Food insecurity (FI) is the lack of access to enough food to live an active healthy life. Current efforts to address FI include developing and implementing policies, programs, and practices at the federal, state, and local level. Many food banks and pantries have made efforts to improve the nutritional quality of the foods they offer. However, food pantries have limited resources and may lack the knowledge to develop policies to improve the quality of food offered. There is limited information available to determine the potential impact on the nutritional quality of foods distributed if pantries adopt specific policies to guide donations and distribution. This study used the RE-AIM framework to determine the reach of nutrition policies at the food pantry level. Reach was calculated to determine the number and overall proportion of food pantries that had a formal written nutrition policy, an informal nutrition policy, or no nutrition policy. A cross-sectional survey was developed and distributed to geographically representative sample of U.S. based food pantries (N=5220). Chi-squares tested for significant differences in demographics and location of food pantries with a formal nutrition policy and those without. N=819 pantries completed the survey and only 18% reported a formal, written policy to guide food donation or distribution. Sixty-five percent reported informal nutrition policies. Barriers identified by the food pantries to having a nutrition policy included: limited ability to get more healthful foods from other donors and food sources (e.g. food drives, retailers), costs to purchase more healthful foods, and limited/no ability to store more healthful foods. There were no significant differences between types of pantries that had a written formal policy and those that did not ($X^2=0.269$, $p=0.604$). The reach of formal, written nutrition policies at food pantries is limited. Many pantries reported informal nutrition policies, however past studies have shown that strong written language in policies improve implementation and adherence. This study adds to the very limited literature on food pantries and a strength is the large sample size of food pantries, geographically dispersed throughout the U.S., which can help inform future efforts targeting food pantries.

A TALE OF TWO CITIES: EARLIER, MORE COMPREHENSIVE SEXUAL EDUCATION LINKED WITH REDUCTION IN RISKY SEXUAL BEHAVIORS

Val S. Everett, B.A., Daniel Flack, M.A., Natalie L. Peppercorn, B.A., Gerald Martin, B.A., Stephanie Manasse, PhD

Drexel University, Philadelphia, PA

Preliminary research suggests that sexual education reduces sexual risk-taking behaviors, but considerable variation exists in the approaches that local governments take to provide sexual education to high school students. As such, inconsistent and non-optimal (i.e. limited) sexual education could lead to problematic health behaviors in high school students. Potential examples of non-optimal sexual education include: abstinence-only sexual education, late exposure to sexual education, and low frequency of exposure. However, at this time, little research has compared the behavioral impact of differing local sexual education policies. Cities like New York City have mandated comprehensive sexual education policy for every year of middle and high school (sixth through twelfth grades) on the premise that it will optimally inhibit high-risk sexual behaviors. By contrast, the county of Miami-Dade, Florida mandates a "one half-credit" course, required for high school graduation, which teaches only HIV/STD education and abstinence, which reduces the burden of more comprehensive education, but may increase the risk of sexual risk behavior. It is possible that high schoolers exposed to earlier, more comprehensive sexual education (e.g., in the case of New York City) partake in fewer sexual risk behaviors than high schoolers who are given a more delayed, abstinence-focused sex education (i.e. from Miami-Dade). This study seeks to compare the behavioral impact of these different sexual education policies at a city-wide level. The present analysis examines public data from the Youth Risk Behavior Surveillance System (YRBSS), exploring a variety of risky sexual behaviors in high school students. In order to isolate the effects of two substantively different sexual education approaches on risky sexual behavior, we compared risky sexual behavior outcomes between New York and Miami. These two cities were selected due to their match on key demographic distributions. Specific behaviors of interest were risky contraceptive methods (i.e., not using birth control) and pre-adolescent (under the age of 13) intercourse. No significant difference was observed in race distribution between the cities ($p = 0.752$). New York City had significantly lower rates of risky contraceptive behaviors (8.80%) compared to Miami (11.87%; $p < .001$), as well as significantly lower rates of pre-adolescent intercourse (8.22% and 10.00%, respectively; $p < .001$). A Bonferroni correction was used on all analyses. These results suggest that in demographically similar metropolitan areas, local policy that mandates a comprehensive approach to sexual education from an earlier age is associated with reduced risk of high schoolers participating in risky sexual behaviors. These findings suggest the need for a greater push for mandated comprehensive sexual education in local governments.

