptual model of expression.

Methods: Utilizing targeted ethnography, we conducted 41 semi-structured key-informant interviews with gender minority individuals throughout the USA. Interviews queried gender expression experiences and goals, how these change in various settings and over time, and how respondents identified their gender expression being perceived by others. Interviews were audio recorded and transcribed. Data was coded and analyzed for key themes using NVIVO 11.

Results: Respondents discussed expressing gender through 1) visual markers (clothing, hairstyles, make-up, adornment); 2) physical changes through medical interventions (hormones and surgeries); and 3) behavioral means (mannerisms, hobbies, sexual behavior). Respondents reported changes in gender expression over time and setting, frequently attributed to safety and discrimination concerns. Respondents reported minimal experiences being queried about gender expression in previous data collection activities.

Conclusions: As no standard means of measuring gender expression currently exist, this data offers a preliminary conceptual framework that can serve as the basis for survey item development. Such a measure could help understand discrimination and its health correlates. More research on cisgender experiences is necessary to develop a conceptual model that can work for people of all genders.

EXPLORING QUANTITATIVE APPROACHES TO EXAMINING THE EFFECT OF MULTIPLE DISADVANTAGED SOCIAL STATUS INDICATORS ON HEALTH

Lindsey Potter, M.P.H.¹, Collette P. Eccleston, PhD², Stephanie T. Lanza, Ph.D.¹, Elizabeth Brondolo, Ph.D.³, Martin Sliwinski, PhD⁴, Joshua M. Smyth, PhD⁵¹The Pennsylvania State University, University Park, PA; ²Lieberman Research Worldwide, New York, NY; ³St. John's University, Jamaica, NY; ⁴Penn State University, University Park, PA; ⁵Pennsylvania State University, University Park, PA

Individuals possess multiple characteristics and related social identities that may render them vulnerable to discrimination. To understand how social status factors influence health, competing theoretical approaches such as “double jeopardy” and “intersectionality” have variously proposed additive (i.e., adding the relative contribution of predictors using main effects) and multiplicative (i.e., synergistic contribution of predictors using statistical interactions) methods. There is, however, limited empirical work testing the relative benefit of these approaches for predicting disparities in exposure to discrimination or in health. The current study utilized both additive and multiplicative approaches to examine the effect of social status factors on discrimination and indicators of health (stress, depression, physical activity, metabolic risk, average waking cortisol, and cognitive functioning [working memory and processing speed]). A diverse community sample ($N = 260$; 39% Black, 53.08% female; $M_{age} = 52.39$ years, age range: 20–83 years) reported demographic and social status factors (race, gender, income, education) as well as experiences of discrimination. Additive models tested the main effects of social status factors on discrimination and indicators of health. Multiplicative models tested the effects of higher-order interactions of social status factors on discrimination and indicators of health. Finally, we tested the association of the number of stigmatized identities with discrimination and health indicators. Blacks (relative to whites) reported higher discrimination, stress, depressive symptoms, physical activity, had higher metabolic risk, and lower levels of average waking cortisol and impaired cognitive functioning ($p's < .05$). Yet, multiplicative models suggested the effect of race was moderated by other factors (e.g., a race by education interaction, $p = .04$, suggested higher education was protective against depressive symptoms for whites but not blacks). A count of the number of stigmatized identities was predictive of stress, depressive symptoms, physical activity, cortisol, and cognitive functioning ($p's \leq .001$), consistent with a “dose response” relationship between number of stigmatized identities and poor health. These results suggest that employing a combination of quantitative approaches (e.g., additive and intersectional models) may provide a more comprehensive understanding of how social status factors contribute to the complex inequalities experienced by marginalized groups.

INITIAL VALIDATION OF A NEW CONCEPTUALIZATION OF PSYCHOLOGICAL SCARCITY

Maysa De Sousa, PhD¹, Charlie Reeve, PhD², Amy Peterman, PhD², Hannah Peach, PhD²¹Springfield College, Springfield, MA; ²UNC Charlotte, Charlotte, NC

The purpose of this study was to begin the development of a measurement device designed to allow for an empirical evaluation of a new conceptualization of the construct Scarcity. This study used the standard process of scale development to generate an initial item pool, conduct item review and content validation by subject matter experts, and pilot the items in a general U.S. population sample. Forty-five items were developed based upon qualitative data that was collected about individuals' experiences with scarcity; twenty items were generated to represent material scarcity; 15 items were generated to represent time scarcity; 10 items were generated to represent psychological resource scarcity. Next the items were formally reviewed by subject matter experts. Five items were determined to be irrelevant. A national sample of 203 participants was used to test the remaining 40 items that were generated to assess scarcity. Exploratory factor analyses showed that a three-factor model of scarcity best fit the data, and evaluation of each of the factors confirmed the proposed structure of the Scarcity construct: a *time scarcity*, a *psychological resource scarcity*, and a *material scarcity* dimension. The scale was then provided to a sample of college students ($N = 117$), and again two weeks later ($N = 110$; 94% of original sample) in order to examine the degree to which the items on the measure were stable over time. Coefficients of stability for the scarcity total score and two of the subscales met the traditional (though arbitrary) minimum standard of $r \geq .70$. The coefficient of stability for the *psychological resources scarcity* subscale was $r = .67$. The proposed model has implications for both theoretical and applied practice. This model ensured that the construct of scarcity is as comprehensive as possible by identifying the dimensions of scarcity that are most salient to individuals. Moreover, the results of this study provided the basis for the development of a scarcity measure that can be used in future projects assessing the relationship between subjective indicators of SES and health disparities.

MEASURING HEART RATE VARIABILITY USING THE EMPATICA E4 WRISTBAND: RELIABILITY WITH HOLTER MONITOR

Elizabeth Van Voorhees, Ph.D.¹, Paul A. Dennis, PhD², Louise Carter, M.S.³, Lydia C. Neal, B.A.⁴, Patrick Calhoun, Ph.D.¹, Jean Beckham, Ph.D.¹, Lana Watkins, Ph.D.³¹Durham Veterans Affairs Medical Center/Duke University Medical Center, Durham, NC; ²Duke University Medical Center, Hillsborough, NC; ³Duke University Medical Center, Durham, NC; ⁴Durham Veterans Affairs Medical Center, Durham, NC

Recent research has suggested that heart rate variability (HRV), an index of the largely vagal parasympathetic afferents to the heart, reflects the capacity of an individual to flexibly regulate physiological and emotional responses to external events. Because HRV reflects parasympathetic tone and general autonomic balance, it has been proposed as a particularly useful index of psychological and physiological stress (Thayer, Åhs, Fredrikson, Sollers Iii, & Wager, 2012). The gold standard for measuring ambulatory HRV is the Holter monitor, a device the size of a flip phone that requires chest electrodes and is either clipped to a belt or worn on a lanyard. Recent wristband devices have purported to measure HRV, but none have been demonstrated to provide reliable measures when compared to the Holter monitor. One potentially promising device for less intrusive HRV measurement is the Empatica E4 wristband, a medical-grade wireless device that allows for real-time acquisition of photoplethysmography (PPG), electrodermal activity (EDA), motion (via a 3-axis accelerometer) and temperature. We evaluated the reliability of HRV readings from the Empatica E4 wristband compared to a Holter monitor in 13 individuals with Posttraumatic Stress Disorder who were enrolled in a treatment trial. Participants underwent 36 hours of simultaneous Holter and E4 monitoring. Reliability of the E4 was measured by comparing second-by-second interbeat intervals from both sources. Mean intraclass correlation across the 13 participants was .67 (minimum = .40, maximum = .89). Missing E4 data (due to movement artifacts) and reliability of aggregate HRV measurements are discussed in the context of the utility of the E4 for research purposes. These findings suggest that the E4 wristband may be a less intrusive and reliable alternative for HRV research in ambulatory settings.

REFLECTIONS IN THE MIRROR: A NOVEL EXPERIENTIAL MEASURE OF BODY IMAGE DISSATISFACTION IN WOMEN

Brittney N. Dixon, M.P.H.¹, Aviva Ariel-Donges, M.S.¹, Eliza L. Gordon, M.S.², Abraham Eastman, M.A.¹, Vivian Bauman, B.S.³, Kathryn M. Ross, Ph.D. M.P.H.¹, Michael G. Perri, PhD¹

¹University of Florida, Gainesville, FL; ²University of Florida, Gainesville, FL; ³University of Florida, Clinical and Health Psychology, Gainesville, FL

Introduction: Negative body image is a significant and increasingly common problem among college-aged women. Previous studies have typically measured body image using self-report questionnaires; however, it is unclear whether questionnaires alone adequately capture the multidimensional nature of body image dissatisfaction. The current study evaluated the impact of a yoga intervention on a traditional self-report measure and a novel experiential assessment of body image.

Methods: The study included 75 college-aged women ($M \pm SD$: age=21.3+/-2.5 years, BMI=24.4+/-5.1 kg/m², 73.3% White) enrolled in a randomized trial examining the effects of a yoga intervention on body image dissatisfaction. Changes in body image dissatisfaction were compared on two measures: the gold-standard multidimensional Body-Self Relations Questionnaire – Appearance Evaluation subscale (MBSRQ) and an innovative experiential Mirror Exposure Task (MET). For this task, participants were asked to listen to a brief audio recording which guided them to pay close attention to certain body features (e.g., body parts, overall physique, weight) and comfort (e.g., how they feel in their skin) while viewing themselves in a full-length mirror in a private office, wearing only undergarments. After task completion, participants rated their distress using a Subjective Units of Distress Scale (SUDS; 0=No Distress, 100=Greatest Distress). Changes in scores for both measures were evaluated using a mixed ANOVA with Bonferroni post hoc.

Results: While there was no difference between MET and MBSRQ scores at baseline ($p > .05$), there was a significant Time X Condition interaction for change in body dissatisfaction on both the MET ($p = .005$) and MBSRQ ($p = .004$); compared to the wait list control group, participants in the yoga condition reported improved body image scores on both the MET ($p = .001$) and MBSRQ ($p = .003$) post-treatment. Further, MET scores were significantly correlated with MBSRQ scores at each time point (baseline $r = -.363$, post-treatment $r = -.569$, change $r = -.429$, $p < .05$).

Discussion: The current study was the first to demonstrate an impact of a yoga intervention on improvement in body image as measured by the MBSRQ and a novel experiential assessment (MET). Results further demonstrated a moderate association between MBSRQ and MET scores. Future research should examine the efficacy and validity of the MET as a stand-alone assessment of body image dissatisfaction, and how it could be integrated into various settings with different populations to assess body image.

THE CAREGIVER SICKLE CELL DISEASE SELF-MANAGEMENT SKILLS CHECKLIST: PRELIMINARY RELIABILITY AND VALIDITY

Megan Loew, M.S.¹, Justin L. Williams, PhD², Kathy Russell, Ph.D.³, Patricia J. Barker, PharmD², Jane Hankins, MD, MS², Jerlym Porter, PhD, MPH²

¹St. Jude Children's Research Hospital, augusta, GA; ²St. Jude Children's Research Hospital, Memphis, TN; ³St. Jude Children's Research Hospital, Memphis, TN

Background Individuals with sickle cell disease (SCD) are increasingly surviving and transitioning into adulthood, Greaterdisease-specific self-management skills are associated with improved transition from pediatric to adult-centered care. Adolescents with SCD need assistance developing the knowledge and skills that help increase disease self-management. Caregivers may play an important role in transition preparation, however the assessment of caregiver perception of adolescent disease self-management behaviors is not yet defined in SCD. The Self-Management Skills Checklist-Caregiver version (SMSC-C) is a 21-item measure to assess caregivers' perception of adolescents' SCD-specific and general self-management behaviors. This study aims to evaluate the preliminary psychometric properties of the SMSC-C.

Method A retrospective cross-sectional design was applied. The SMSC-C was administered to 114 caregivers of adolescents with SCD. It was administered twice in adolescence during routine SCD-related clinic visits at a pediatric research hospital located in the southeastern region of the United States. The SMSC-C consists of two subscales: skills (11 items, range 1–5) and knowledge (9 items, range 1–3), with higher scores indicating greater knowledge and skills. Correlational coefficient alphas, reliability, and preliminary construct (hydroxyurea refill rate) and predictive validity (completion of first adult provider visit) analyses were conducted to examine the psychometric properties of each subscale.

Results Cronbach's coefficient alphas for caregiver skills and knowledge subscales were 0.79 and 0.77, respectively, indicating good internal consistency. The predictive and construct validity of the SMSC-C subscales was not supported. However, SMSC-C scores between the first administration ($M_{age} = 15.2$ years) and second administrations ($M = 630$ days after, $M_{age} = 17.4$ years) significantly increased, indicating the scales were sensitive to longitudinal changes in caregivers' reports of adolescent disease self-management.

Conclusions The SMSC-C is a clinical tool with strong internal consistency and sensitivity to score changes. Pediatric SCD medical providers can administer the SMSC-C to assess caregivers' perceptions of their adolescent's current disease self-management behaviors. Additionally, providers can utilize the SMSC-C to tailor programming to help caregivers prepare their adolescent for transition from pediatric to adult healthcare.

THE SELF-REGULATION QUESTIONNAIRE: PSYCHOMETRIC CONSIDERATIONS

Brittany E. Blanchard, MA, Angela K. Stevens, MA, MPH, Andrew K. Littlefield, PhD

Texas Tech University, Lubbock, TX

Individual differences in *self-regulation*, often defined as the ability to execute planned behavior, are important in understanding a myriad of behavioral health outcomes, ranging from diet and exercise to alcohol and substance use. Despite that differences in self-regulation are relevant for both, positive and negative health outcomes, little psychometric work has examined self-regulation measures. For example, the Self-Regulation Questionnaire (SRQ) is a 63-item self-report measure which is purported to assess seven aspects of behavioral self-regulation (i.e., receiving relevant information, evaluating information, triggering change, and searching for options, as well as formulating, implementing, and assessing a plan). Given that understanding which aspects of self-regulation are most difficult for individuals who engage in specific maladaptive behaviors (e.g., alcohol misuse) can inform prevention and treatment, the current study sought to evaluate the psychometric properties of the SRQ. Using a sample of college students (i.e., 18–25 year olds; $N = 790$; 65% female; 68% White; 25% Hispanic), the original factor structure, as well as one- and two-factor alternatives were tested using confirmatory factor analyses. Because neither fit the data well, an exploratory factor analysis was conducted. This suggested a two-factor solution (i.e., poor self-regulation and good self-regulation), which demonstrated good fit in confirmatory factor analyses (CFI = .91; RMSEA = .07). Chi-square difference testing indicated that both factors demonstrated measurement invariance across gender (DIFFTEST $X^2(134) = 153.57, p = .12$). Next, regression analyses were conducted using the alcohol-consuming subset of the sample ($n = 577$). Poor self-regulation ($B = .13, p < .01$) and good self-regulation ($B = -.16, p < .05$) were both significantly associated with binge drinking in multivariate analyses, adjusting for gender. The current study created a shortened, modified version of the Self-Regulation Questionnaire which demonstrated measurement invariance across gender. Alcohol-related results were theoretically consistent, with poor self-regulation positively associated with binge drinking. However, psychometrically-sound assessments which assess specific aspects of behavioral self-regulation are still needed.

VALIDITY OF GIGAPAN TECHNOLOGY TO OBSERVE ENVIRONMENTAL FEATURES AND ATTRIBUTES

Erica Twardzik, MSc¹, Cathy Antonakos, MUP, PhD², Ross Baiers, N/A², Tamara Dubowitz, MSc, PhD³, Philippa Clarke, MSc, PhD⁴, Natalie Colabianchi, MA, PhD⁵

¹School of Kinesiology, University of Michigan & Department of Epidemiology, School of Public Health, University of Michigan, Ann Arbor, MI; ²University of Michigan, Ann Arbor, MI; ³RAND Corporation, Pittsburgh, PA; ⁴Department of Epidemiology, School of Public Health, University of Michigan & ⁵Institute for Social Research, University of Michigan, Ann Arbor, MI; ⁵School of Kinesiology, University of Michigan & Institute for Social Research, University of Michigan, Ann Arbor, MI

Background: Surrounding environments can encourage or constrain an individual's ability to participate in healthy behaviors. Built environmental characteristics have been identified as potential causal factors contributing to obesity and physical inactivity. However, measurement of environmental attributes has remained a challenge. GigaPan is a robotic system that obtains high-resolution photos using an everyday camera, by taking numerous photos that are stitched together using GigaPan software. This study examines the validity of GigaPan technology, compared to direct observation, for documenting environmental attributes. For comparison, we also examined the validity of using Google Earth to conduct the same environmental audit.

Methods: A total of 465 street segments in Pittsburgh, Pennsylvania were assessed using GigaPan, direct observation, and Google Earth audits. A 50-item audit instrument was used to capture three broad environmental constructs: land use, traffic and safety, and amenities and litter. Direct observation and GigaPan photos were captured by trained field staff, where pairs of observers walked each street while completing the audit tool or taking GigaPan photos. Audits of GigaPan and Google Earth images were completed by trained research staff. Sensitivity and specificity were used to estimate the validity of GigaPan and Google Earth audits using direct observation as the gold standard.

Results: Of the 50 items assessed, 24 items were excluded from the analysis (21 items due to low prevalence, 3 items due to low reliability). When an attribute was coded as present via direct observation, GigaPan audits identified the attribute correctly at least 80% of the time, for 7 of 24 items. When an attribute was coded as absent via direct observation, GigaPan audits identified the absence of the attribute correctly at least 80% of the time, for 16 of 24 items. Using Google Earth sensitivity was 80% or higher for 8 of 23 items and specificity was 80% or higher for 16 of 23 items. Overall, the validity of GigaPan and Google Earth were similar, with significant differences in sensitivity and specificity for 7 items and 3 items, respectively.

Conclusion: GigaPan performed well, especially when identifying features absent from the environment. A major strength of the GigaPan technology is its ability to be implemented quickly in the field (e.g. in response to environmental change). Temporal change to environmental attributes may be difficult to capture using web-based audits and researchers cannot control the timing of web-based audits (e.g. Google Earth). GigaPan is a valid method that can be used to characterize features and attributes within the environment that influence health behaviors.

VALIDITY OF SOCIAL SUPPORT MEASURES UTILIZED AMONG PEOPLE LIVING WITH HIV OR AT RISK FOR HIV-INFECTION: A SYSTEMATIC REVIEW

Deshira Wallace, MSPH¹, Allison P. Pack, MPH², Breana Uhrig Castonguay, MPH³, Sruthi Cherkur, MPH⁴, Christine Schalkoff, BS⁵, J.L. Stewart, BFA⁶, Margot Schein, BA⁷, Matthew Go, N/A⁵, Jackson Devadas, N/A⁸, Edwin B. Fisher, PhD¹, Carol Golin, MD⁵

¹UNC Gillings School of Global Public Health, Chapel Hill, NC; ²UNC Gillings School of Global Health, Chapel Hill, NC; ³UNC Center for AIDS Research, Carrboro, NC; ⁴University of North Carolina at Chapel Hill, Carrboro, NC; ⁵Gillings School of Global Public Health, Chapel Hill, NC; ⁶North Carolina State University, Raleigh, NC; ⁷UNC-Chapel Hill Gillings School of Global Public Health, Chapel Hill, NC; ⁸UNC Gillings School of Global Public Health, Kensington, MD

Background: Social support is a key protective factor for self-management among at-risk of or people living with HIV (PLWH). Having higher levels of social support is also associated with better physical and psychological health outcomes. Social support is typically assessed using self-report measures. Often such measures are developed in the general population. However, little is known about the extent to which such measures have been validated among PLWH. The aim of this systematic review is to identify, characterize and synthesize available validated self-reported social support measures used among PLWH. The goal is to produce a database of validated HIV-specific social support measures that is readily available for use by researchers.

Methods: In April 2017, we conducted a search of the literature using a list of expert-refined search terms in the following electronic databases: PubMed, PsycTESTS, PsycINFO, CINAHL, and Cochrane Reviews. The search yielded 1,757 citations. After assessing for duplication, 1,208 articles remained for screening. All remaining articles underwent paired abstract reviews, full-text reviews, and data abstraction. During data abstraction, reviewers focused on study characteristics and reliability and validity characteristics of measures.

Results: We abstracted information for 32 social support measures. Just over half (17/32) were validated in samples of PLWH. The remaining 15 measures were used repeatedly among PLWH, but not explicitly validated in this population. Study characteristics include (4/32) women-only studies, (4/32) gay-or bisexual-men-only studies and 9 studies conducted in international settings. Scales varied in length (5–40 items), tended to have Likert response options (30/32), and most (27/32) assessed positive social support only. All but one study reported Cronbach's alpha (31/32). Types of validity reported were: convergent validity (21/32), discriminant validity (8/32), known-group validity (8/32), and criterion-related validity (8/32). There was little explicit evidence of reported examination of alternative modes of administration of these measures, cultural or language adaptations, or the responsiveness of these measures over time.

Conclusions: Results suggest that while numerous social support measures are used with PLWH, only 17 were validated in this population. Additional validation studies are necessary to improve the confidence in the use of an array of social support measures in research and the field.

ACCURACY OF NUTRITIONAL GUIDANCE PROVIDED TO BARIATRIC SURGERY PATIENTS ON FACEBOOK SUPPORT GROUPS

Dylan Jester, B.S.¹, Sarah E. Domoff, PhD², Marissa Pruit, RD³, Jill Henschied, RD³, Rebecca Cripe, RD³, Afton Koball, PhD³

¹School of Aging Studies, University of South Florida, Tampa, FL; ²Central Michigan University and University of Michigan, Mount Pleasant, MI; ³Gundersen Health System, La Crosse, WI

Background: Increasingly, individuals who are interested in or who have undergone bariatric surgery turn to online social media platforms to get information and support. With over 80% of bariatric patients joining or following support groups on Facebook (Martins, et al., 2015), it is essential to understand the content fully, particularly in relation to nutrition recommendations. The aims of this study were: (1) to describe the type of nutrition-related information sought on bariatric Facebook support groups; and (2) to evaluate the accuracy of this content.

Method: To address Aim 1, posts collected via an analysis of the content of Bariatric Surgery Facebook pages were extracted for additional coding of nutrition-related content. A total of 315 posts were analyzed that contained content referring to seeking recommendations on nutrition. To address Aim 2, three registered dietitians examined the posts providing nutrition recommendations and coded for accuracy according to American Society for Metabolic and Bariatric Surgery (ASMBS) nutrition guidelines. Posts were coded as accurate, not accurate, containing both accurate and inaccurate information, and need more information to determine accuracy. Disagreements among dietitian experts was resolved via consensus. Frequencies of accurate versus inaccurate nutritional guidance were calculated.

Results: Analyses suggest that the greatest proportion (35%) of the nutrition-related support seeking was related to seeking advice on products or practices that would make it easier (and more enjoyable, e.g., variety) to follow nutrition guidelines. Members were looking for advice on ways to make following nutrition recommendations easier. The next most prevalent area of support seeking (21% of nutrition-related support posts) focused on the question of "Is this OK to eat?" Members were concerned with whether it was too early to have certain types of foods or amounts of food; other members expressed questions about whether it would be possible for them to ever consume the food or beverage because they had the surgery. Regarding the accuracy of the recommendations provided to those seeking nutrition advice (Aim 2), expert RDs identified that 47% of the posts were consistent with ASMBS nutrition guidelines and that 29% contained content that was not consistent with ASMBS nutrition guidelines. The remaining 24% required more information to code the post as containing accurate or inaccurate content.

Conclusion: Results suggest that individuals seek nutrition-related support for a variety of reasons and that the information provided may be consistent with ASMBS nutrition guidelines <50% of the time. Providing this information to individuals using these platforms is critical in ensuring they understand the need to consult with their bariatric team prior to adopting recommendations gathered from online modalities.

ALLOWING AD LIB CONSUMPTION OF FRUITS, VEGETABLES, AND LEAN PROTEIN IN A COMMERCIAL WEIGHT LOSS PROGRAM OVER 6 MONTHS

Karen E. Hatley, MPH¹, Alexis Wojtanowski, CCRP², Julianne M. Power, MS³, Brooke T. Nezami, PhD¹, Molly A. Diamond, MPH³, Kristen Polzien, PhD³, Gary Foster, PhD⁴, Deborah F. Tate, Ph.D.³

¹UNC Chapel Hill, Chapel Hill, NC; ²Weight Watchers Intl, New York, NY; ³University of North Carolina at Chapel Hill, Chapel Hill, NC; ⁴Weight Watchers, Inc, New York, NY

Most weight loss programs recommend self-monitoring of all foods and beverages that are consumed. The objective of this study was to evaluate the effect of a new approach to dietary monitoring within Weight Watchers using a pre-post evaluation design and to determine predictors of 10% weight loss at 6 months. The approach assigned every participant a personalized Weight Watchers™ SmartPoints® Budget (daily and weekly energy goals). Over 200 foods (including but not limited to: skinless turkey and chicken breast, eggs, fish, lentils, vegetables and most fruits) were zero Points® foods that did not require tracking. All other foods were assigned SmartPoints values and participants tracked the portion and Points values of these foods. Participants attended weekly group meetings led by Weight Watchers leaders and used a digital monitoring app created for the study. Assessments at baseline, 3, and 6 months were conducted by trained research staff not affiliated with Weight Watchers and included objectively measured weight and waist circumference. Self-reported variables included food cravings, hunger/fullness, happiness, and sleep. Meeting attendance was the sum of those attended out of 24. Multiple imputation was used to impute missing data and results were pooled across imputation sets. A paired t-test evaluated weight change from baseline to 6 months. Demographic characteristics and 3-month values of self-reported variables, controlling for baseline levels, were used in logistic regression models to determine predictors of 10% weight loss (WL) at 6 months.

Participants (N = 152) were on average, 48.4 (±12.3) years old, had a BMI of 32.8 (±4.8), and 94% were female. At 6 months, 91% completed assessments. The average weight loss was 7.9% (±6.1; *pp* < .0001; 95% CI: 5.4, 6.4). Demographic characteristics and former participation in Weight Watchers (57% of the sample) did not predict 10% WL at 6 months. Higher attendance at group meetings over the 6 months predicted 10% WL (*p* < .01). Reductions in ratings of hunger from baseline to 3 months predicted 10% WL at 6 months (*p* < .01), but ratings of fullness did not. Reductions in ratings of fast food cravings from baseline to 3 months predicted 10% WL (*p* < .01), but changes in cravings for sweets, fats, carbs, and fruits and vegetables at 3 months did not. Change in sleep and happiness at 3 months did not predict 10% WL. In sum, average weight losses using an approach that does not require self-monitoring of all foods and beverages were almost 8%. Those who were most successful with the approach attended more group meetings and had greater reductions in hunger and fast food cravings over the first 3 months. The study suggests that monitoring of all foods may not be required for weight loss.

DO GOAL-DIRECTED OR OUTCOME-BASED FINANCIAL INCENTIVES PROMOTE PATIENTS' WEIGHT LOSS? THE FIREWORK INTERVENTION PROTOCOL

Stephanie L. Orstad, PhD¹, Joseph A. Ladapo, MD, PhD², Sandra Wittleder, PhD¹, Christina Hernandez, MPH¹, Miguel A. Cuevas, BS², Victoria Sweat, MA¹, Melanie Jay, MD, MS³

¹New York University School of Medicine, New York, NY; ²UCLA David Geffen School of Medicine, Los Angeles, CA; ³New York University School of Medicine, Brooklyn, NY

Background: Obesity is a major public health challenge and exacerbates economic disparities through its adverse effects on employment discrimination and personal health expenditures. Financial incentive strategies for weight loss may intensify individuals' utilization of evidence-based behavior change techniques, while addressing obesity-related economic disparities in low-income populations. Trials have focused on testing incentives contingent on achieving weight loss outcomes. However, based on social cognitive and self-determination theories, incentives contingent on attaining intermediate behavioral goals may be preferable to incentivizing outcomes if they enhance individuals' skills and self-efficacy for sustaining long-term weight loss.

Objective: Describe the components and methods of the Financial Incentives for Weight Reduction (FIREWoRK) study, a primary care-based behavioral weight loss randomized controlled trial to test the comparative- and cost-effectiveness of two novel financial incentive strategies (goal-directed vs. outcome-based) among low-income adults with obesity, as compared to the provision of health behavior change resources alone. We hypothesize that goal-directed incentives will promote weight loss more effectively and efficiently than outcome-based incentives or resources alone.

Methods: We are recruiting 795 adults, 18–70 years-old with a body mass index ≥ 30 kg/m², from three primary care clinics serving residents of socioeconomically disadvantaged neighborhoods in New York City and Los Angeles County. All participants receive education, a weight loss program voucher and referrals, self-monitoring tools (Fitbit Alta HR, bathroom scale, and food journal) and monthly check-in visits. In addition to these resources, those in the two intervention groups can earn up to \$750 over 6 months for 1) participating in an intensive weight loss program, self-monitoring weight and diet, and meeting physical activity guidelines (goal-directed), or 2) a 2.5% to 5% reduction in baseline weight (outcome-based). Participants in the intervention groups also receive feedback framed using the behavioral economics principle of regret aversion. We will use generalized mixed-effect models for repeated measures to examine intervention effects on weight at 6, 9, and 12 months.

Discussion: This study addresses an important gap in obesity research by comparing goal-directed and outcome-based incentives for weight loss. We anticipate that the results will inform the design of scalable financial incentive programs to address obesity in public and private health systems.

EXPERIENCES OF DAILY SELF-WEIGHING AMONG AFRICAN AMERICAN BREAST CANCER SURVIVORS IN A WEIGHT GAIN PREVENTION INTERVENTION

Julianne M. Power, MS, Deborah F. Tate, Ph.D., Carmina G. Valle, PhD, MPH
University of North Carolina at Chapel Hill, Chapel Hill, NC

Little is known about the acceptability of daily self-weighing (DSW) in African American women and breast cancer survivors. This study explored subjective experiences of DSW among a sample of African American breast cancer survivors (AABCS) participating in a technology-based weight gain prevention intervention.

Data are from participants in the WELL Body study, a 6-month pilot randomized controlled trial of weight gain prevention interventions that promoted DSW as the primary self-monitoring strategy, and also focused on self-regulation of diet and physical activity. AABCS were randomized into one of three groups: 1) DSW (INT); 2) DSW + daily activity tracking (INT+); and 3) delayed intervention control. Intervention participants received a wireless scale and activity tracker (INT+ only), email lessons, and tailored feedback on weight and activity. A subsample of AABCS (n=21 of 24 intervention participants) completed post-intervention semi-structured interviews that covered barriers, facilitators, and adherence to DSW, as well as benefits of the program. Interviews were conducted in-person or over the phone, were audio recorded, and transcribed verbatim. The lead author read each transcript to identify key themes and develop a codebook. Each transcript was coded using Atlas.ti software and code outputs were used to identify overarching themes and patterns in the data.

On average, women in the qualitative subsample were 52.6 ± 8.3 years of age, obese at baseline (BMI: 33.1 ± 5.9), and weighed on 123.4 ± 48.0 out of the 168 days in the study period, with no differences compared to women not in the subsample (n=3). Women viewed DSW as a tool to achieve a healthier lifestyle. Barriers included initiating DSW and experiencing weight fluctuations. Seven women found that incorporating DSW into a morning routine reduced burden and facilitated adherence. Nine women felt discouraged by weight fluctuations; however, continuing to weigh daily normalized fluctuations and reduced negative emotions toward weighing. Fourteen women felt that DSW increased awareness of how diet and physical activity impact weight. Women framed the benefits of the program in terms of improved quality of life and prolonged survival following cancer treatment. These findings suggest that DSW is an acceptable self-regulation strategy for behavioral weight control interventions among AABCS. Future research could examine the potential benefits of DSW for posttreatment breast cancer survivors.

GENDER DIFFERENCES IN THE WEIGHT LOSS PROGRAM EXPERIENCE

Adrita Rahman, MPH¹, Kara L. Gavin, PhD, MPH², Jennifer A. Linde, Ph.D.¹

¹University of Minnesota, Minneapolis, MN; ²Northwestern University, Chicago, IL

Introduction: Men tend to be understudied in the field of weight loss, while women are more likely to participate in weight loss programs. The object of this study was to examine similarities and differences between men and women in their motivations to participate and experiences during a behavioral weight loss program.

Methods: Focus group interviews were conducted with men and women following the conclusion of the Tracking Study, a behavioral weight loss intervention. Five focus groups were conducted with men and four with women. Each focus group had 5–9 people. All interviews were audiotaped and transcribed. Thematic analysis was conducted using NVivo 11. Themes and codes were created by two independent reviewers, who then compared codes and discussed discrepancies to reach consensus on themes. A data matrix was created to display responses, categorized by these themes.

Results: Weight loss was the primary factor that motivated both men and women to participate in the study. A majority of men and women told people that they were participating in the study. Both men and women heard mixed feedback from people about changes they had made and their weight loss progress. Many participants had positive feelings about the weight loss process, although some thought they did not lose enough weight. Neither men nor women wanted segregated gender groups, or only same-sex instructors. Both men and women found topics on nutrition such as Volumetrics to be very useful. However, women thought recipes and grocery lists were useful as well, while men did not. Women also reported applying more lessons learned in the study to real life than men. Some men mentioned that topics in the groups tended to be more women-centric. The majority of men heard about the study by radio, while women heard about it in many different ways. The majority of men had no prior weight loss experience, while the majority of women did.

Discussion: Overall, focus group participants had a positive experience in the Tracking Study intervention. This work highlighted differences between genders in previous weight loss experience and in preferences and motivations during weight loss. Future studies may benefit from reaching out to men through radio stations with male listener demographics and by tailoring topics and activities to men's needs and preferences to better engage and retain men in weight loss programs. More work is needed to design and test strategies that encourage both men and women to successfully lose weight.

HEALTH BEHAVIORS ASSOCIATED WITH POSTPARTUM WEIGHT-LOSS RESILIENCE AMONG LOW-INCOME NEW MOTHERS

Lorraine O. Walker, RN, EdD, MPH, Bobbie S. Sterling, RN, MSN, PhD

University of Texas at Austin, Austin, TX

Weight-loss interventions for overweight and obese low-income mothers of infants and young children have had disappointing results. Competing demands and limited resources foil many mothers' weight loss efforts. Despite these barriers, during a 13-week randomized-control group weight-loss intervention, we found a subgroup within both treatment and control groups that was resilient in losing weight. The purpose of this study is to compare health behaviors that differentiated weight-loss resilient mothers within treatment and control groups from other women who generally gained weight. Overall, 49 healthy low-income new mothers (16 White, 20 African American, and 13 Hispanic) with a mean age of 25.2 years and body mass index of 32.5 completed the study. Health behaviors were measured by 15 items from the Self Care Inventory at 7 and 13 weeks of the intervention. Weights were measured on a digital scale. Group differences were evaluated using the t-test. Weight loss did not differ significantly between treatment (loss = 1.2 lb) and control (loss 1.1 lb) groups ($p < .05$). But despite being in a demanding life stage, we found 10/22 women in the treatment group were resilient in losing 3.4 to 30.2 lbs., and 11/27 women in the control group in losing 1.8 to 14.2 lbs. Compared to less weight-resilient mothers ($n = 28$ with minimal weight losses or weight gains up to 13.8 lb), weight-loss resilient mothers in treatment and control groups ($n = 21$) showed five behaviors. At both the 7th- and 13th-week of the intervention, weight-loss resilient mothers more often ate meals at regular times and ate a nutritious breakfast; in turn they less often substituted "junk" food for a regular meal, missed a main meal, or snacked on junk food. At the 13th-week, resilient mothers compared to other mothers also reported they more often ate a variety of foods from major food groups, and took time to exercise vigorously and do exercises to tone muscles. Our findings indicate some of these dietary and activity habits may have enabled weight-loss resilient women to reduce energy intake for weight loss. More so than calorie intakes, which are cumbersome to measure, our findings delineate habits that are quickly assessed. Conversely, our findings indicate that a more unhealthy or disorganized lifestyle shown by meal skipping and substituting "junk" food for meals may impair weight loss efforts. These patterns may explain disappointing results of some past interventions.

PARENTAL ROLE MODELING, SUPPORT, AND CONTINGENCY MANAGEMENT PREDICTS CHILD DIETARY OUTCOMES IN A COMMUNITY-BASED SAMPLE

Margaret Clark, B.S.¹, Joanna Buscemi, Ph.D.¹, Lara Blumstein, MS², Angela Odoms-Young, PhD², Linda Schiffer, MS, MPH³, Marian L. Fitzgibbon, IL²¹DePaul University, Chicago, IL; ²University of Illinois at Chicago, Chicago, IL; ³University of Illinois at Chicago, Oak Park, IL

In young children, parental factors play a crucial role in establishing child dietary behaviors. However, research is limited on how parental role modeling and support of dietary behaviors and contingency management strategies to reinforce dietary behaviors affect child diet outcomes, especially among underserved children. This study examined the relationship between parental role modeling of healthy dietary behaviors, parental feeding style practices, and child dietary outcomes in a low-income, community-based sample of parents and preschool-aged children receiving a dietary intervention through The Expanded Food and Nutrition Education Program (EFNEP) or the Supplemental Nutrition Assistance Program-Education (SNAP-Ed). Children participating in the trial were 2–5 years old, 55% female, 37% African American and 36% Latino ($N = 153$). Parent/caretaker ages ranged from 20–74 ($M = 34.4$; $SD = 9.2$), and 81% were mothers. Forty-one percent of the children and 69% of parents enrolled were overweight/obese. At baseline and 6-week post-intervention, parents reported on: child's diet (Starting the Conversation), parental feeding styles (Caregiver's Feeding Style Questionnaire), and role modeling and supportive skills for dietary intake (Parental Support and Role Modeling (PS-RM)). Linear regressions were calculated to predict child diet outcomes at 6 weeks based on PS-RM and feeding styles. When controlling for child's baseline diet, PS-RM measures taken at baseline ($F(2, 124) = 26.36$, $p < .000$, $R^2 = .30$) and post-intervention ($F(2, 118) = 31.24$, $p < .000$, $R^2 = .35$) significantly predicted post-intervention diet scores, such that parent support and role modeling positively predicted dietary behaviors in children ($\beta = .159$, $p < .05$), ($\beta = .236$, $p < .000$). When controlling for baseline diet, post-intervention parent-centered contingency management ($F(2, 118) = 26.95$, $p < .000$, $R^2 = .314$) significantly predicted post-intervention diet scores, such that contingency management practices negatively predicted dietary behaviors in children ($\beta = -.172$, $p < .05$). These findings suggest that parent influences such as role modeling and support of positive dietary behaviors, and decreasing the use of food and non-food related rewards, may positively predict healthy dietary behaviors among at-risk children. Given their importance on establishing healthful dietary patterns, future studies should involve parents in obesity prevention efforts.