CONSUMER KNOWLEDGE, TRUST, AND PERCEIVED SAFETY REGARDING GOVERNMENT REGULATIONS OF TOBACCO, E-CIGARETTES, AND RX DRUGS

Janine B. Beekman, PhD¹, Kathryn Ziemer, PhD², Aysha Keisler, PhD³, Megan Weber, BA⁴¹Ipsos Public Affairs, Washington, DC, DC; ²Ipsos, Alexandria, VA; ³Ipsos Public Affairs, Washington, DC; ⁴Ipsos, Washington DC, DC

Many consumers do not fully understand the government's role in regulating health-related products and advertising. The current study explored beliefs about government regulation and perceptions of trust and safety for tobacco products, e-cigarettes (EC), and prescription (Rx) drugs. We investigated whether perceptions changed over a time when two events transpired: A shift in presidential administrations, and the start of new FDA regulations of EC, allowing for a natural experiment to test the effect of shifts in policy on perceptions of government regulations.

A national panel of consumers completed an online survey; N=1006 in 2015, and N=1003 in 2017. There was a significant increase in awareness of government regulation of manufacturing standards ($\chi^2=65.3$) and approval of new EC products ($\chi^2=35.6$). 2017 respondents were also more likely to incorrectly believe that the government regulates the advertising of EC ($\chi^2=26.1$). Respondents trusted tobacco products ($\chi^2=9.3$), tobacco ad content ($\chi^2=15.2$), EC products ($\chi^2=13.6$), and EC ad content ($\chi^2=20.8$) if they were regulated more in 2017 than in 2015. 2017 respondents felt safer about EC ($\chi^2=18.9$), EC ads ($\chi^2=13.4$), tobacco ($\chi^2=18.6$), and tobacco ads ($\chi^2=9.9$) if regulated by the government than 2015 respondents ($ps < .01$).

After merging both waves, multivariate logistic regression analyses estimated adjusted odds ratios of binary knowledge, trust, and safety perceptions by wave, political orientation, and smoker status. Liberals were more likely than conservatives to know that the government regulates online (AOR=1.3) and TV (AOR=1.5) Rx ads. However, liberals were more likely to trust EC (AOR=1.8), EC ads (AOR=1.7), tobacco products (AOR=1.5), tobacco ads (AOR=1.7), TV (AOR=1.8) and online (AOR=1.6) Rx ads if regulated by the government ($ps < .03$). Liberals were more likely than conservatives to think that EC (AOR=1.6) and tobacco (AOR=1.6) are safer if regulated by the government ($ps < .001$). Smokers were more likely than non-smokers to report that tobacco (AOR=2.1) and EC (AOR=3.5) are regulated. However, smokers were also more likely to trust tobacco (AOR=2.1) and EC (AOR=2.4) and perceive them as more safe (both AOR = 1.2) if regulated (all $ps < .001$).

A knowledge gap remains regarding government regulations. Further, particularly among liberals and smokers, increased belief that products are regulated is coupled with greater trust in perceived regulations – leading to a potential false sense of security.

DISPARITIES IN RURAL ACCESS TO THE NATIONAL DIABETES PREVENTION PROGRAM FOR OBESITY TREATMENT

Vivian Bauman, B.S.¹, Aviva Ariel-Donges, M.S.², Eliza L. Gordon, M.S.³, Britney N. Dixon, M.P.H.², Abraham Eastman, M.A.², Kathryn M. Ross, Ph.D. M.P.H.², Michael G. Perri, PhD²¹University of Florida, Clinical and Health Psychology, Gainesville, FL; ²University of Florida, Gainesville, FL; ³University of Florida, Gainesville, FL

Introduction: The higher prevalence of obesity in rural communities serves as a major driver of urban/rural health disparities, yet rural communities have fewer resources that promote weight management. In 2009, the U.S. Congress approved funding for the Centers for Disease Control and Prevention (CDC) to partner with YMCAs and local health care agencies to broadly disseminate the Diabetes Prevention Program (DPP) for obesity treatment. The current study examined the dissemination of the CDC's National Diabetes Prevention Program (DPP) to assess its impact on the availability of empirically-based obesity treatment services in urban and rural counties across the U.S.

Methods: Names and locations of national DPP community partnership sites were collected from the CDC and cross-referenced with the 2010 Census classification of counties as rural versus urban. The total number of rural and urban counties with YMCA and other CDC-designated National DPP partnership sites was tallied in order to assess the proportion of counties with access to the DPP. A two-tailed chi-square test was utilized to determine whether overall access to the DPP differed between rural and urban counties.