THE SMARTER LUNCHROOM MOVEMENT: IMPLEMENTATION CHALLENGES FOR SCHOOLS SERVING LOW-INCOME CHILDREN AND ADOLESCENTS

Margaret Clark, B.S.¹, Joanna Buscemi, Ph.D.¹, Shannan D. Young, RDN, SNS²¹DePaul University, Chicago, IL; ²Dairy Council of California, Sacramento, CA

School meals are an important factor to consider in childhood obesity prevention efforts among low-income children, as schools may provide these students with up to two meals per day. The Smarter Lunchroom Movement (SLM) is an intervention designed to increase the consumption of nutrient-dense foods among students by promoting small, inexpensive changes to the school lunchroom. These strategies include naming foods fun names, putting fruits in attractive bowls and placing the healthiest items at the front of the lunch line. Overall, the SLM has been shown to be effective in nudging children toward more healthful food options. However, little research has investigated how implementation of these strategies may differ in schools serving low-income students. The purpose of this study was to determine the impact of school SNAP-Ed eligibility and percent of students receiving Free or Reduced Priced Meals (FRMP) on the change in SLM strategies implemented following a SLM intervention. Data was collected from 25 schools in California who collectively serve approximately 15,800 students. Training on SLM implementation was provided to schools, and scorecards were administered before and after interventions by school staff with the assistance of Technical Advising Professionals to determine pre-post change in number of SLM strategies implemented. Across schools, there were statistically significant differences in pre- ($M=40.68$, $SD=7.34$) and post- ($M=57.48$, $SD=13.25$) scorecard totals ($t(24)=-7.06$, $p<.000$), indicating that schools were able to implement significant changes to their school lunchrooms. However, change scores were significantly different among SNAP-Ed eligible ($M=13.00$, $SD=10.39$) and ineligible ($M=24.44$, $SD=11.19$) schools ($t(22)=-2.54$, $p<.05$), such that SNAP-Ed eligible schools implemented fewer new SLM strategies post-intervention. Linear regressions were calculated to predict scorecard change scores based on percentage of FRMP students in schools, and findings showed that FRMP significantly predicted scorecard change scores ($F(1,23)=9.61$, $p<.01$, $R^2=.304$) such that schools with higher percentages of students receiving FRMP negatively predicted change scores ($\beta=-.551$, $p<.01$). These findings suggest that schools serving low-income students may require additional resources in order to implement more SLM strategies. Future research should examine what additional resources may be required to increase SLM implementation in these schools.

TIME IS OF THE ESSENCE: THE IMPORTANCE OF SESSION LENGTH TO OUTCOMES IN BEHAVIORAL WEIGHT LOSS TREATMENT

Brittney Evans, BA¹, Gerald Martin, B.A.¹, Val S. Everett, B.A.¹, Evan Forman, PhD²¹Drexel University, Philadelphia, PA; ²Drexel University, Phila., PA

Introduction: Obesity is a serious public health concern and over 70% of Americans are overweight or obese. Behavioral weight loss treatment (BWL) is the first line of treatment for obesity. BWL generally produces weight losses of 5–10%, a benchmark associated with key health and quality of life benefits. In order to produce clinically significant weight loss, systematic reviews have concluded that an intensive duration of BWL is necessary (≥ 14 visits over a 6-month period; 22 sessions in 12 months). However, no systematic review to date has evaluated how individual session length influences weight loss outcomes.

Methods: A systematic review was conducted to identify articles that conducted in-person BWL in adults and reported individual session lengths. A 2014 systematic review investigating treatment duration in BWL was identified in the search. Results from this review were used as a basis of the current review, as inclusion criteria were similar, and the search was updated to identify articles reporting on BWLTs published since 2014. A regression was performed including treatment duration and number of sessions as covariates.

Results: A total of 25 studies were included. Session length (in minutes) was a significant predictor of weight loss when controlling for treatment duration (in weeks) and number of sessions ($B = -.06$, $SE = .02$, $t = -3.55$, $p = .001$). Confirming previous findings, treatment duration was also a significant predictor of weight loss ($B = -.05$, $SE = .02$, $t = -2.45$, $p = .02$). Number of sessions was not a significant predictor of weight loss in the model ($B = .04$, $SE = .03$, $t = 1.54$, $p = .013$).

Discussion: Results indicate that for every minute of additional session time in BWLT, participants lose .06% more weight when controlling for treatment duration and number of sessions. This amount is statistically as well as clinically significant. This finding has important implications for the design of BWLTs and suggests that individual session length as well as overall treatment duration should be carefully considered in order to optimize weight loss outcomes in BWLT programs.

AUTONOMOUS MOTIVATION AND ACTIVE FEEDBACK: INTERVENTION EFFECTS ON BODY MASS INDEX IN OVERWEIGHT UNDERSERVED YOUTH

Allison Sweeney, PhD¹, Dawn K. Wilson, PhD¹, Heather Kitzman-Ulrich, PhD², Ken Resnicow, PhD³, M Lee Van Horn, PhD⁴¹University of South Carolina, Columbia, SC; ²University of North Texas Health Science Center, Fort Worth, TX; ³University of Michigan, Ann Arbor, MI; ⁴University of New Mexico, Albuquerque, NM

Behavioral interventions that tailor around differences in social-cognitive factors hold great promise for engaging underserved groups in health behavior change. However, it remains unclear which aspects of one's values/beliefs are most critical for developing effective tailored interventions. In the present research, we examine whether future interventions may benefit from tailoring around individual differences in motivation. People's motivation for engaging in health behaviors range from autonomous (viewing a behavior as important/enjoyable) to controlled (viewing a behavior as a means to an end). According to Self-Determination Theory, people are more likely to maintain health behavior changes if they are autonomously motivated, and increases in competency and volition are essential for the development of autonomous motivation (AM). Thus, we propose that youth low in AM should be more responsive to interventions that foster volition/competency than youth high in AM. We hypothesize that behavioral skills training (BST), which promotes self-regulation through goals, planning and monitoring, should facilitate a lower z-BMI among youth low in AM relative to youth high in AM. As part of an 8-week intervention, youth ($N = 58$, Age $M = 12.7$, z-BMI_{baseline} $M = 2.1$, Income M 40k) enrolled in the Families Improving Together for Weight Loss trial completed weekly one-on-one BST sessions. During the BST sessions, the interventionist guided youth in creating a calorie goal and action-plan, provided feedback on progress, and reviewed youth's self-monitoring logs. The interventionist completed a weekly checklist, which was used to index the total number of times youth received feedback, set goals and engaged in self-monitoring. Linear regressions tested whether feedback, goal-setting and self-monitoring predicted z-BMI at post-intervention, and whether baseline AM for diet moderated these effects. Baseline youth z-BMI, attendance, family income, age and sex were covariates. There was a significant interaction between AM and goal feedback ($b = .03$, $SE = .01$, $p = .02$), but not goal-setting or monitoring. Among youth who started the program with relatively low AM, a greater level of goal feedback was associated with a lower z-BMI ($b = -.03$, $SE = .01$, $p = .04$). However, among youth who started the program with relatively high AM, goal feedback was not significantly associated with z-BMI ($b = 0.19$, $SE = .01$, $p = .15$). Thus, consistent with the proposed perspective that AM impacts how youth respond to different intervention components (presumably due to differences in volition/competency), we found that youth low in AM were more responsive to feedback. These results suggest that youth may have different needs/interests based on their motivation, and that tailoring intervention components to match differences in AM may be an effective strategy for increasing engagement.

COMPARING EFFECTIVENESS AND USER BEHAVIORS BETWEEN TWO VERSIONS OF A JUST-IN-TIME ADAPTIVE INTERVENTION FOR WEIGHT LOSS

Stephanie P. Goldstein, MS¹, Gerald Martin, B.A.¹, Gabrielle Turner-McGrievy, PhD MS RD², Gary Foster, PhD³, J. Graham Thomas, PhD⁴, Meghan Butryn, Ph.D.¹, James D. Herbert, PhD⁵, Evan Forman, Ph.D.¹¹Drexel University, Philadelphia, PA; ²University of South Carolina, Columbia, SC; ³Weight Watchers, Inc, New York, NY; ⁴Brown University School of Medicine & The Miriam Hospital, Providence, RI; ⁵University of New England, Biddeford, ME

Research suggests that even small lapses from a weight control diet could explain suboptimal outcomes in behavioral weight loss programs. Just-in-time adaptive interventions (JITAI) delivered via smartphone apps can allow for the prediction and prevention of lapse behavior through momentary alerts to risk. Our team developed an app (OnTrack) that has been programmed to: (a) record data via ecological momentary assessment (EMA) on dietary lapse behavior and variables known to predict lapses, (b) apply machine learning to determine risk of a dietary lapse, (c) alert individuals when risk is high, and (d) offer a brief text-based micro-intervention (approximately 150–250 words) tailored to momentary risk factors. Phases I and II trials of OnTrack provided initial evidence for the feasibility, acceptability, and effectiveness of the app. However, during app development, there has been a tension between reducing participant burden by assessing fewer questions per prompt and having a more complete dataset from which to generate lapse predictions. Given outstanding user compliance in the initial study phases (>85% over 8 weeks), we hypothesized that adding additional EMA questions per prompt to OnTrack would have no effect on EMA adherence, increase app usage behaviors (i.e., accessing the library of brief interventions, and opening alerts to lapse risk) via more time spent in-app, and enhance algorithm predictions via reduced missing data. In turn, we believe a version of OnTrack with additional EMA questions per prompt could enhance user outcomes (i.e., lapses and weight change). The study (current $n=37$, projected n by April 2018=112) evaluates these research questions by randomizing participants to use either the original app (i.e., eight questions per prompt; OT) or an app with a longer question distribution scheme (i.e., 16 questions per prompt; OT+) for ten weeks. Preliminary data thus far reveal small differences in percentage of completed EMA ($M_{OT}=76.1\%$ v. $M_{OT+}=71.7\%$) and percentage of opened risk alerts ($M_{OT}=51.2\%$ v. $M_{OT+}=50.6\%$). Participants in OT+ are accessing the intervention library more than the OT group ($M_{OT}=12.6$ v. $M_{OT+}=20.9$). Minimal differences in percent weight loss ($M_{OT}=-5.4\%$ v. $M_{OT+}=-5.2\%$) and reported lapses ($M_{OT}=30.0$ v. $M_{OT+}=27.8$) have been observed. Between-groups statistical differences, algorithm performance, and associations between app usage and outcomes (i.e., lapse reduction and weight loss) will be presented with the full sample in April. Results from the current study provide scientific insight into the association between app design and user behavior, as well as leveraging this relationship to enhance effectiveness of just-in-time technologies for weight loss.

DEPRESSION SUBTYPES AND LOSS OF CONTROL EATING IN SEVERE OBESITY

Caitlin E. Smith, B.S., Misty Hawkins, PhD

Oklahoma State University, Stillwater, OK

Background: Despite physiological and psychological differences across depression subtypes (melancholic vs. atypical), the role of these subtypes in eating and obesity is unclear. The atypical depression subtype may be particularly important given that it is characterized by somatic disturbances, including hyperphagia. Thus, one factor that may be influential in atypical depression is loss of control eating (LOC). LOC is the subjective sense of loss of control when eating and is often associated with higher caloric consumption. Adults with obesity and atypical depression may at an increased risk for LOC, which may account for obesity progression or maintenance.

Objective: To examine atypical vs. melancholic depression subtypes in relation to LOC among severely obese adults seeking bariatric surgery. We hypothesized that atypical depression would be associated with greater LOC compared to the melancholic subtype.

Method: The sample consisted of 334 obese adults (body mass index; $BMI \geq 35 \text{ kg/m}^2$) who received a pre-surgical evaluation for bariatric surgery (aged 46.27 ± 12.78 years; 75.9% female). The Beck Depression Inventory-II (BDI-II) was utilized to categorize depression subtypes. A patient was categorized with atypical depression if they endorsed both hyperphagia and hypersomnia symptoms. All other patients were categorized in the melancholic subtype. LOC was indexed by averaging the standard z -scores of two items on the Binge Eating Scale (BES). The hypothesis was tested using a one-way ANCOVA covarying for age, gender, and BMI.

Results: An ANCOVA comparing the depression subtypes revealed a significant effect of depression subtype on LOC, $F(1,334) = 10.3, p \leq .001$. Patients with the atypical subtype endorsed LOC scores that were 43% higher than the sample average after controlling for BMI.

Conclusions: Adults with severe obesity and an atypical depression subtype exhibited significantly higher LOC compared to their severely obese peers with a melancholic subtype. These cross-sectional results suggest that obese adults with atypical depression may be at an increased risk for LOC but could also point to a third variable issue, where LOC and atypical depression are driven by a shared external factor. Future studies testing directionality and potential confounders and mechanisms are critical.

DEVELOPMENT AND CAPACITY EVALUATION OF A PARENT ADVISORY TEAM ENGAGED IN CHILDHOOD OBESITY RESEARCH

Ramine C. Alexander, PhD MPH¹, Paul Estabrooks, PhD², Donna J. Brock, MS³, Jennie Hill, PhD², Melicia Whitt-Glover, PhD⁴, Jamie Zoellner, PhD³

¹UNC-Chapel Hill, Chapel Hill, NC; ²University of Nebraska Medical Center, Omaha, NE; ³University of Virginia, Christiansburg, VA; ⁴Gramercy Research Group, Winston-Salem, NC

OBJECTIVE: Guided by community-based participatory research principles, this mixed-methods process evaluation examined the capacity of a newly developed Parental Advisory Team (PAT) engaged in childhood obesity research in a medically underserved region.

METHODS: Following the successful completion of a 3-month evidence-family-based childhood obesity treatment program (*iChoose*), 26 parents/caregivers who completed 18 sessions ($\geq 50\%$) of *iChoose* were contacted to participate in the PAT; 39% ($n=10$) consented. Between June 2015 and March 2016, the PAT had 9-monthly meetings with the purpose of building capacity to develop and pilot test maintenance phase intervention sessions and support future *iChoose* efforts. During the first 4 meetings, the PAT engaged in key activities related to understanding *iChoose* program outcomes and defining their role and purpose as a partnership. During the next 5 meetings, the PAT initiated content development and pilot testing of intervention sessions for an *iChoose* maintenance phase. Assessments included a 39-item quantitative survey at baseline and 9-month follow-up and a 12-item qualitative interview at follow-up.

RESULTS: Survey data indicated that PAT members perceptions of the identified capacity, dimensions (i.e. collective efficacy, communication, community's power, leadership, participation and influence, problem assessment, personal and community influence, satisfaction) were positive at baseline (3.8–4.3 on 5-point scale) and remained positive at follow-up (3.9–4.4 on 5-point scale); changes were not statistically significant. Qualitative data revealed that PAT members understood their roles and were confident that the continuation of monthly meetings would lead to future capacity improvements. Prioritized by the PAT, *iChoose* maintenance sessions focused on activities such as healthy snack and meal preparation, group-based physical activity opportunities, and body image concerns among youth. The PAT also engaged in the development of a Patient Centered Outcomes Research Institute grant proposal.

CONCLUSION: Despite the small sample size, the PAT was able to develop and pilot test weight maintenance activities, participate in grant development, and remain engaged throughout the CBPR process. Engaging parents as key collaborators and equal partners in research efforts and understanding changes in their capacity fills an important gap in the childhood obesity treatment literature.

DIET, SEDENTARY BEHAVIOR, AND PHYSICAL ACTIVITY RATES AMONG HISPANIC CHILDREN IN RURAL COMMUNITIES

Linda K. Ko, PhD¹, Eileen Rillamas-Sun, PhD¹, Sonia Bishop, BS¹, Norma Mariscal, BS¹, Oralia Cisneros, Washington², Sarah Holte, PhD¹, Yesol Kim, N/A¹, Eric J. Choi, MS¹, Beti Thompson, PhD¹

¹Fred Hutchinson Cancer Research Center, Seattle, WA; ²Sunnyside School District, Seattle, WA

Background: Hispanic children in rural communities are disproportionately obese compared to their urban counterparts. Little is known about obesogenic behaviors in this population. This study assessed the relationship between diet, sedentary behavior, physical activity (PA), and Body Mass Index (BMI) among Hispanic children in Eastern Washington rural communities.

Methods: Together We STRIDE is a community-based obesity intervention trial (n=665). A subset of the children (n=167) were measured on diet (fruit, vegetable, and sugar-sweetened beverage (SSB) intakes), sedentary behavior, and PA by wearing an accelerometer at baseline. Eligible Hispanic children were ages 8–11 (grades 3–4). Means and frequencies were estimated using t-tests or Chi-square tests. We built linear regression models to estimate the association of diet and PA on BMI Z-scores adjusting for gender and accelerometer wear time.

Results: Participants' mean (SD) age was 9.5 (0.6) years and half were boys. Mean BMI-percentile was 76.9 (26.1), and BMI Z-score was 1.05 (1.04). Mean daily intake of fruits was 1.3 (0.5) cups and 0.9 (0.3) cups of vegetables. Mean SSB intake was equivalent to 5.5 (2.5) teaspoons, with boys consuming more than girls (p=0.004). Mean weekend day sedentary time was 6.4 (3.6) hours per day, and boys spent more hours sedentary than girls (p=0.02). Of sedentary hours, 4.9 (3.2) were screen time; boys had more screen time than girls (p=0.001). Mean daily moderate and vigorous PAs were low with 29.4 (12.1) minutes and 11.3 (8.4) minutes respectively. Boys engaged in more moderate (p=0.003) and vigorous (p=0.04) PA than girls. There was a significant association of SSB intake on BMI Z-score (p=0.07); for every 1 teaspoon increase in daily SSB intake, Z-score was higher by 0.71. There was a reverse association of moderate and vigorous PA on Z-score, for every 1 minute increase in moderate PA, Z-score was lower by 0.04, and 0.05 for vigorous PA.

Conclusion: Hispanic children in rural communities did not meet the daily recommendations for fruit and vegetable intakes. Children spent more than double the daily recommended limit of 1–2 hours in front of a screen and achieved less than the daily recommendation of 60 minutes for moderate-vigorous PA. SSB intake and all levels of PA impacted children's BMI regardless of gender. The findings underscore the need for lifestyle behavior interventions for Hispanic children in rural communities.

DOES GROUP SIZE MATTER IN AN ONLINE BEHAVIORAL WEIGHT CONTROL PROGRAM WITH FACILITATED CHATS?

Delia West, PhD¹, Jean Harvey, PhD², Rebecca Krukowski, PhD³

¹University of South Carolina, Columbia, SC; ²University of Vermont, Burlington, VT; ³University of Tennessee Health Science Center, Memphis, TN

Purpose: Data suggest behavioral weight control delivered in a group format may offer better outcomes than the same intervention delivered individually. However, group size varies considerably in the reported literature and no data inform how group size in online weight control might influence outcomes. Therefore, we compared program engagement and weight losses based on group size.

Methods. Overweight individuals (N= 495, mean BMI = 35.7, mean age= 48.4 years, 90% women, 24% African American) engaged in an online group-based behavioral weight control program were treated in 27 separate groups ranging in size from 13 to 21 participants as part of a randomized controlled trial examining the addition of motivational interviewing to group-delivered behavioral weight control. At study entry, participants indicated times they were available to meet and were then assigned to a group based on their stated availability. All participants were offered 24 weekly synchronous chat sessions moderated by an interventionist and each chat sessions followed a protocol-specified treatment content. Groups were closed and did not admit new members after the initiation of intervention. Weight was measured at 6-months. Correlations between group size and attendance at chat sessions, 6-month weight loss and number of drop outs (i.e., participants failed to get weight measured at 6-months) within the group were examined.

Results. On average, individuals successfully lost weight, with mean weight losses of 5.9 kg at 6-months, and no differences between treatment conditions. Participants attended an average of 15.7 (out of 24) chats and a 10% drop out rate was observed. There was no association between group size and weight loss (r=-0.20, p=0.32) or between group size and program attrition (r=0.09, p=0.66). However, there was a significant positive association between group size and chat attendance (r= 0.70, p

Conclusion. Larger group size was significantly associated with higher attendance at online group chats, although there was no association between group size and weight losses achieved in the program. This suggests that larger group size may promote greater engagement in online behavioral weight control interventions. However, because individuals were not randomly allocated to group sizes, these findings must be viewed as hypothesis generating and are in need of examination in a prospective experimental design before definitive conclusions on the optimum structure for online group-based programs. Data on treatment factors associated with group size will offer critical program design guidance to researchers, treatment providers and policy makers.

DOES PLACE MATTER? PERCEPTIONS OF NEIGHBORHOODS AS PREDICTORS OF TREATMENT OUTCOME IN A CHILDHOOD OBESITY PREVENTION STUDY

Nana Yaa A. Marfo, B. Phil¹, Michelle Cloutier, M.D.², Amy A. Gorin, Ph.D.³¹University of Connecticut, Machester, CT; ²UCONN Health Center, Farmington, CT; ³University of Connecticut, Storrs, CT

Introduction: Though social ecological models of health and cross-sectional studies have established a relationship between neighborhood environment and weight status, few have looked at how these environmental factors influence response to obesity intervention in adults or children (e.g. Farley et al., 2007; Kerr et al., 2010). This study explored these potential links in children ages 2 to 4 years of age in an obesity prevention study conducted in Hartford CT, one of the poorest, mid-sized cities in the country. We hypothesized that 1) lower scores on four key neighborhood environmental factors (i.e. accessibility, walkability, neighborhood surroundings, and safety) would predict poorer response to treatment than higher scores, and 2) neighborhood safety would be the strongest predictor of these outcomes.

Methods: Prior to the start of the primary care-based intervention program (Cloutier et al., 2015), parents (n=200) completed a modified version of the *Neighborhood Environmental Walkability Scale (NEWS)* to assess their perceptions of their child's neighborhoods. Baseline responses were analyzed as potential predictors of BMI percentile change from baseline to one-year follow-up.

Results: Parents endorsed relatively high levels of accessibility, walkability, safety, and favorable neighborhood surroundings (i.e. means of 3 or higher on a scale of 1–4). While variation in BMI percentile change was observed (M = 0.10; SD = 20.05), none of the environmental factors predicted intervention outcomes ($p \geq 0.23$).

Discussion: The results of the present analyses suggest that parental perceptions of the neighborhood environment may not be relevant in predicting treatment outcomes. Future studies should utilize more objective measures of neighborhood design to study the relationship between environmental factors and obesity intervention outcomes. Furthermore, studies comparing neighborhoods across different cities might help illuminate the potential relationship between disparate neighborhood conditions and treatment outcomes.

EFFECTIVENESS OF A PEER-LED, COMMUNITY-BASED WEIGHT LOSS INTERVENTION FOR RURAL ADULTS

Kristine Zimmermann, MPH¹, Manorama M. Khare, PhD², Vicki Vicki Weidenbacher-Hoper, MSW³, Martin MacDowell, DrPH²¹School of Public Health, University of Illinois at Chicago, West Chicago, IL; ²College of Medicine at Rockford, University of Illinois at Chicago, Rockford, IL; ³University of Illinois College of Medicine Rockford, Rockford, IL

Background: Rural adults in the US have disproportionately high obesity rates compared to non-rural adults. Effective, accessible, and sustainable strategies are needed to reduce obesity in rural adults. Win With Wellness (WWW) is a collaborative partnership in two rural counties in northwest Illinois with a goal of addressing obesogenic behaviors using multiple strategies. One such strategy is the implementation of community-based weight loss groups.

Methods: WWW recruits and supports community-based partners to implement a weekly, group-based, peer-led, weight loss groups using an evidence-based intervention. Participant data, including demographics, weight, health status, and physical activity (PA) and dietary behaviors, were collected at baseline and one-year follow-up. Using paired and two-sample t-tests, we assessed participant changes in weight over one year, as well as demographic, health-related, and behavioral factors associated with weight loss.

Results: To date, WWW has partnered with businesses, community organizations, and healthcare agencies to initiate 26 weight loss groups. At the time of analysis, eight groups had completed one-year follow-up (n=49 participants). Overall, participants had significant reductions in weight and body mass index (BMI) from baseline (weight: M=206.1, SD=42.9; BMI: M=33.1, SD=5.6) to one year (weight: M=194.1, SD=41.5, $p < .0001$; BMI: M=31.1, SD=5.9, $p < .0001$). Smaller reductions in weight were associated with non-white race ($p = .0001$), high school education or less ($p < .05$), and having a Type 2 diabetes diagnosis ($p < .0001$). Additionally, while meeting recommended PA guidelines at baseline was not associated with weight loss ($p = .95$); meeting recommended PA guidelines at one-year follow-up was associated with greater weight loss ($p = .0007$).

Conclusions: Community-based weight loss groups can be effective for addressing obesity in rural adults, and peer leadership of weight loss groups for rural adults may provide a feasible and sustainable solution. Weight loss outcomes for rural adults may be improved through promoting PA and addressing barriers to PA engagement. However, interventions may require additional tailoring and support to address participant needs, such as barriers to participating in weight loss programs and having multiple chronic health issues.

10:00 AM-11:00 AM

EFFECTIVENESS OF THE NATIONAL DIABETES PREVENTION PROGRAM FOR AFRICAN AMERICANS, INCLUDING BY GENDER AND AGE

Natalie D. Ritchie, PhD¹, Phoutdavone Phimphasone-Brady, PhD²¹Denver Health; University of Colorado School of Medicine, Denver, CO; ²University of Colorado, Anschutz Medical Campus, Aurora, CO

Introduction: Reducing diabetes and obesity risk is a public health priority, especially for racial/ethnic minority groups who experience related health disparities. The National Diabetes Prevention Program (NDPP) is a widely disseminated, evidence-based lifestyle intervention that promotes moderate weight loss to prevent diabetes. Yet, previous research suggests that the NDPP is least effective for non-Hispanic black (NHB) participants in terms of weight loss outcomes. Studies have also shown that women, including younger women in particular, have disparately worse NDPP outcomes than men. This study aims to assess whether there are gender and age differences in NDPP outcomes among NHBs, which is currently unknown, yet important for developing tailored program improvements.

Methods: The NDPP was delivered in an urban safety net healthcare system to adults with diabetes risks (e.g., A1c 5.7–6.4). In an observational study, we compared attendance and weight loss outcomes among 487 eligible NHB and non-Hispanic white (NHW) individuals who enrolled in the program, including differences by gender and age. Age differences were examined using a median split (median=52.0 years). Data were collected between 2013–2017. Analyses were conducted in 2017.

Results: There were no significant differences between NHW (n=224) and NHB (n=263) enrollees in income, age, gender, baseline body mass index, or baseline hemoglobin A1c. NHB enrollees were 37% less likely to attend at least one NDPP session in adjusted models (OR=0.63; 95%CI 0.43–0.93) than NHW enrollees. In particular, younger NHBs enrollees were almost half as likely to attend one or more sessions (OR=0.54, 95%CI 0.32, 0.90) than older NHB enrollees. However, there were no significant differences in total attendance or weight outcomes. No significant gender differences in NDPP outcomes were found among NHBs. Both groups had 3.1% (SD=5.6) mean weight loss.

Conclusions: While NHB enrollees were less likely to attend the NDPP, once engaged they achieved similar weight loss than NHW enrollees, including across gender and age groups. This study highlights the need for earlier and more intensive efforts to engage NHBs with diabetes risks in the NDPP, especially for younger individuals.

EFFECTS OF PARENT PERCEIVED STRESS AND ADOLESCENT WEIGHT-RELATED CONCERNS ON BMI IN OVERWEIGHT AFRICAN AMERICAN ADOLESCENTS

Haylee Loncar, Experimental Psychology, B.S.¹, Allison Sweeney, PhD¹, Dawn K. Wilson, PhD¹, Claire M. Miller, MPH, MSW¹, Elizabeth L. Lombardo, BS²¹University of South Carolina, Columbia, SC; ²University of South Carolina, Chester, SC

Family Systems Theory highlights the importance of positive parenting in creating nurturing and supportive environments for youth. Previous studies have shown that parental practices can influence youth health behaviors such as adolescent weight. Although the effects of parental practices on adolescent health have been examined, limited research has been conducted regarding its relationship with parent perceived stress and with adolescent obesity and adolescent weight-related concerns. The present study assessed the impact of parent perceived chronic stress and parenting practices related to food restriction, feeding responsibility, monitoring and adolescent weight-related concerns on adolescent zBMI. It was hypothesized that less positive parent feeding practices and higher parent perceived stress would interact in predicting poorer adolescents' zBMI outcomes among families enrolled in the Families Improving Together (FIT) for Weight Loss trial. Data were collected from African American adolescents (N =115; M_{age} = 12.98; 64.3% female) and their parents (N =115; M_{age} = 45.01; 93% female; M_{income} <40k) who took part in Project FIT. Parent perceived stress was self-reported using the Cohen Perceived Stress Scale and parenting practices, including adolescent weight-related concerns, were self-reported by adolescents using the Birch Child Feeding Questionnaire. Adolescent zBMI was calculated using objective measures of height and weight and were standardized using CDC growth curves. Age, parent BMI, and family yearly income were covariates. Linear regression analyses demonstrated a significant interaction between parent perceived stress and adolescent weight-related concerns in predicting adolescent zBMI ($b = .13, SE = .06, p < .05$). This interaction revealed that higher adolescent zBMI was associated with higher parental stress and higher adolescent weight-related concern as compared to those with low perceived stress and low weight related concerns. These results suggest that parental perceived stress level is related to adolescent weight-related concerns and adolescent weight status, and should be the focus of future health promotion programs in underserved African American adolescents.

IMPACT OF A SCHOOL-BASED WEIGHT MANAGEMENT PROGRAM ON MEXICAN-AMERICAN ADOLESCENTS DURING THE SUMMER MONTHS

Layton M. Reesor, BA¹, Arlinghaus Katherine, MS, RD², Jennette P. Moreno, PhD³, Craig Johnston, PhD², Daphne C. Hernandez, PhD, MEd²¹University of Houston, Katy, TX; ²University of Houston, Houston, TX; ³Baylor College of Medicine, Houston, TX

BACKGROUND: Mexican-American adolescents have the highest obesity rates of any race/ethnic group. Schools are an ideal location to provide weight management education as a large majority of adolescents attend public schools. While school-based weight management programs have been able to create short-term success, maintenance of weight management remains an important research area. One potential factor for lack of long-term success in school-based programs is that benefits are lost during the summer.

OBJECTIVE: The purpose of this study was to examine seasonal weight patterns in low-income Mexican-American middle school students and the impact of a school-based weight management program on these patterns. The first aim of this study was to evaluate changes in students' standardized body mass index (zBMI) during the school year compared to the summer when not enrolled in a weight management program (e.g. control condition). The second aim of this study was to compare the impact of the program on school year zBMI and summer zBMI.

METHODS: Middle school students (n=425) were recruited from a primarily Mexican-American (95%) school in Houston, Texas. Participants were randomly assigned to a weight management (n=230) or control condition (n=195). Height and weight were measured at baseline, spring (March-May), and the beginning of the next school year (August-October). All analyses evaluated healthy weight and overweight/obese students separately. Paired sample t-tests compared zBMI change scores during the school year versus summer. Two-by-two repeated measures ANOVAs determined program group differences in zBMI scores across school versus summer periods.

RESULTS: Among the control group, students' zBMI scores changed differently during the summer compared to the school year ($p < .001$). Students' zBMI scores decreased during the school year ($p < .001$) for both healthy weight and overweight/obese students. Program participants showed similar changes (e.g. school year decreases and summer increases) ($p < .05$). However, zBMI did not differ by program status for healthy weight students. Students who were overweight/obese in the program decreased zBMI during the school year ($p < .01$) and increased zBMI to a lesser extent over the summer ($p < .01$) compared to the control group.

CONCLUSION: A school based weight management program provides some protection against summer weight gain among Mexican-American middle school students.

INTERACTIVE PHYSICAL ACTIVITY LAB: UTILIZING EXPERIENTIAL EDUCATION TO PROMOTE BEHAVIOR CHANGE AMONG CHILDREN AND YOUTH

Holly Kihm, PhD, CCLS, CFLE, Sarah Taravella, NA, Callie Lambert, NA
Southeastern Louisiana University, Hammond, LA

In Louisiana, 28% of children are overweight or obese, two-thirds do not meet physical activity recommendations, and more than half fail to meet fitness standards. Latest trends show a need for innovative interventions and creative motivational techniques to be used while working with children who struggle with weight management. The purpose of the project was two-fold: (1) to teach university students assessment skills needed to work more effectively with youth who struggle with maintaining a healthy weight, and (2) to implement two interventions aimed toward increasing physical activity participation.

Twenty-one children participated in the project. First, their preferences for exergaming versus using traditional cardio equipment were assessed. Results showed participants who chose exergaming spent more time participating in physical activity than participants who chose traditional cardio equipment ($p = .010$).

The first intervention examined the role of competition to elicit vigorous intensity physical activity, measured by heart rate, while exergaming. Competition was manipulated through both performance-based praise and two-player competitive play. Intensity was significantly higher following the performance-based praise vs. pre-praise ($p < 0.05$), and the post-praise session reached vigorous intensity (67% HR_{max} vs. 59% HR_{max}). Heart rate did not differ between competitive play vs. solitary play ($p = 0.06$), but both sessions met vigorous intensity criteria (70% HR_{max} vs. 65% HR_{max}).

The second intervention tested the efficacy of auditory and visual stimuli to increase children's physical activity intensity while exercising. The children participated in four exercise conditions (treadmill with/without music and cycling with/without video). Heart rate and distance travelled were monitored. T tests were used to compare %HR above rest between conditions. Results showed that children reached levels of vigorous intensity in all conditions. There was a small but non-significant effect in %HR above rest in the expected direction for the treadmill activity (94 ± 18 with music and 87 ± 18 without music, Cohen's $d = 0.39$) but in the unexpected direction for the cycling activity (49 ± 25 with video and 59 ± 30 without video, Cohen's $d = 0.37$). There were no differences in other heart rate metrics or in distance travelled.

Increasing opportunities for competition and utilizing a variety of auditory and visual stimuli, may lead children to participate in longer, more intensive bouts of physical activity, which is important for good physical health and weight management.

IS EARLY WEIGHT LOSS A TREATMENT-SPECIFIC OR GENERAL PREDICTOR OF WEIGHT LOSS SUCCESS?

Jena Shaw Tronieri, PhD¹, Thomas Wadden, PhD¹, Ariana M. Chao, PhD, CRNP², Rebecca L. Pearl, PhD¹, Naji Alamuddin, MB BCh, MTR³, Robert Berkowitz, MD²

¹Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA; ²University of Pennsylvania, Philadelphia, PA; ³Perelman School of Medicine of the University of Pennsylvania, Philadelphia, PA

Background: Early weight loss (EWL) in the first 1–2 months of behavioral treatment is a strong predictor of total loss at later follow-up points. However, no studies have examined whether this relationship is attributable to the early differences alone or to ongoing differences in treatment response. Further, no study has investigated whether EWL in behavioral treatment predicts weight loss when a different treatment modality, such as pharmacotherapy, is introduced.

Methods: Data were from 170 participants with obesity (baseline BMI = 40.8 ± 5.8 kg/m², age = 44.5 ± 11.1 yrs; 87.6% female; 71.3% black, 21.8% white) who enrolled in a two-phase trial. Data from the weight loss phase, which provided weekly lifestyle counseling and a 1000–1200 kcal/d meal replacement diet, were used to examine the relationship between EWL (i.e., 4-week) and subsequent rate of weight loss in behavioral treatment. Data from the maintenance phase, in which participants who had lost $\geq 5\%$ of initial weight were randomized to 52 weeks of maintenance counseling with lorcaserin or placebo, were used to determine whether EWL with behavioral treatment moderated the effect of medication condition or predicted weight change among lorcaserin-treated participants.

Results: EWL in the first 4 weeks of behavioral treatment ($3.6 \pm 1.7\%$) predicted greater total losses ($r^2 = .61$, $p < .001$) and a faster rate of weight loss in the subsequent 9 weeks of the program ($b = -0.11$, $SEb = 0.02$, $p < .001$). However, EWL in behavioral treatment did not moderate the efficacy of lorcaserin, in comparison to placebo, for the maintenance of lost weight and did not predict total weight loss or rate of weight change among lorcaserin-treated participants.

Conclusions: EWL predicted subsequent weight loss in a behavioral treatment program, but did not predict weight change with pharmacotherapy. These findings suggest that EWL is a treatment-specific indicator of a patient's potential to successfully lose weight and support recommendations to modify treatment for individuals with poor early weight loss.

LOCUS OF CONTROL AND WEIGHT LOSS AFTER BARIATRIC SURGERY FOR OBESITY

Amanda Lynch, PhD, RD¹, Kerstyn C. Zalesin, MD²

¹Oakland University, Rochester, MI; ²William Beaumont Hospital, Royal Oak, MI

Background: Bariatric surgery for obesity results in drastic, sustainable weight loss for most recipients. However, not all are successful. Locus of control theory may help explain differences in weight loss outcomes. Individuals with an internal locus of control believe they determine their outcomes, while those with an external locus of control believe outside forces determine their outcomes. This world-view orientation may impact weight management behaviors. We hypothesized that high internal locus of control would lead to greater weight loss post-bariatric surgery.

Methods: 30 pre-bariatric surgery patients were recruited to participate in a mixed methods study of dietary and weight changes after bariatric surgery. 22 participants were available for a 12-month follow-up and completed a series of questionnaires. Locus of control was measured using two validated scales: Weight Locus of Control Scale (WLOC) and Levenson's Internality, Control and Powerful Others Scale (ICP), which is a general measure of control orientation. Weight and height were obtained from the medical records pre-surgery, one year and two years post-surgery. Nonparametric statistics were used to test relationships between scores on the locus of control scales and weight outcomes (percent weight loss, total weight lost, and change in BMI).

Results: Mean BMI decreased from 47.1 kg/m² pre-surgery to 33.5 kg/m² at one year. Mean BMI at 2 years was 33.8 kg/m². Neither pre-surgery BMI nor pre-surgery weight loss correlated with locus of control measures. At one year, WLOC was not related to weight loss outcomes. At 2 years, higher scores (indicating external weight locus of control) negatively correlated with weight outcomes ($p < 0.05$). The ICP subscales related to weight outcomes as follows: Scores on Internality negatively correlated with weight outcomes ($p < 0.01$) at both time points. Scores on Powerful Others also negatively correlated with weight outcomes at 2 years ($p < 0.05$). No relationship was found between Chance and weight outcomes at either time point. Internality scores were not related to WLOC scores, but scores on Powerful Others and Chance positively correlated with WLOC ($p \leq 0.001$).

Conclusion: Higher internal locus of control orientation was associated with less weight loss following bariatric surgery, contrary to the predicted relationship. Higher externality scores for WLOC were associated with less weight loss, consistent with the hypothesis. Further research is needed to explain these discrepant findings.

OPPORTUNITIES FOR OBESITY MANAGEMENT IN US PRIMARY CARE PRACTICES

Jodi Summers, Holtrop, PhD¹, Phoutdavone Phimphasone-Brady, PhD², Zhehui Luo, PhD³, Mark Gritz, PhD¹, Rowena Dolor, MD, MHS⁴, Hanyue Li, M.A.⁵, Laurie Fitzpatrick, BS⁶, Lauri Connelly, MS⁷, Nikita Shah, BS⁴

¹University of Colorado School of Medicine, Aurora, CO; ²University of Colorado, Anschutz Medical Campus, Aurora, CO; ³Michigan State University, East Lansing, MI; ⁴Duke University School of Medicine, Durham, NC; ⁵Michigan State University Department of Epidemiology and Biostatistics, Lansing, MI; ⁶Michigan State University, Grand Rapids, MI; ⁷University of Colorado, Aurora, CO

Background: In November 2011, the Centers for Medicare and Medicaid Services approved the use of a new Healthcare Common Procedure Coding System code in primary care for providing Intensive Behavioral Therapy (IBT) services for obese patients. Despite the widespread prevalence of obesity in the Medicare population, use of this benefit has been low suggesting significant underutilization of this service. The study objective is to describe provider experiences billing services for IBT for obesity from 2012 - 2015 and strategies used by providers successfully delivering and being paid for this service.

Methods: Descriptive, exploratory study using the Medicare Provider Utilization and Payment Physician and Other Supplier Public Use Files, written surveys and telephone interviews. Descriptive statistics and qualitative thematic analysis was used. Participants included primary care providers who have utilized the benefit for more than 10 unique patients in at least one calendar year.

Results: Approximately 38% of the almost 32.3 million Medicare full/nearly full fee-for-service beneficiaries in 2012 met obesity criteria, however, only 28,135 received IBT for obesity from all providers billing this service. In 2015, 80,333 beneficiaries received IBT for obesity from such providers and yet this still represents less than 1% of obese beneficiaries. Data from 2015 reveal that most claims were filed by primary care providers in the South (587), followed by the Northeast (472), West (339), and Midwest (195). Most providers were internal medicine (865) or family medicine (559) practitioners. Examining providers' use of this payment over time reveals varying patterns of stopping, starting and continuing use between 2012–2015. Qualitative analysis of interview data reveals specific models of providing IBT used by providers such as group visits, specific training and programs, and use of specific provider types (usually nurse practitioners or registered dietitians). However, even among regular IBT providers, complaints about the barriers to use of the benefit were significant and include inadequacy of reimbursement, limitations on provider type approved for use and difficulties with billing and payment.

Conclusions: The Medicare IBT for obesity payment code is severely underutilized. Even among practices utilizing it, there are significant barriers to use. Policy changes are likely needed to improve the assistance provided to obese patients in the primary care setting.

RESPONSE TO A WEIGHT MANAGEMENT PROGRAM: RURAL VS. URBAN DWELLING INDIVIDUALS

Anna M. Gorczyca, PhD¹, Richard Washburn, PhD¹, Jeff Honas, MS¹, Joseph Donnelly, ED.D.²

¹University of Kansas Medical Center, Lawrence, KS; ²University of Kansas Medical Center, Kansas City, KS

Individuals living in rural communities have lower levels of physical activity, consume less healthy diets, and have higher rates of obesity compared to urban residents. Residents of rural communities have diminished opportunities for physical activity and access to healthy nutrition options (e.g., food desert) compared to their urban dwelling counterparts and this may diminish weight loss efforts of rural residents compared to urban residents. However, the differential effectiveness of behavioral weight management interventions delivered to overweight/obese rural or urban adults is unknown. Data from a recently completed 18 mo. weight loss (0–6 mos.) and maintenance (7–18 mos.) trial allowed for an evaluation of rural/urban differences in response to the same weight management intervention (Donnelly et al., Obesity, 2013).

Methods: Overweight and obese adults (N=267, age= 45.5 years, 67% female) participated in a randomized equivalency trial to compare a behavioral weight management delivered face-to-face (FTF) or by group conference calls (GP). Weight change between the FTF and GP arms was equivalent at both 6 and 18 mos., thus data from both groups was combined for this analysis. Participants were prescribed a reduced energy diet (1,200–1,500 kcal/d.), increased physical activity (300 min./wk.), and were asked to attend 60 min behavioral sessions each week during weight loss. During maintenance participants were prescribed energy intake sufficient to maintain weight loss, 300 min./wk. of physical activity, and asked to attend 60 min behavioral sessions/biweekly. Energy intake was assessed using 3-day diet records. Physical activity and sedentary time were assessed in a sub-sample (n=161) using an ActiGraph GT1X portable accelerometer. Rural/urban status was determined using the American Fact Finder web site maintained by the US Census Bureau. The Kruskal-Wallis nonparametric test was used to compare weight change, energy intake, physical activity, and sedentary time between rural and urban participants using SAS 9.4.

Results: Out of the 267 participants, 36 were considered rural dwelling. Weight change from baseline to 6 months was significantly greater in rural participants $-15.3 \pm 7.4\%$ compared to urban $-13.2 \pm 6.9\%$ ($P = 0.0359$). Weight change from baseline to 18 months was $-9.4 \pm 8.5\%$ and $-7.7 \pm 8.2\%$ ($P = 0.3397$) for rural and urban participants, respectively. Total energy intake at 6 months was significantly lower in rural participants (1349 ± 332 kcals) compared to urban participants (1510 ± 429 kcals) ($P = 0.0394$). There were no differences in physical activity or sedentary time between rural and urban participants.

Conclusions: Despite disparities in opportunities for physical activity and diet, rural dwelling individuals lose and maintain weight comparable to their urban counterparts.

STAYING ON TRACK: THE ASSOCIATION BETWEEN PERCEIVED EFFORT, IMPORTANCE, AND SELF-WEIGHING BEHAVIOR

Abraham Eastman, M.A.¹, Brittney N. Dixon, M.P.H.¹, Aviva Ariel-Donges, M.S.¹, Eliza L. Gordon, M.S.², Vivian Bauman, B.S.³, Michael G. Perri, PhD¹, Kathryn M. Ross, Ph.D. M.P.H.¹

¹University of Florida, Gainesville, FL; ²University of Florida, Gainesville, FL; ³University of Florida, Clinical and Health Psychology, Gainesville, FL

Introduction: Consistent and frequent self-monitoring of body weight has been linked with improved weight loss outcomes in behavioral weight management programs, yet adherence to self-weighing can be challenging for participants. Preliminary qualitative research suggests that barriers to self-weighing includes factors such as perceived effort of self-monitoring and the impact of competing life priorities. The proximal association between these factors and self-weighing behavior during a weight management intervention, however, is unknown.

Methods: The current study examined the week-to-week association between perceived effort, relative importance of weight loss, and self-weighing during a 12-week, Internet-based weight management program. Participants were 74 overweight/obese adults (mean±SD age=50.6 ± 10.4 years, BMI=31.1 ± 4.4kg/m², 69% Female, 84% White) who logged onto a study website each week to submit self-monitoring information and to rate (on a 7-point Likert scale) perceived effort and importance of “staying on track” with program goals.

Results: On average, participants self-weighed 6.8±.87 days per week during the 12-week program. Mean effort throughout the intervention was 4.8 ± 1.6 and importance was 5.2 ± 1.5. A two-level longitudinal multilevel model demonstrated that self-weighing frequency decreased over time, $\beta=-.03$, $p\beta=.05$, $p=.035$, such that participants self-weighed on more days during weeks that they reported higher importance of staying on track with program goals. There was no association between perceived effort of staying on track and self-weighing, $p>.05$.

Discussion: The current study was the first to prospectively examine the impact of perceived effort and importance of staying on track with program goals for participants in a behavioral weight management intervention. Results demonstrated that self-weighed more frequently on weeks that they reported higher importance of staying on track, relative to other competing priorities. Given that self-weighing information and ratings were collected at the same time, these results could be interpreted in three ways: 1) greater relative importance of staying on track led to more frequent self-weighing; 2) on weeks where an individual engaged in less self-weighing, they decreased their ratings of importance of staying on track; 3) a third factor influenced both perceived importance and self-weighing. Future research should investigate whether perceived importance of staying on track can predict self-weighing frequency, and whether this may be an important treatment target during intervention.

TRANSLATING THE GROUP LIFESTYLE BALANCE PROGRAM FOR USE IN PEOPLE WITH ARTHRITIS: EFFECTS ON BIOMARKERS OF CARDIOMETABOLIC RISK

Cheryl Der Ananian, PhD¹, Natasha R. Birchfield, MS², Aubry Merkel, BS³, Sonia Vega-López, Ph.D.¹

¹Arizona State University, Phoenix, AZ; ²Arizona State University, Chandler, AZ; ³Arizona State University, Tempe, AZ

Background: While weight loss is recommended for people with osteoarthritis, there are few evidence-based programs available to guide weight loss efforts. Co-morbid conditions including diabetes and cardiovascular disease are common among individuals with arthritis and it is well established that weight loss can also benefit these conditions. The Group Lifestyle Balance (GLB) ProgramTM is an effective program for weight loss among individuals with prediabetes or metabolic syndrome but it has not been evaluated in people with arthritis specifically.

Purpose: The purpose of this pilot study was to evaluate the efficacy of an adapted version of the GLB on markers of cardiometabolic risk in overweight individuals (Body Mass Index (BMI) ≥27 kg/m²) with arthritis.

Methods: A single-group, pre-post design was used to examine the effects of an adapted GLB program on cardiometabolic risk factors (fasting serum glucose, lipids, insulin, and high-sensitivity C-Reactive Protein [hs-CRP]). All participants (N=25) received the adapted GLB program and were asked to provide a fasting blood sample at baseline and 12-weeks. Insulin resistance was assessed using the Homeostasis Model Assessment calculation (HOMA-IR). Dependent t-tests and Wilcoxon sign rank tests were used to examine differences between baseline and 12-week values.

Results: Participants were primarily female (88%), white (84%), and college educated (68%) with a mean age of 68.9 [6.1] years. Most participants were obese (72%) with a mean percent body fat of 44.0 [5.1%] at baseline. The most commonly reported co-morbid conditions were hypertension (44%), heart disease (8%) and diabetes (28%). Baseline fasting glucose concentrations suggested 60% (n=15) of participants had levels associated with prediabetes and 8% (n=2) had levels corresponding to diabetes. Fasting glucose decreased significantly from baseline (median = 106.0 mg/dL; IQR = 18.5) to 12 weeks (median = 103 mg/dL; IQR = 16; p=0.046) and the effect was small (r = -0.25). Insulin resistance also declined significantly from baseline (median= 4.97; IQR=5.17) to 12 weeks (median = 4.60; IQR = 3.97; p=.025) and the effect was small (r = -0.30). There were no differences between baseline and 12-week hs-CRP, cholesterol (total, HDL and LDL), or triglyceride concentrations (p>0.05).

Conclusions: The Group Lifestyle Balance program may be an effective way to improve cardiometabolic risk factors among overweight and obese individuals with arthritis.

WEIGHT SUPPRESSION IN BEHAVIORAL WEIGHT LOSS: RELATIONSHIP TO WEIGHT LOSS AND TREATMENT SATISFACTION

Christine C. Call, A.B.¹, Amani D. Piers, B.S.¹, Emily Wyckoff, B.A.², Savannah Roberts, B.S.¹, Michael Lowe, Ph.D.¹, Evan Forman, Ph.D.¹, Meghan Butryn, Ph.D.¹

¹Drexel University, Philadelphia, PA; ²University of Connecticut, Storrs, CT

Identifying predictors of suboptimal outcomes is crucial to enhancing the efficacy of behavioral weight loss (BWL). Weight suppression (WS), the difference between one's highest lifetime weight and current weight, may be an important factor in BWL given recent research implicating a biological drive towards weight regain following a loss. To elucidate the role of WS in treatment outcomes, this study examined the relationship between baseline WS and: 1) BMI before and after BWL, 2) weight loss during BWL, 3) difference between highest lifetime weight and weight after BWL, and 4) perceived treatment effectiveness and satisfaction.

Adults with overweight/obese BMI's (N=283) in a 12-month BWL program with a 24-month follow-up self-reported their highest lifetime weight. Weight was measured by research staff at treatment start ("baseline"), end of treatment, and follow-up. For categorical analyses, baseline WS of at least 10 lbs was considered "high WS;" weight suppression less than 10 lbs was considered "low WS."

Highest lifetime BMI was greater in adults with high WS (39.3 kg/m²) vs. low WS (35.4 kg/m²), $p < .001$. BMI did not differ at baseline, and was non-significantly greater in the high WS group at end of treatment (32.1 kg/m² vs. 30.8 kg/m², $p = .1$) and follow-up (33.0 vs. 32.2, $p = .3$). Controlling for baseline BMI, those with high WS lost *less* weight than those with low weight suppression at end of treatment (17.5 lbs vs. 24.7 lbs) and follow-up (9.9 lbs vs. 17.2 lbs), $p < .05$, but had a significantly *larger* difference between highest lifetime weight and weight at end of treatment (40.5 lbs vs. 27.4 lbs) and follow-up (32.1 lbs vs. 19.8 lbs), $p < .001$. Those with high WS reported lower perceived treatment effectiveness and satisfaction, $p < .05$.

Adults entering BWL with high WS reached a higher BMI during their lifetime than those low in weight suppression, but did not differ in BMI at the onset or end of BWL. Nonetheless, adults with high WS lost significantly less weight in BWL. Although the overall difference in their weight from highest lifetime weight to end of treatment/follow-up was greater than those low in WS, their reduced weight losses during treatment are still of concern, particularly given their lower treatment satisfaction ratings. Future research should examine changes in other health markers (e.g., blood pressure, blood glucose levels) during BWL by WS to further explore whether additional intervention is needed for those high in WS.

WHAT CAN SOCIAL AND ENVIRONMENTAL CONTEXT TELL US ABOUT WEIGHT LOSS?

Talea Cornelius, Ph.D., M.S.W.¹, Katelyn Gettens, M.A.², Erin Lenz, Ph.D.³, Alexis Wojtanowski, CCRP⁴, Gary Foster, PhD⁵, Amy A. Gorin, Ph.D.⁶

¹Columbia University Medical Center, New York, NY; ²University of Connecticut, New York, NY; ³Bedford VA Medical Center, Southbridge, MA; ⁴Weight Watchers Intl, New York, NY; ⁵Weight Watchers, Inc, New York, NY; ⁶University of Connecticut, Storrs, CT

Background. Behavioral weight-loss programs achieve variable success. It may be that environmental context impacts the success of weight-loss interventions, and that the social environment shapes reactions to environmental cues. Drawing from Self-Determination Theory and social-ecological approaches, this study examined how the home food-environment (i.e. low- and high-fat foods) and spousal support (i.e. autonomy support, directive support) interact to predict weight-loss outcomes.

Methods. Participants were randomized to a 6-month weight-loss intervention (Weight Watchers, WW) or a Self-Guided control condition (SG), and were weighed at baseline, three, and six months. Participants also completed baseline questionnaires assessing spousal provision of autonomy support (supporting individual choice) and directive support (concrete suggestions or advice) and reported on the number low- and high-fat foods in the home. Of the 130 participants, 113 provided data on key variables (86.9%).

Results. Low-fat foods were related to percent weight loss, but only in WW, and the direction of the association depended on spousal support provision. When autonomy support was high (+1SD), more low-fat foods at was associated with significantly greater percent weight loss at 3 months, $B = -.64$, $p < .001$. When autonomy support was low (-1SD), more low-fat foods was associated with weight gain at 3 months, $B = .30$, $p = .03$. This pattern replicated at 6 months: high autonomy support, $B = -.78$, $p < .01$; low autonomy support, $B = .34$, $p = .08$.

The same pattern occurred for directive support in WW: high directive support: 3 months, $B = -.48$, $p < .01$, 6 months, $B = -.57$, $p = .02$; low directive support: 3 months, $B = .44$, $p < .01$, 6 months, $B = .48$, $p = .04$.

No significant interactions between support and high-fat foods emerged predicting percent weight loss at 3 or 6 months in WW or SG.

Discussion. Low-fat foods predicted greater weight loss in the WW condition, but only when supports were high. It may be that the combination of intervention structure, healthy cues, and support creates a multilevel context conducive to health-enhancing behaviors. Further studies are needed to examine food availability and cue salience (e.g., home food placement) to parse potential reciprocal effects between intervention structure, food availability, food placement, and social supports. Such studies would shed light on what works—and when—and could be used to create adaptive, tailored interventions to promote weight loss.

A QUALITATIVE STUDY OF CLINICIAN STRATEGIES TO MANAGE PATIENT EXPECTATIONS FOR PAIN MANAGEMENT AND OPIOID PRESCRIPTIONS

Alma Jusufagic, MPH¹, Michelle S. Keller, MPH¹, Brennan Spiegel, MD, MSHS²
¹Cedars-Sinai Center for Outcomes Research and Education (CS-CORE), Los Angeles, CA; ²Cedars-Sinai Medical Center, Los Angeles, CA

Introduction: In response to the opioid crisis, states and health systems have recently overhauled opioid prescribing policies and guidelines. Given the shifts in perceptions of the risks of opioid prescribing, particularly for long-term use, clinicians are now tasked with adjusting patient expectations with regards to pain management and opioid use. To understand how providers are working with patients to navigate these changes, this qualitative study assessed clinician perceptions of patient expectations for pain treatment and strategies used to manage these expectations.

Methods: We conducted 60-minute semi-structured interviews with 11 providers from primary care, pain management, and rheumatology specialties from one academic medical system. Employing grounded theory methodology, we performed a qualitative descriptive analysis and coded transcripts for instances where informants discussed patient expectations and approaches to meeting or setting expectations for pain management. We organized the codes under several overarching themes around patient expectations for pain treatment including: treatment efficacy, prescription therapies, referrals, refills, function assessment, follow-up visits, side effects, and dosing.

Results: Providers perceived that patients anticipated pharmacologic treatments would eliminate their pain and that patients frequently had misguided beliefs about the efficacy of opioids. Providers employed several strategies to manage patient expectations, including: screening out patients seeking opioids alone, establishing goals around function instead of pain relief, having patients keep pain diaries to track improvements in pain, having frank conversations about realistic pain improvement prior to treatment, and relying on health system policies and resources, such as an outpatient opioid pharmacy program, to treat patients outside a clinician's established comfort zone. Clinicians also noted that negotiating expectations was extremely time-consuming, which was often a challenge, particularly in the primary care setting.

Discussion: Providers struggled with managing patient expectations around opioids, particularly given the time burden. These findings elucidate opportunities for systemic approaches to educate clinicians on effective strategies for managing patient expectations for pain management and to reduce the burden of opioid prescribing on clinicians.

BMI, SELF-EFFICACY, AND PHYSICAL PERFORMANCE AS RISK FACTORS FOR PAIN AMONG INDIVIDUALS WITH KNEE OA

Warren Feaster

Bethune Cookman University, Daytona Beach, FL

Background: As individuals age, the risk of developing knee osteoarthritis (OA); a degenerative, painful disease increases, reducing functional mobility and effecting health-related quality of life. Understanding the risk factors (self-efficacy, physical performance, and BMI) associated with knee osteoarthritis pain holds promise for improving treatment outcomes and patient health-related quality of life.

Methods: A systematic literature review was conducted, following 2009 PRISMA guidelines and an analysis of reviewed studies. Search criteria included: body mass index (BMI), self-efficacy, physical performance, men and women, knee osteoarthritis, knee OA pain and intervention/clinical studies. Published studies were reviewed from 2006 – 2017 (July), using PubMed and Google scholar databases.

Results: Participants in the studies included both men and women. Studies included primarily African Americans, non-Hispanic Whites. However, results focused on outcomes related to pain physical functioning, associated with BMI and self-efficacy without a specific focus on sex/gender group differences or race/ethnic group comparisons. Findings from the studies revealed meaningful differences in weight status (BMI), self-efficacy and pain resulting in a decrease in performance as a function of increasing levels of body weight. Weight was measured greater than or equal to 24kg/m². Self-efficacy was operationalized as one's confidence to perform a task(s) (e.g. very uncertain-very certain). Results also indicated long term benefits associated with managing self-efficacy and BMI. Moreover, mindfulness was found to have a role; how individuals cope with knee OA pain was impacted by mindfulness (e.g. depression, stress, self-efficacy).

Conclusion: Differences in BMI, self-efficacy, and physical performance are risk factors in knee OA pain for individuals. Such findings are relevant for addressing health and health disparities among the adult population.

DEVELOPMENT OF THE PAIN RESPONSE STYLE INVENTORY: A NEW MEASURE FOR EXAMINING AMBIVALENCE TOWARD CHRONIC PAIN TREATMENTS

Robert Bailey, M.S.¹, Lena Bolling, B.A.², Mark Jensen, Ph.D.³, Kevin Vowles, PhD²¹University of New Mexico, Seattle, WA; ²University of New Mexico, Albuquerque, NM; ³University of Washington, Seattle, WA

Over the previous half-century, the framework for chronic pain management has expanded beyond the biomedical perspective to include psychosocial treatments that fall within the cognitive-behavioral tradition. Patients with chronic pain, however, often perceive their pain as a problem requiring medical interventions. Enhancing motivation to engage in cognitive-behavioral treatment has therefore been a major focus in the research literature, much of which has been informed by Motivational Interviewing (MI) and the Transtheoretical Model. At present, there is a paucity of empirical evidence supporting the efficacy of motivational enhancement in chronic pain. Research has also largely overlooked the importance of ambivalence, a core aspect of MI, which reflects patient interest in treatments targeting behavior change. The objective of the present study was to develop and test a new instrument, the Pain Response Style Inventory (PRSI), which was designed to measure ambivalence toward psychosocial pain treatment. Data were examined from 398 community-dwelling participants with chronic pain. The majority of participants identified as non-Hispanic White (80%), were female (61%), had completed a bachelor's degree or some college (68%), and were married or living with a partner (57%). The most frequently reported pain location was the lower back (43%), and average duration of pain was 7.9 years (*Median* = 5; *SD* = 7.0). Participants completed the PRSI candidate item pool and other measures of pain-related functioning, including measures of pain acceptance, pain-related anxiety, depression, and physical and psychosocial disability. The final version of the PRSI consisted of 19 items, which were best represented by a three-factor structure that showed good internal consistency (Cronbach's $\alpha = .92$). A set of simultaneous regression analyses for the three PRSI factors was performed to evaluate the variance accounted for in measures of pain-related functioning. Results showed that the PRSI had significant direct effects on these measures, after controlling for age, sex, usual pain intensity, and pain duration as well the Pain Stages of Change Questionnaire, a theoretically similar measure. The overall results indicated that the PRSI was capable of assessing ambivalent attitudes about chronic pain treatment and had good psychometric properties. The PRSI demonstrates promise for use in future studies assessing the relationship between attitudes and treatment response.

INCREASING THE REACH OF PAIN PSYCHOLOGY IN THE VA: VETERAN EXPERIENCES OF A FOUR-WEEK, MANDATORY COGNITIVE BEHAVIORAL CLASS

Eleni Romano, PhD¹, Amitha Gumidyala, PhD¹, Stephanie Stewart, MD², Chrisana Olson, PhD¹, Michael Craine, PhD¹¹Eastern Colorado HCS, Denver, CO; ²University of Colorado, Denver, CO

Approximately 66% of Veterans report chronic pain, and 10% (Q4 FY 2017) of Veterans receiving care at the VA are prescribed opioid therapy despite limited efficacy of opioids for chronic pain and potential harms including escalating rates of opioid overdose deaths, opioid misuse, and endocrine and immune dysfunction. Therefore, initiatives to promote safe, effective, and non-pharmacological pain management are a priority in the VA. The psychology and pharmacy led Chronic Pain Care Clinic is an innovative solution, designed to optimize chronic pain management by delivering education about the biopsychosocial model of chronic pain, promoting the use of behavioral coping strategies and utilizing extended and frequent appointments with clinical pain pharmacists. In addition to 45-minute monthly visits with a pharmacist, Veterans who enroll in the clinic are required to attend a four-week, cognitive behavioral therapy (CBT) class led by clinical psychologists. Veterans who would not typically enroll in pain psychology services often present to classes with low self-efficacy to manage pain with non-opioid therapies, and may be less open to use of CBT strategies to manage pain. The purpose of this program evaluation is to explore the uptake of the CBT class. Class topics include the following: 1) introduction to the biopsychosocial model of pain, 2) relaxation training, 3) activity pacing, and 4) cognitive restructuring. Participants were administered an anonymous survey between April, 2017 and November, 2017 after each class. This resulted in 188 completed surveys. Veterans were asked to rate items on a five-point Likert scale from "not at all" to "very much." Across all classes, Veterans responded that they "learned something new about pain" ($M = 3.60$, $SD = 1.18$), found the class "helpful" ($M = 3.76$, $SD = 1.07$), and "plan to use the information to manage pain" ($M = 4.02$, $SD = .93$). Veterans who had completed all four classes reported they "have used information presented in an earlier class to manage pain" ($N = 35$, $M = 4.14$, $SD = .84$). Participants rated the skills based classes (relaxation training, activity pacing and cognitive restructuring) as more useful compared with the psychoeducation class. Overall, results indicate Veterans benefited from a four-week, mandatory class designed to promote CBT strategies to manage pain. This suggests a potential for broad reach and benefit to Veterans who may not seek out pain psychology services.

A PICTURE IS WORTH A THOUSAND WORDS: USING PHOTOVOICE TO UNDERSTAND EXERCISE CONTEXT EXPERIENCED BY RURAL WOMEN CANCER SURVIVORS

Laura Q. Rogers, MD, MPH¹, Tamika Smith, PhD¹, Latoya Goncalves, MS¹, Danielle Hessong, MPH², Maria Pisu, PhD¹, Robert A. Oster, PhD¹, Haiyan Qu, PhD, MSHA¹, Richard Shewchuk, PhD³, Mary Sheffield, MD⁴, Alex Minter, MD⁴, Ana Baumann, PhD⁵, Michelle Martin, PhD⁶

¹University of Alabama at Birmingham, Birmingham, AL; ²University of Alabama at Birmingham, Denver, CO; ³University of Alabama Birmingham, Birmingham, AL; ⁴Russell Medical Center, Alexander City, AL; ⁵Washington University in St. Louis, St. Louis, MO; ⁶University of Tennessee Health Science Center, Memphis, TN

Background: Rural cancer survivors (CS) suffer greater physical and mental health risk compounded by a greater risk of insufficient exercise (EX), when compared to non-rural CS. Adapting efficacious EX behavior change programs for rural implementation is needed yet requires a deeper understanding of the context. Photovoice is an innovative yet infrequently used strategy for achieving such understanding. Hence, our study aim was to use photovoice to better describe exercise barriers and facilitators experienced by rural women CS.

Methods: Women CS (n=17) were provided a cellphone or digital camera and notepad for notes. They were asked to take photos of EX barriers and facilitators in their community for one week. Devices were then returned, images downloaded, and photo discussion groups completed (participants explained their photos, told their stories, and brainstormed solutions). Group transcripts and images were imported into NVivo for coding by two independent coders and analysis.

Results: Most participants were White (82.4%). Mean age was 61.9 ± 11.6 years, education was 15.2 ± 2.8 years, and time since cancer diagnosis was 33.2 ± 24.1 months. Cancer types included breast (n=8), bladder (n=2), lung (n=2), or single occurrence of other (n=5). All were post-primary treatment. The 17 participants providing photos participated in a discussion group session (3 to 8 participants per session). The most frequent barriers included safety (n=119 comments), weather (n=73), negative feelings about EX (n=64), cancer-specific adverse effects (n=60), low motivation (n=55), and location (n=54). Photovoice images and resultant discussions revealed aspects specific to the rural context: 1) safety - wild animals and road design, 2) weather - prevented driving to an EX facility, 3) negative feelings - terrain perceived as too difficult to walk, and 4) location - greater travel time required for daily activities limited time available for EX. The most frequent facilitators included local EX resources (e.g., parks, schools; n=187 comments), multiple options (e.g., gardening; n=76), EX support (e.g., neighbors, family; n=67), access (e.g., if done at home; n=61), and enjoyable (e.g., lake, dance videos; n=52).

Conclusions: Several aspects of the rural context present unique challenges for rural CS. EX program implementation in this setting requires novel community-wide approaches to address these barriers while also capitalizing on EX facilitators.

REGULAR DANCING INCREASES OLDER LATINOS' PHYSICAL ACTIVITY

David X. Marquez, PhD¹, Susan Aguinaga, PhD², Isabela G. Marques, BS³, Michael Berbaum, PhD⁴, Hai Nguyen, MS⁴

¹University of Illinois at Chicago, Chicago, IL; ²University of Illinois at Urbana-Champaign, Urbana, IL; ³University of Illinois at Chicago/CAPES Foundation, Chicago, IL; ⁴UIC, Chicago, IL

Older Latinos are expected to constitute 20% of the older adult population by 2050. Physical activity (PA) can influence potential declines in the health outcomes of physical and cognitive function, unfortunately, Latinos aged 65–74 are 46% less likely to engage in leisure time PA than older non-Latino whites. Also, little is known about PA maintenance among ethnic minorities compared to non-Latino whites. Dance is a widely popular form of PA among Latinos and holds considerable promise as a culturally appropriate form of PA. This study used a randomized controlled trial with randomization at the level of the individual to the BAILAMOS© dance program or a health education control group. BAILAMOS© is a 4-month dance intervention, and has a 4-month maintenance dance program. Physical activity in this study was measured with the CHAMPS Physical Activity Questionnaire for Older Adults, a change-sensitive PA scale. Measurements were taken at months 0 (baseline), 4 (post-intervention), and 8 (post-maintenance intervention). General linear model analysis adjusting for age, sex, education, income, and health status revealed significant mean changes in leisure time PA between Dance participants and Health Education participants post-intervention ($p < .05$), with changes approaching significance post-maintenance intervention ($p = .07$). It appears that attempts to increase the PA of older Latinos should use culturally appropriate forms of PA. Older Latinos understand the physical and psychological benefits of exercise. They value functional independence, and relate physical fitness to feeling healthy and being able to perform normal activities with ease. However, this understanding has not led to their adoption and maintenance of PA. Dance has long been an important form of socialization, entertainment, and leisure in Latin cultures, and appears to be an important way to get older Latinos more physical activity.

THE FEASIBILITY OF A REMOTE PHYSICAL ACTIVITY PROGRAM FOR ADULTS WITH ALZHEIMER'S DISEASE AND THEIR CAREGIVERS

Lauren T. Ptomey, PhD, RD, LD¹, Eric Vidoni, PhD², Mike Thompson, MS², Richard Washburn, PhD³, Joseph Donnelly, ED.D.², Amanda Szabo-Reed, Ph.D.⁴

¹University of Kansas Medical Center, Kansas City, MO; ²University of Kansas Medical Center, Kansas City, KS; ³University of Kansas Medical Center, Lawrence, KS; ⁴University of Kansas Medical Center, Kansas City, KS

Individuals with Alzheimer's Disease (AD) are more likely to be physically inactive, leading to further cognitive and functional decline. Increased moderate-to-vigorous physical activity (MVPA) in individuals with cognitive impairment has been associated the maintenance of cognitive and functional performance. One major barrier to MVPA for adults with AD, is dependence on a caregiver, typically a spouse or adult child, to plan, transport and supervise their efforts to be physically active. Home-based exercise programs could potentially overcome these barriers. However, proven scalable home-based intervention strategies are not available for this population. The purpose of this study was to evaluate the feasibility of a group video conference approach for increasing MVPA in adults with AD and their caregivers. Participants and their caregiver attended 30-minute group exercise sessions 3 times a week, and individual support sessions once a month, for 12 weeks. Exercise sessions and support sessions were delivered in participant homes by video conferencing on a tablet computer. Nine participants (74.1 ± 10.2 years of age, 55.6% female) and their caregivers (67.4 ± 13.2 years of age, 66.7% female) enrolled and seven participants and caregivers completed the 12-week intervention. On average participants attended 77.2% of the group exercise and caregivers attended 78.3% of group exercise sessions. All participants reported that they enjoyed the exercise program and would be willing to do it again. Fifty seven percent of caregivers reported that they felt more confident about getting exercise in on their own, and 42.9% felt more confident about helping the person they care for get exercise in. Group-based exercise sessions delivered remotely may be a feasible approach for delivering exercise to adults with AD and their caregivers.

#MCSCOTSMOVE: A STRATEGY FOR INCREASING ENGAGEMENT IN PHYSICAL ACTIVITY IN THE SELFIE GENERATIONJeremy Steeves, PhD MPH¹, Matthew Redaja, Student¹, Elizabeth Anderson Steeves, PhD, RD²¹Maryville College, Maryville, TN; ²University of Tennessee, Knoxville, TN**Purpose:** The purpose of this study was to assess the feasibility of using a social media platform to engage students at a liberal arts college in a physical activity (PA) promotion campaign.**Methods:** In fall of 2016, 23 students engaged in a social media based PA promotion pilot campaign called #MCScotsMove. As part of #MCScotsMove, students downloaded the social media application, Instagram, on their phones. For one week (7 days) students were instructed to photographically document their daily PA sessions and post pictures, along with brief captions, and locations on Instagram using the #MCScotsMove and #My150 hashtags. Demographics, social media app use, #MCScotsMove engagement, change in PA levels, and knowledge of the PA guidelines for Americans were assessed in this study.**Results:** Twenty-three students (61% male, 48% athletes, average age 21.2 ± 1.9) participated in the 7-day pilot of #MCScotsMove. The majority of students (69%) reported using social media apps frequently (1–9 times/day) or very frequently (10+ times/day). The three most popular apps used by students were Snapchat, Instagram and Facebook. Students posted as part of the #MCScotsMove campaign on average 5.0 ± 1.2 of 7 days. The week before the campaign students reported 460.9 ± 309.3 min/week of PA, which was not significantly different than PA levels during the #MCScotsMove campaign (485.7 ± 277.1 min/week). Before the #MCScotsMove campaign only 43% of students knew the PA guidelines recommended 150 min/week of moderate-to-vigorous PA for adults, but 87% knew the guidelines after the campaign.**Conclusion:** The majority of students in this study habitually used social media, and were willing to engage in a social media based PA promotion campaign, which increased their knowledge of the recommended levels of PA needed to promote health. Based on self-report, the majority of students in this study were meeting the recommended levels of PA. Through additional mining of the Instagram images, captions, and locations collected during this pilot campaign, a qualitative understanding of what college students are doing in terms of PA, with whom they do PA (friends, alone, teammates, etc), and locations where students regularly engage in PA could be identified.

FACTORS INFLUENCING WALKING AND SEDENTARY BEHAVIOURS IN PATIENTS SUFFERING FROM SEVERE MENTAL ILLNESSAhmed-Jerome Romain, PhD¹, Samuel St-Amour², Antony D. Karelis³, Amal Abdel-Baki²¹University of Montreal Hospital Research Centre (CRCHUM), Montreal, PQ, Canada; ²University of Montreal Hospital Research Centre, Montreal, PQ, Canada; ³Universite du Quebec à Montreal, Montreal, PQ, Canada**Introduction:** Physical inactivity and sedentary behaviours are important modifiable risk factors to prevent cardiovascular diseases in individuals with severe mental illness (SMI). Walking is an effective way to initiate physical activity (PA), however, factors involved in walking and sedentary behaviours are not well known in this population.**Methods:** Cross-sectional study including ISMIs who completed the Global Physical Activity Questionnaire to assess their walking behaviour and sedentary time. Participants were also evaluated on the perception of their physical activity status, and their stages of change.**Results:** Ninety-one participants (50 males, mean age: 31.5 ± 9.9 years old, mean body mass index (BMI): 26.0 ± 7.1 kg/m²) with psychosis were recruited for this study. They walked 379.9 ± 433.7 min per week and spent 346.9 ± 210.0 min per day in a sedentary state. Total walking was correlated with the perception of physical activity status ($r = 0.29$; $p = 0.005$). Also, participants in post-action stages had greater perception of their physical activity status ($p < 0.0001$). When we used a model a regression, perception of PA status ($\beta = 0.27$; $p = 0.009$), cultural group ($\beta = -0.23$; $p = 0.03$), and age ($\beta = 0.20$; $p = 0.04$) were significantly associated with walking. None of the variables considered had an association with sedentary time.**Discussion:** In ISMIs, perception of physical activity and stages of change were found to be related to walking behaviour. Given its association with walking, the perception of SMI regarding their PA should not be neglected.