Results: Among the 3,140 counties in the U.S., 1,889 were designated as urban and 1,251 as rural according to the U.S. Census Bureau's 2010 database. Nationwide, 488 urban counties (39.0%) had access to sites offering National DPP obesity treatment services compared with just 141 rural counties (11.3%), $\chi^2(1) = 332.2, p < .001$.

Discussion: Decreasing rural health disparities and promoting equitable access to preventive health services, including lifestyle treatments for obesity, remains a high public health priority of the CDC. However, the data from this study suggest that, while the National DPP has provided greater availability of obesity treatment in the U.S., its implementation may have unintentionally increased rural-urban disparities in access to weight management services by disproportionately increasing access primarily in urban counties. Thus, the development of alternative approaches to increasing access to obesity treatment in rural counties remains an important need—one that may require greater resources directed specifically to rural communities.

HEALTH-RELATED PRACTICES OF URBAN MIGRANT WORKERS IN METRO MANILA: DETERMINANTS AND OUTCOMES

Kenneth Jim Joseph Jimeno, MHSS, RN

Department of Health, Valenzuela City, N/A, Philippines

The rapid urbanization in developing countries presents new opportunities and challenges especially to migrants who face multiple health vulnerabilities. This cross-sectional study aims to describe the health-related practices of urban migrant workers in Metro Manila and their associated personal characteristics. It also ascertains the correlation of their health condition with related practices and work performance level. Filipino migrant workers (n=119) were mainly selected from peri-urban areas of Bulacan, Cavite, and Rizal through purposive sampling. Main inclusion criteria were (1) working regularly in Metro Manila and (2) living outside Metro Manila or returning weekly to place of origin. The mean age of the respondents is 25 (SD=3) ranging from 18 to 41 years. Majority were males (57%), not married (93%), college-educated (79%), white-collar workers (58%), living with family (76%), and earning median monthly income of 16 000 PHP (~320 USD). A 53-item self-administered survey questionnaire was developed and distributed for a period of two weeks in October 2016. The primary outcome was score rating on a five-point Likert scale indicating frequency of engagement. Cramer's V and Spearman's rank correlation coefficient (rs) were utilized in the analysis of data. Education and occupation are major determinants of health-related practices among urban migrant workers in Metro Manila. Sleep tends to have the most impact on health while interpersonal relationships affect work performance. Healthy migrant hypothesis appears true for this population and the results can be attributed to resiliency, family-oriented values, and importance of harmonious relationships in Filipino culture. The findings of this study can be used in developing migrant-sensitive health system in cities and further inquiry in this emerging research field.

WHAT DO PATIENTS SAY ABOUT PHYSICIANS AND HOSPITALS ONLINE? A SYSTEMATIC REVIEW OF STUDIES ON ONLINE RATINGS AND COMMENTS

Y. Alicia Hong, Ph.D., Tiffany A. Radcliff, Ph.D.

Texas A&M University, College Station, TX

OBJECTIVE: More and more people have used online reviews to share their medical experiences and choose healthcare providers. These online reviews reveal patients' direct experiences of healthcare providers and can serve as an indicator of the quality of care and patient-physician relationship. This study aims to systematically review studies on patients' online reviews, summarize the major findings and study characteristics, identify literature gaps, and make recommendations for future research.

METHODS: Major databases were searched in August 2017. Inclusion criteria for studies were: 1) focused on patients' online reviews of physicians and hospitals, 2) used qualitative or quantitative methods to analyze patients' online review and reported the outcomes, and 3) peer-reviewed publications. Exclusion criteria were: 1) not focused on patients' online reviews, 2) did not report outcomes of analysis, and 3) review study, commentary, or editorial.

RESULTS: A total of 40 studies that met the above criteria were included in the review. Most (n=23) were conducted for either the U.S. or specific areas within the U.S. Earlier studies (published before 2010) used content analysis and were limited to small sample sizes. More recent studies retrieved and analyzed larger datasets using machine learning technologies such as natural language processing. The number of ratings or reviews ranged from less than 200 to over 700,000. The most studied websites were RateMD, Yelp, Google, HealthGrades, and Vitals. Out of 40 studies, 9 were focused on hospitals and the remaining were focused on physicians, and mostly specialists such as orthopedists or OB/GYNs. Most studies indicated patients' online reviews of their providers were favorable. While all studies were descriptive, some studies compared patient online ratings with traditional surveys and found a high degree of correlation; some compared patient ratings with clinical outcomes and found low-level of correlation.