IMPACT OF LATIN DANCE ON EPISODIC MEMORY AND EXECUTIVE FUNCTION AMONG LATINOS WITH COGNITIVE IMPAIRMENT

Susan Aguinaga, PhD¹, David X. Marquez, PhD²¹University of Illinois at Urbana-Champaign, Urbana, IL; ²University of Illinois at Chicago, Chicago, IL

The number of Latinos in the United States with Alzheimer's disease (AD) is projected to increase by 850% by 2060. Currently, there is no cure for AD, however evidence suggests that engaging in physical activity may be effective at reducing the risk of cognitive decline and may reduce the risk of dementia. The purpose of the present study was to determine if a Latin dance program would have an impact on episodic memory and executive function among older Latinos with cognitive impairment. Spanish-speaking older Latinos [N=21, 75.4 ± 6.3 years old, 76.2% female, 22.4 ± 2.8 Mini Mental State Examination score] were randomized into a 4-month, twice-weekly dance intervention or to a wait-list control group. Participants completed a cognitive battery that included the Logical Memory test I (immediate recall) and II (delayed recall), and the Stroop test word and color test at baseline and at 4-months posttesting. Repeated measures ANOVA were used to determine overall time and interaction effects. Cohen's *d* values were subsequently calculated as an estimate of the effect sizes. Results indicated no significant time or interaction effects for the logical memory tests or the Stroop tests; however, Cohen's *d* values showed positive changes favoring the dance group. For example, there was a non-significant effect size for Logical Memory test I, (*d* = .14) and a medium effect size for Logical Memory II, (*d* = .69), driven by higher scores in the dance group and a decrease in scores in the control group at 4-months, ([Dance, Baseline, 4.80 ± 2.66; 4-months, 6.38 ± 3.21]; [Wait-list, Baseline, 6.00 ± 4.07; 4-months, 5.18 ± 3.16]). For the Stroop word test, there was a small effect size (*d* = .33) driven by higher scores in the dance group at 4-months, ([Dance, Baseline, 34.91 ± 12.31; 4-months, 40.97 ± 12.50]; [Wait-list, Baseline, 35.18 ± 16.96; 4-months, 36.36 ± 13.03]). Cohen's *d* values for the Stroop color test indicate a medium effect size (*d* = .42) driven by higher scores in the dance group and a decrease in scores in the control group at 4-months, ([Dance, Baseline, 10.32 ± 7.50; 4-months, 13.71 ± 6.58]; [Wait-list, Baseline, 11.91 ± 10.31; 4-months, 11.45 ± 5.37]). Findings indicate that participation in a Latin dance program may improve episodic memory and executive function among older Latinos with cognitive impairment when compared to a wait-list control group. Latin dance may be a culturally appropriate type of physical activity that may slow cognitive decline among older Latinos with cognitive impairment; however, larger randomized controlled studies are warranted for generalizability of findings.

IMPLEMENTATION OF EXERCISE REFERRAL FOR TREATMENT OF MAJOR DEPRESSIVE DISORDER

Chad C. Rethorst, PhD

UT Southwestern Medical Center, Dallas, TX

Purpose: Despite its proven efficacy in research trials, exercise is rarely used as a treatment for Major Depressive Disorder (MDD) in real-world clinical settings. Clinicians cite a lack of training in exercise prescription as a barrier, and indicate a preference for referral to community resources. The purpose of this project was to assess the feasibility and preliminary efficacy of referral from primary care to a research-tested exercise program in the treatment of MDD.

Methods: Patients diagnosed with MDD in a primary care clinic were provided a written prescription by their provider and referred to a research-tested exercise program. Patients met weekly for 12 weeks with an exercise specialist at a community recreation center. In addition, patients received access to the recreation center and a Fitbit ChargeHR to monitor their activity. Depressive symptoms were assessed on a weekly basis using the PHQ-9.

Results: Of the 38 eligible patients, 31 patients have been referred to the program and 19 patients have been enrolled. Patients have attended 73.75% of supervised exercise sessions. Based on Fitbit data, patients have engaged in an average 136.80 minutes of moderate-vigorous physical activity per week ("Very Active" minutes + Fairly Active" minutes). Depressive symptoms, as assessed by the PHQ-9, reduced from 9.11 at baseline to 4.61 at last observation (*p* < 0.01).

Conclusions: Clinic referral rates demonstrate providers' willingness to refer patients for an exercise treatment program. Patient adherence data indicates exercise referral is a feasible intervention in patients with MDD. Furthermore, patients experienced a significant reduction in depressive symptoms demonstrating the potential of referral to exercise as a viable treatment option.

IN EXERCISE PLANS, THE DEVIL IS IN SOME OF THE DETAILS: PLAN COMPONENT SPECIFICITY AND SUBSEQUENT PHYSICAL ACTIVITY

Scout M. Kelly, PhD¹, Caleb Myatt, MA²¹Coe College, Cedar Rapids, IA; ²Kent State University, Kent, OH

Background: Implementation intentions (IIs) are plans made in the form of "if-then" contingencies and have been shown to promote physical activity (Gollwitzer & Sheeran, 2006). However, not all plans are equally effective. Recent research indicates that the specificity of plans may moderate their effectiveness, and that specificity may be more beneficial in plans designed to cope with barriers (coping plans) than plans for when, where, and how one will exercise (action plans). To better understand the role of specificity in IIs, the present study examined whether specificity of particular components of coping and actions plans (i.e., activity, moment, place, and duration) differentially predict physical activity.

Method: 151 undergraduates (72.9% female, 65.1% non-Hispanic white, mean age = 19.9) completed baseline questionnaires and a short II intervention, in which they formed 3 action plans and 3 coping plans for physical activity. Pairs of independent coders coded the IIs for specificity in activity, moment, place, and duration. Participants self-reported physical activity one and two weeks later.

Results: Multivariate regressions were used to examine the effects of the 8 components of coping and action plan specificity on physical activity one and two weeks post-baseline. Controlling for baseline activity and intentions, of the 8 specificity components, only moment specificity of coping plans was associated with significantly higher physical activity one week post-baseline ($\beta = .24, p = .006$). Activity specificity of action plans was associated with marginally lower physical activity one week post-baseline ($\beta = -.18, p = .098$). No specificity components remained significant predictors two weeks post-baseline (*p*'s > .10).

Conclusions: People who were specific about the moment in which they would enact a coping plan were more physically active in the subsequent week than those who were less specific. However, those who were very specific about which activity they would engage in were less physically active. Thus, the value of highly specific IIs for physical activity may depend on the type of plan and the plan component being specified. No specificity components predicted physical activity two weeks post-baseline, suggesting that the effects of specificity may be limited to short-term behavior. Better understanding the plan components that matter for successful behavior change will support the development of more effective planning interventions.

LOW BODY IMAGE ASSOCIATED WITH FEWER MINUTES OF MVPA IN FEMALE UNIVERSITY STUDENTS

Jamie Faro, MS¹, Jessica Whiteley, PhD², Laura L. Hayman, PhD, MSN, FAAN³, Melissa A. Napolitano, PhD⁴

¹University of Massachusetts Boston, Boston, MA; ²UMass Boston, Boston, MA; ³College of Nursing & Health Sciences, UMass Boston, Boston, MA; ⁴The George Washington University, Washington, DC, DC

Evidence indicates declines in body satisfaction and image as well as physical activity during college years, which may be more pronounced in overweight/obese females. Body satisfaction has been associated with achieving moderate- to vigorous physical activity (MVPA) guidelines, thus understanding this relationship could better inform interventions designed to increase MVPA in this population.

PURPOSE: To examine the relationship between body image, objective measures of MVPA (average minutes per day) and gender in overweight/obese university students.

METHODS: 149 university students (80% female; mean age=23.2, SD=3.8; mean BMI=31.9 kg/m², SD=4.3) completed baseline clinic-measured weight, demographic questions and the *Body Image Quality of Life Inventory (BIQL)*. Participants also wore an Actigraph activity monitor (wGT3X-BT) for 7 days at baseline. Valid wear-time for inclusion into the analyses was a minimum of 4 days and 10 waking hours (600 minutes). Body image was dichotomized into “high” and “low” based on the median *BIQL* score (64.84) of the sample.

RESULTS: Average minutes of MVPA/day for males (41.33 ± 4.8) were higher than females (31.04 ± 2.2; $p = 0.063$). Females with low body image had significantly ($p=0.004$) lower average minutes of MVPA per day (31.8 ± 2.6) than males with low body image (45.1 ± 7.3), whereas no statistical differences ($p=0.49$) were found between females (32.3 ± 3.5) and males (37.6 ± 6.4) with high body image. Simple linear regressions indicated that gender significantly predicted lower average minutes of MVPA per day, $F(1, 71)=4.41, p=0.039$, in those with low body image, but not in those with high body image. When controlling for age, race, ethnicity and BMI, gender was not predictive of averages minutes of MVPA per day in those with both low ($p=0.071$) and high ($p=0.7$) body image.

CONCLUSION: In this population of college students low body image, irrespective of weight status, was associated with fewer average minutes of MVPA per day in females, but not in males. Interventions targeting increasing MVPA in females may need to provide additional support for those with low body image. Future research is needed to investigate the effectiveness of promoting positive body image as a means of increasing MVPA in college females experiencing low body image.

MOTIVATORS OF AND BARRIERS TO PHYSICAL ACTIVITY AMONG PARENTS OF ADOLESCENT CHILDREN

Tya Arthur, PhD, MPH, CPH, Teresia Mbogori, PhD, Monica Sanchez, BS

Ball State University, Muncie, IN

Background: Current guidelines recommend at least 150 minutes per week of moderate-intensity physical activity (PA). Despite these guidelines, only 21% of adults get the recommended amount of PA. The lack of PA in adults is particularly concerning given the health benefits of such activity. Active adults have longer lives and lower risk for chronic conditions (e.g., obesity, hypertension, and some cancers). Given the relationship between PA and chronic conditions, it is important to conduct research aimed at understanding how to improve PA among adults, particularly parents who serve as role models for their adolescent children. The purpose of the study was to investigate (1) if motivators to engage in PA predicted increased PA, (2) if barriers to engage in PA predicted decreased PA, and (3) if these relationships differed by sex, age, education, and race/ethnicity.

Methods: The study sample included 1,839 adults from the Family Life, Activity, Sun, Health, and Eating (FLASHE) study. The vast majority were non-Hispanic White (66.8%), were female (72.1%), and were aged 35 to 59 years (83.7%). All were parents of adolescent children. A hierarchical regression was used to examine the relationships under investigation.

Results: The final hierarchical regression model to examine whether demographic variables (i.e., sex, age, education, and race/ethnicity), motivators to engage in PA (e.g., believing PA is an important thing to do), and barriers to engage in PA (e.g., not wanting to sweat) predicted PA frequency was significant, $F(5, 1779)=15.91, p<.001, R^2=.104, \text{adjusted } R^2=.098$. Adding the motivators in block 2 to the demographic variables resulted in a significant change to the overall model, $\Delta R^2=.051, \Delta F(4, 1779)=24.05, p<.001$ and adding the barriers in block 3 also resulted in a significant change, $\Delta R^2=.052, \Delta F(5, 1779)=20.49, p<.001$. The results revealed that feeling bad without PA and believing PA is an important thing to do were significant positive predictors of PA and not liking to engage in PA and not being athletic were significant barriers to PA. No other variables were significant predictors of PA.

Conclusions: The results of the study have implications for interventions aimed at increasing PA in adults, particularly adults who are parents to adolescent children. It would be appropriate to design these interventions to help adults increase their PA using (1) motivating strategies focused on the importance of PA and how going without PA makes them feel, and (2) strategies to overcome barriers like lack of athleticism and not liking PA.

OLDER LATINOS' PERCEPTIONS OF A LATIN DANCE PROGRAM

Jacqueline Guzman, B.S, B.A, David X. Marquez, PhD

University of Illinois at Chicago, Chicago, IL

Latinos have low physical activity levels but high morbidity and mortality rates. It is currently unknown how older Latinos will feel after participating in a dance intervention as a way to be active. The purpose of this study was to analyze older Latinos' perceptions of a Latin dance program (BAILAMOS®). A randomized controlled trial was conducted, and participants were randomized to either a 4-month dance program or a 4-month health education program. Dance group participants also participated in a 4-month maintenance program. Participants: (1) were aged > 55 years old; (2) self-identified as Latino/Hispanic; (3) were able to understand Spanish; (4) participated in < 3 days/week of aerobic exercise; (5) were at risk for disability; (6) had adequate cognitive status as assessed by the Mini Mental State Examination (>14/21). Participants completed program evaluation forms on the last day of the 4-month dance program (n=103) and at the end of the 4-month maintenance program (n=89). After the 4-month dance program participants had high ratings of satisfaction (1 = strongly agree and 4 = strongly disagree) for: general reaction to the program (M=1.27; SD=.57); general reaction to dance instructor (M=1.28; SD=.54); physical satisfaction level (M=1.37; SD=.64); and felt that the program was worth it (M=1.0; SD=.00). On another scale of 1–4, (1 = strongly disagree and 4 = strongly agree) participants had high ratings of satisfaction for: adequate increases in dance difficulty level (M=3.61; SD=.74); likelihood to keep dancing BAILAMOS dances (M= 3.48; SD= .72); and likelihood of recommending BAILAMOS to family and friends (M=3.81; SD= .47). At the end of the 4-month maintenance program ratings were virtually the same: general reaction to the program (M=1.29; SD=.67); general reaction to dance instructor (M=1.38; SD=.64); physical satisfaction level (M=1.34; SD=.61); felt that the program was worth it (M=1.0; SD=.16); adequate increases in dance difficulty level (M=3.59; SD=.62); likelihood to keep dancing BAILAMOS dances (M= 3.37; SD= .80); and likelihood of recommending BAILAMOS to family and friends (M=3.79; SD= .51). Based on the obtained results we conclude that participants who completed the program had very positive perceptions about the BAILAMOS® program.

PERCEIVED BENEFITS, SOURCES OF MOTIVATION, AND FACILITATORS OF PHYSICAL ACTIVITY AMONG LATINAS IN LOW-INCOME CLINICS

Andrea S. Mendoza-Vasconez, MPH, PhD Candidate¹, Aysell Medina², Mario A. Muñoz, PhD³, Britta Larsen, PhD⁴, Samantha Hurst, PhD⁵

¹UC San Diego/San Diego State University Joint Doctoral Program in Public Health, La Jolla, CA; ²University of California, San Diego, Downey, CA; ³University of Massachusetts in Boston, Watertown, MA; ⁴University of California, San Diego, San Diego, CA; ⁵UCSD, San Diego, CA

Background: Latinas are one of the least physically active ethnic minority groups in the US, yet we know little regarding what facilitates and motivates them to stay active, and what role health concerns and the healthcare setting might play in helping them to lead active lives. This qualitative study aimed to understand how low-income community clinics could be capitalized on as settings for the promotion of PA among Latina women, specifically focusing on women's perceived benefits, sources of motivation, and facilitators of PA within these settings.

Methods: In-depth individual interviews were conducted with 24 Latina patients in two low-income community clinics in San Diego, California. Data were collected in English and Spanish, transcribed, translated to English, and analyzed using structural coding procedures, under a Thematic Analysis framework. Two investigators jointly coded each interview using a codebook. Codes were then compared and grouped into themes.

Results: When asked about benefits, the large majority of women mentioned health. The most frequently reported sources of motivation were staying healthy or recovering health, along with losing weight or avoiding weight gain. Family and loved ones were also important sources of motivation, as many exercised to be a role model, and to live longer lives with their loved ones. Those reporting the most physical activity (PA) were less likely to report being motivated by avoidance of weight gain, and more likely to be motivated by previous personal or family experiences with inactivity and related illnesses. Support from family and friends was the most commonly reported facilitator of PA, while support from healthcare professionals and the healthcare setting were not salient facilitators.

Conclusions: Health was a predominant topic in themes related to benefits and motivation for PA. However, the healthcare setting and healthcare professionals were only infrequently identified as facilitators. This may be indicative of a need and also an important opportunity to strengthen and capitalize on the role of health clinics for the promotion of PA among Latinas. Additionally, this study strengthened the evidence supporting the need to include family members or the concept of family in the promotion of PA among Latinas. Moreover, results revealed the potential usefulness of tailoring program materials to include information pertaining previous personal and family history of inactivity and related illnesses.

PRE-EXISTING PAIN SYMPTOMS AND BELIEFS MAY LIMIT PA IMPROVEMENT IN PATIENTS WITH CHRONIC LOW BACK PAIN

Jeni Lansing, M.S., Maria Perez, M.S., Kathryn J. Southard, M.S., Laura Ellingson, PhD

Iowa State University, Ames, IA

INTRODUCTION: Moderate to vigorous physical activity (MVPA) provides symptom relief for individuals with chronic low back pain (CLBP). However, intrapersonal factors like pain symptoms and maladaptive pain-related beliefs (catastrophizing and locus of control), as well as baseline levels of physical activity, may influence the effectiveness of interventions targeting increases in MVPA.

PURPOSE: The aim of this study was to investigate the influence of baseline levels of pain symptoms, pain-related beliefs, and physical activity on changes in MVPA over a 12-week intervention.

METHODS: Fifty-seven adults with chronic low back pain (49% male; 43 ± 10 years old) simultaneously wore ActiGraph GT3X+ and activPAL3 accelerometers for 7 days to assess MVPA, and completed the McGill Pain Questionnaire (MPQ), Pain Locus of Control Scale, and the Pain Catastrophizing Scale pre- and post a 12-week physical activity intervention. For the intervention, participants were randomized to receive a Fitbit alone or in combination with motivational interviewing, or were assigned to a wait-list control condition. Data from the accelerometers was processed using Sojourns Including Posture (SIP) methods to calculate average MVPA minutes/day for both time points. A regression analysis was performed with intervention group, baseline MVPA levels, pain intensity (MPQ), pain catastrophizing, and locus of control included as predictors and changes in MVPA as the outcome.

RESULTS: The overall regression model was significant ($F_{(5, 29)} = 4.35, p = 0.002$), with lower levels of baseline MVPA ($\beta = -0.46, p = 0.001$) and a less internally focused locus of control ($\beta = -0.25, p = 0.05$) significantly predicting increases in MVPA. While non-significant, lower levels of pain catastrophizing ($\beta = -0.29, p = 0.07$) and lower symptom severity ($\beta = 0.28, p = 0.08$) may have also contributed to improvements in MVPA over the intervention.

CONCLUSION: Consistent with previous research, these results suggest that factors related to symptom severity and pain-related beliefs may influence the effects of interventions targeting increases in health-promoting behaviors, like physical activity. Understanding the influence of these factors may improve the efficacy of future similar intervention trials. Data regarding patient knowledge of physical activity as treatment and level of trust in its prescription may be especially beneficial for changing these determinants.

SOCIODEMOGRAPHIC DIFFERENCES IN THE RELATIONSHIP BETWEEN THE NEIGHBORHOOD ENVIRONMENT AND OBESITY-RELATED BEHAVIORS

Natalicio Serrano, MPH¹, Jacqueline F. Hayes², Brian Saelens, Ph.D.³, Denise Wilfley, PhD², Richard I. Stein, PhD²

¹Washington University in St. Louis, St. Louis, MO; ²Washington University in St. Louis, St. Louis, MO; ³University of Washington / Seattle Children's Research Institute, Seattle, WA

Background: In the US, only about a quarter of children meet physical activity (PA) guidelines, and children have a healthy eating index (HEI) that is relatively low compared to the dietary guidelines. The neighborhood environment has been shown to influence both PA and dietary habits in children. Specifically, having better access to parks has been consistently associated with greater PA, and some studies have shown that more access to more healthy food retail or less access to less healthy food retail is associated with healthier eating habits. However, few studies have examined whether sociodemographics interact with neighborhood environments to impact obesity-related behaviors in youth with overweight/obesity.

Objectives: To examine the association of, and interactions between, socio-demographics and neighborhood environmental correlates with objective PA and the HEI.

Methods: A subsample of children ($n = 116$) with BMIs $> 85^{\text{th}}$ percentile for sex and age participating in a family-based weight loss program in St. Louis, MO/Seattle, WA, participated in an ancillary study that included Geographic Information Systems (GIS) measures. Information on obesity-related behaviors obtained at baseline was used in the present analysis. Accelerometry data were collected to assess daily moderate to vigorous physical activity (MVPA). Child HEI scores were obtained from up to 3 days of 24-hour food recalls. Objective measures of the neighborhood environment were collected including park counts, distance to school, and counts of healthy and unhealthy food retail outlets. Additionally, parents provided information about socio-demographics (child age, child race/ethnicity, household income). Generalized linear models examined main effects and interactions of three intrapersonal and four environmental factors on average daily MVPA and the HEI.

Results: On average, participants attained 46.7 min/day ($SD = 21.8$) of MVPA and had a HEI of 60.2 ($SD = 9.5$, range 0–100). Higher age was associated with less PA and a higher HEI. There were no significant relations between the neighborhood environment and PA or HEI. However, park counts and household income interacted for daily MVPA ($b = -4.98, p = 0.044$), children with lower income and more parks near their home engaged in less PA.

Conclusions/Future Plans: Among this sample of treatment-seeking children with overweight/obesity, there were no significant direct associations between neighborhood environment factors explored and corresponding behaviors, but unexpectedly lower income children with higher number of parks nearby the home were associated with less PA, when compared to higher income children. Further work should be done examining these sub-group differences in order to better inform strategies to promote physical activity and healthy eating in children.

THE INFLUENCE OF THE SOCIAL ENVIRONMENT ON ETHNIC MINORITIES' CYCLING BEHAVIOR: AN EXPLORATORY STUDY

Jacqueline N. Beltran¹, Eric R. Petroski², Oliver W. A. Wilson, MSpEx³, Melissa Bopp, Ph.D.⁴, Scherezade K. Mama, DrPH⁵, Nicole Vairo⁶¹Pennsylvania State University, state college, PA; ²Department of Kinesiology, The Pennsylvania State University, Pittston, PA; ³Department of Kinesiology, The Pennsylvania State University, University Park, PA; ⁴Pennsylvania State University, University Park, PA; ⁵The Pennsylvania State University, University Park, PA; ⁶Pennsylvania State University, Jackson Heights, NY

Though cycling offers many physical and mental health, environmental, and economic benefits, rates of cycling are low among ethnic minorities and are linked with physical inactivity-related health disparities. At present there is limited research regarding the influence of the social environment on cycling participation among ethnic minorities. This study examined the influence of family and friends in supporting or hindering cycling among ethnic minorities

Methods: An online survey distributed to members of minority cycling clubs used open-ended questions to examine different aspects of their cycling participation, including the role of one's family and friends in supporting/hindering involvement in cycling. Basic demographic information was also collected. Responses were coded using standard qualitative methods and common themes identified using NVivo.

Results: Participants ($N=33$) were mostly middle-aged adults ($M_{age} = 51.21$ years, $SD = 11.20$), and predominantly African American ($n=13$, 68.4%), male ($n=13$, 68.4%), and held a Bachelor's degree or higher ($n=13$, 68.4%). The two major themes that emerged were the support for cycling from family and friends ($n=10$) that encouraged further participation and the way the relationship between the cyclist and family and friends changed in a positive manner as a result of cycling participation ($n=7$). Other themes included family and friends being indifferent to cycling ($n=5$), being impressed by cycling-related accomplishments ($n=4$), or social relationships being a hindrance to cycling participation ($n=2$). Some differences in themes by gender were noted, with females emphasizing the importance of supportive relationships as a motivator.

Discussion: Findings of this study provide an insight into the role and importance of the social environment for ethnic minority cycling participation. For the most part family and friends were supportive of participants cycling, however, some results indicated that family and friends were also indifferent or hindered some participants' cycling. Interventions that develop social support for cycling could lead to more ethnic minorities participating in cycling. Future research is warranted to examine the complex role of social support for cycling for ethnic minorities to improve physical activity participation.

TOWARDS CULTURALLY RELEVANT PHYSICAL ACTIVITY INTERVENTION: A PILOT STUDY EXAMINING PA IN YOUNG BLACK WOMEN

Keri Kirk, M.S.¹, Breanna Beard, B.S.², Ebony Elder², Claudia Byer-Tyre², Denee T. Mwendwa, PhD²¹Howard University, Detroit, MI; ²Howard University, Washington, DC

Background: Despite the multidimensional benefits of regular physical activity (PA), Black women participate in leisure-time PA at much lower rates than their Caucasian counterparts. This is a significant issue given that several chronic diseases have an inverse relationship with regular PA including: cardiovascular disease, hypertension, type 2 diabetes, obesity, breast cancer, anxiety, and depression. Many Black women are not meeting weekly PA benchmarks placing them at a significantly increased risk for obesity. Furthermore, the PA habits of young Black women and interventions to address these habits are understudied, which could have implications for chronic health concerns related to PA at older ages.

Aims: The current pilot study attempted to address the following questions: 1) Is there a difference in reported PA amounts pre- and post- study? 2) Are weekly afro-centric themes associated with weekly PA amounts?

Methods: A community sample of 36 African-American women between the ages of 18 and 39 were eligible to participate in a six-week, pilot physical activity intervention. The women were randomly placed in an information-only group or intervention group. Thirty women started the study during week one (Information-only participants $N=13$; Intervention $N=17$). Twenty-one women attended at least four of six weekly sessions (Information-only participants $N=10$; Intervention $N=11$) and analysis is based on this portion of the sample. Self-report physical activity was collected for each group. The intro group received non-culturally tailored handouts that included workout tips, stress management ideas, and basic nutrition. The intervention group received the same weekly information, but it was tailored to Black women with the use of representative pictures and used themes that are central to African-centered wellness. These themes included cultural worldview, self-awareness, authenticity, Black women's hair care, and African-centered principles of wellness in the context of PA.

Results: There was not a significant difference in weekly pre- and post-study physical activity duration in either group, nor was there a significant difference when comparing groups. For the class group, Afrocentric weekly themes encouraging PA were not significantly associated with weekly PA; although participants reported value of the themes in other areas of their lives. The results suggest more exploration of cultural themes is needed with larger sample sizes.

USING THE IPAQ LONG-FORM TO EXAMINE SELF-REPORTED PHYSICAL ACTIVITY LEVELS IN WOMEN WITH DIFFERENT EMPLOYMENT STATUSES

Sarah J. Cosgrove, PhD¹, Katie M. Heinrich, PhD², Walker S. C. Carlos Poston, PhD, MPH³¹Kansas State University, Council Grove, KS; ²Kansas State University, Manhattan, KS; ³National Development and Research Institutes, Leawood, KS

Background Regular physical activity is associated with improved health. Despite clear benefits, only 21% of US adults meet current physical activity guidelines. Women are less active than men, with variation over the lifespan. Further, women's participation in the US labor force has increased since WWII, which may affect the perceived time for physical activity – a key barrier. Continuing labor force changes (e.g., technological advances, overtime) may have adverse health effects (e.g., decreased physical activity, sedentary time during working hours). This study examined the relationship of self-reported physical activity levels among women by employment status.

Methods Participants were 569 women (age 44.9 ± 14.6 and married $n=301$, 52.9%). Participants were from 21 census block groups, stratified by household income and percent ethnic minority across a metropolitan city in the Midwest. Participants completed a 60-minute household survey including demographics and the International Physical Activity Questionnaire (IPAQ; long form). Activities were reported in hours/day. Values were transformed into METs to estimate energy expenditure and categorized into three activity levels (*high*, *moderate*, and *low* using the IPAQ scoring guide). Employment was categorized as *employed* (employed, self-employed, $n=342$, 60.1%), *unemployed* (out of work, $n=25$, 4.4%), *not employed for wages* (homemaker, student, $n=104$, 18.3%), and *other* (retired, other, refused, $n=98$, 17.2%). Chi-square analysis with SPSS 25 was conducted to examine differences in self-reported physical activity by employment status.

Results The majority of women who were *employed* reported mostly *high* ($n=160$, 46.8%) and *moderate* ($n=109$, 31.9%) levels of physical activity (few reported *low* levels; $n=73$, 21.3%). In contrast, the majority of women in all three other employment categories reported *low* levels of physical activity (*unemployed* $n=18$, 72.0%; *not employed for wages* $n=54$, 51.9%; *other* $n=69$, 70.4%). These differences were statistically significant, $\chi^2=111.8$, $p<.001$.

Conclusions Women who are employed are significantly more likely to report moderate to high levels of physical activity, despite potentially having less available time to do so. This may be associated with reporting activities related to working as physical activity participation. Future research should prospectively study women of different employment groups to determine sources of physical activity and inform behavioral physical activity interventions.

ASSOCIATIONS BETWEEN COLLEGE STUDENTS' AND THEIR PEERS' PHYSICAL ACTIVITY USING PEER SOCIAL NETWORK MEASURES

Natalie R. Smith, MS¹, Leah Frerichs, PhD¹, Kristen Hassmiller Lich, PhD¹, James Moody, PhD², Giselle Corbie-Smith, MSc, PhD¹, Allison E. Aiello, MS, PhD¹¹University of North Carolina at Chapel Hill, Chapel Hill, NC; ²Duke University, Durham, NC

Introduction. Many college students do not meet physical activity recommendations and their level of physical activity tends to decline throughout college. Despite knowledge of dramatic changes in social environments during college, little research has examined how this may relate to physical activity in college. The purpose of this study was to examine associations between college students' physical activity levels using data from a large network of predominantly freshman.

Method. Data were derived from the eX-FLU social network study, which studied common respiratory infectious disease transmission among primarily freshman students living on-campus at a large public university during the 2012–13 academic year. 590 enrolled students who were recruited via chain-referral filled out online demographic and health surveys at baseline and reported their social contacts over 10 weeks. For participants who reported at least one contact during the study, we computed aggregate network demographic and behavior measures. An unweighted and weighted average of contact physical activity were calculated. In the weighted average, weights were based on the number of times participants reported interacting with a given contact over the 10-week period. We used generalized linear models to examine associations between participant's physical activity and average contact physical activity, controlling for relevant demographic, health behavior, and network-level variables as well as clustering within campus residence house.

Results. Under half (44%) of participants reported being active on 4+ days/week. Participant's physical activity and average contact physical activity were significantly associated ($\beta=0.411$, $p<0.001$) and this association remained after adjustment ($\beta=0.332$, $p<0.001$). In analyses that used the weighted average contact physical activity, associations were slightly larger in magnitude in both the unadjusted ($\beta=0.439$, $p<0.001$) and adjusted ($\beta=0.347$, $p<0.001$).

Discussion. This study provides evidence of an association between physical activity levels in a network of college students. Physical activity promoting interventions in college settings could consider strategies that capitalize on social environments, e.g., by engaging small groups of peers in active social activities instead of targeting individuals. Future research should collect longitudinal network and physical activity data so analyses can explore dynamic physical activity relationships within social networks.

10:00 AM-11:00 AM

EVEN A LITTLE EXERCISE INCREASES MOTIVATION TO BE MORE PHYSICALLY ACTIVE: SELF-DETERMINATION THEORY AND EXERCISE DOSAGE

Kelsey Ufholz, PhD¹, Kyle Flack, PhD, RD², Roemmich N. James, Ph.D.³¹USDA Grand Forks Human Nutrition Research Center, Grand Forks, ND; ²University of Kentucky, Lexington, KY; ³USDA-ARS Grand Forks Human Nutrition Research Center, Grand Forks, ND

Background: Self-determination theory (SDT) states intrinsic motivations drive greater participation in exercise than external or amotivations. Similarly, exercise and exercise self-efficacy increase in reciprocal fashion. It is unknown whether differing amounts of, or exposure to, exercise influence changes in motivations over time.

Objectives: To determine whether exercise self-efficacy and motivations are increased by engaging in a greater dose of exercise.

Methods: Sedentary adults (N = 104; BMI 19.3–34.9) completed 6 weeks of treatment. Participants were randomly assigned to 150 kcal/session, 300 kcal/session, or a no-exercise control group. Exercise groups engaged in aerobic exercise of self-chosen mode (treadmill, elliptical, stair stepper), intensity and pattern 3 days/week, with a 4 week follow-up. Exercise adherence and energy expenditure was self-monitored (Sensewear Mini) and reviewed weekly by staff. Motivations, competence, autonomy, relatedness, and self-efficacy were tested at baseline, 6 and 10 weeks.

Results: There were few group differences in motivation change. Amotivation decreased ($p < 0.01$) from baseline to 6 weeks with no difference in treatment groups. Identified, integrated, intrinsic regulation, and autonomy increased ($p < 0.05$) from baseline to 6 and 10 weeks. ‘Sticking to it’ decreased ($p < 0.05$) from baseline to 6 and 10 weeks. ‘Making time’ showed both treatment ($p < 0.05$) and time effects ($p < 0.05$), but no interaction. Specifically, ‘making time’ decreased from baseline to 6 and 10 weeks ($p < 0.05$) and the 150 kcal group reported greater ‘making time’ than the control group. Self-efficacy showed significant treatment ($p < 0.05$), time ($p < 0.001$), and interaction ($p < 0.05$) effects. All groups reported decreases ($p < 0.05$) from baseline to 6 and 10 weeks in self-efficacy; however the 300 kcal group did not decrease as much as the control group ($p < 0.05$).

Conclusion: Motivations are equally impacted regardless of exercise dosage, suggesting that even dosages that are lower than activity guideline recommendations can improve motivations. Novice exercisers showed decreases in exercise-self-efficacy. However greater exercise doses may attenuate this decrease.

10:00 AM-11:00 AM

EXERCISE PREFERENCE AND TOLERANCE AS MEDIATORS BETWEEN EXERCISE MOTIVATIONS AND BEHAVIOR

Kelsey Ufholz, PhD¹, Kyle Flack, PhD, RD², Roemmich N. James, Ph.D.³¹USDA Grand Forks Human Nutrition Research Center, Grand Forks, ND; ²University of Kentucky, Lexington, KY; ³USDA-ARS Grand Forks Human Nutrition Research Center, Grand Forks, ND

Background: Tolerance for exercise intensity facilitates usual physical activity. Novice exercisers may need to develop such tolerance for exercise to become a habit. Self-determination theory states internal motivations drive exercise participation, while external or amotivations are less predictive. Increases in exercise self-efficacy also increase exercise participation. Developing tolerance for exercise intensity via exposures to intense exercise may increase the relative reinforcing value of exercise (RRV) and the self-efficacy for exercise. The relationships between increases in exercise motivations or self-efficacy and greater physical activity may be mediated by an increased ability to tolerate exercise discomfort. Conversely, changes in tolerance may be mediated by changes in exercise reinforcement and self-efficacy.

Objectives: To determine whether changes in the preference for or tolerance of exercise intensity mediates or is mediated by changes in exercise motivations and behavior.

Methods: Sedentary adults (n = 93, BMI 19.0–34.9 kg/m²) participated in a 6 week aerobic exercise program (3 days/week, 150 or 300 kcal/day at self-chosen intensity or no exercise control), followed by 4 weeks of no prescribed exercise. Outcomes included changes in RRV exercise and tolerance of exercise intensity and MET intensity of training bouts (AveMETs).

Results: At 6 weeks, AveMETs correlated ($p < 0.05$) with changes in amotivation ($r = -0.38$), integrated regulation ($r = 0.23$), identified regulation ($r = 0.24$), and tolerance ($r = 0.23$), and with amotivation at 10 weeks ($r = -0.23$); RRV change correlated with changes in integrated regulation ($r = 0.22$) and tolerance ($r = 0.31$) at 6 weeks and negatively with external regulation ($r = -0.22$) at 10 weeks. When amotivation and tolerance predicted AveMETs, only amotivation was significant ($\beta = -0.32$, $p < 0.05$), suggesting amotivation mediates between tolerance and AveMETs. When external regulation and tolerance predicted RRV, only tolerance ($\beta = 0.29$, $p < 0.05$), remained significant. When integrated regulation and tolerance predicted RRV, only tolerance ($\beta = 0.26$, $p < 0.05$) remained significant, suggesting mediation between RRV and these factors.

Conclusion: Changes in exercise were predicted by decreases in amotivation, not increases in intrinsic motivation. Tolerance mediates between external and integrated regulations and RRV, while amotivation mediate between tolerance and AveMETs.

FAMILY CHILD CARE PHYSICAL ACTIVITY ECOLOGY: A QUALITATIVE GIS STUDY

Roger Figueroa, PhD, MPH, MSc

Harvard University, Boston, MA

Background and Purpose: Most preschoolers fail to meet recommended guidelines for physical activity, and those attending family child care settings spend 9 minutes or less per hour of care in physical activity compared to the recommended 15 minutes per hour of care. Family child care providers (FCCPs) and settings play a fundamental role in shaping preschool children's development, including their physical activity behaviors. However, there is a dearth of research focused on the promotion of children's physical activity within the family child care context.

Objectives: This mixed-method study examines the spatial and social processes by which FCCPs shape opportunities for preschoolers' physical activity engagement in their community context.

Methods: Data from this study came from a sample of family child care providers from a Midwestern U.S. state, gathered between December 2013 to April 2017 as part of the Family Child Care Health Study. Approximately 342 family child care homes with a sub-set of 21 FCCPs were recruited from the larger pool that completed 42 qualitative, semi-structured interviews (two per FCCP). Descriptive GIS visualization methods were used to shed light on environmental features linked to each family child care home. Descriptive statistics were performed to summarize demographic characteristics of FCCPs in the qualitative subsample. Sociospatial grounded theory and analytical induction approaches facilitated analyses of narrative data from these FCCPs, and subsequent development of theoretical frameworks shed light on the processes by which they promote physical activity in the family child care context.

Findings: Overall, a theoretical framework emerged from the data that explains sociospatial processes shaping preschoolers' physical activity opportunities within the Family Child Care Physical Activity ecology. Key contextual factors (i.e., state- and site-level policies, access to indoor and outdoor spaces, FCCPs program capabilities) shape these opportunities through the core category of flexible physical activity programming. This programming ensures developmentally diverse children in mixed-age groups are able engage in what is known in the literature as "children's play." While FCCPs were asked about physical activity more generally, their conceptualization within this context revolves around the promotion of play for various purposes, including play for: 1) enjoyment and self-expression; 2) for expending children's exuberant excess of energy; 3) free, aimless, and diverting activity without purpose; 4) motor skill development. This framework may now serve as a secondary tool for examining opportunities for preschoolers' physical activity in this understudied context and with this underserved population.

IDENTIFYING AND DESCRIBING SEGMENTS OF OFFICE WORKERS BY ACTIVITY PATTERNS

Michael A. Close, MS, Leslie A. Lytle, PhD, Anthony J. Viera, MD, MPH, Ding-Geng Chen, PhD, Laura A. Linnan, ScD, Carmina G. Valle, PhD, MPH

University of North Carolina at Chapel Hill, Chapel Hill, NC

Background: Many office workers struggle to engage in recommended levels of physical activity. Identifying segments of office workers by their existing patterns of activity behaviors may facilitate development of workplace health programs.

Purpose: The purpose of this study is to identify segments of office workers by the types of activity behaviors in which they typically engage. Associations of identified segments with demographic characteristics and objectively-measured weekly minutes of light and moderate-vigorous physical activity are examined.

Methods: Data are from the 12-month baseline phase (March 2015 - March 2016) of the Effects of Physical Activity Calorie Expenditure (PACE) Food Labeling study conducted in three worksites of a health insurer in North Carolina. Participants were invited to complete a demographics questionnaire, self-reported physical activity questionnaire (CHAMPS), and wear an accelerometer (Actigraph) for seven consecutive days. Latent class analysis was used to identify segments of office workers (n=239) by self-reported activities of daily living and exercise behaviors. The Vermont 3-step approach was used to examine the association of demographic characteristics with segment membership, and estimate segment-specific weekly minutes of objective physical activity.

Results: A majority of the analytic sample was female (n = 196; 82.0%), with a Bachelor's degree (n = 154; 64.4%), and married or in a domestic partnership (n = 129; 54.0%). A two-segment solution demonstrated best fit; segments were labeled "exercise, heavy domestic" and "non-exercise, light domestic." Being female was associated with lower odds of membership in the "exercise, heavy domestic" segment (OR = 0.18; 95% CI = 0.06, 0.52), while those with at least a Bachelor's degree had higher odds of membership (OR = 2.12; 95% CI = 1.02, 4.40). Age, children in the household, occupation, race/ethnicity, and marital status were not significantly related to segment membership. Mean weekly minutes of moderate-vigorous physical activity were significantly greater (p < 0.001) for the "exercise, heavy domestic" segment (mean = 209.5 minutes; SE = 13.5) than the "non-exercise, light domestic" segment (mean = 77.5 minutes; SE = 4.0).

Conclusions: We found two segments of office workers that correspond to sufficiently active and insufficiently active behavioral patterns. Findings suggest that female and lower educated office workers might have particularly greater need for physical activity behavior change. An understanding of activity patterns among office workers may help workplace physical activity promotion efforts appeal to more workers.

INTERRELATIONSHIPS BETWEEN PHYSICAL ACTIVITY, BINGE EATING, AND EMOTIONAL EATING WITHIN AN OVERWEIGHT AND OBESE POPULATION

Megan C. Pejsa-Reitz, MS¹, Jennifer Battles, M.S.², Karen K. Saules, Ph.D.³¹Eastern Michigan University, Ann Arbor, MI; ²Eastern Michigan University, Ypsilanti, MI; ³Eastern Michigan University, Ypsilanti, MI

Although engaging in moderate levels of exercise is an adaptive health behavior, excessive exercise is associated with disordered eating. Likewise, physical inactivity is linked with adverse health outcomes. We hypothesized that binge eating (BE) and emotional eating (EE) may adversely moderate the relationship between exercise and weight. We conducted two studies to explore these hypotheses. College students ($N=1485$; Mean Age=21.09, 66% Female; 67% White, Mean BMI=25.70) completed an online battery of assessments measuring excessive exercise for weight/shape reasons (Excessive Exercise), exercise barriers, BE, and EE. In Study 2, Amazon Mechanical Turk participants (MTurk; $N=585$; Mean Age=39.66, 58% Female; 77% White, Mean BMI=27.46) completed these same measures. As expected, BMI was associated with BE ($p=.001$). Notably, overweight individuals reported more Excessive Exercise than normal weight individuals ($p=.003$). We conducted subsequent analyses, and found at step 1 of a hierarchical regression analysis, exercise barriers and Excessive Exercise contributed significantly to BMI, $F(2,746)=7.86$, $p<.001$, $R^2=.021$). Introducing BE in step 2 explained an additional 4.3% of variance in BMI, $F(3,745)=17.05$, $p<.001$, $R^2=.064$. Importantly, the introduction of BE to the regression model reduced exercise barriers and Excessive Exercise to nonsignificant in predicting BMI ($p>.05$). These findings suggest that BE may be a more important treatment target than exercise barriers or Excessive Exercise for some individuals. Reasoning that EE was connected to BE and obesity, we conducted moderation analyses using the bootstrapping approach (Preacher & Hayes, 2004). EE and BMI were associated with BE ($F(3,918)=73.23$, $p<.001$, $R^2=.193$), with main effects revealing that individuals with higher BMI and who endorsed more EE, also endorsed more BE. Results were consistent across both studies. Because EE is a known precursor to BE, and our findings suggest that individuals with obesity are susceptible to reporting more exercise barriers, less Excessive Exercise, and BE, interventions targeting emotion regulation are recommended for this population. Future research should examine potential differences between obese treatment-seeking individuals and their counterparts.

IS SEDENTARY BEHAVIOR AN IMPORTANT INTERVENTION TARGET FOR CAREGIVERS OF INDIVIDUALS WITH ALZHEIMER'S?

Chelsea Larsen, MPH, Delia West, PhD

University of South Carolina, Columbia, SC

PURPOSE: Caregivers of individuals with Alzheimer's Disease (AD) experience challenges to maintaining healthy behaviors. To date, no health promotion interventions have focused on decreasing sedentary behavior in this population, despite the known detrimental effects of sedentary behavior on health. The current study examines the sedentary behavior patterns of the caregivers of individuals with AD.

METHODS: Adults with AD who resided in their homes were identified in a mandatory statewide Alzheimer's Disease Registry as a part of a population-based survey. Caregivers were surveyed about their personal health behaviors, including body weight and self-reported sedentary behavior. The validated sedentary behavior questionnaire included estimates of time spent in various sedentary activities (e.g., traveling, watching TV, sitting at computer or tablet, etc.). A subset of the caregivers also wore a BodyMedia SenseWear armband for 7 days to provide an objective measure of sedentary behavior and physical activity. Activity level was classified according to the following MET values: 1.0–1.5 METs was classified as sedentary, 1.6–2.9 METs as light physical activity (PA), and > 3.0 METs as moderate-to-vigorous PA (MVPA).

RESULTS: Caregivers ($N=47$) were mostly obese (M BMI = 32.28 ± 7.7) and self-reported an average daily sedentary time of 7.6 ± 1.6 hours/day, with TV watching (2.9 ± 0.3 hours/day) emerging as the most common sedentary activity which they identified. Objective measures of sedentary behavior collected on the subset of participants ($N=14$) indicate that they wore the armband an average of 6.9 ± 0.4 days with an average total wear time of 21.9 ± 2.3 hours/day and waking wear time of 16.4 ± 2.0 hours/day. Caretakers spent an average of $77.8 \pm 11.3\%$ of the day or 12.8 ± 2.8 hours sedentary. They engaged in light PA an average of $18.3 \pm 7.8\%$ of the day or 2.9 ± 1.7 hours and were engaged in MVPA on average only $3.9 \pm 4.3\%$ of the day or 0.6 ± 0.6 hours.

CONCLUSION: Caregivers spend a significant amount of time engaged in sedentary behavior. Objective measures indicate that the actual time spent sedentary was much greater than the amount of time caregivers perceived themselves to be sedentary. However, caregivers recognized that they are sedentary for a large proportion of their day. Given the negative impact of sedentary time on health outcomes, caregivers would benefit from interventions to reduce sedentary behavior.

MEASURING GROUP COHESION FOLLOWING AN EXERCISE INTERVENTION IN BREAST CANCER SURVIVORS

Heather J. Leach, PhD¹, Kelley Covington, B.S.², Corrine H. Voss, MS³, Steven Schuster, MD⁴, Samantha M. Harden, PhD⁵

¹Colorado State University, Fort Collins, CO; ²Colorado State University, Fort Collins, CO; ³Colorado State University, Aurora, CO; ⁴University of Colorado Health, Fort Collins, CO; ⁵Virginia Tech, Blacksburg, VA

Background: Group-dynamics based (GDB) interventions target perceptions of group cohesion. Group cohesion is positively associated with physical activity adherence in several populations, but no previous interventions for breast cancer survivors have utilized GDB exercise or measured group cohesion.

Purpose: To report on the reliability of the Physical Activity Group Environment Questionnaire (PAGE-Q) and levels of group cohesion following an 8-week exercise intervention in breast cancer survivors (BCS).

Method: BCS who completed chemotherapy and/or radiation treatment within the previous year ($N=12$, M Age= 51.7 ± 9.1) were enrolled in three cohorts (Group 1 $n=5$, Group 2 $n=4$, Group 3 $n=3$). The intervention consisted of exercise sessions 2x/week for 1-hour, and 4, 1-hour PA behavior change education/discussion sessions. Group cohesion was measured at week 1 and week 8 using the four subscales of the PAGE-Q: attraction the group-task (ATG-T), and -social (ATG-S), group integration- task (GI-T), and -social (GI-S). Example items include, "If this program ended, I would miss my contact with others", and "We encourage each other to get the most of the program". Responses use a 9-point Likert scale, from strongly disagree to strongly agree. Subscale items were summed and averaged. Higher scores indicate a greater perception of cohesion. Reliability analyses were conducted for each subscale using Chronbach's α . Analysis of variance (ANOVA) compared subscale scores between groups.

Results: Week 8 PAGE-Q subscales scores, and change from week 1 were: ATG-S $M=7.3 \pm 1.1$, $\Delta=.19$; ATG-T $M=8.3 \pm .71$, $\Delta=.26$; GI-T $M=8.0 \pm .89$, $\Delta=1.5$; GI-S $M=6.4 \pm 1.4$, $\Delta=1.0$. Reliability of the PAGE-Q was high for ATG-S ($\alpha=.855$) and ATG-T ($\alpha=.902$), but relatively low for GI-T ($\alpha=.513$), and GI-S ($\alpha=.533$). Chronbach's α if deleted was $\alpha=.733$ for "Members of our group enjoy helping if work needs to be done to prepare for activity sessions" in GI-T, and $\alpha=.616$ for "We spend time socializing with each other before or after our activity sessions" in GI-S. GI-S was significantly different between groups [$F(2,11)=7.7$, $p=.011$], with lower scores in group 3 ($M=4.5 \pm .9$) compared to group 1 ($M=7.1 \pm .91$) and group 2 ($M=7.0 \pm 1.1$).

Conclusion: A high level of group cohesion was observed, providing a useful benchmark for future researchers. The ATG-S and ATG-T subscales were reliable in a sample of BCS. Future studies in BCS should examine the impact of intervention strategies on targeted group cohesion outcomes.

MOTIVATION FOR EXERGAME PLAY INVENTORY: CONSTRUCT VALIDITY AND RELATIONSHIP TO GAME PLAY

Gregory Norman, PhD¹, Amanda E. Staiano, PhD², Marc A. Adams, PhD, MPH³

¹West Health Institute, La Jolla, CA; ²Pennington Biomedical Research Center, Baton Rouge, LA; ³Arizona State University, Phoenix, AZ

Introduction: Identifying innovative physical activity tools that motivate adolescents to engage in sustained MVPA remains a public health priority. Exergames are video games that involve physical activity and provide an opportunity to transform sedentary screen-time into active screen-time. In this study, we evaluated the construct validity of a tool to measure motivation to play exergames and its relationship with game play.

Methods: Data were from a trial of sixty-one adolescents (11 to 15 years of age, 38% female and 38% of Hispanic origin) assigned to one of four exergames to play in their home for 4 weeks. Parents provided baseline demographic information. Adolescents completed the Motivation for Exergame Play Inventory (MEPI) at the end of week 1 and completed game logs to record exergame play over the four weeks. Factor analysis with varimax rotation was used to determine the number of distinct composite factors within the MEPI. Cronbach's α assessed internal consistency of each resulting factor. Separate regression models were used to examine the association of each factor with total game play over 4 weeks.

Results: Twenty-two of 28 items were retained in the MEPI to measure five distinct constructs of motivation: sensory immersion/flow, user control, goals of the game, performance feedback, and challenge/difficulty. Cronbach's α ranged from .50 to .87. Sensory immersion/flow ($\beta = .39$, $p = .005$) and user control ($\beta = .27$, $p = .043$) were significantly associated with total game play in adjusted regression models.

Conclusion: Evidence of construct validity for the MEPI was demonstrated. Sensory immersion and flow was the strongest factor related to higher amounts of total game play. This finding supports the hypothesis that exergame play allows a player to experience flow and that flow is an important predictor for accumulated minutes of exergaming. Control was the second strongest factor contributing to total game play and may have been influenced by the game controller peripherals, which mimicked authentic sports such as a tennis racquet, bowling ball, and boxing gloves. The MEPI is a useful tool to assess players' motivation for exergaming, an important contributor to sustained physically active game play. The MEPI survey should be validated in other populations and with other active videogame platforms to further test its validity.

MOTIVATIONAL INTERVIEWING AND PHYSICAL ACTIVITY CHANGE IN PARKINSON'S DISEASE

Edeth Engel, BS¹, Amy Eisenstein, PhD², Allison Todd, CCRC³, Danny Bega, MD⁴, Linda Ehrlich-Jones, PhD, RN⁵¹Shirley Ryan AbilityLab, Chicago, IL; ²CJE SeniorLife, Chicago, IL; ³The Shirley Ryan AbilityLab (formerly The Rehabilitation Institute of Chicago), Chicago, IL; ⁴Northwestern University, Chicago, IL; ⁵Shirley Ryan AbilityLab, Aurora, IL

Background: Parkinson's disease (PD) is the second most common neurodegenerative disorder affecting up to 1 million people in the US and has no known cure. Exercise plays a critical role in managing chronic illnesses, such as PD, and in promoting healthy aging. This study phase sought to identify common physical activities that people with PD engage in and ways to use a web-based application (app) for motivation; in order to create a targeted intervention, with input from persons with PD, for the subsequent randomized clinical trial...

Method: Participants in two focus groups of people with PD were asked about their physical activity and preferences for an educational intervention about PD. The focus groups discussed a prototype of an app to monitor physical activity on a smartphone, tablet or computer, as part of the physical activity intervention. Focus groups were recorded and transcribed by a court reporter. Usability testing of the app was conducted to further refine preferences and barriers for use of the app intervention. Eight participants from the focus groups participated in a 1-week testing period. Participants provided feedback on the app during a semi-structured telephone interview after the testing period.

Results: Focus group participants included 8 men and 6 women. Usability testing participants included 5 men and 3 women. The majority of all participants were between 65–74 years old. Focus group transcripts and telephone interviews were reviewed and coded by two team members. Focus groups informed us of the exercise categories that needed to be in the app and how participants might use the app for goal setting and activity monitoring. Both individual exercise, such as walking, and group exercises, such as Tai Chi, Pilates, and boxing were identified by 64% of the participants. Educational materials requested included fatigue management, new research findings, and available community resources. Usability testing participant suggestions included more positive reinforcements on the app, decreased app screen scrolling, and an easier to follow user manual.

Conclusions: People with PD are involved in a variety of physical activities that include, stretching, strengthening, and aerobic activities. Stakeholder input in the early stages of this project helped to shape the app for tracking physical activity and led us to create a user-friendly website for the educational control intervention.

NOT FOR EVERYONE: PERCEPTIONS OF POKÉMON GO AND PHYSICAL ACTIVITY IN APP USERS AND NON-USERS

Madelaine Gierc, MPH, PhD¹, Sean Locke, PhD², Larry Brawley, PhD³¹Queen's University, Duncan, BC, Canada; ²University of British Columbia, Windsor, ON, Canada; ³University of Saskatchewan, Saskatoon, SK, Canada

Pokémon Go is an augmented-reality game that moves players around the community collecting monsters, acquiring items, and battling opposing teams. Social critics and health researchers have identified Pokémon Go as a high-impact health promotion tool, with the ability to increase physical activity and prompt community engagement. However, do we really understand the motivational factors that draw people toward Pokémon Go? Equally important: do we understand the barriers preventing Pokémon Go use? Answers may provide researchers with insights into the individual-level factors associated with technological intervention uptake. Our purpose was to investigate how Pokémon Go users (N=448) and non-users (N=166) differ in their perceptions of Pokémon Go and physical activity. Participants completed an online questionnaire that examined the social cognitive constructs of barriers, outcome expectancies (motivation), and self-efficacy. Non-users primarily identified not having enough time as a barrier to game uptake. Wilk's statistic indicated significant differences between users and non-users in Pokémon Go outcome expectancies, $p < 0.001$, and physical activity outcome expectancies, $p < 0.001$. Whereas users had more-favourable views of Pokémon Go, non-users had more-favourable views of physical activity. Non-users reported significantly higher self-efficacy for walking 2km, 5km, and 10km distances, $p < 0.001$; and perceived walking as more enjoyable, $p < 0.001$. Overall, findings suggest barriers to Pokémon Go use may be rooted in individuals' perceptions of the app rather than perceptions of physical activity. Indeed, this preliminary data suggests that Pokémon Go may be particularly effective for encouraging physical activity in those with relatively low views of activity.

PARENTAL COMMUNICATION AND PARENTAL STRESS AS PREDICTORS OF PHYSICAL ACTIVITY IN OVERWEIGHT AFRICAN AMERICAN ADOLESCENTS

Colby J. Kipp, B.S.¹, Lauren H. Law, MA², Dawn K. Wilson, PhD², Allison Sweeney, PhD², Asia M. Brown, B.S.³, Mary B. Hoover, MBA, B.S.²

¹University of South Carolina, Wagener, SC; ²University of South Carolina, Columbia, SC; ³University of South Carolina, High Point, NC

Overweight adolescents struggle to meet recommended physical activity (PA) levels as compared to healthy weight adolescents. Family Systems Theory affirms that positive parenting skills, such as open communication between adolescent and parent may contribute to behavior change and positive adolescent health outcomes such as PA. Perceived stress of the parent could have an effect on communication between parent and adolescent regarding health outcomes, but little research has been conducted analyzing this relationship. The current study aimed to examine the interaction between parental communication frequency and parental stress as predictors of adolescent moderate-to-vigorous PA (MVPA) and adolescent light PA (LPA). Participants were African American adolescents ($N = 60$; $M_{\text{age}} = 13.05$ years; 73% female; $M_{\text{BMI}} = 2.05$) and their caregivers ($M_{\text{age}} = 43.92$ years; 92% female) enrolled in the Families Improving Together (FIT) for Weight Loss trial, which tests the efficacy of a motivational plus positive parenting intervention on weight loss in African American adolescents and their parents. Parental communication frequency and parental stress were measured using validated self-report surveys. Minutes of MVPA and LPA were measured using 7-day Actical accelerometry estimates. Regression analyses indicated that the model predicting adolescent MVPA was significant beyond covariates (child BMI, child age, child sex, family income) ($F(6, 53) = 2.37, p < 0.05; R^2 = 0.21$). Parent-reported communication frequency about health behaviors was a significant positive predictor of adolescent MVPA ($B = 4.73, SE = 2.32, p < 0.05$) such that greater communication frequency was associated with more minutes of daily MVPA in adolescents. Parent-reported stress was not a significant predictor of MVPA ($B = -0.92, SE = 2.52$). Additionally, regression analyses indicated that the model predicting adolescent LPA was significant ($F(6, 53) = 3.48, p < 0.05; R^2 = 0.28$). Child age was a significant predictor of LPA ($B = -12.00, SE = 3.50, p < 0.05$) such that older youth engaged in lower levels of LPA, however, no other factors were significant. Results indicate frequent communication between parents and adolescents about health behaviors is predictive of MVPA but not LPA. Interestingly, parent communication did not interact with stress in predicting PA outcomes. Further research should replicate these findings showing the positive relationship between positive parental communication and PA in underserved overweight African American adolescents.

PHYSICAL ACTIVITY CONSISTENT WITH ONE'S VALUES IS ASSOCIATED WITH HIGHER LEVELS OF PHYSICAL ACTIVITY IN A COLLEGE STUDENT SAMPLE

John T. Freeman, M.A.¹, Matthew Whited, PhD, Licensed Psychologist¹, Jordan Ellis, MA¹, Ansley Taylor Corson, MA¹, Emily P. Midgett, B.A.²

¹East Carolina University, Greenville, NC; ²East Carolina University, Vanceboro, NC

Introduction: Engaging in physical activity (PA) is associated with numerous physiological and psychological benefits. However, as few as 21% of Americans obtain adequate PA. Many newer PA promotion interventions, based on Acceptance and Commitment Therapy (ACT) or Behavioral Activation (BA), emphasize value-driven behavior, and have found promising results. Therefore, leveraging an individual's existing values and incorporating PA into their values may be an impactful method for increasing PA. However, there is a dearth of evidence for this assertion. The purpose of the current study was to evaluate whether congruence between values and PA behavior was associated with greater PA.

Methods: 1,738 undergraduates completed an online survey. Participants completed the International Physical Activity Questionnaire (IPAQ) short form and the PHQ-9. To assess for congruence between values and PA behavior, the Valued Living Questionnaire (VLQ) was modified for PA. Participants were asked to rate how important 12 values were to them, then subsequently rated how often they participated in 1–3 PA behaviors for each value area. For example, participants rated how much they valued family on a 1–7 scale, then rated how often they exercise with family. Congruence scores were calculated by dividing value importance by average rating of value-consistent PA; scores closer to 1 indicated greater congruence.

Results: Associations between values-PA congruence and weekly PA (IPAQ), converted to METs, were examined using linear regressions, controlling for age, gender, and race. Greater congruence between values and PA behaviors was significantly associated with: greater total METs ($t = 14.10, p < .001$); more average minutes/week of walking ($t = 4.72, p < .001$), moderate-intensity PA ($t = 10.41, p < .001$), and vigorous-intensity PA ($t = 14.94, p < .001$). Results were similar when each of the 12 value areas were analyzed individually (all p 's $< .05$). Additionally, both total METs ($t = -3.97, p < .001$) and values-PA congruence ($t = -7.45, p < .001$) were significantly associated with lower self-reported depressive symptoms.

Discussion: Greater congruence between an individual's values and value-consistent PA was associated with higher levels of PA. These results suggest that values-based interventions may be particularly effective for increasing PA. Future research using more objective measures of PA is warranted to better understand the association between PA and values and determine how this can be used to promote PA.

PHYSICAL HEALTH AND BINGE WATCHING

Natalia Prokop, N/A¹, Julia Carroccio, N/A², Alexandra Sanders, N/A¹, David Rivetti, N/A², Chelsey Parker, BS³, Thomas Lawler, N/A², Jacob Burmeister, PhD¹

¹University of Findlay, Findlay, OH; ²University of Dayton, Findlay, OH; ³Ball State University, Findlay, OH

Across numerous domains, binge behavior is carries a negative or unhealthy connotation as in “binge eating.” Previous research has shown that binge watching 3 or more times each week is associated with increased levels of anxiety and depression. The current study tested whether binge watching (as defined by participants) is associated with an avoidant coping style and whether it is associated with poor physical health. Participants (N = 177) were recruited online in the spring of 2017 and completed self-report measures of binge watching, anxiety, depression, physical health, and avoidant coping. As predicted, binge watching more than 3 days each week was associated with poorer physical health ($F(1,177)=7.31$; $p = .008$; $\eta^2 = .05$). Counter to predictions, it was not associated with greater avoidant coping ($F(1,177)=6.25$; $p = .058$; $\eta^2 = .02$). As in previous research, binge watching most days of the week was associated with higher levels of anxiety and depression. The results of this study suggest that binge watching at high levels is associated with poor emotional and physical health, though no causal relationships can be inferred. Future studies will need to test whether binge watching is distinct from other forms of sedentary behavior such as reading and playing video games. It also remains to be seen whether binge watching is different than simply having a lot of time in front of screens. Future work should also test whether higher levels of binge watching for those with high depression, high anxiety, and poor health could reflect a healthy coping response. For example, individuals with poor mobility or those lacking access to a safe options for physical activity may spend more time watching.

PREDICTING TREATMENT ADHERENCE FROM BELIEFS ABOUT TREATMENTS' GENERAL-HEALTH VERSUS DIABETES-MANAGEMENT BENEFITS

Kathryn Bunda, B.A.¹, L. Alison. Phillips, B.A., M.A., Ph.D.²

¹Iowa State University, Ames, IA; ²Psychology Department, Iowa State University; War Related Illness and Injury Study Center, Veterans Affairs, New Jersey Health Care System, Ames, IA

This study aimed to identify the influence of patients' beliefs about physical activity (PA) and medication for Type 2 Diabetes (T2D) management on adherence to these treatments in a sample of T2D patients ($N=80$ with complete data). Previous research shows that patients' beliefs regarding medication predict medication adherence (Horne et al., 2014), and patients' beliefs about the benefits of PA for T2D management predict PA engagement (Broadbent et al., 2011). Interestingly, qualitative research indicates that diabetes patients' motives for engaging in PA focus more on general health benefits than illness management (Lascar et al., 2014). The influence of framing treatment as important for general health versus illness management on adherence has not yet been studied. We expect that beliefs about the importance of PA for general health (vs. illness management) will be more strongly related to PA engagement in our sample. In contrast, given that medications are prescribed for a specific illness, we expect that patients' beliefs about medications for illness management (vs. general health) will predict medication adherence more strongly. Participants completed baseline measures of beliefs about PA and medicines, used electronic monitors of behavior for one month, and self-reported PA and medication adherence at one-month follow-up. We used factor analysis to verify expected belief variables: PA-for-diabetes-management; PA-for-general-health; medications-for-diabetes-management; medications-for-general-health. Bivariate correlations between belief variables and treatment adherence (medication adherence separately from PA) were compared to test the hypotheses. Analyses revealed that neither set of beliefs about PA predicted subsequent PA ($p>.05$ for self-reported and objective PA). Thus, our hypothesis that general (vs. illness-specific) beliefs would better predict PA was not supported. Further, neither set of beliefs about medication predicted subsequent medication adherence ($p>.05$ for self-reported and objective adherence). Thus, our hypothesis that illness-specific (vs. general) medication beliefs would better predict adherence was not supported. In conclusion, the current data found no relationships between patients' treatment-related beliefs and predicted treatment adherence. Future research should continue to investigate predictors of adherence so that health practitioners can utilize strategies that will affect the most adherence in their patients.

THE EFFECT OF MESSAGE FRAMING ON FITNESS CLASS PREFERENCES AND ATTENDANCE INTENTIONS: A FLABBERGASTING DISCONNECT

Pamela Lundeberg, MA, Daniel Graham, Ph.D

Colorado State University, Fort Collins, CO

Background: Despite the irrefutable benefits of exercise, less than 25% of Americans currently meet the ACSM's physical activity (PA) recommendations (Katzmarzyk et al., 2017). Inspiring change in PA behavior is dependent in part on the way in which the benefits of PA – or costs of physical inactivity – are conveyed, or *framed*. A number of studies have been conducted to determine the most effective framing strategy for PA promotion. However, these studies have focused on increasing individual PA participation (i.e., encouraging an individual to engage in exercise his/herself) rather than at the group level (e.g., attending Group Fitness [GF] classes). As GF classes aid in gym retention rates and assist in regular exercise adherence (Nielsen, 2014; IHRSA, 2014), promoting fitness at the group level may be beneficial for inspiring lasting change in PA behavior. Accordingly, the present study sought to determine the effect of different types of message framing on college students' preferences for – and intention to attend – a variety of group fitness classes.

Method: In study 1, participants (N = 143) read four versions of different fitness classes and were asked which version of the class they liked best. Each version presented class information with a different type of frame – health-related gain, health-related loss, appearance-related gain, and appearance-related loss – allowing us to compare within-participant preference for these frames. In study 2, participants (N = 513) read descriptions of 10 fitness classes – all of which contained descriptions with one of the four framings tested in study 1 or none of these framings – and were asked how likely they were to attend each of these 10 classes.

Results: In study 1, participants reported greater preference for the class descriptions that contained gain-framed appearance-related outcomes. In study 2, however, participants did not differ in their reported intention to attend fitness classes based on the manner in which the classes were framed (i.e., message framing of the class descriptions did not affect how likely participants were to indicate they would attend a fitness class.)

Conclusions: In our study, intention to attend GF classes did not follow reported preferences. Future research should consider including a more consequential measure (e.g., actual attendance) to determine if action is similarly unaffected by individuals' stated preferences for gain-framed appearance-related GF class descriptions.

THE NEW RUNNER'S HIGH?: EXAMINING RELATIONSHIPS BETWEEN CANNABIS USE AND EXERCISE BEHAVIOR IN COLORADO

Sophie YorkWilliams, MA¹, Charleen Gust, BA², Arielle S. Gillman, MA³, Kent Hutchison, PhD⁴, Angela Bryan, PhD⁵

¹University of Colorado Boulder Boulder, Boulder, CO; ²Department of Psychology and Neuroscience, Boulder, CO; ³University of Colorado Boulder, Boulder, CO; ⁴University of Colorado Boulder Boulder, Department of Psychology and Neuroscience, Boulder, CO; ⁵University of Colorado Boulder, BOULDER, CO

The increasing legal and cultural acceptance of cannabis necessitates that research on its health impact be extended. In the present study, we attempt initial steps toward understanding its impact on exercise behavior in Colorado, a state with legalized cannabis. An anonymous survey on cannabis use and health was advertised through social media and cannabis dispensaries. We explored the relationship between cannabis use and exercise, such as behavior frequencies, and use of cannabis within 1 hour before and/or 4 hours after exercise (CE).

Among the 270 respondents, mean age was 38.9 (SD=17), 144 were male, and 211 (78%) endorsed CE. While CE respondents reported more exercise per week ($p < .05$; $d = .4$), they were also younger ($p < .001$; $d = .5$), and CE was not associated with exercise frequency after controlling for age. Among those who endorsed CE: 75% agreed that cannabis increases *enjoyment* of exercise; 18% were neutral; 7% disagreed. 76% agreed that cannabis enhances *recovery* from exercise; 16% were neutral; 8% disagreed. 55% agreed that cannabis increases *motivation* to exercise; 26% were neutral; 19% disagreed. In the full sample, minutes of aerobic exercise was not correlated with days of traditional cannabis use (flower or edibles) per week. However, each day of high-potency cannabis concentrate use was associated with 6 additional minutes of aerobic exercise per week, even after controlling for age and frequency of traditional cannabis use ($p < .05$; $d = .02$). Concentrate use frequency was not highly correlated with flower ($r = .21$) or edible use frequency ($r = .25$).

These data suggest that many cannabis users in Colorado engage in CE, and that most who do so believe it increases enjoyment of, recovery from, and, to a lesser extent, motivation to engage in exercise. As these factors positively correlate with exercise behavior, CE may play a beneficial role in the health of cannabis users. The positive correlation between use of high-potency concentrates and exercise may reflect lower perceived harm of concentrates compared to smoked flower. Future research will refine and expand upon this foundational study.

UNDERSTANDING ACTION CONTROL OF PHYSICAL ACTIVITY IN MOTHERS WITH YOUNG CHILDREN

Stina J. Grant, BA¹, Madeline V. Juba, BSc. Kinesiology (in progress)², Dr. Ryan E. Rhodes, PhD³

¹Behavioural Medicine Lab, University of Victoria, Victoria, BC, Canada; ²Behavioural Medicine Laboratory - University of Victoria, Victoria, BC, Canada; ³University of Victoria, Victoria, BC, Canada

Background: Mothers with young children in the home are a critical target for physical activity promotion. Current research on the correlates of physical activity during early motherhood has generally considered intention as the primary determinant of behavior, yet the intention-behavior relationship is often modest. The purpose of this paper was to apply a framework designed to evaluate the intention-behavior gap, known as multi-process action control (M-PAC), to understand physical activity among mothers with young children.

Method: A community sample of 181 mothers (mean age 34.76 years) of at least one child under five years of age in Victoria, Canada completed M-PAC measures of motivational (instrumental attitude, affective attitude, self-efficacy), regulatory (planning), and reflexive (automaticity, identity) processes as well as intention to engage in physical activity and behavior (150 min of moderate or higher intensity).

Results: Three main intention-behavior profiles emerged: a) non-intenders who were not active (34%; n=62), b) unsuccessful intenders who failed to enact their positive intentions (18%; n=32), and c) successful intenders who were active (39%; n=71). A discriminant function analysis [$\chi^2(15) = 61.86, p < 0.01$; canonical $r = 0.53$] showed that automaticity ($r = 0.42$), planning ($r = 0.33$) and self-efficacy ($r = .43$) distinguished between non-intenders and both profiles of intenders but only affective attitude ($r = 0.19$) could predict the intention-behavior gap.

Conclusions: The majority of parents with young children in this sample had positive physical activity intentions, yet over 30% fail to meet these intentions. While behavioral regulation (e.g., setting a concrete plan), habit (e.g., making routines and cues) and self-efficacy (e.g., problem solving of barriers) differentiate active compared to inactive mothers, interventions focused on the affective qualities of physical activity (e.g., enjoyable circumstances, pleasant feeling states) may help overcome difficulties with translating intentions into action.

COMMUNITY HEALTH AND WELLNESS ASSESSMENT USING CBPR METHODOLOGY IN A RURAL REGION

Judy A. Johnston, MS, RD, LD¹, Lisette T. Jacobson, PhD, MPA, MA², Benjamin Anderson, MBA, MHCDS³, Jacey Hilbers⁴, Kristen R. Argueta⁵

¹University of Kansas School of Medicine - Wichita, Wichita, KS; ²University of Kansas School of Medicine-Wichita, Wichita, KS; ³Kearny County Hospital, Lakin, KS; ⁴Baylor University, Elkhorn, NE; ⁵Baylor University, Houston, TX

Background: A 2016 pilot study of a frontier county assessed their health/wellness needs by economic sector. A community assessment tool, available in English and Spanish, was administered by trained community volunteers. Questions focused on availability of health/wellness resources in the county and health/wellness resources offered at the worksite, daycare/preschool, school, church, County Extension office, and in the community. Incentives were provided and 85% of households completed the survey. Follow-up focus groups were conducted in December 2016.

Objective: The purpose of this study was to use this CBPR methodology to assess community members' perceptions, knowledge, attitudes, and desires related to health/wellness resources in two additional counties in an extremely rural region of a Midwestern state.

Methods: Using the same CBPR methodology and assessment tool, households in two contiguous counties (2,707 and 1,411 households) were targeted. Trained community volunteers and university interns collected one survey per household in June-August 2017. Descriptive analyses were conducted.

Results: A total of 1,332 (49%) and 881 (62%) surveys were completed. Median age of survey respondents was 45 years with >70% female respondents. Household income of 47% of respondents was at or below the county's median income. The majority (33% and 38% respectively in each county) defined health and wellness as an "active, lifelong process of becoming aware of choices and making decisions toward a more balanced and fulfilling life," and 58% reported that "health/wellness is influenced by the environments where I live, learn, work, play and pray." About 47% reported that they partially agreed with the statement "the healthcare system is responsible for my health/wellness" followed by 33% who disagreed. Themes of identified needs appeared in all sectors across the three counties: breastfeeding support, weight management/diet counseling, support for caregivers, access to healthy foods, community gardens, biking trails, health education for all ages, parenting education, work-life balance programs, and assistance with insurance decisions for seniors.

Conclusion: This CBPR community assessment process demonstrates effectiveness in identifying concerns that should be addressed in order to enhance the quality of health/wellness resources and to engage communities to action. Follow-up studies are needed to identify feasible interventions thereby improving health and wellness for this population.

A CITIZEN SCIENTIST APPROACH TO PROMOTE HEALTHY AGING AMONG LESBIAN GAY BI-SEXUAL AND TRANSGENDER (LGBT) ELDERERS IN ALASKA

Diane K. King, Alaska¹, Ken Helander², Julie Schmidt³, Katelyn Saft¹¹University of Alaska Anchorage, Anchorage, AK; ²AARP Alaska, Anchorage, AK; ³SAGE Alaska, Anchorage, AK

Background: There is a pressing need for safe, accessible communities that support the physical and social determinants of health for a diverse and aging society. LGBT elders may face additional obstacles to healthy aging, including concerns about personal safety, social isolation, access to informed providers, and welcoming places. We piloted the use of Citizen Science methods with LGBT elders residing in Anchorage, to identify problems and solutions, and build collective efficacy.

Methods: Participants were recruited through community events and direct outreach. Data collection included participant walks/drive-abouts using the Our Voice Neighborhood Discovery Tool, a smartphone app that combines photo, voice recording, and Global Positioning Systems (GPS), to create route maps. All participants completed baseline and 6-month surveys to assess social cohesion and loneliness. Walks/drive-abouts occurred in summer of 2017.

Results: Participants (N=8) were diverse in age (median age of 62.5; range 53–71), sex (4 male, 4 female), sexual orientation (3 lesbian, 3 gay, 2 bisexual), gender identity (1 transgender man, 1 transgender woman) and zipcode. Participants completed 8 walks, took 66 photos with narratives, and participated in 2–5 group meetings to identify themes and potential solutions. *Social Participation*, and *Respect and Inclusion* were top concerns. Solutions included plans to present findings to aging councils and state employee associations, and identify partners to promote a Safe and Welcoming Anchorage. Self-reported social cohesion and loneliness scores improved at six months, with medium ($d=.42$) to large ($d=1.03$) effect sizes. Participants identifying as Transgender (either female to male or male to female) rated lack of training for healthcare providers and community fear or dislike of LGBT people as a significant to major problem.

Conclusions: This pilot project demonstrated the potential for Citizen Science methods to identify needs and feasible solutions for vulnerable elders, and to increase social cohesion and decrease loneliness in participants.

ASSOCIATION BETWEEN DISORDERED GRIEF CRITERIA, BLOOD PRESSURE AND SELF-REPORTED HEALTH

Eva-Maria Stelzer, MSc Psychology, Mary-Frances O'Connor, PhD Psychology, Candace Mayer, BSc Psychology, Lindsey M. Knowles, MA, Psychology

University of Arizona, Department of Psychology, Tucson, AZ

Background: Spousal bereavement is associated with increased mortality and morbidity in the surviving spouse. Although most widow(er)s are resilient, approximately 10% develop a chronic debilitating course of grief. Grief severity has an adverse impact on individuals' health over and beyond bereavement. Different criteria exist to assess grief symptoms including Complicated Grief (CG), Prolonged Grief Disorder (PGD), and Persistent Complex Bereavement Disorder (PCBD). Considerable debate exists regarding the exact criteria of disordered grief, although each criteria set describes the underlying phenomenon. The present study seeks to add to the current debate by exploring the association of CG, PGD, and PCBD with health-relevant measures including blood pressure and self-reported health.

Methods: Data for the present study came from the baseline of a sample of 100 widow(er)s (mean age = 67.7, SD = 9.1) who participated in a randomized controlled trial of a grief intervention from August 2015 – August 2017. Diagnosis with CG, PGD, and PCBD were assessed through matching grief criteria and relevant questionnaire items from several well-validated grief and depression scales. Self-reported health was a one-item question on a five-point Likert scale. Regression analyses were run with each diagnostic criteria set (CG, PGD, PCBD diagnosis vs. no diagnosis) predicting resting diastolic (DBP), systolic (SBP) blood pressure and self-reported health in separate models (9 models total) accounting for relevant covariates.