CONCLUSIONS: Online patient reviews contain valuable information that can generate insights on quality of care and patient-provider relationship, but have not been systematically used for studies of provider quality. With advancement of machine learning and data analysis tools, we anticipate more research on online patients' reviews based on testable hypotheses and rigorous analytic methods.

CULTURAL ENGAGEMENT AS A HEALTH BEHAVIOUR: LONGITUDINAL ASSOCIATIONS WITH MENTAL HEALTH AND WELLBEING IN OLDER AGE

Daisy Fancourt, PhD, Urszula Tymoszuk, PhD, Andrew Steptoe, PhD DSc

Department of Behavioural Science and Health, University College London, London, England, United Kingdom

Introduction and Purpose: 1 in 4 older adults in the UK is affected by depression, which is associated with a range of physical health outcomes. So there is a recognised need to identify behavioural interventions that can support mental health and wellbeing in older age. There is a large body of literature linking *participatory* arts and cultural engagement with mental health and wellbeing. However, there is much less research into the effects of *receptive* cultural engagement (such as visiting museums, galleries, the theatre and concerts) and mental health. Given that these cultural sites engage people in meaningful activities and help them to form relationships (both of which are protective factors for mental health), it is possible they are being underutilised as sites for public health interventions. Consequently, this study explored whether receptive cultural engagement in older age is associated with better mental health and wellbeing.

Methods: This study used data from the English Longitudinal Study of Ageing assessed between 2004/5 and 2014/15. We selected individuals who had no indication of depression at baseline using the Centre for Epidemiologic Studies Depression Scale (CES-D) and used logistic regression models to explore the odds of developing depression over the following 10 years in relation to how often people visited museums/galleries or attended the theatre/concerts. We also used OLS regression models to explore associations between cultural engagement and changes in wellbeing across the 10 year period using CASP-15. For all analyses, we controlled for all identified demographic confounders, health confounders (including sensory impairment, chronic conditions and pain) and social confounders (including other forms of social/civic engagement).

Results: Independent of confounders, visiting museums/galleries every few months or more was associated with a lower risk of developing depression over the following 10 years (OR=0.50 SE=0.11, CI 0.32–0.78). However, results for attending the theatre/concerts were attenuated when considering social confounders. Both attending museums/galleries and attending the theatre/concerts once or twice a year or more were associated with higher wellbeing 10 years later (B=1.10, SE=0.37, CI 0.37–1.83 & B=0.86, SE=0.37, CI 0.14–1.58). Sensitivity analyses confirmed effects were unaffected by considerations of mobility, attrition or pre-clinical symptoms of baseline depression.

Conclusions: In light of the results presented here, it is suggested that further behavioural intervention studies are designed to test further whether cultural engagement can decrease the risk of developing mental health conditions and improve quality of life in older adults.

MINDFULNESS-BASED STRESS REDUCTION AND TRAIT HOSTILITY AMONG OLDER INDIVIDUALS AT RISK FOR CAD: A PILOT RCT

Louisia Starnino, BSc¹, Christina Gentile, B.A.², Gilles Dupuis, Ph.D.³, Bianca D'Antono, PhD⁴¹Montreal Heart Institute, Vaudreuil, PQ, Canada; ²Montreal Heart Institute, Saint-Laurent, PQ, Canada; ³Université du Québec à Montréal, Montréal, PQ, Canada; ⁴Research Centre, Montreal Heart Institute/Université de Montréal, Montreal, PQ, Canada**Background:** Hostility and stress increase risk for coronary artery disease (CAD). Mindfulness-Based Stress Reduction (MBSR) has been shown to improve stress and other psychological outcomes in diabetes mellitus and hypertension. Research on its effects on hostility in individuals at risk for CAD is scant.**Objectives:** To examine whether trait hostility among older individuals at greater risk for CAD would decrease following MBSR.**Methods:** 19 men and women ($M_{age} = 67.20 \pm 7.70$) with current or past metabolic syndrome and non-normative physiological responses to stress were randomized to a 9-week MBSR program or to a wait-list control group (WLC). Participants were evaluated immediately pre- and post-MBSR, as well as 2 months later. Hostility was measured using the 39-item Cook-Medley Hostility Scale (CMHo-S). Between-group comparisons were performed on post-pre change scores using t-tests, while repeated measures ANOVA (pre-, post-, 2-months after MBSR) were used for within-group comparisons. Given the sample size, the focus was on effect sizes (ES) rather than statistical significance.**Results:** Between-group analyses showed a slight 1.7% decrease in hostility post-intervention following MBSR in contrast to the WLC group who displayed a 10.8% increase ($d=0.45$, medium ES). An increase in hostility was observed across most subscales for WLCs ($d=0.10$ to 1.12) over the first two evaluations. Repeated measures analyses revealed a continuous decline (4.8–14.7%) in CMHo-S from pre-MBSR to 4 and 8 weeks post-intervention ($p=0.22$; $d=0.93$). Decreases were observed for the cynicism and aggressive responding subscales in particular ($d=0.27$ and 0.87 , respectively). Change in hostility correlated with minutes of practice/week ($r=-0.45$ $p=0.11$).**Conclusion:** This randomized-controlled pilot study provides encouraging preliminary support that MBSR decreases hostility, particularly hostile behaviour, in older individuals at risk for CAD. Moreover, benefits cumulate over time, and with greater practice. Large-scale research is needed to corroborate these findings and to identify pathways by which MBSR impacts trait hostility.Keywords: MBSR, hostility, CAD, stress, metabolic syndrome, RCT, pilot study