Results: After accounting for covariates, a diagnosis of CG significantly predicted lower self-reported health [$b = 0.45$, $t(91) = 2.33$, $p < .05$; $F(4,91) = 6.42$, $p < .05$, $\Delta R^2 = .19$]. On the other hand, PGD or PCBD diagnoses did not predict self-rated health ($p > .05$). No main effects emerged for the regression of DBP or SBP on CG, PGD or PCBD ($p > .05$).

Conclusion: These findings suggest more similarities than differences between existing grief criteria sets in their associations with health-relevant parameters. Of note, CG criteria (vs. PGD and PCBD) diagnose the largest number of bereaved individuals with disordered grief and only CG diagnosis was significantly associated with self-reported health. For comparison, depression was also not predicted by any of the health-relevant variables. Future research would benefit from a larger sample and longitudinal study design to explore the impact of grief severity on diverse health-relevant measures linked to increased morbidity and mortality in bereaved adults.

COMPARING HEALTH INFORMATION ACCESS BETWEEN U.S. RURAL AND URBAN POPULATIONS

Xuewei Chen, PhD¹, Heather Orom, PhD¹, Jennifer L. Hay, Ph.D.², Erika Waters, PhD, MPH³, Caitlin Biddle, Ph.D⁴, Elizabeth Schofield, MPH², Yuelin Li, PhD.², Marc T. Kiviniemi, PhD¹

¹University at Buffalo, Buffalo, NY; ²Memorial Sloan Kettering Cancer Center, New York, NY; ³Washington University in St. Louis, St Louis, MO; ⁴CCNY Inc, Buffalo, NY

Purpose: Relative to their counterparts in urban areas, Americans living in rural areas face unique health disparities such as lower rates of screening and preventive health behaviors. The ability to make informed decisions to engage in health promoting behaviors is influenced by access to health information. Compared to urban populations, rural populations have limited access to a variety health information sources. We conducted a fine-grained exploration of which health information sources might be less accessible to rural vs. urban residents. We also hypothesized that having low health literacy might exacerbate rural disparities in access to health information.

Methods: Six hundred participants (evenly divided between urban and rural residence) completed an online survey. We assessed whether participants were able to easily and affordably get health information from a variety of sources, their health literacy, and demographic characteristics. Data were weighted so the rural and urban subsamples would be representative of the U.S. rural and urban populations. We used unadjusted and adjusted (controlling for race/ethnicity, income, and education) logistic regressions to test associations between rurality and access to health information and if rurality interacted with health literacy to predict access to health information.

Results: There were no differences in health literacy, household size, or age between rural and urban participants; however, the former had lower income and education and were less likely to be minority than rural participants. In unadjusted models, rural participants had lower odds of access to health information from primary care providers ($OR = 0.65, p = .037$), specialist doctors ($OR = 0.58, p = .007$), dentists ($OR = 0.68, p = .049$), magazines ($OR = 0.65, p = .034$), radio ($OR = 0.67, p = .047$), blogs or celebrity webpages ($OR = 0.67, p = .049$), federal government ($OR = 0.63, p = .027$), and scientists ($OR = 0.70, p = .049$). In adjusted models only the difference in access to health information from specialist doctors remained significant ($OR = 0.63, p = .024$). Rural/urban status interacted with health literacy, predicting access to health information from newspaper ($OR = 0.17, p = .001$), magazines ($OR = 0.33, p = .042$), and scientific literature ($OR = 0.29, p = .020$). Among rural participants, having limited health literacy was associated with lower access, whereas it was not among urban participants.

Discussion: Sociodemographic differences may account for several of the disparities in information access given that when we controlled for income, education, and race/ethnicity, differences were eliminated. In addition, there may be structural barriers such as more limited media exposure, that make it harder for rural populations to access to health information, especially among rural populations with limited health literacy.

EFFECT OF PERCEIVED NORMS, HEAVINESS OF SMOKING, AND GENDER ON SMOKING QUIT ATTEMPTS AMONG LOW INCOME SMOKERS IN BALTIMORE, MD

Norah Crossnohere, MHS¹, Melissa Davey-Rothwell, PhD², Carl Latkin, PhD², Tuo-Yen Tseng, MA², Lauren Czaplicki, MPH², Amy Knowlton, PhD²

¹Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; ²Johns Hopkins University, Baltimore, MD

Background: Declines in smoking prevalence among disadvantaged populations lag behind national samples. Both nicotine dependence and social factors may impact smoking cessation, and recent literature suggests that smoking behaviors may spread throughout social networks. This study explores how smoking dependence, descriptive norms and injunctive norms impact likelihood of a current smoking quit attempt among men and women in a sample of hard-to-reach, low income, predominately African American respondents in Baltimore, MD.

Methods: Participants completed a survey regarding tobacco use, smoking norms, and their heaviness of smoking index (HSI; 0–6, lowest to highest dependence). Descriptive norms were conceptualized as having friends who quit smoking, and injunctive norms as having friends who disapprove of smoking. Three logistic regression models explored the effect of the following predictors on current quit attempt: 1) friends quit and HSI; 2) friends disapprove and HSI, and; 3) friends quit, friends disapprove, and HSI. All models were stratified by gender, and all models adjusted for age, income, and race.

Results: Among women (n=200), neither HSI nor norms were associated with current quit attempts in any model. Among men (n=335), friends quitting smoking and friends disapproving of smoking were both associated with reduced odds of quitting when examined separately in models 1 and 2 (Table 1). When examined collectively in model 3, men with friends who had quit smoking had twice the odds of having a current quit attempt (AOR=2.01 [1.06–3.79]), while having friends who disapproved of smoking was no longer associated with having a current quit. Higher HSI was associated with reduced odds of quitting in all three models among men (model 1: AOR=0.75 [0.63–0.90]; model 2: AOR=0.74 [0.62–0.88]; model 3: AOR=0.76 [0.63–0.90]).

Discussion: Friends' normative behaviors and attitudes regarding smoking impacted the likelihood of current quit attempts for men but not women, suggesting that it is important to examine gender differences when creating socially-oriented smoking cessation interventions. These results offer a foundation to consider the varying impact of descriptive and injunctive norms on smoking behaviors.

GAINING INSIGHT INTO THE NEIGHBORHOOD PERSPECTIVE THROUGH PHOTOVOICE

Jeanette Gustat, PhD, MPH, W. A. Lawson Smith, BSPH

Tulane University School of Public Health and Tropical Medicine, New Orleans, LA

The neighborhood environment can impact the health behaviors of its residents. Neighborhood characteristics such as availability of grocery stores and parks can influence shopping and physical activity habits. As part of a larger project to address healthy living in New Orleans, we wanted to explore the issues that affect residents of three New Orleans neighborhoods. A community-based participatory research method called photovoice was employed. Photovoice is a process where participants use images to share aspects of their environment and experience. In collaboration with community partners, residents of three under-resourced neighborhoods of New Orleans were recruited. Participants were asked to attend four meetings over four weeks, each lasting one hour. They were loaned digital cameras and trained in basic camera operation and appropriate ethical conduct in photography. Each week, topics were assigned by facilitators to guide the participants to identify challenges and/or supports that influence a healthy diet, physical activity, and general health. After each assignment, participants were asked to select at least two photos they took and discuss them with study facilitators. The SHOWeD questioning technique, typically used in photovoice studies, was used to assist participants in elucidating the themes in their photos.

A total of 26 community residents participated in the sessions and selected 138 photos. Common nutrition-related themes highlighted access to community gardens, lack of access to grocery stores, and food preparation of personal meals. Common physical activity-related themes included neighborhood parks, presence of sidewalks, and abandoned spaces that were either perceived as scary or wasted space that could be used as parks or gardens. Overall, the most common theme focused on displeasure with the abundance of abandoned properties in their neighborhoods. One participant stated when describing their photograph of a large trash bag discarded in the middle of a residential road with blighted properties, "...someone had no respect for the area because of these abandoned properties...if [the owners of these] blighted properties cannot find residents, then they should be turned into parks or something that makes the neighborhood healthier....." The results of this project may be used to guide future interventions in these neighborhoods. Photovoice can be used to help researchers gain insight into resident's perspectives.

HARNESSING TECHNOLOGY AND CITIZEN SCIENCE TO SUPPORT AGE-FRIENDLY NEIGHBORHOODS IN TAIWAN

Yi-Jou Chou, M.S.¹, Jenna Hua, RD, MPH, PhD², Ann Banchoff, MSW, MPH², Sandra J. Winter, PhD, MHA³, Der-Ming Liou, PhD¹, Abby C. King, PhD²

¹Kaohsiung Medical University, Qianzhen Dist., Kaohsiung, Taiwan (Republic of China); ²Stanford Prevention Research Center, Palo Alto, CA; ³Stanford University School of Medicine, Palo Alto, CA

Taiwan's population is rapidly aging at a rate more than twice that of Europe and the US. In response to this challenge, creating an activity-friendly environment that meets the diverse needs of the aging population and fosters aging in place are essential. Yet, it is currently unclear how best to build age-friendly environments that meet seniors' needs. To capture seniors' perspectives in a contextually valid way, a community-engaged participatory process, called *Our Voice*, was tested for the first time in Taiwan. *Our Voice* involves seniors acting as "citizen scientists" through systematically gathering data, using a simple GPS-enabled mobile app (Stanford Discovery Tool- DT), on barriers to and facilitators of healthy aging in their local environments. They use these data to build consensus and collectively advocate for local environmental and policy-level changes to support healthy aging. The seniors lived in Cijin, Taiwan, where 14.3% of the population are 65 years and older, and transportation and medical resources are scarce.

15 seniors (≥60 years; 33%women; 76% men; 100% high school education only) were recruited in June 2017 to use the DT to take photos and record audio narratives on neighborhood barriers and facilitators that impact healthy aging. Upon completion of data gathering, participants attended a community meeting to analyze and discuss their photos and audio narratives, and prioritize neighborhood issues to address. A second community meeting (3 weeks later) was then conducted whereby the seniors shared their results with relevant village officials and discussed realistic solutions to improve their neighborhood for healthier aging.

A total of 78 photos and narratives were collected by participants, and the issues identified included poor state of sidewalks, lack of public places to gather, abandoned buildings, a dysfunctional sewage system, and personal safety issues. Participants concluded that improving abandoned buildings and personal safety were the priority issues to address in Cijin. During the second community meeting, participants and relevant stakeholders decided that together they would start remodeling an abandoned building and turn it into a community center where the goals of creating a public space for seniors to gather and improving personal safety could be achieved simultaneously. This work is currently ongoing.

This study demonstrated the feasibility and value of using the *Our Voice* citizen science approach to advance sustainable age-friendly neighborhoods in Taiwan. Cijin seniors were able to use the DT app to identify local barriers and, with local stakeholders, develop feasible solutions to promote healthy aging. Next steps include continued evaluation of the local changes initiated in this first-generation project, and expanded evaluation of the *Our Voice* approach in other communities in Taiwan and China.

HEALTH-PROMOTING BEHAVIORS IN CANCER CAREGIVERS

Avery Perez, BS¹, Li Yang, MS¹, Margaret F. Bevens, PhD, RN, AOCN®, FAAN², Leslie Wehrlen, RN, MSN, OCN®, ACRP-CP®¹, Jumin Park, PhD, RN¹, Brenda Roberson, RN, BSN, OCN¹, Lori Wiener, PhD³, Sima Zadeh Be-doya, PsyD³, Stephen Klagholz, BS⁴, Alyson C. Ross, PhD, RN¹

¹National Institutes of Health Clinical Center, Bethesda, MD; ²National Institutes of Health, Office of Research on Women's Health, Bethesda, MD; ³National Cancer Institute, Bethesda, MD; ⁴Georgetown University Medical Center, Department of Physiology & Biophysics, Washington, DC

Background: The stress of caregiving for a loved one with cancer might negatively impact physical and mental health. Participation in health-promoting behaviors such as physical activity, proper nutrition, and stress management can potentially lessen those effects.

Objective: To describe the health-promoting behaviors practiced by caregivers of cancer patients, and to identify those personal, interpersonal, and situational factors that influence health-promoting behaviors in cancer caregivers.

Participants: Family caregivers of patients beginning cancer treatment (\pm 14 days) at the National Institutes of Health Clinical Center.

Methods: Cross-sectional, web-based survey used descriptive statistics and regression analyses to examine which personal (e.g., age, sex, race, income, body mass index, sleep disturbance, depression, stress, caregiver burden, self-efficacy), interpersonal (e.g., mutuality, relationship to patient), and situational (e.g., sole caregiver versus part of team, inpatient versus outpatient, work status) factors predicted health-promoting behaviors. Measures: Health-Promoting Lifestyle Profile II (HPLP-II); Caregiver Reaction Assessment (CRA); Family Care Inventory Mutuality subscale; NIH Toolbox Perceived Stress and Self-Efficacy; Patient-Reported Outcomes Measurement Information System (PROMIS®) Sleep Disturbance and Depression.

Results: Caregivers (N=137) included mostly spouses (48.9%) and parents (35.0%) of patients; they were 48.5 ± 11.7 years of age, and primarily white (70.6%), female (68.6%), and educated (70.1% had a college degree). Physical activity and stress management were practiced the least frequently of all health behaviors. Most (60.7%) agreed that they exercised less since becoming a caregiver, and 45.9% agreed that their diet worsened. Final predictors of HPLP-II scores included income ($\beta = 0.182, p = 0.025$), self-efficacy ($\beta = 0.282, p = 0.002$), depression ($\beta = -0.198, p = 0.035$), and mutuality ($\beta = 0.244, p = 0.004$).

Conclusions: Caregivers who have lower incomes, are more depressed, and who score lower on mutuality and self-efficacy are less likely to participate in health-promoting activities. These individuals may be at increased risk of negative health effects associated with caregiving. Understanding which caregivers are at risk is important in order to tailor future interventions and research.

INCORPORATING SOCIAL AND COMMUNITY VARIABLES INTO A PREDIABETES RISK REGISTRY: CREATING RESEARCH INFRA-STRUCTURE

Bethany M. Kwan, PhD, MSPH¹, Wilson Pace, MD², Amanda Ratigan, PhD, MPH², Daniella Meeker, PhD³, Jennifer Carroll, MD¹

¹University of Colorado School of Medicine, Aurora, CO; ²DARTNet Institute, Aurora, CO; ³Keck School of Medicine, University of Southern California, Los Angeles, CA

Objective: The DARTNet Institute recently created a large database from real-world clinic settings to explore diabetes and cardiovascular risk factors. This database will be used for research on social and environmental determinants that influence risk and disease progression and health disparities in diabetes and cardiovascular outcomes. The purpose of this project was to establish a set of social and community variables from population databases (e.g., US Census) that could be linked with clinical data to ensure a 360-degree view of the determinants of health.

Methods: We used literature and expert review to select social and community variables to integrate into the database. The framework used was the Criteria for inclusion in the database were a) not available at the patient level in the electronic health record, b) available from existing large population databases (e.g., US Census, the American Community Survey), c) linkable to clinical data at the zip code level, d) consistent with the World Health Organization Social Determinants of Health Framework domains and subdomains, and e) have rationale for association with risk for transitioning from prediabetes to diabetes.

Results: As of 2017, the database contained clinical data for nearly 4 million patient lives from 13 healthcare organizations and 450 clinical sites. We identified nine WHO SDOH domains and subdomains relevant to diabetes and cardiovascular risk from existing population databases that could be linked with the clinical data at the zip code level: social class, education, occupation, income, living and working conditions, food and nutrition, resources, health insurance, and stressors. Within these domains, we selected 14 community-level variables from population databases: poverty level, SNAP benefits, educational attainment, food desert, food quality, food insecurity, household income, walkability, neighborhood safety, medically underserved area, health insurance access, disability rates, and unemployment rates.

Conclusion: A comprehensive set of social and community variables is available to link with clinical data for the study of diabetes and cardiovascular risk. The integrated data will be used to test hypotheses about diabetes and cardiovascular risk and disparities. Population databases can be useful for enhancing clinical data for the study of complex chronic disease prevention. Population databases lack key risk variables - such as health behaviors and social capital - and must be gathered from other sources.

LONELINESS MODERATES THE ASSOCIATIONS BETWEEN CHILDHOOD TRAUMA AND ADULT DISEASE IN THE HISPANIC COMMUNITY HEALTH STUDY

Samantha A. Reina, MS¹, Marisa Perera, MS¹, Carmen R. Isasi, MD/PhD², Linda C. Gallo, PhD³, Angela P. Gutierrez, M.S.⁴, Krista M. Perreira, PhD⁵, Shakira F. Suglia, ScD, MS⁶, Martha L. Daviglius, MD, PhD⁷, Aida L. Giachello, PhD⁸, Neil Schneiderman, PhD¹, Donglin Zeng⁹, Maria Llabre, PhD¹

¹University of Miami, Coral Gables, FL; ²Albert Einstein College of Medicine, Bronx, NY; ³San Diego State University, San Diego, CA; ⁴San Diego State University / University of California San Diego, Joint Doctoral Program, San Diego, CA; ⁵UNC School of Medicine, Carrboro, NC; ⁶Emory University, Atlanta, GA; ⁷University of Illinois at Chicago, Chicago, IL; ⁸Northwestern University, Oak Lawn, IL; ⁹University of North Carolina, Chapel Hill, NC

Traumatic experiences in childhood are associated with negative health consequences in adulthood. Examining moderators of the relationship between adverse childhood experiences (ACEs) and adult health in Hispanics/Latinos is particularly important because, despite usual risk factors, Hispanics/Latinos have lower overall mortality rates. Prior research in the Hispanic Community Health Study sample has shown that the relationship between childhood trauma and adult disease in Hispanics/Latinos is not as strong as has been reported in other studies. This study examined potential moderators (loneliness, number of friends, years in the U.S., and nativity status) to understand for whom the relationship between childhood trauma and adult disease holds. Outcomes included mental (depression), physical (asthma, coronary heart disease, BMI), and behavioral (smoking, sedentary time) health. In this sample (N = 5313), loneliness (B=0.06 95%CI: 0.02, 0.11) and number of friends (B=-0.08, 95% CI: -0.14, -0.03) significantly moderated the relationship between childhood trauma and adult depression only (*p*'s <.05). The relationship between childhood trauma and depression was stronger at higher levels of loneliness and for individuals reporting having few friends. Given the same number of ACEs, those with higher levels of loneliness experienced more depression than counterparts with lower levels of loneliness. Nativity did not moderate any relationships but positively related to smoking status (OR = 1.82, 95%CI: 1.41, 2.36), asthma (OR = 1.96, 95%CI: 1.39, 2.76), BMI (B=1.46, 95%CI: 0.69, 2.23), depression (B=1.28, 95%CI: 0.57, 1.99), and sedentary time (B=59.49, 95%CI: 38.54, 80.45, *p*'s <.05). For non-natives, years living in the U.S. was not a moderator but was significantly associated with increased odds of coronary heart disease (OR = 1.02, 95%CI: 1.00, 1.04) and higher BMI (B=0.04, 95%CI: 0.02, 0.07, *p*'s <.05). Assessing and addressing loneliness in U.S. Hispanics/Latinos who have experienced trauma may help reduce development of depression symptoms. Further research should aim to explore if these relationships hold longitudinally.

PERCEIVED DISCRIMINATION AND NEIGHBORHOOD VIOLENCE PREDICT GREATER NUMBER OF HEALTH SYMPTOMS

Yehsong Kim, BA, Corey Pettit, BA, Gayla Margolin, Ph.D.

University of Southern California, Los Angeles, CA

Exposure to crime and violence increases unhealthy behaviors and stress, which link to hypertension and weakened immunology (Ellen, Mijanovich, & Dillman, 2001). Perceived discrimination is similarly associated with physical health problems, including hypertension and breast cancer (Williams & Mohammed, & Jackson, 2009). Together, neighborhood disadvantage and perceived discrimination have adverse mental health risks (Prelow, Danoff-Burg, Swenson, & Pulgiano, 2004). However, research has yet to examine physical health symptoms. Moreover, studies on discrimination have largely focused on racial discrimination whereas this study captures a broader range of discrimination experiences. We hypothesize that neighborhood violence and perceived discrimination interact to predict more negative health symptoms.

Young adults (N = 241, *M* age = 22.1 years; *SD* = 3.7; 12.0% Asian, 15.7% African American, 27.7% Caucasian, 15.3% Multi-racial, 24.8% Hispanic/Latino) completed an 11-item questionnaire assessing community violence, such as witnessing an assault or break-in in the community. Participants also reported on experiencing judgment or unfair treatment on a 27-item perceived discrimination survey. Participants also completed a 23-item survey on past year health symptoms.

Bootstrapped moderation analyses assessed the interaction between perceived discrimination and neighborhood violence on health symptoms from the past year. As hypothesized, the interaction between perceived discrimination and neighborhood violence was significant (*b* = .68, *p* = 5.26, *p* < .01), but not low levels of discrimination (*b* = -.70, *ns*). The main effect of perceived discrimination was also significant (*b* = .17, *p* < .05).

These results suggest that experiencing multiple forms of adversity in the form of neighborhood violence and discrimination negatively impact health. Discrimination appears to heighten the impact of other adverse events on health. Neighborhood violence did not have an effect until coupled with discrimination. Studies on the multiplicative effects of different forms of adversity can more closely model the circumstances of at-risk communities. Future studies on discrimination's impact on other experiences of violence could further elucidate the relationship between cumulative adversity and health risks.

PERCEIVED DISCRIMINATION PREDICTS HEALTH RISK BEHAVIORS AND SUBJECTIVE HEALTH IN RURAL APPALACHIAN COLLEGE STUDENTS

Julia Dodd, PhD, Abbey Mann, PhD, Diana Morelen, PhD, Gabrielle Caselman, BA

East Tennessee State University, Johnson City, TN

Discrimination has been linked to various negative health outcomes, including health risk behaviors such as unhealthy food choices, decreased physical activity, and alcohol/substance use (e.g., Richman et al., 2016); however, much of this research has understandably focused on racial/ethnic discrimination with less work focusing on other types of perceived discrimination, (e.g., due to weight, age, religiosity). Additionally, fewer studies have examined this relationship among individuals in rural Appalachia. This study aims to expand the previous literature through use of a broad, personally-defined perspective on discrimination (the Everyday Discrimination Scale; Williams et al., 1997) in a sample of students at a mid-sized university in rural Appalachia. Perceived discrimination was found to predict participants' higher body mass index ($R^2 = .11$, $F(5, 382) = 9.47$, $p < .001$), poorer self-rated general health ($R^2 = .13$, $F(5, 379) = 11.68$, $p < .001$), increased somatic symptom complaints ($R^2 = .18$, $F(5, 381) = 16.86$, $p < .001$), decreased fruit and vegetable consumption ($R^2 = .06$, $F(5, 380) = 4.51$, $p < .01$), decreased physical activity ($R^2 = .03$, $F(5, 362) = 2.37$, $p < .05$), and increased engagement in risky sexual behaviors ($R^2 = .07$, $F(5, 369) = 5.70$, $p < .001$), while controlling for age, gender, race, and family income. We were also interested in possible mechanisms to explain the relation between perceived discrimination and health outcomes. We investigated the role of emotion regulation (ER) difficulties (Difficulties in Emotion Regulation Scale [DERS]; Gratz & Roemer, 2004) as a possible mediator, given that research has shown emotion regulation processes to be linked to physical health outcomes (Gross, 2015). Of all outcomes, ER difficulties were only significantly correlated with somatic symptom complaints ($r = .43$, $n = 492$, $p < .001$), and thus only one mediation model was tested using Hayes Process Macro with bootstrapping (5000 samples). Difficulties with ER were found to mediate the link between perceived discrimination and somatic symptom complaints [$R^2 = .26$, $F(366) = 21.64$, $p < .001$; indirect effect of DERS total $t(366) = 8.02$, $p < .001$, LCI = .03 UCI = .08], when controlling for age, gender, race, and family income. Taken together, these findings establish a link between perceived discrimination and health outcomes in a rural Appalachian sample and identify ER difficulties as one mechanism through which discrimination may heighten risk for somatic complaints.

PREVALENCE AND COMPARISON OF OBESITY AND HEALTH BEHAVIOURS BETWEEN URBAN AND RURAL RESIDENTS: AN ATLANTIC PATH STUDY

Cynthia C. Forbes, PhD¹, Zhijie Michael Yu, PhD², Yunsong Cui, MSc², Vanessa DeClercq, PhD², Scott Grandy, PhD¹, Melanie Keats, PhD¹, Louise Parker, PhD², Ellen Sweeney, PhD², Trevor Dummer, PhD³¹Dalhousie University, Halifax, NS, Canada; ²Atlantic PATH, Halifax, NS, Canada; ³University of British Columbia, Vancouver, BC, Canada

Objective: The primary purpose of this study was to describe and compare the demographic, medical, and behavioural characteristics between urban and rural residents in Atlantic Canada. A secondary purpose was to examine the influence of any differences found in the primary purpose on various measures of body composition.

Methods: A cross-sectional analysis of data from the Atlantic Partnership for Tomorrow's Health (Atlantic PATH) was conducted. Physical measures, sociodemographic characteristics and health behaviours (i.e. diet, alcohol consumption, physical activity) were collected from 31,173 participants aged 35–69 across the four Atlantic Provinces. This study includes data from 11,489 participants that had both completed measures for body composition and the health behaviours of interest.

Results: Multiple linear regression (adjusting for age, sex, and province) found that when compared to urban participants, rural residents were significantly less likely to be regular or habitual drinkers and more likely to be classified as very active. Rural residents were less likely to be classified as obese based on BMI but more likely to be classified as having abdominal obesity (Model 1). Significant differences remained after further adjustment in Model 2 for ethnicity, education, marital status, HEI, smoking, alcohol use, multimorbidity, BMI, PA, and body composition measures as applicable. No significant differences in body mass index (BMI), waist circumference, or body fat percentage were found in the initial regression model. Model 1 revealed a significant difference for fat mass index (FMI) that remained after full adjustment in Model 2. BMI and waist circumference differences remained non-significant in Model 2.

Conclusion: Overall, we found that participants living in a rural area engaged in more healthy behaviours than urban residents. Our results also showed lower levels of overall body adiposity but higher abdominal obesity among rural residents. These results are mixed and generally contrary to literature that suggests rural residents are generally less healthy than urban residents.

RELATIONSHIP BETWEEN CHANGES IN NEIGHBORHOOD ENVIRONMENT PERCEPTION AND BLOOD PRESSURE CHANGES: DALLAS HEART STUDY DATA

Marcus Andrews, MPH¹, Colby Ayers, MS², Joniqua Ceasar, BS³, Sandeep Das, MD, MPH⁴, Ian Neeland, MD¹, Kosuke Tamura, PhD², Sophie E. Claudel, B.S.⁶, James de Lemos, Professor⁷, Tiffany Powell-Wiley, MD, MPH⁸

¹Research Fellow, National Institutes of Health: Heart Lung and Blood Institute, Washington, DC; ²UT Southwestern Medical Center, Dallas, TX, Dallas, TX; ³National Institutes of Health - NHLBI, Rockville, MD; ⁴University of Texas Southwestern Medical Center, Dallas, TX; ⁵National Heart, Lung, and Blood Institute, National Institutes of Health, Bethesda, MD; ⁶National Heart, Lung, and Blood Institute, Bethesda, MD; ⁷UT Southwestern, Dallas, TX; ⁸Cardiovascular Pulmonary Branch, National Heart Lung and Blood Institute/ National Institutes of Health, Bethesda, MD

Background: Although much is known about the relationship between neighborhoods and health outcomes, knowledge about neighborhood environment perceptions and their impact on cardiovascular markers is burgeoning. We examined the relationship between neighborhood perceptions and blood pressure (BP).

Methods: Using longitudinal data from the multi-ethnic, Dallas Heart Study, we examined the relationship between changes in neighborhood perception and BP over the 7-year study period. Neighborhood perception scores were generated using items from the Project on Human Development in Chicago Neighborhoods Community Survey. Three sub-scores were created using factor analysis (Factor 1: neighborhood violence, Factor 2: physical environment [i.e. aesthetics], and Factor 3: social cohesion). Higher scale scores are associated with more unfavorable perceptions. Systolic and Diastolic blood pressure was measured during two exams between 2000–2009. Using linear regression, we investigated the relationship between changes in neighborhood perception factors over the follow-up period and BP for participants without baseline hypertension. Models were adjusted for age, sex, race, smoking, income, education, physical activity, years in neighborhood, BMI, moving status and Heckman correction factor (to account for self-selection into improved neighborhood).

Results: The study population (N=1174) consisted of 57% non-Hispanic Blacks, 27% non-Hispanic Whites, and 13% Hispanics. In fully adjusted models, only changes in Factor 2 (physical environments) were associated with changes in systolic blood pressure ($\beta=0.24$ $p=0.03$), but not Factor 1 (neighborhood violence [$\beta=0.43$ $p=0.09$]) or Factor 3 (social cohesion [$\beta=0.28$ $p=0.11$]). However, in fully adjusted models, each perception factor was linked to changes in diastolic blood pressure, Factor 1: ($\beta=0.31$ $p=0.03$), Factor 2: ($\beta=0.21$ $p=0.0004$), and Factor 3 ($\beta=0.23$ $p=0.02$).

Conclusion: More unfavorable neighborhood perceptions were related to increases in blood pressure among a diverse population in Dallas County, Texas. Examining the psychological factors in relation to cardiovascular health may better represent the impact of adverse neighborhood conditions than only objective measures. Future research should examine both perceived and objective measures of neighborhoods and neighborhood built environment amenities in relation to cardiovascular markers to further understand these complex relationships.

RELATIONSHIP SATISFACTION, COMMUNICATION SELF-EFFICACY, AND CHRONIC FATIGUE SYNDROME (CFS)

Sara F. Milrad, M.S.¹, Daniel L. Hall, PhD², Devika Jutagir, PhD³, Sara Czaja, PhD⁴, Dolores Perdomo, Ph.D.¹, Mary Ann Fletcher, Ph.D.⁵, Nancy Klimas, MD⁶, Michael H. Antoni, PhD⁷

¹University of Miami, Miami, FL; ²Harvard Medical School, Boston, MA; ³Memorial Sloan Kettering Cancer Center, New York, NY; ⁴University of Miami Miller School of Medicine, Miami, FL; ⁵Nova Southeastern University, Miami, FL; ⁶Nova Southeastern University, Miami VA MedicalCenter, Miami, FL; ⁷University of Miami, Coral Gables, FL

Introduction: Relationship dissatisfaction has been linked with worse health outcomes in many patient populations, though the mechanism(s) underlying this effect are unclear. Among patients with chronic fatigue syndrome (CFS) and their partners, there is a bi-directional correlation between poorer relationship satisfaction and the severity of CFS-related fatigue. Here, we hypothesize that depression mediates this relationship, such that relationship dissatisfaction negatively impacts CFS fatigue severity by way of greater depression and less patient satisfaction about communication about symptoms to partners.

Methods: Baseline data were drawn from diagnosed CFS patients (N = 150) participating in studies testing the efficacy of a remotely-delivered cognitive behavioral stress management (CBSM) intervention. Data derived from fatigue severity, depression, relationship and communication satisfaction questionnaires were used for bootstrapped indirect effect analyses using SPSS and the PROCESS macro. Age, education and BMI were entered as covariates.

Results: The majority of the sample (67.3%) had clinically significant depressive symptoms (CES-D ⁵ 16). Co-mediation analyses (using parallel multiple mediators) revealed that better relationship satisfaction relates to less fatigue severity by way of less depressive symptoms ($b= -0.0106$, $se= 0.0053$, Bootstrapped LLCI, ULCI: -0.0225 , -0.0021), but not by way of communication satisfaction (bootstrapped CI included 0).

Discussion: Results highlight the importance of considering depression when examining the effects of relationship satisfaction on CFS symptoms. Further mechanism-based, longitudinal research might identify relationship-related mediating variables that can be targeted therapeutically.

THANK GOODNESS I'M FEMALE (TGIF) AND GIRLS ACTION LEAGUE (GAL) DETER FEMALE PEER RELATIONAL AGGRESSION ACROSS 6TH GRADE

Julianna M. Nemeth, PhD, MA¹, Amy Hawthorne, BA², Stephanie Christie, MSW, MA³, Nancy Radcliffe, BA², Maylin S. Sanchez, BA³

¹The Ohio State University College of Public Health, Columbus, OH; ²HelpLine of Delaware and Morrow Counties, Inc., Delaware, OH; ³CompDrug, Columbus, OH

Background: Adolescence is a time of increased peer relational aggression (bullying) among girls. Thank Goodness I'm Female (TGIF) and Girls Action League (GAL), created by 2 non-profit organizations in response to a student's request, are programs designed to empower girls to support each other and deter increase in peer relational aggression across 6th grade.

Methods: A quasi-experimental repeated measures design with attention control group was selected for use in this outcome evaluation. Parental consent and participant assent were obtained. The experimental 6th grade cohort recruited from 2 Ohio middle schools received TGIF and GAL programs in fall and spring semesters, respectively, while an attention control cohort was recruited from a comparable school received Pharming Effects, a prescription drug misuse prevention program, in fall. Participants completed a self-administered online survey at 3 time points: 1) baseline: the beginning of the fall semester, 2) 1st follow-up: the end of the fall semester after receipt of TGIF (experimental) or Pharming Effects (control), and 3) 2nd follow-up: end of the spring semester, after GAL participation (experimental). Measures included developmental asset profile, gender identity, adolescent femininity ideology, defending behavior when witnessing relational aggression, self-reported peer aggression and victimization, and knowledge regarding prescription drug misuse. Participants received pizza lunches at each survey administration, and a \$5 gift card for completing all 3 surveys.

Results: One hundred, female identified, 6th graders enrolled in the 2016–2017 school year study (n=61 experimental, n=39 control). Follow up rates among experimental and control participants, respectively, were 83% and 90% at the 1st follow-up and 87% and 85% at the 2nd follow-up. Group differences were not found at baseline or the first follow-up. However, in comparison to the control group, exposure to the TGIF & GAL programs, combined, was significantly associated with lower rates of victimization by peers (adj β =-2.5, p=.0009), lower rates of aggression towards peers (adj β =-0.8, p=.03), and higher total developmental asset scores (adj β =4.2, p=.02) at the end of 6th grade, controlling for baseline scores.

Conclusion: Exposure to TGIF and GAL were effective at deterring an increase in relational aggression and victimization, and helping girls maintain developmental assets, across the 6th grade year.

THE IMPORTANCE OF GROCERY STORE BASED INTERVENTIONS IN DECREASING CHRONIC DISEASE PREVALENCE IN THE CITY OF DETROIT

Ameen A. Masoodi, MD¹, Alex B. Hil, MA²

¹Wayne State University School of Medicine, Detroit, MI; ²Wayne State University, Detroit, MI

Background: Obesity, cardiovascular disease, and diabetes have been shown to more negatively impact low-income, minority communities. Geospatial studies have debated the connection between environmental indicators and obesity prevalence rates. Most studies used counts of grocery stores rather than indexing the availability, price, and quality of food items at stores. Early research looking at obesity and availability in Detroit found that family income was more highly correlated with healthy eating than distance to a grocery store.

Objective: The purpose of this study was to examine potential correlation between neighborhood effects in Detroit including access to healthier, affordable, and quality food options, and lower prevalence of chronic diseases.

Methods: Data were collected using a modified Nutrition Environmental Measures Survey (NEMS). Full-line grocery stores were identified from a database maintained by the Green Grocer Project. Each store was verified, visited, and surveyed using the NEMS criteria. Chronic disease prevalence data were used from the CDC/RWJF 500 Cities project which relies on the BRFSS 2014 in order to generate census tract level small area estimates. Data were analyzed by measuring the number and average score of grocery stores within a 1 mile radius of the census tract centroid. The store data was then paired with corresponding 500 Cities data for high blood pressure, chronic heart disease, cholesterol, diabetes, and obesity for adults age \geq 18.

Results: When looking at the prevalence of chronic disease by census tract, there were only two correlations found that held statistical significance: obesity was negatively correlated with the NEMS score, $r = -0.138$, $p < 0.05$, and high blood pressure was negatively correlated with store count (range 1 to 6), $r = -0.128$, $p < 0.05$. Furthermore, there was a significant positive correlation found between a census tract having a higher store count within a 1 mile radius, and the NEMS score for that tract, $r = 0.195$, $p = 0.002$.

Conclusion: Typically research focuses on the environmental impact of biobehavioral outcomes, but there is potential for communities facing higher rates of obesity to impact their environments through targeted food retailer interventions. Further work is necessary in establishing other possible correlations between biobehavioral disparities and the availability, price, and quality of healthier food options within specific neighborhood areas. Furthermore, from the established correlation, future interventions should be focused towards food retailers in areas that have fewer grocery stores.

THE NEXUS BETWEEN HOUSING INSTABILITY AND INCARCERATION: EARLY TRAUMA, CRIMINOGENIC RISKS AND HEALTH AMONG WOMEN EXITING JAIL

Vanessa Schick, PhD¹, Isabel Roth, DrPH, MS², Andrea Link, MD³, Alycia Welch, MPA⁴¹University of Texas School of Public Health, Houston, TX; ²UTHealth School of Public Health, Houston, TX; ³Healthcare for the Homeless- Houston, Angela House, Houston, TX; ⁴Lone Star Justice Alliance, Austin, TX

Introduction: The role of adverse childhood events (ACEs) on the lives of women with experiences in the criminal justice system is well documented with these early traumatic experiences contributing to criminogenic risk and health/wellness among women in the criminal justice system. Current measurements of ACEs include a variety of potential traumatic events that may be common among youth but may not capture the specific types of early trauma experienced by women with involvement in the criminal justice system. Experiences of incarceration and instable housing are intricately intertwined with both increasing risk for the other. The Present Study: Given the nexus between incarceration and homelessness, housing insecurity was added as a potential ACE to examine whether trauma resulting from childhood experiences of housing insecurity may contribute to criminogenic risk factors and overall health and wellness among women with experiences in the criminal justice system.

Methods: Women in county and state jail participated in a structured interview immediately upon release. Participants were asked about ACEs, criminogenic risks (e.g., LSI-R), and their current physical and mental health (e.g., Depression - PHQ-2). Two items were added to the ACE to explore early experiences of housing instability. Participants received a \$50 gift-card to compensate them for their time.

Results: Reliability of the ACE with the addition of the housing instability items was good ($\alpha = .72$) relative to the Cronbach's alpha if the items were removed ($\alpha = .65$). Housing instability was significantly related to reported arrest before the age of 16 with over double the number of participants with early housing insecurity reporting early arrest relative to those with stable housing conditions throughout childhood ($X^2 = 6.86, p < .01$). In a multivariate model including all ACEs, housing insecurity emerged as the only significant predictor of arrest before the age of 16. Early experiences of housing insecurity was also significantly related to depression ($F = 10.85, p < .005$), emerging as the only significant ACE in a multivariate model ($b = 1.26, p = .01$).

Discussion: Adding housing instability to the ACE may help to identify women at increased risk for early incarceration and depression. This data informs the importance of targeted interventions towards housing insecure youth. The present data was from a larger study evaluating an intervention providing trauma-informed wraparound care to women upon release from jail/prison. The importance of diverse forms of early trauma on the lives and wellbeing of women with experiences in the criminal justice system points to the importance of programs that provide stable housing with a focus on trauma-informed care.

TOWARDS MEASURING CONTEXTUAL DISTRESS INCLUDING RACE-BASED STRESS IN THE ONCOLOGY ARENA

Kimlin Ashing, PhD¹, ndifreke Etim, PhD¹, Bin Xie, PhD², Veronica Jones, MD¹, Anna Napoles, PhD, MPH³¹City of Hope, Duarte, CA; ²Claremont Graduate University, Claremont, CA; ³UCSF School of Medicine, San Francisco, CA

The deleterious health effects of race-based distress including discrimination and racism are receiving increasing prioritization (American Psychological Association, 2016; Krieger, 2017). The emphasis on understanding and measuring the effects of distress on health, brings long over-due attention and new opportunities for investigating the intersectionality of race-based stress with broad contextual (i.e., behavioral and place-based) determinants of health. This abstract presents an investigation that aims to address the troubling gap in our science regarding measuring patient reported contextual distress including race-based distress in the oncology arena. The goal is to create a tangible assessment of distress including race-based distress that can translate into meaningful, systemic policies and practices to address discrimination and inform interventions that benefit patients and communities affected by discrimination. A total of 320 BCS (88 African-American and 232 Latina-American) recruited from the California Cancer Registry and hospital registries completed a self-report questionnaire assessing demographic and cancer-related medical status, and healthcare and social environment/daily-living discrimination. BCS between 26 and 89 years (mean=54.5) completed an 18-item stress Life Stress Scale to rate multiple sources of stress including discriminatory and race-based stresses. Exploratory factor analysis was conducted using maximum likelihood analysis. Factor analysis and item refinement yielded a two-factor solution with racism and discrimination loading as Factor 1 and accounted for 21% of the total variance. Factor 2 - 13-items that accounted for 47% of the total variance, identifying stress related to was related to disease outcomes and socioeconomic loaded as a single factor. The Cronbach's alpha for these four items was 0.87 (95% CI = .84 - .89), suggesting that the items have relatively high internal consistency. Additionally, the distribution of response to Factor 1 is significantly different between African Americans and Latinos; while the distribution of responses to Factor 2 is undifferentiated for African Americans and Latinos. Overall, this area of research holds great promise for better understanding the health effects of racism and discrimination, and stimulating equity efforts in health services and behavioral medicine science and practice towards reducing health disparities.

“WHAT WOULD MAKE YOUR LIFE BETTER?”: UNMET BASIC NEEDS, HEALTH, AND HEALTH BEHAVIORS AMONG MEDICAID BENEFICIARIES

Tess Thompson, PhD, MPH¹, Matthew Kreuter, PhD, MPH¹, Amy McQueen, PhD², Nicole Caito, MPH, MS, RD³, Karyn Quinn, MSN⁴, Jennifer Funaro, BA, Communications⁵

¹Washington University in St. Louis, St. Louis, MO; ²Washington University School of Medicine, St Louis, MO; ³Washington University in St. Louis, Fenton, MO; ⁴Centene, Hampton, NH; ⁵Envolve PeopleCare, Cheshire, CT

Unmet basic needs—including those for food, shelter, and utilities—have been associated with negative outcomes, including higher mortality, worse self-reported health, and higher levels of depressive symptoms. We sought to examine the association between unmet basic needs, health, and health behaviors in a national sample of adults on Medicaid, as well as participants' perceptions of what would make their lives better.

In 2016–2017, people with Medicaid insurance in the U.S. completed a survey about demographics, health, health behaviors, life values, perceived stress, and unmet basic needs. Seven items assessing basic needs were combined into an index in which higher scores indicated higher levels of unmet needs. Participants were also asked what one thing they believed would make their lives better. Participants were recruited through a range of methods (letters, emails, phone messages, fliers, and volunteer databases) and were eligible if they were ≤ 18 , had Medicaid, and spoke English or Spanish. Surveys were completed online using Qualtrics. Analyses were conducted in SPSS. Results are for participants who took the survey in English and answered at least one basic needs question ($N = 1217$).

The sample was predominantly female (87%); most had at least one child 18 or younger living in the home (71%) and reported household income $< \$20,000$ (52%). 51% were White and 35% were African American. Average age was 36 ($SD = 12$). Mean number of unmet basic needs was 1.3 ($SD = 1.3$). The most common needs were not enough money for unexpected expenses (54%) and not enough space in the home (25%). The most frequent answers to “What would make your life better?” were “Taking care of your family” (22%) and “Helping your child(ren) thrive” (13%). Multivariate analyses controlling for income, sex, marital status, employment, age, and presence of children in the home showed that increasing levels of unmet basic needs were positively associated with stress and negatively associated with self-reported health, exercise, and fruit/vegetable consumption ($p < .01$ for all).

Results add to the growing body of evidence about the relationship of unmet basic needs and health. Interventions such as navigators that help people meet basic needs may hold potential both to help low-income people improve their economic situations and to improve their health. Medicaid beneficiaries with children may be especially receptive to interventions designed to address the needs of the entire family.

AN ASSESSMENT OF HEALTH DISPARITIES AMONG A COMMUNITY SAMPLE OF LGBQ COLLEGE STUDENTS

Ashlee N. Sawyer, MS, Paul B. Perrin, PhD, Eric G. Benotsch, MA, Ph.D.

Virginia Commonwealth University, Richmond, VA

Lesbian, gay, bisexual, and queer (LGBQ) individuals are a marginalized population in the United States, and this status places them at a greater risk for adverse health outcomes, such as tobacco and substance use, obesity, cancer, sexually-transmitted infections, violence, mental health issues, and suicide. The present study used individual- and microsystem-level data from the American College Health Association (ACHA)-National College Health Assessment (NCHA) to compose a risk assessment for LGBQ students at a mid-Atlantic university. The study incorporated various levels of the ecological social model in an analysis of potentially influential factors on the development of LGBQ health disparities. 856 participants completed a self-administered anonymous survey that included questions assessing a broad variety of health indicators, such as alcohol, tobacco, and other substance use, sexual health, mental health, nutrition, and personal safety and violence. A significant minority of the sample identified with a sexual orientation other than heterosexual ($n=184$, 21.6%). Sexual minority students reported significantly higher rates of various types of substance use [e.g., sedatives $\chi^2(1, N=856)=3.543$, $p\chi^2(1, N=856)=3.198$, $p\chi^2(1, N=856)=10.813$, $p\chi^2(1, N=856)=11.649$, $p\chi^2(1, N=856)=13.157$, $p\chi^2(1, N=856)=29.048$, $p\chi^2(1, N=856)=38.436$, $p\chi^2(1, N=856)=6.210$, p

CARING AND COPING: THE ROLE OF INFORMATION IN FAMILY-BASED ILLNESS MANAGEMENT

Lindsay K. Brown, BA, MHI (in progress), Tiffany C. Veinot, BA, MLS, Ph.D

University of Michigan - Ann Arbor, Ann Arbor, MI

Background/Significance: Family-based care is critical for effective chronic illness management, but behavioral interventions may not account for the role of information in this care. An understanding of this relationship may inform novel informatics interventions.

Purpose: To examine the relationship between collaborative information behavior (CIB) and both coping and social support in families managing chronic illness. Family coping is defined as problem-solving and behavioral strategies used in difficult situations, and social support as a coping resource. CIB includes 1) mediated information acquisition (e.g., caregiver search the Internet for a patient) and 2) joint information acquisition (e.g., caregiver and patient search the Internet together).

Methods: 38 families managing Type 2 Diabetes or HIV/AIDS were recruited, including 38 patients and 59 caregivers. Families participated in 2 individual and 3 family group semi-structured interviews over 2 years. At times 1 and 5 (T1, T5), participants completed a survey with a 13-item CIB scale, the Family Crisis-Oriented Personal Scale and the Multidimensional Survey of Perceived Social Support (PSS).

Results: CIB was associated with the external coping patterns of acquiring social support (T1: $r=.28$, $p=.006$; T5: $r=.36$, $p=.003$) and mobilizing family to seek community resources (T1: $r=.25$, $p=.01$; T5: $r=.25$, $p=.04$). Similarly, interviews showed that caregivers approached organizations to help with practical needs such buying medication and patients sought experiential knowledge from relatives with a disease history. Among patients, PSS was associated with joint information acquisition at T1 ($r=.30$, $p=.04$) but not T2. Among caregivers, there was an association between mediated information acquisition and PSS (T1: $r=.31$, $p=.02$; T5: $r=.33$, $p=.04$, T5). Qualitative results showed that CIB was seen as emotionally supportive: expressions of caring and mutual respect. CIB was part of tangible support, including adapting healthcare recommendations to daily life and identifying and responding to crises.

Conclusions: CIB was integral to both coping and social support in families, though patients and caregivers may experience the CIB-support relationship differently. Informatics interventions could facilitate CIB, with specific options for caregivers and patients. This intervention-supported CIB could be a pathway towards facilitating supportive interactions and resource mobilization in families managing chronic illness.

CLASSISM AND ALCOHOL USE: RACIAL DIFFERENCES IN THE MODERATING EFFECT OF ATTITUDES TOWARD GOD

Erin Smith, MS, Erin Smith, MS, Sarah Griffin, MS, Allison Williams, MS, Paul B. Perrin, PhD, Bruce Rybarczyk, PhD

Virginia Commonwealth University, Richmond, VA

Background: Individuals living in poverty experience a profound amount of stress and are likely to be exposed to class-based discrimination (i.e., classism). Experiences of discrimination have been linked to greater alcohol use, which has been consistently linked to chronic stress and low socioeconomic status (SES). Personal religiosity may protect individuals experiencing discrimination against alcohol use. However, racial differences in discrimination, religiosity, and alcohol use exists for White and Black individuals which may impact this relationship. Despite the abundance of work linking SES and race to health and problematic drinking, little research has examined the potential association between experiences of classism and drinking or the role of religious coping, especially in the context of race.

Objectives: The purpose of this study was to examine the effect of classism on problematic drinking, as moderated by comfort with God, and determine the presence of conditional effects of this moderated association by race.

Methods: Participants (N = 189) were patients of an urban, safety-net primary care clinic and completed questionnaires assessing experiences of classism, attitudes towards God, and alcohol use. Data were collected from 2015–2016 and analyzed using the Hayes PROCESS macro.

Results: There was a significant main effect for race predicting problematic drinking with Black participants having lower alcohol use scores than their White counterparts. Two-way interaction analyses identified a significant comfort with God by race interaction, whereby comfort with God was more protective against excessive alcohol use for White participants than for Black participants. Conditional direct effects showed that experiences of classism were associated with higher alcohol use for Black participants who endorsed low to moderate, but not high, levels of religiosity. No conditional effects were observed for White participants.

Conclusion/Importance: This study provides insight on how religion, classism, and race may interact to shape excessive alcohol use in low-income, urban primary care patients. Clinicians' awareness of risk and protective factors, as well as how race tempers the effects of such factors, is vital to providing better care for this population.

DYADIC COPING, SELF-EFFICACY FOR WEIGHT LOSS, AND WEIGHT IN HISPANIC MALES ENROLLED IN A WEIGHT LOSS INTERVENTION

Melissa A. Flores, MS¹, Luis A. Valdez, PhD, MPH¹, Melanie Bell, PhD¹, David O. Garcia, PhD²¹The University of Arizona, Tucson, AZ; ²The University of Arizona / Mel and Enid Zuckerman College of Public Health, Tucson, AZ

Introduction: Hispanic men experience the highest levels of overweight and obesity in the US. As obesity is associated with myriad diseases including cardiovascular disease, diabetes, and cancer, weight loss is becoming increasingly important for this at-risk group. Weight loss activities such as diet restriction and exercise can be stressful, potentially affecting one's confidence in their ability to lose weight (self-efficacy for weight loss). During stressful times, couples often rely on each other to cope with the situation at hand. Dyadic coping may be especially important for Hispanics who value close, supportive, familial relationships.

Purpose: The aims of our study were to assess the following in Hispanic men enrolled in a weight loss intervention: 1) the association between dyadic coping and weight, and 2) the association between dyadic coping and self-efficacy for weight loss.

Methods: A community sample of 50 Hispanic men enrolled in gender- and culturally-sensitive weight loss intervention (GCSWL). Participants completed surveys and were weighed at baseline, 12 weeks, and 24 weeks. The weight loss intervention included two arms: 1) a GCSWL, and 2) a wait-list control (WLC) including a GCSWL plus mHealth technology. Participants completed the Dyadic Coping Inventory (DCI), and the Weight Efficacy Lifestyle Questionnaire (WEL). Dyadic coping was person-mean-centered to disaggregate within-person and between-person longitudinal effects. Linear mixed models using an unstructured mean and covariance were utilized to assess both aims. Control variables included age, education, treatment condition (treatment vs. wait-list control), and diabetes diagnosis status.

Results: Men had a mean age of 43.3, and a mean, baseline BMI of 34.4 kg/m². Forty-six men reported having a significant other, and 37 men reported being married or cohabiting with their partner. Dyadic coping was marginally, negatively associated with the subsequent measure of weight (intervals of 12 weeks), $b = -11.9$, $se = 5.4$, $t(11) = -2.19$, $p = 0.05$, 95% CI (-22.87; -0.99). Additionally, dyadic coping was positively, associated with the concurrent weeks' self-efficacy for weight loss, $b = 1.16$, $se = 0.4$, $t(7) = 2.89$, $p = 0.02$, 95% CI (0.30; 2.01).

Conclusion: Dyadic coping may be an important form of support utilized by Hispanic men attempting to lose weight. Future research may benefit from considering the important aspects of partner and spousal influences on health in this population.

EXAMINING BODY-FOCUSED SOCIAL COMPARISON MOTIVATIONS IN COLLEGE WOMEN USING ECOLOGICAL MOMENTARY ASSESSMENT

Rachel MacIntyre, B.S.¹, Kristin Heron, Ph.D.²¹Virginia Consortium Program in Clinical Psychology, Norfolk, VA; ²Old Dominion University, Norfolk, VA

Although the social comparison theory postulates that people have a drive to compare themselves to others for self-evaluation, recent research suggest people may also be motivated for self-improvement (i.e., to make positive changes). These two motivations have been examined experimentally as women make upward body-focused comparisons (i.e., comparisons between themselves and people they perceive to be thinner or more physically fit), but have not been examined in real-life settings. The present study examined the natural occurrence of these two motivations (self-evaluation, self-improvement) and their associations with body dissatisfaction and thoughts of exercising using ecological momentary assessment (EMA). Undergraduate women ($N=74$, ages 18–25) completed surveys five times daily for seven days via a smartphone survey app. EMA surveys included measures of body-focused comparisons, body dissatisfaction, and thoughts of exercise. Baseline measures of physical activity, body dissatisfaction, and tendency to engage in appearance social comparisons were collected prior to EMA and examined as moderators. Multilevel analyses revealed that both momentary self-improvement and self-evaluation ratings were positively associated with thoughts of exercise ($ps<.05$). Moderator analyses revealed baseline physical activity and body dissatisfaction moderated the association between self-improvement motivations and thoughts of exercise; these associations were stronger for women who reported more baseline physical activity ($p=.01$) and less body dissatisfaction ($p=.02$). Baseline social comparison tendency moderated the associations between self-evaluation motivations and both thoughts of exercise and body dissatisfaction, as well as self-improvement motivations and body dissatisfaction ($ps<.05$). Stronger positive associations between the motivations and body dissatisfaction were found for women with lower baseline social comparison tendency ($ps<.05$). For the self-evaluation and thoughts of exercise relationship, a stronger positive relationship was found for women with higher baseline social comparison tendency ($p<.001$). This is the first study to assess naturally occurring self-evaluation and self-improvement body-focused comparisons in women's everyday lives. Both motivations were associated with momentary thoughts of exercise, but person-level factors moderated these associations. In particular, the stronger association between self-improvement and thoughts of exercise for women with more baseline physical activity and lower body dissatisfaction suggests self-improvement comparisons may contribute to positive thoughts and attitudes women have about their bodies and exercise. These findings about self-improvement comparisons have the potential to help inform interventions aimed at increasing physical activity in women.

EXAMINING CHALLENGES AND LIMITATIONS OF MEASURING FINANCIAL STRAIN IN HEALTH OUTCOMES RESEARCH: A LITERATURE REVIEW

Marquita Lewis, PhD, MPH, MS¹, Samantha K. Greaney, BA², Martha M.O. McGilvray, MD³, Aimee S. James, PhD MPH⁴¹Washington University School of Medicine at St. Louis, St. Louis, MO; ²Washington University in St. Louis, Dept. of Surgery, Division of Public Health Sciences, St. Louis, MO; ³Washington University School of Medicine, Department of Surgery, St. Louis, MO; ⁴Washington University in St. Louis, St. Louis, MO

The examination of financial strain in health outcomes research has been growing steadily for the past four decades. Despite this increase, few studies have addressed the limitations and challenges associated with collecting these personally sensitive data, especially in the most marginalized populations. The purpose of this literature review is to 1) briefly summarize key constructs of flagship financial strain scales commonly used in health outcomes research; 2) report repeated financial strain measurement challenges and limitations, and 3) identify demographic trends of financial strain, particularly among vulnerable subpopulations. A search was conducted in 2017 via the SCOPUS database. Articles were included in this review if the full-text version was available to the authors, measured financial strain, measured a health-related or health outcome, and were published within the last 40 years. Based on these criteria, we identified 121 articles for this review. Four financial strain scales were used in 58 different studies, representing the most frequently used financial strain scales in health outcomes research. The most commonly investigated health outcomes in this literature review were mental health, health behaviors, and self-rated health. Findings revealed repeated methodological limitations throughout the reviewed literature. A repeated methodological limitation observed was a choice of study design that failed to compliment study objectives. This limitation was observed in five studies aimed to measure chronic or accumulated financial strain, but used a cross-sectional study design that took a single measure of financial strain, unlike the more appropriate longitudinal study designed employed by three studies. Another repeated limitation was the use of customized scales that failed to incorporate both absolute financial need or lost and perceived need, as observed in 16 studies. Common financial strain trends were also observed within certain underrepresented populations including the elderly, women, racial and ethnic minorities, and individuals from low socioeconomic subpopulations. These findings revealed recurrent challenges and limitations associated with financial strain data collection, but rarely reported. Implications of these findings suggest a need for validated measures and a comprehensive methodological framework for the measurement of financial strain.

FINANCIAL STRAIN IS ASSOCIATED WITH HIGHER STRESS AND REDUCED EXECUTIVE FUNCTION

Jessica O'Neill, MPH¹, Heather Orom, PhD²¹University at Buffalo, The State University of New York, Buffalo, NY; ²University at Buffalo, Buffalo, NY

Background: A growing body of research demonstrates that living with financial scarcity impairs cognition. Habitual tasks like budgeting impair cognition when financial resources are limited. Additionally, financial strain is associated with greater stress. The specific executive functions impacted by financial scarcity and the degree that stress mediates these relationships are not well understood.

Purpose: The purpose of this study was to identify decrements in executive function that are associated with financial scarcity and test whether stress mediates the relationships between financial scarcity and executive function.

Methods: Participants were 249 female Amazon Mechanical Turk workers recruited to be part of a larger study. We oversampled individuals currently living with financial scarcity (32.9% had 2 or more experiences of financial scarcity) Participants' median income was \$55K, median education was a bachelor's degree; 83% were white; and mean age was 37.2 (SD=11.9)). We quantified financial scarcity by counting the number of current financial scarcity experiences, as described in Butterworth et al (2012) (e.g., welfare, pawned items to make ends meet, skipped meals). Stress was measured with Cohen's Perceived Stress Scale, and executive function was assessed with the Behavior Rating Inventory of Executive Function for Adults (BRIEF), which is composed of 9 scales (inhibit, shift, emotional control, self-monitor, initiate, working memory, plan/organize, task monitor, and organization of materials). We used multivariable linear regression to examine associations between financial scarcity, stress, and executive function and bootstrap estimates to test for indirect effects of financial scarcity on executive function through stress. Because poverty in childhood is a plausible cause of poverty in adulthood, and age and education influence executive function, we controlled for these in all analyses.

Results: All relationships were significant for all 9 BRIEF scales in unadjusted analyses. After adding controls, financial scarcity was associated with 3 BRIEF scales: emotional control, initiate, and plan/organize (all Bs=0.51 to 0.68, all ps<0.04) as well as stress (B=0.95, p<0.0001). There were significant indirect effects of financial scarcity on the 3 BRIEF scales through stress (indirect effects=0.47 to 0.61, 79.3% to 98.9% of total effect).

Discussion: Living with financial scarcity may cause stress and, in turn, difficulty modulating emotions, starting tasks, and sticking with future-oriented goals. Policies to reduce poverty may have the added benefit of decreased stress and improved executive function. The impact of financial scarcity on executive function might be mitigated by stress-reduction interventions, such as mindfulness and exercise programs, which likely must be tailored to individuals who struggle to make ends meet.

GREEN SCHOOLYARDS IN URBAN NEIGHBORHOODS: SETTINGS FOR PHYSICAL ACTIVITY AND PRO-SOCIAL BEHAVIOR

Amy Bohnert, Ph.D.¹, Carolyn Bates, M.A.², Laura Nicholson, BA², Dana Engel Gerstein, MPH, RD³¹Loyola University of Chicago, Chicago, IL; ²Loyola University Chicago, Chicago, IL; ³University of California Agriculture and Natural Resources Nutrition Policy Institute, Evanston, IL

Children are increasingly growing up in high-crime urban environments with limited access to green spaces (Markevych et al., 2014). High-crime neighborhoods may contribute to health disparities through associations with few opportunities for physical activity (PA) (Keenshaw-Prince et al., 2015) and high levels of negative externalizing behaviors among children (Manly, Oshri, Lynch, Herzog, & Wortel, 2013). Studies show that park renovations in urban communities promote increased PA (Cohen et al., 2015; Tester & Baker, 2009). In particular, renovated green schoolyards may most effectively promote PA and positive social interactions among urban youth (Anamathen et al., 2011; Anderson et al., 2015; Chawla et al., 2014). Utilizing the RE-AIM framework, the current study examined child PA and social interactions in the context of recently renovated green schoolyards within high-crime urban neighborhoods. Students in pre-k through 8th grade were assessed across two time points 6-months apart to examine the sustainability of outcomes over time. Additionally, gender and ethnicity were tested as characteristics influencing PA and social interactions. The study observed children on three green schoolyards around the city of Chicago (total observations N = 7,025) in spring and fall of 2016 (i.e., T1 and T2). Children were pre-k through 8th grade (Median = middle school; 55% male). The majority of children observed were African American (44.7%) or Latino/Hispanic (39.2%). Data were collected on schooldays and weekends. The study utilized behavioral mapping (Cosco, Moore, & Islam, 2012) to capture PA (Child Activity Rating Scale; Durant et al., 1993) and social interactions (System for Observing Children's Activity and Relationships during Play; Ridgers, Stratton, & McKenzie, 2010). Several statistical analyses were used to answer study questions, including t-tests, analyses of variance, and chi-square tests. Children evidenced a range of PA on the renovated green schoolyards, with nearly one-third walking or running when observed at T1. Males were more active than females (t(3250)=7.55, p<.001). There were no ethnic differences in PA. Follow-up analyses demonstrated increases in PA from T1 to T2 (t(7024) = -2.84, p<.001). Socially, 64% of children were interacting with others when observed at T1. Females (t(3253)=-3.44, p<.01) and African American children (F(4, 3245)=3.81, p<.01) were more likely to interact with others on the schoolyard. Of observed interactions, 43% were positive and 4% were negative. Negative interactions, while few, were more common among African American children (F(4, 2037)=3.075, p<.05). Follow-up analyses demonstrated more positive interactions and fewer negative interactions at T2 compared to T1 (x²= 98.80, p<.001). Results suggest that renovated green schoolyards may combat health disparities by providing zones of PA and positive social interactions within high-crime urban neighborhoods.

GROUP-LEVEL PREDICTORS OF NCAA ATHLETES' ATTITUDES TOWARD RISKY BEHAVIOR

Scott Graupensperger, PA¹, Alex Benson, ON², M. Blair Evans, PA¹¹The Pennsylvania State University, State College, PA; ²Western University, ON, Canada

While involvement in intercollegiate sport is broadly beneficial, student-athletes also face many opportunities to engage in risky behavior. In the current study, we investigated how athletes' perceptions of their sport team environment predicted attitudes towards: alcohol, marijuana, drinking-and-driving, playing through concussion, performance-enhancing drug use, and hazing rituals. Existing evidence indicates that peer-acceptance and social cohesion may relate to risk-taking attitudes (e.g., Grossbard et al., 2009; Zamboagna et al., 2008), although researchers have yet to determine whether these relations are due to variation occurring within or between groups. We hypothesized that athletes who reported stronger feelings of peer-acceptance and social cohesion, relative to teammates, would have riskier attitudes towards the behaviors in-focus. In contrast, we hypothesized that, at the team-level, higher group-wide perceptions of peer-acceptance and social cohesion would create an environment of psychological safety that would *negatively* relate to risk-taking attitudes. Participants were 389 NCAA athletes from 23 teams, representing a variety of sports. Controlling for gender, age, tenure with team, and self-esteem, we specified six multilevel models to examine how between-group and within-group variation in peer-acceptance and social identity related to each of the risky attitudes. Across all six behaviors, models accounted for between 5–20% of the variance in athletes' risk-taking attitudes. At the individual level, peer-acceptance was *positively* associated with riskier attitudes towards alcohol ($b = .21, p < .05$), hazing ($b = .27, p < .01$), and playing through concussion ($b = .26, p < .01$). Meanwhile, individual perceptions of social cohesion were *negatively* associated with playing through concussion ($b = -.16, p < .05$). At the group level, athletes who belonged to teams with high peer-acceptance, relative to other teams, were less likely to support playing through concussion ($b = -.98, p < .05$), while those belonging to teams with high ratings of social cohesion were *more* likely to support playing through concussion ($b = .38, p < .05$). These findings extend theoretical understanding of how peer relationships shape athletes' attitudes towards risky behavior. Despite the value in forging strong relationships to reduce some risky behaviors, this research reveals how group environments may also support risky behavior and raises numerous theoretical and practical questions (i.e., do tightknit teams create an atmosphere where athletes make bodily sacrifices for the sake of the team?).

INDIVIDUAL, NATIONAL AND GLOBAL ESTIMATION OF MORTALITY RISK FACTORS: ESTIMATIONS FROM GERMAN UNIVERSITY STUDENTS

Ftan 2017 AG1, N/A¹, Gertraud Maskarinec, MD, PHD², Claudio Nigg, Ph.D.³¹German University Students, Honolulu, HI; ²University of Hawaii Cancer Center, Honolulu, HI; ³University of Hawaii, Honolulu, HI

Background: German university students of different fields reported about factors contributing to their health. This was based on their personal experience, public opinion, media and special interests. The goal was to assess differences in personal health expectations between both participants' estimations versus what is known.

Methods: Participants ($n=79$; 31% female; 29% studying the Humanities, 43% Math/Informatics/Natural Sciences/Technology, 28% Medicine/Psychology) in a summer academy completed a questionnaire addressing mortality risk factors for themselves, their nation (Germany), and the world. The risk factors provided were smoking, accidents, poor sanitation, poverty, poor environment, physical inactivity, stress, poor diet, and infectious diseases. Further, they reported what the most important health achievements were in the past 200 years, and what they believed would be the most important efforts to improve health in the future.

Results/Discussion: At the individual level, stress (64%) and accidents (53%) were the highest mortality risk factors, whereas nationally they were physical inactivity and poor diet (65% each), and globally they were poverty (80%) and poor sanitation (76%). Most participants were able to evaluate the national and global risks accurately but not for their own risk factors. The individual estimation may reflect psychological coping with one's own responsibility for one's mortality. Therefore, more education especially about how risk factors influence one's own health may be helpful.

The most important health achievements over the past 200 years were antibiotics (31%) and vaccines (27%), whereas education (25%) was deemed as most important for the future. These answers show an awareness of the relation between education and future mortality risks. Therefore, we recommend supporting education globally to decrease mortality risks.

The participants were homogeneous in that they were all scholars of an academic foundation. However, they did represent a broad range of content areas allowing some confidence in the results' generalizability. Future studies using a more representative sample are likely to be informative on University students' understanding of mortality risk factors.

INSTA-INFORMATION: SOCIAL ENDORSEMENT AND YOUNG ADULTS' PERCEPTION OF SOCIAL MEDIA DELIVERED HEALTH INFORMATION

Patrece Joseph, MA, Jessica Pappagianopoulos, MA, Sasha A. Fleary, PhD
Tufts University, Medford, MA

Background: According to the Health Research Institute, 90% of young adults (YA) would engage in health activities or trust information on social media. Given that YA receive a host of potentially inaccurate health information via social networking sites (SNS) and are more likely to pay greater attention to positively socially endorsed SNS messages, it is important to understand YAs' perception of the accuracy of such messages. Thus, the present study examined whether YA would perceive positively socially endorsed images (i.e., images with a high number of likes) as containing accurate health information. We hypothesized that YA would select images with high likes as accurate.

Method: Data were collected from YA ages 18–21, via Amazon Mechanical Turks ($N = 122$, $M_{Age} = 20$, $SD_{Age} = .95$ 35% White, 68% male, 36% students, 69% US born). Participants completed demographic measures, the eHealth Literacy Scale (eHEALS), and an Instagram task. In the Instagram task, participants were presented two images with contradictory health information (e.g., image A: 100% fruit juice is healthy; image B: 100% fruit juice is unhealthy). Of these two images, participants were asked to select the image with accurate health information. Each participant randomly responded to three image sets from the pool of nine. Within the nine image sets, four images with high likes contained accurate health information and five images with low likes contained accurate health information. Frequencies were computed to examine participants' response to each image set.

Results: Participants average eHEALS score was 2.47 ($SD = 1.01$), 27% often used social media for health information, and 23% responded correctly to all three images. For six image sets, participants were more likely to select the image with the high amount of likes as accurate. This response option was correct for four of the six images. For three image sets, participants were more likely to select the image with the low amount of likes as accurate. This response option was correct for all images.

Discussion: Our hypothesis was partially supported; YA perceived more positively socially endorsed images as accurate. However, participants also correctly identified three low-liked images as containing accurate health information. Health literacy may play a role in these unintended findings. Thus, future studies should examine whether media health literacy is associated with YAs' perception of the accuracy of SNS delivered health information.

RELATION OF PRONOUN USE TO RELATIONSHIP AND HEALTH OUTCOMES: A META-ANALYTIC REVIEW

Kim Hochstedler, PA, Vicki Helgeson, Ph.D., Howard Seltman, M.D., Ph.D.
Carnegie Mellon University, Pittsburgh, PA

There is a growing literature that documents how pronoun usage is related to relationship and health outcomes. The literature in this field, however, has produced mixed results. In order to better understand the results, we conducted a meta-analytic review of the studies relating personal pronoun usage to a variety of health and relationship outcomes: relationship quality, negative interactions, attraction and liking, depression and anxiety, treatment outcomes, physical symptoms, and physical health. We located 45 studies from 1989 to 2016 that correlated a measure of pronoun use to at least one relationship or health factor. Correlation effect sizes (r) and 95% confidence intervals were calculated within each category of pronoun type and outcome. The heterogeneity statistic (Q) was calculated to determine the degree to which effect sizes were consistent and the Fail-Safe N (N) was calculated to evaluate the robustness of effect sizes. Results showed that first-person plural pronouns (we, us, our) was associated with increased relationship quality ($r = 0.12$, 95% CI: -0.02, 0.25), decreased negative interactions ($r = -0.15$, 95% CI: -0.24, -0.05), and better treatment outcomes ($r = 0.12$, 95% CI: 0.03, 0.20). Second-person pronouns (you, your) were associated with increased negative interactions ($r = 0.31$, 95% CI: 0.14, 0.46). First-person singular pronouns (I, me, my) were associated with increased depressive and anxiety symptoms ($r = 0.13$, 95% CI: 0.01, 0.25) and decreased positive treatment outcomes ($r = -0.11$, 95% CI: -0.21, -0.01). We were able to examine moderators of the relations of pronoun use to depression/anxiety because there were a sufficient number of studies ($k = 16$) and Q statistic was significant. In sum, these findings suggest that the use of first-person plural pronouns is generally related to positive relationship and health outcomes. In contrast, the use of first-person singular and second-person pronouns is generally related to negative relationship and health outcomes. These findings have implications for medical treatment and therapy programs where specific language use may impact patient outcomes.

SOCIAL STRATIFICATION AND RISK FOR CARDIOVASCULAR DISEASE: EXAMINATION OF EMOTIONAL SUPPRESSION AS A PATHWAY TO RISK

Jenny M. Cundiff, Ph.D.¹, Richard Jennings, PhD², Karen A. Matthews, PhD²

¹Texas Tech University, Lubbock, TX; ²University of Pittsburgh, Pittsburgh, PA

This paper examines whether there are socially stratified (e.g., socioeconomic position; SEP) differences in emotional suppression in a community sample of Black and White men, and whether such differences may help explain the aggregation of multiple biopsychosocial risk factors for cardiovascular disease at lower SEP (social support, depression, cardiovascular stress reactivity). Study 1 tests whether multiple indicators of SEP show a consistent graded association with self-reported trait emotional suppression, and whether suppression mediates associations between SEP and perceived social support and depressive affect. In a subsample of participants from Study 1, Study 2 examines SEP and self- and observer reports of suppression during a laboratory anger recall task, and whether suppression during the task mediates associations between SEP and cardiovascular reactivity to the task (another potential pathway to risk).

Results: All measures of SEP were inversely associated with self-reported trait suppression and suppression statistically mediated the link between SEP and social support and depressive affect. SEP was not associated with self-reports or observer ratings of state suppression or cardiovascular reactivity during anger recall in the laboratory. However, suppression during anger recall by both self-report and observer ratings showed theoretically consistent associations with concurrent physiology.

Conclusions: Findings in this racially diverse sample of adult men suggest that socioeconomic disparities in emotional suppression may help explain parallel disparities in health-protective social relationships and health-damaging negative affect. However, SEP did not show reliable associations with multimethod behavioral measurement of state suppression or cardiovascular physiology during an anger recall task; hence, momentary changes in autonomic physiology do not appear a likely avenue to risk although suppression was reliably associated with physiology.

SOCIOECONOMIC STATUS REPORTING TRENDS IN THE APA JOURNALS: AN EPIDEMIOLOGICAL ANALYSIS OF THE PSYCHOSOCIAL LITERATURE

John M. Ruiz, Ph.D.¹, Lloyd S. Spece, N/A¹, Caroline Y. Doyle, BA¹, Jamie Q. Hoang, NA¹, Krystal S. Jovel, BA¹, Sana M. Khan, NA¹, Noor Mohamed, NA¹, Danny N. Thompson, NA¹, Sarron Asrat, NA¹, Christian Goans, MS²

¹University of Arizona, Tucson, AZ; ²University of North Texas, Denton, TX

Background. Socioeconomic Status (SES) is among the most robust psychosocial determinants of health and disease. Although specific metrics vary by field and population of interest, the inverse relationship between SES and health remains robust, reliable, and constant. Given the breadth of these effects, the 2006 APA Task Force Report on Socioeconomic Status recommended its standard reporting (like age, sex) as a critical demographic variable in all human factors research. The current aim was to examine SES reporting trends in all 93 APA journals for the last 5 years as a benchmark to inform efforts aimed at improving the quality of the scientific literature.

Method. Online searches using PsycINFO as the primary engine and complemented with additional databases (e.g., WebofScience) were conducted for each individual journal for the period of January 1, 2012 to December 31, 2016. Search terms derived from the APA Task Force Report were combined using Boolean-compatible syntactical array methods. Results were saved to Endnote X8.1 and screened for redundancy.

Results. A total of 24,087 papers publications were identified in all APA journals over the 5-year period. The overall prevalence of SES terms in those papers was 17.95% with no appreciable difference by year. Reporting rates varied from 0% to 100% with the median 5-year average reporting rate at 14.84%. A 10% random sample of papers reporting searched terms were downloaded as PDFs to ascertain where in the papers SES terms were being reported. Two coders examined each paper, noting the study type and sections of empirical papers where the terms were reported (abstract/intro, methods, results, discussion). Boolean searches were used and discrepancies were resolved by the two raters with a third weighing in when necessary. Of the 432 papers examined, 318 (73.61%) were identified as empirical in nature. Of these, 75.79% reported SES terms in the methods or results section.

Conclusions. Despite recommendations, the overall prevalence of SES terms in APA journals is quite low. However, when SES is reported in empirical papers it is generally occurring in the recommended sections. These findings document important limitations in the reporting quality of the literature and suggest the need for editorial interventions to establish guidelines and improve reporting standards.

STIGMA AND AVOIDANT COPING IN COLLEGE STUDENTS WITH CHRONIC ILLNESS

Morgan E. Longstreth, B.S.¹, Jacob Burmeister, PhD²

¹The University of Wyoming, Laramie, WY; ²University of Findlay, Findlay, OH

Adults with chronic illness who encounter stigmatization often exhibit an avoidant coping style and experience significant detriments to health-related quality of life (HRQoL) and psychological and social functioning. The impact of these factors on college students' HRQoL and psychological and social functioning is not well understood. The two studies presented here tested the hypotheses that stigma and avoidant coping are associated with HRQoL, social functioning, and psychological well-being in undergraduates students who have chronic illness. Participants in both studies were undergraduates diagnosed with at least one chronic illness. They completed self-report measures online. In Study 1 (N = 145), stigma and avoidant coping significantly predicted diminished HRQoL, $R^2 = .508$, $F(2, 142) = 73.371$, $p < .001$, diminished social support, $R^2 = .051$, $F(2, 142) = 3.781$, $p < .05$, depression, $R^2 = .569$, $F(2, 142) = 93.686$, $p < .001$, and anxiety, $R^2 = .476$, $F(2, 142) = 64.625$, $p < .001$. Study 2 (N = 199) confirmed the results of Study 1 finding that stigma and avoidant coping significantly predict diminished HRQoL, $R^2 = .520$, $F(2, 196) = 106.180$, $p < .001$, depression, $R^2 = .487$, $F(2, 196) = 93.083$, $p < .001$, and anxiety, $R^2 = .401$, $F(2, 196) = 65.496$, $p < .001$, though the association with social support was not replicated. As hypothesized, stigma and avoidant coping were associated with diminished HRQoL, social functioning, and mental health in Study 1. Second study data suggests that experienced stigma and avoidant coping significantly predict diminished HRQoL and mental health, but not social functioning. Findings suggest that college students with chronic illness face significant challenges associated with and during their undergraduate career. Stigma and avoidant coping may be targets for intervention.

THE ECOLOGY OF MATERNAL CHILD HEALTH: HOW DRUG POLICING IMPACTS INFANT MORTALITY IN STRUCTURALLY DISADVANTAGED COMMUNITIES

Robert J. Kane, Ph.D.¹, Anne-Marie O'Brien, Ph.D., RN, WHNP-BC²

¹Drexel University, Philadelphia, PA; ²Marymount University, Arlington, VA

Despite the considerable monetary resources the United States devotes to health-care, its infant mortality rate ranks as one of the highest in the world. A disproportionate percentage of infant mortality stems from its urban minority population. This disparity can be largely attributed to the high levels of structural disadvantage, violent crime, and social isolation that characterize many urban communities in the US. A high proportion of infant deaths are linked to low birthweight and very low birthweight, which often results from pregnant women receiving late and/or inadequate prenatal care. Research has found that community-level violence and distrust of social institutions often plays a role in discouraging women from seeking prenatal care, partly to avoid public places, and partly to avoid perceived provider discrimination. And despite the fact that the police are deployed in communities to maintain public safety, their presence -- particularly aggressive enforcement activities in disadvantaged communities -- often contributes to (1) the distrust via compromised legitimacy, and (2) increased violence by creating power vacuums within block-level drug markets. To this extent, police are often viewed as more a hazard than a public health asset in troubled communities, which may further contribute to overall maternal child health outcomes. The present study integrates the social ecology of urban policing with the social ecology of urban health to examine the extent to which neighborhood-level drug enforcement (i.e., arrests) was associated with infant mortality counts across census tracts of the District of Columbia. The study used data from the US Census, the DC Metropolitan Police Department, and the DC Department of Public Health to construct Mixed Models and Geographically Weighted Regression that tested both the multilevel effects of drug enforcement on infant mortality, as well as conditional effects in specific neighborhoods. Findings indicate that while controlling for neighborhood violence and disadvantage, as well as a set of individual-level factors, drug arrests at the community level were associated with significant increases in infant mortality counts. In addition to illustrating the findings, the poster also includes a section that considers the implications for social policy.

THE IMPACT OF MALTREATMENT AND EARLY LIFE STRESSORS ON FOSTER YOUTH HEALTH AND WELLBEING

Imani Crosby¹, Sarah Beal, PhD², Katie Nause, BS², Mary Greiner, MD, MS²¹University of Cincinnati/Cincinnati Children's Hospital Medical Center, Cincinnati, OH; ²Cincinnati Children's Hospital Medical Center, Cincinnati, OH

Introduction: Teens in foster care have more physical and behavioral health problems than their peers (Woods et al., 2011). Youth enter foster care due to maltreatment, an early life stressor (ELS) they experience. Maltreatment and ELS likely contribute to health disparities for foster youth by increasing risks and subsequent health issues. This study examined associations among child-reported and child welfare-reported maltreatment, ELS, and physical and behavioral health issues (i.e., pain, BMI, mental health, substance use) captured in the electronic health record (EHR) of 151 foster youth. It was hypothesized that maltreatment and ELS would be associated with more medical and behavioral health problems.

Methods: Foster youth (N=151; 77% minority) ages 16–21 reported maltreatment, ELS, and substance use behaviors. Child-reported maltreatment and ELS were summed into three scales: trauma (e.g., being robbed), risk (e.g., parent mental health problem), and abuse (e.g., sexual abuse) exposure. Child welfare administrative records provided reason for entry into foster care (i.e. neglect, physical abuse, sexual abuse, emotional abuse, parental substance abuse) and number of placement changes. EHR provided data on medical (BMI, pain complaints (y/n), chronic conditions (y/n)) and behavioral health issues (mental health diagnoses). Analyses controlled for age of entry into foster care, current age, gender, and race.

Results and Discussion: There was a significant association of maltreatment and ELS with all four health outcomes; however, types of maltreatment and ELS were differentially related to each outcome. Risk exposure was positively associated with increased BMI (22% with BMI >30), substance use, and depression, but not with pain or other mental health concerns. Physical abuse was positively associated with BMI and bipolar disorder; sexual abuse was associated with bipolar disorder; and emotional abuse was positively associated with pain, substance abuse, trauma-related mental health concerns, ADHD, bipolar disorder, and depression. These findings indicate that it is important to assess maltreatment and ELS separately, raise awareness to healthcare providers, and distinguish among types of maltreatment, as they are differentially associated with a number of adverse outcomes.

INVESTIGATION OF HEALTH BEHAVIOR RISKS AMONG TRANSGENDER MEN, WOMEN, AND NONBINARY-IDENTIFIED INDIVIDUALS

Loren Bauerband, PhD¹, Wayne Velicer, PhD²¹University of Missouri, Columbia, MO; ²University of Rhode Island, Kingston, RI

Transgender individuals are at heightened risk for health disparities including depression, anxiety, and poor access to healthcare. Similar to lesbian, gay, and bisexual individuals (LGB), this population experiences minority stressors that contribute to poorer health outcomes, and increase their overall experience of daily stress. However, the physical health disparities and needs of transgender individuals are unknown. Stress, mental health, and access to resources all increase barriers to engaging in healthy behaviors, increasing the likelihood that transgender persons will be at risk of poor health behaviors. Currently, population data that includes transgender identifiers is scarce, continuing to limit researchers' ability to investigate transgender health needs. The purpose of the current research was to explore the health risks of transgender individuals via a nonprobability online survey of lesbian, gay, bisexual, and transgender individuals (oversampling transgender individuals), to provide a similar demographic comparison (LGB) sample.

An anonymous online survey yielded 460 transgender and 523 nontransgender LGB respondents from 48 US States and DC. We compared the rates of health behaviors (e.g. physical activity (PA), fruit and vegetable consumption (FV), alcohol consumption, smoking history, and stress management) across transgender individuals and nontransgender LGB individuals. Overall, there were low rates of meeting recommendations for PA and FV for all individuals, and high reports of current smoking and stress across all identities.

Multivariate analysis of variance demonstrated interactions of transgender status and gender identity for physical activity and vegetable consumption. Although rates were still low, transgender men and nontransgender LGB women were most likely to consume vegetables, and transgender men, women, and nontransgender GB men were more likely to report engagement in physical activity. Nonbinary-identified individuals reported smoking rates similar to nontransgender LGB respondents, low rates of PA and FV, and stress rates similar to transgender men and women. The presentation of this research will include comparison of actual health behavior rates with the overall population, and primary health behavior concerns for transgender men, women and nonbinary persons individually. Discussion will focus on next steps for community based research and suggestions for practitioners working with transgender patients.

“I’M NOT THE ONE CARRYING THE BABY, BUT I’M WORRIED!”: A QUALITATIVE ANALYSIS OF STRESS IN EXPECTANT FATHERS

Sirena M. Ibrahim, M.A.¹, Victoria N. Hass, B.A.², Marci Lobel, Ph.D.³¹Stony Brook University, Port Jefferson, NY; ²Stony Brook University, Stony Brook, NY; ³Stony Brook University, Stony Brook, NY

Traditionally, women have been the focus of much research on psychosocial aspects of pregnancy; however, pregnancy can be viewed as a developmental phase and as a challenging process for men, also (Darwin et al., 2017). Limited research suggests that expectant fathers may experience distinct types of stress which have the potential to adversely affect their health and well-being (Forsyth, Skouteris, Wertheim, Paxton, & Milgrom, 2011). Thus, the goal of the present study was to examine the stress that men experience during a partner’s pregnancy.

The present study included men who were recruited from a university hospital midwifery practice (n = 7) and through social media platforms (n = 10). The majority of participants and their partners were White/European, and were between 28 and 42 years old. Semi-structured interviews lasting 15 to 20 minutes were conducted in person or by phone with each participant. Interviews included some items adapted for men from the Revised Prenatal Distress Questionnaire (Lobel et al., 2008), a well-validated measure of pregnancy-specific stress in women. Interviews were audio-recorded and transcribed for in-depth analysis.

Analysis of interviews followed the six core phases of the Sort and Sift, Think and Shift approach for qualitative research: data inventory, written reflection, reflective diagrams, categorization, bridging, and data presentation (Maietta, 2006). Two members of the research team independently reviewed interview transcripts and then met to exchange reflections on the data. Continuous discussion regarding the meaning of potential themes and topics advanced this dynamic qualitative analysis process. Six themes emerged from participants’ data regarding the types of stress they were experiencing during their partner’s pregnancy, listed in descending order of frequency of appearance: 1) health and well-being of the pregnant partner; 2) occupational and financial stressors; 3) health and change in lifestyle of the self; 4) health of the child; 5) familial stressors; and 6) the father role. Some men mentioned these themes more than once throughout their interview.

These results add to a body of evidence demonstrating that pregnancy is a stressful life event for male partners. We will use these findings to develop a quantitative measure of partner stress in order to advance research on the magnitude of this stress, its adverse consequences for families, and how these may be mitigated.

AN EXAMINATION OF THE RELATIONSHIPS AMONG AFFECT, DIURNAL CORTISOL SLOPE, AND MEMORY IN ELDERLY WITH COGNITIVE IMPAIRMENTS

Rainbow T. H. Ho, Prof¹, Ted C. T. Fong, MPhil²¹Centre on Behavioral Health, The University of Hong Kong, Hong Kong, N/A, Hong Kong; ²Centre on Behavioral health, Hong Kong, N/A, Hong Kong

Introduction: Memory deficit is a common symptom of cognitive decline in older adults. It has been linked with emotional factors and flattened diurnal cortisol slopes. The present study aimed to evaluate the mediating role of diurnal cortisol pattern in the relationship between negative affect and memory and functional outcome in elderly with cognitive impairments.

Research Design: The study comprised 190 Chinese older adults who were recruited from local elderly daycare centers and residential homes in Hong Kong. The participants completed self-report measures on affect and functional outcome, two neuropsychological assessments on episodic, short-term, and working memory, and five salivary cortisol measures. Structural equation modeling was used to examine the direct and indirect effects of negative affect on functional outcome via diurnal cortisol pattern and memory.

Results: The cascading structural equation model provided an adequate fit to the observed data. The direct effects specified in the combined model were not significant. There was a significant and negative indirect effect from negative affect to functional outcome via diurnal cortisol slope (but not mean cortisol) and memory.

Conclusions: The current findings support a mediating role for cortisol such that elderly with greater negative affect showed flattened diurnal cortisol slopes which in turn led to poorer memory and functional outcome. Future longitudinal studies should elucidate the temporal ordering and causality of the relationship between the changes in stress and memory.

CHRONIC STRESS, REWARD-DRIVEN EATING, AND METABOLIC HEALTH AMONG CAREGIVERS

Rachel M. Radin, PhD¹, Ashley E. Mason, PhD², Alison R. Hartman, BA¹, Elisa S. Epel, PhD²¹University of California, San Francisco, San Francisco, CA; ²University of California San Francisco, San Francisco, CA; ³UCSF, San Francisco, CA

Objective: Chronic stress and compulsive overeating (e.g., reward-driven eating) have been linked to worse metabolic outcomes, independent of weight. It is unknown how these trait measures work through greater exposure to daily stress to impact metabolic health. We aimed to unpack these associations in a sample of women with varying levels of chronic stress and reward-driven eating.

Methods: We compared chronically stressed mothers of a child with an autism spectrum disorder ('caregivers' 20–50 y; n=92) to age-, ethnicity-, and BMI-matched control mothers of neurotypical children ('controls'; n=91). At a baseline visit, we assessed BMI and metabolic health indices (HOMA-IR, WHR, visceral fat), trait-like reward drive (Reward-based Eating Drive, RED-9), and a weekly average of self-reported daily stress ('high stress day' [dichotomous, yes/no]) and 'stressor severity' (continuous, 0–15). We used PROCESS (v.2.16) for SPSS to evaluate two separate moderated mediation models, after covarying for BMI: (1) The association between chronic stress group (caregivers versus controls) and metabolic health, with daily stress as a mediator ('stress day' and 'stressor severity') and the RED-9 as a moderator; (2) The association between the RED-9 and metabolic health, with daily stress as a mediator, and chronic stress group (caregivers versus controls) as a moderator. We adjusted for baseline BMI in all analyses.

Results: Both chronic stress group and reward-driven eating were associated with insulin resistance but in different ways: Being a caregiver (high chronic stress) was positively associated with HOMA-IR, and greater daily stress ('stressor severity') partially mediated this association (indirect effect: $\beta=0.20$, $SE=0.09$). Reward-driven eating moderated this association: At higher levels of the RED-9, the RED-9 moderated both the indirect (conditional indirect effect: $\beta=0.28$, $SE=0.16$) and direct ($\beta=0.90$, $SE=0.27$, $p<.001$) paths. Reward-driven eating was positively associated with HOMA-IR through daily stressor severity (indirect effect: $\beta=0.08$, $SE=0.05$), but this association was not moderated by chronic stress (i.e., this association applied equally to caregivers and controls).

Discussion: Caregivers who endorse greater reward-driven eating have greater insulin resistance, and these effects operate through exposure to daily stress of greater severity. Malleable daily factors (e.g., types of stress exposures and responses, eating behaviors) may be ideal targets for interventions targeting improvements in metabolic health among high risk populations.

DEVELOPMENT AND VALIDATION OF A MEASURE OF STRESS-IS-CONTROLLABLE MINDSET: THE STRESS CONTROL MINDSET MEASURE (SCMM)

Jacob J. Keech, BPsych(Hons)¹, Martin S. Hagger, PhD², Sheina Orbell, PhD³, Kyra Hamilton, PhD¹¹Griffith University, Mt Gravatt, Brisbane, Queensland, Australia; ²Curtin University, Perth, Western Australia, Australia; ³University of Essex, Colchester, England, United Kingdom

Objective: Recent research has shown that stress mindsets, beliefs about the nature of stress itself as enhancing or debilitating, are influential in determining the adaptiveness of the stress response. Our research has found that holding a stress-is-controllable mindset, the belief that the impact of the stress response is malleable and can be enhancing, is associated with positive health and performance outcomes. The current research aimed to develop and validate the Stress Control Mindset Measure (SCMM) in three samples.

Methods: The SCMM contains 15 items which form four subscales. The study comprised three separate samples of undergraduate students aged 17 to 25. Sample 1 ($N = 218$) was recruited from a major Australian university and conducted in a research laboratory. Sample 2 ($N = 214$) was recruited from a major British university and conducted online. Sample 3 ($N = 88$) was independently collected online from the same Australian university as Sample 1. Participants from Sample 1 and 2 completed measures of stress-is-controllable mindset, stress mindset, perceived stress, psychological well-being, and stress appraisal. Participants from Sample 3 completed measures of stress-is-controllable mindset and demand control at two time points, four weeks apart.

Results: Confirmatory factor analyses indicated adequate model fit and a consistent four-factor structure across Sample 1 from Australia ($CFI=.933$, $TLI=.909$, $SRMR=.042$, $RMSEA=.088$) and Sample 2 from the UK ($CFI=.934$, $TLI=.911$, $SRMR=.045$, $RMSEA=.082$). The four factors were determined *a priori* and refer to stress-is-controllable mindset in the context of: performance and productivity, learning and growth, health and vitality, and getting the most from life. Sample 1 provided support for discriminant validity and convergent validity of the SCMM regarding conceptually-related constructs such as stress mindset, perceived stress, psychological well-being, amount of stress, and stress appraisal. Internal consistency was supported in all three samples, and in Sample 3 the SCMM exhibited adequate test-retest reliability ($r=.61$), and discriminant validity from demand control.

Conclusions: The Stress Control Mindset Measure (SCMM) is a valid and reliable measure with good psychometric properties. It is also related to salient health outcomes under stress. Findings provide evidence to support the utility of the instrument in future research understanding the effects of stress on health.

DEVELOPMENT OF A DAILY MEASURE OF SEXUAL MINORITY STRESSORS IN YOUNG LESBIAN WOMEN

Kristin Heron, Ph.D.¹, Abby Braitman, Ph.D.¹, Robin Lewis, Ph.D.¹, Alexander Shappie, B.A.², Phoebe Hitson, M.S.²¹Old Dominion University, Norfolk, VA; ²Virginia Consortium Program in Clinical Psychology, Norfolk, VA

Lesbian women are at greater risk for a range of maladaptive mental and physical health outcomes as compared to their heterosexual peers, but the mechanisms by which these disparities occur remain unclear. One plausible explanation is sexual minority stressors (SMS), or the unique stressors (e.g., discrimination) sexual minorities experience due to their stigmatized and marginalized social status, contribute to negative health outcomes. Existing studies of SMS are primarily cross-sectional and use global, retrospective measures of SMS. The goal of the present study was to develop a brief daily measure of SMS for use in daily diary or ecological momentary assessment (EMA) studies. Existing retrospective measures of SMS were reviewed; redundant items and those inappropriate for a daily timeframe were removed, resulting in an initial pool of 28 items. Thirty-eight lesbian women (*M*_{age}=24.3, range: 19–30) completed a daily web-based survey including the SMS items for 12 days. Two response scales were tested; participants were randomized to receive a 3-point (for brevity) or 7-point (for precision) scale for the first 6 days and the other response scale for the remaining 6 days to counterbalance order. Histograms of responses for the 3-point and 7-point scales suggested the 7-point scale was optimal because it provided greater variability and participants endorsed medial ratings. To reduce scale length, item correlations were examined and 5 item clusters with intercorrelations >.6 were identified. A single item from each cluster was retained based on item variance, reducing the scale to 18 items. Then, using HLM, null models with each item as the outcome were conducted to examine level-1 and level-2 variances. With the goal of maximizing level-1 variability, items were sorted from largest to smallest level-1 variances and 8-, 10-, 12-, and 18-item scales were compared to identify the ideal number of items. The 8-item scale had the highest Cronbach's alpha (.85) and the smallest intraclass correlation (ICC; .13), suggesting these 8 items are optimal for capturing within-person variability in young lesbian women's daily SMS experiences. This study is the first to develop a reliable measure of SMS appropriate for daily use. As researchers are increasingly interested in using EMA methods, this 8-item measure can assess SMS in lesbian women's everyday lives. Such research is critical for understanding real-world sexual minority stressors and how these contribute to health disparities for lesbian women.

HAIR CORTISOL CONCENTRATION, METABOLIC HEALTH, AND THE CHRONIC STRESS RESPONSE NETWORK AMONG HIGH STRESS CAREGIVERS

Rachel M. Radin, PhD¹, Ashley E. Mason, PhD², Elissa S. Epel, PhD³, Mark L. Laudenslager, PhD⁴¹University of California, San Francisco, San Francisco, CA; ²University of California San Francisco, San Francisco, CA; ³UCSF, San Francisco, CA; ⁴University of Colorado Denver Anschutz Medical Campus, Aurora, CO

Objective: Animal models have shown that chronic stress increases cortisol levels, and such increases in cortisol predict overeating of highly palatable food. Such overeating leads to increased abdominal fat and lower cortisol reactivity. Human models have yet to unpack associations between chronic mental stress, cumulative cortisol levels, stress-induced eating, and change in body weight and metabolic health over time.

Methods: Mothers (20–50 y) of children with an autism spectrum disorder (ASD; caregivers, higher stress) were compared to age-, ethnicity-, and BMI-matched mothers of neurotypical children (controls, lower stress). At a baseline and 24-month assessment, we collected measures of hair cortisol (cumulative cortisol), metabolic health (abdominal fat, HOMA-IR, and lipid profile), stress eating behavior, and psychological functioning. We conducted a series of ANCOVAs comparing groups on these outcomes, adjusting for baseline BMI and metabolic/psychological functioning.

Results: Caregivers had significantly lower cumulative cortisol at baseline ($p \leq .03$) and 2 years later ($p \leq .007$), regardless of adjusting for baseline BMI. From baseline to 24-months caregivers (relative to controls) evidenced increased LDL-cholesterol ($p = .03$), abdominal fat ($pp = .08$), and consumption of junk food ($p = .03$), and this pattern of results and significance remained after adjusting for initial BMI.

Discussion: Caregivers, relative to controls, evidenced lower cumulative cortisol levels over the two years, consistent with studies among adults with clinically significant anxiety who demonstrate hypocortisolemia. Caregivers had worse metabolic health at baseline but still showed worsening metabolic health and increases in stress-related eating over the two years. People under chronic stress may require tailored interventions focusing on emotion regulation and control over eating to prevent early onset of metabolic and cardiovascular disease.

IDENTIFYING PREDICTORS OF PERCEIVED STRESS IN ADULT PATIENTS WITH ASTHMA

Sara E. Voorhees, MS¹, Christine M. Nezu, PhD, ABPP², Arthur M. Nezu, PhD, ABPP, DHL³, Michael Sherman, MD⁴, Jessica Most, MD⁴, Ellen Sher, MD⁵¹University of Florida, Wayside, NJ; ²Drexel University, Philadelphia, PA; ³Drexel University, Philadelphia, PA; ⁴Drexel University College of Medicine, Division of Pulmonary, Critical Care & Sleep Medicine, Philadelphia, PA; ⁵Allergy Partners of NJ, Ocean Township, NJ

Introduction: Asthma is a chronic respiratory illness that has become a major public health concern due to its rapid increase in prevalence and increasing economic burden. Perceived stress has been associated with increases in asthma incidence and asthma hospitalizations along with poor self-management of asthma (Rod et al., 2012). Additionally, patients with high perceived stress are less likely to adhere to a prescribed medication regimen (Rand et al., 2012). Social problem-solving, or the way individuals work to cope with everyday problems (D'Zurilla, 2002), has been shown to be related to perceived stress and the management of various chronic conditions.

Methods: The current study examined adult asthma patients ($N = 104$) from allergy and pulmonary practices. Participants completed self-report questionnaires regarding medication adherence, asthma control, perceived control of asthma, perceived stress and social problem-solving abilities. Additional patient information was gathered from medical and pharmacy records. A hierarchical regression analysis was conducted to examine which of the primary variables (medication adherence, objective asthma control, perceived control of asthma, and social problem-solving) are predictive of perceived stress among adult patients with asthma.

Results: Results indicated that lower self-report of medication adherence ($F(3, 94) = 6.581, p < .01$) and lower perceived control of asthma ($F(5, 92) = 6.970, p < .001$) were predictive of higher perceived stress, when controlling for race/ethnicity and income. In addition, poorer social problem-solving abilities were predictive of higher perceived stress ($F(6, 91) = 12.604, p < .001$) when controlling for demographics and the other primary variables.

Conclusion: Findings indicate that poorer medication adherence, lower perceived control of asthma, and poorer social problem-solving abilities all influence perceived stress among adult asthma patients. These findings help identify which individuals are at greatest risk for negative psychosocial adjustment to asthma and therefore poorer medication management and health outcomes. Psychoeducational and psychosocial interventions should be adapted for these individuals to help increase social problem-solving strategies, medication adherence, and perceived control to decrease stress and provide the support and skills that this population needs.

NARCISSISM AND HEALTH-RELATED STRESS-REACTIVITY

Sulamunn R. M. Coleman, M.S.¹, Aaron L. Pincus, Ph. D.², Joshua M. Smyth, PhD³¹The Pennsylvania State University, State College, PA; ²The Pennsylvania State University, University Park, PA; ³Pennsylvania State University, University Park, PA

Narcissism is a complex aspect of personality characterized by a grandiose sense of self that is vulnerable to disconfirmation. Despite an extensive history in clinical literature, narcissism has only recently gained greater interest in health research and has shown links to a diverse range of generally negative health outcomes. In order to better understand how narcissism may impact health, it is important to identify biobehavioral processes that constitute plausible mechanisms to link narcissism to health outcomes. Stress-reactivity (i.e., changes in psychological, biological, and behavioral processes that arise in response to perceived threats) has been associated with a variety of health outcomes (e.g., impaired immune function, obesity, and the onset and progression of cardiovascular disease). Clinical observations (e.g., case studies) have noted that individuals high in narcissism exhibit a variety of maladaptive reactions when grandiosity is threatened (e.g., heightened aggression, avoidance of social situations). Thus, it is plausible that narcissism is associated with maladaptive stress-reactivity more broadly. We applied systematic review methodology to identify studies using within-person methods to examine associations between narcissism and stress-reactivity. The results of the studies identified indicate that narcissism is associated with potentially maladaptive stress-reactivity (e.g., heightened negative affect, exaggerated neural, cardiovascular, and cortisol responses), and a few potentially adaptive stress responses (e.g., increases in self-esteem and physical activity). Furthermore, clinically relevant dimensions of narcissism (i.e., grandiosity and vulnerability) may differentially influence stress-reactivity. For example, grandiosity has been associated with potentially adaptive and maladaptive stress responses, whereas vulnerability appears less consistently related but primarily associated with maladaptive responses. Finally, moderators, such as contextual factors (e.g., type of stressor, presence of observers, or characteristics of interaction partners) and additional individual differences (e.g., attachment patterns, stability of grandiosity), may influence associations between narcissism and stress-reactivity. Overall, the findings from this review provide initial evidence that stress-reactivity is a plausible mechanism through which narcissism may impact long-term health.

PATHWAYS TO WELL-BEING: MINDFULNESS IN THE STRESS-COPING PROCESS

Ivan H.C. Wu, Ph.D.¹, NiCole T. Buchanan, Ph.D.²¹MD Anderson Cancer Center, Houston, TX; ²Michigan State University, East Lansing, MI

Rooted in eastern philosophy, mindfulness has garnered significant attention in the U.S. A recent 2007 National Institute of Health report showed that Americans spent about \$4 billion on mindfulness-based treatments in 2009 (as referenced in Pickert, 2014). Given the significant evidence highlighting the psychological benefits of mindfulness, the current study seeks to contribute to research on mechanisms of change. Grounded in stress and coping theory (e.g., Berry, Kim, Minde, & Mok, 1987; Lazarus & Folkman, 1984), the current study examines how mindfulness influences perceived stress, coping strategies (i.e., emotion- and problem-focused coping strategies), and psychological well-being. It was hypothesized that: (1) daily experiences of mindfulness would predict lower levels of perceived stress during a stressful event, more adaptive coping strategies, and better psychological well-being; and (2) less perceived stress and adaptive coping would account for the relationship between mindfulness and psychological well-being.

Thirty Chinese international students from a large mid-Western university completed an online survey on mindfulness and psychological well-being, and then engaged in a two-week daily diary about their experiences of stress, coping and daily affect. Results using multilevel structural equation modeling (MSEM) found that: (1) mindfulness predicted less perceived stress, (2) mindfulness predicted less emotional suppression and greater problem-solving coping, and (3) less stress and adaptive coping mediated the relationship between mindfulness and psychological well-being. Results contribute to the growing evidence that mindfulness can help individuals cope with stress through perceiving less stress and using adaptive coping strategies during duress.

PROJECT OM: TESTING ONLINE MINDFULNESS-BASED STRESS REDUCTION PROGRAM TO REDUCE STRESS AMONG LESBIANS IN APPALACHIA

Jennifer M. Jabson, PhD, MPH, Joanne G. Patterson, MSW, MPH, Kristina Gordon, PhD

University of Tennessee, Knoxville, TN

Background: Lesbians residing in Appalachia may face greater stress resulting from geographic isolation and economic strain, as well as from systemic minority stressors (including stigma, discrimination, and social isolation) that are reinforced by discriminatory state and regional policies. Stress among lesbians residing in Appalachia is 40% higher than norms and could significantly increase lesbian's risk for stress-related diseases. Behavioral stress-reduction interventions are one possible individual-level solution to reduce stress and related health risks in the absence of comprehensive policy reform. Mindfulness-based stress reduction programs are proven to reduce stress; however, transportation, cost, and outing oneself are all barriers to in-person participation reported by lesbians in Appalachia. Innovative, accessible solutions are needed. Online mindfulness-based stress reduction (OMBSR) programs could be a solution. OMBSR has never been tested with lesbians residing in Appalachia and there is a complete lack of evidence concerning how OMBSR relates to stress among this group. We addressed this gap by testing the feasibility of an 8-week, online, mindfulness-based stress reduction (OMBSR) program to reduce perceived and minority stress among lesbians in Appalachia.

Methods: Lesbians residing in Appalachia were recruited using convenience and snowball sampling techniques, into a one-armed feasibility test of an 8-week, online, mindfulness-based stress reduction program. Perceived and minority stressors, and salivary cortisol were assessed at baseline, post-OMBSR, and 4-weeks after completing OMBSR. Semi-structured interviews were conducted with participants at weeks 4 and 8. Intent-to-treat analyses assessed change in stress from baseline to post-OMBSR.

Results: 16 lesbians enrolled in and 11 completed the OMBSR. Perceived stress was reduced by 15% from pre- ($M = 24.06$) to post- OMBSR ($M = 20.44$) ($t = 2.77$, $p = .01$), and was maintained at 12-week follow-up ($M = 20.88$; $t = 2.31$, $p = .04$). Distress from minority stressors declined 14% from pre- to post- OMBSR ($t = 3.12$, $p = .0007$) and was maintained at 12-week follow-up ($t = 2.47$, $p = .03$).

Conclusion: In the absence of comprehensive, multi-level anti-discrimination policies, individual-level behavioral interventions such as OMBSR may be one way to reduce stress and risk for stress-related diseases among lesbians. OMBSR appeared to be a feasible option for reducing stress among lesbians in Appalachia.

STANDING ENHANCES VASOVAGAL SYMPTOMS ELICITED BY STIMULI ASSOCIATED WITH BLOOD BUT NOT OTHER EMOTIONAL STRESSORS

Philippe Thomas, Gilchrist, Ph.D.¹, Arielle Coopersmith, B.A.², Mona Li, B.Sc.², Vanessa Woroniak, B.A.², Blaine Ditto, Ph.D.²¹University of Cambridge, Cambridge, England, United Kingdom; ²McGill University, Montreal, PQ, Canada

BACKGROUND: Various stimuli (orthostatic stress, blood-related stimuli, fear, haemorrhage, etc.) are capable of triggering a vasovagal response (VVR). It remains unclear to what extent these represent identical or just similar physiological reactions. This study hypothesized that VVR are based on the prevention of excessive blood loss and thus triggered by stimuli that suggest as well as produce actual loss. As a result, the effects of certain emotional blood-related stressors should interact with certain postural stressors.

METHODS: 48 healthy young adults completed a questionnaire assessing medical fears (Medical Fears Survey –MFS-SF; Olatunji et al., 2012) and watched five 5-minute stimulus videos with different emotional content. All participants watched the Neutral video followed by 4 subsequent videos presented in counter-balanced orders: a Blood/Injury video depicting an open heart surgery, and three additional videos (Medical, Chase/Fear, and Loss/Sadness). Participants were randomly assigned to watch the videos either standing or sitting in an arm-chair. Vasovagal symptoms, blood pressure (BP), and heart rate (HR) were assessed during each video.

RESULTS: The primary analyses were 2 Posture (sitting/standing) x 4 Video (Loss/Chase/Medical/Blood-Injury) x Medical Fear (treated as a continuous measure) repeated-measure general linear models (GLMs) with sex and Neutral video value as covariates. As predicted, there was a significant Posture x Video interaction, $F(3,129) = 3.53$, $p = .040$, $\eta_p^2 = .076$, due to a specific enhancement of symptoms during the Blood/Injury video by standing. This effect was moderated by fearfulness leading to a significant Posture x Video X Medical Fear interaction, $F(3,129) = 5.30$, $p = .010$, $\eta_p^2 = .11$. Standing significantly increased symptoms experienced by more fearful participants during Blood/Injury but not other videos. This pattern was corroborated by SBP and HR with significant Posture x Film interaction effects, $F(3,117) = 2.84$, $p = .048$, $\eta_p^2 = .068$, and $F(3,117) = 4.20$, $p = .011$, $\eta_p^2 = .097$, respectively. As expected, this was due to a notable decreases among those who watched the surgery film while standing.

CONCLUSION: Blood-related fears play a key role in eliciting VVR and orthostatic stress enhances this effect. These findings provide support for the theory that VVR may have developed as a means to facilitate the survival of animals who were injured and experiencing significant blood loss.

THE ROLE OF TRAIT AND MOMENTARY PERSEVERATIVE COGNITION ON NEGATIVE AFFECT IN EVERYDAY LIFE

Jillian A. Johnson, PhD¹, Andreas B. Neubauer, N/A², Martin Sliwinski, PhD³, Joshua M. Smyth, PhD¹¹Pennsylvania State University, University Park, PA; ²German Institute for International Educational Research (DIPF), Frankfurt, Hessen, Germany; ³Penn State University, University Park, PA

Perseverative cognition (PC), repetitive or sustained thoughts about stressful events, can be triggered by stress. PC, at both trait and momentary levels, is associated with decrements in affect and prolonged physiological responses that can have negative health consequences. Prior work has largely examined trait and momentary PC separately, leaving synergistic effects unexplored. In response to everyday stress we investigated: 1) momentary PC, 2) the role of trait PC on momentary PC responses, and 3) the interaction of trait and momentary PC on negative affect (NA). A diverse sample of adults (N=159; 51% women; age M=50, SD=17), completed baseline measures, including trait PC (with intrusion and suppression subscales). Participants completed three weeks of ecological momentary assessment (EMA); each report (5 times each day) included whether a stressor had occurred, how severe/unpleasant the stressor was when it happened, how much they thought about the stressor, how much they tried to stop thinking about the stressor, and their current affect. More momentary intrusive thoughts ($b=.601, p<.001$) and suppression attempts ($b=.209, p<.001$) were reported after more severe stressors. Individuals higher in trait intrusion reported more momentary intrusive thoughts following more severe stressors ($b=.136, p=.015$), and those higher in trait suppression reported more momentary suppression attempts in response to more severe stressors ($b=.140, p=.034$). More NA was reported following more severe stressors ($b=.179, p<.001$) and after stressors that were accompanied by more intrusive thoughts ($b=.304, p<.001$). A trait by momentary suppression interaction revealed that, for individuals lower in trait suppression, momentary suppression attempts in response to stressors were associated with more NA; in contrast, for individuals higher in trait suppression, momentary suppression attempts in response to stressors were associated with less NA. In sum, momentary PC may be evoked by more severe stressors in everyday life, and this association appears stronger in those with higher trait PC. The results also highlight a nuanced perspective on suppression in daily life; namely, that a match between trait and momentary response styles may be adaptive (in the moment) by reducing the amount of NA experienced in response to stressors. This research provides some insight into how everyday stress and person-situation fit in response styles could influence health through effects on NA.

TRAIT MINDFULNESS AND REACTIONS TO STRESS IN YOUNG ADULTS

David Ede, Jr., B.S.¹, Joel W. Hughes, PhD¹, Fawn A. Walter, M.S.²¹Kent State University, Kent, OH; ²Kent State University, Stow, OH

Introduction: Exaggerated cardiovascular reactivity and delayed cardiovascular recovery following stress have been linked to hypertension and other risk factors for cardiovascular diseases. Mindfulness meditation interventions have been examined as a potential means of stress reduction and have been linked to cardiovascular benefits. However, it is unknown if trait mindfulness is also associated with healthier cardiovascular stress responses. In the present study, it was hypothesized that greater trait mindfulness would predict lower perceived stress levels, attenuated cardiovascular reactivity, and faster cardiovascular recovery following a laboratory stress task.

Methods: Participants were 99 college students, aged 19.44 ($SD = 1.44$), from a midwestern university. Trait mindfulness was assessed using the Five Facet Mindfulness Questionnaire (FFMQ) and stress was assessed using the Perceived Stress Scale (PSS). The laboratory stress protocol included a 10 min baseline, 5 min speeded arithmetic stress task, and 14 min recovery period. Blood pressure (BP) was measured during the protocol using an automated oscillometric BP monitor. Hierarchical regressions were used to analyze whether trait mindfulness predicted PSS scores, BP reactivity, and BP recovery after controlling for sex.

Results: The Acting with Awareness facet and the Non-Judgment facet of the FFMQ negatively predicted perceived stress ($\beta = -.310, p = .002$; $\beta = -.342, p < .001$). A similar trend was observed for the Non-Reactivity facet ($\beta = -.162, p = .080$). A composite mindfulness score also negatively predicted perceived stress ($\beta = -.590, p < .001$). Mindfulness did not predict systolic or diastolic BP during baseline. The Acting with Awareness facet positively predicted diastolic BP reactivity ($\beta = .276, p = .025$), though no other effects for reactivity were found. Mindfulness scores did not predict systolic or diastolic BP recovery.

Discussion: As hypothesized, trait mindfulness, and some facets, predicted lower levels of perceived stress. However, trait mindfulness generally did not predict baseline BP levels, stress reactivity, or recovery. Contrary to the hypothesis, the Acting with Awareness facet predicted stronger diastolic BP reactivity. Greater awareness during the stress task may have enhanced the experience of stress and contributed to diastolic BP elevations. Trait mindfulness predicted perceived stress, but not changes in blood pressure. Thus, whereas trait mindfulness may affect the perception of stress, inclusion of mindfulness in comprehensive interventions may be necessary to produce physiological effects.