CHALLENGES IN INFLAMMATION MEASUREMENT: ASSOCIATIONS BETWEEN SOCIAL WELL-BEING AND MULTIPLE INFLAMMATORY BIOMARKERS

Devika R. Jutagir, PhD¹, Bonnie B. Blomberg, Ph.D.², Charles S. Carver, PhD³, Suzanne Lechner, PhD³, Kiara Timpano, PhD³, Laura C. Bouchard, Ph.D.⁴, Lisa Gudenkauf, PhD⁵, Jamie Jacobs, Ph.D.⁶, Alain Diaz, PhD⁷, Susan Lutgendorf, Ph.D.⁸, Steve Cole, PhD⁹, Aaron Heller, PhD³, Michael H. Antoni, PhD³¹Memorial Sloan Kettering Cancer Center, New York, NY; ²University of Miami Miller School of Medicine, Miami, FL; ³University of Miami, Coral Gables, FL; ⁴Northwestern University, Chicago, IL; ⁵Mayo Clinic, Rochester, MN; ⁶Massachusetts General Hospital/Harvard Medical School, Boston, MA; ⁷University of Miami, Miami, FL; ⁸University of Iowa, Iowa City, IA; ⁹UCLA, Los Angeles, CA**Objective:** Understanding of how psychosocial variables relate to inflammation during adaptation to cancer may be complicated by variability in biomarkers measured. More research is needed to understand how inflammatory marker selection influences findings. This study examines concordance of associations between social well-being (SWB) and pro-inflammatory gene expression, versus associations between SWB and circulating pro-inflammatory cytokines encoded by those genes in women post-surgery for BCa.**Methods:** SWB was self-reported on the Social/Family Well-Being subscale of the Functional Assessment of Cancer Therapy – Breast by 36 women diagnosed with early-stage BCa 2–12 weeks post-surgery, before adjuvant treatment. Leukocyte gene expression was measured by microarray analysis of peripheral blood mononuclear cells. Circulating pro-inflammatory cytokines were measured from serum samples by ELISA. Gene expression and circulating cytokine composite scores were created by averaging scores of individual genes and cytokines, respectively. Bivariate correlations assessed relationships between levels of circulating cytokines and of gene expression encoding those cytokines. Multiple regression analyses controlling age, disease stage, days since surgery, education, and body mass index assessed associations between SWB and pro-inflammatory gene expression (IL1B, IL6, TNFSF10, TNFRSF21), and between SWB and circulating pro-inflammatory cytokines encoded by those genes (IL-6, IL-1 β , and TNF- α).**Results:** Correlations between gene expression and corresponding circulating cytokines ranged from non-significant to moderate. SWB was significantly negatively associated with pro-inflammatory cytokine IL-6 ($\beta=-0.393$, $p=0.023$) and marginally negatively associated with IL-1 β ($\beta=-0.297$, $p=0.099$) and the pro-inflammatory circulating cytokine composite ($\beta=-0.329$, $p=0.066$). SWB was significantly negatively associated with pro-inflammatory gene expression of TNFRSF21 ($\beta=-0.404$, $p=0.024$).**Discussion:** Results replicate prior findings that social resources inversely relate to inflammation. Yet, discrepancies were found such that circulating cytokines associated with SWB were not encoded by gene expression related to SWB. While gene expression reflects the sum total of cytokine gene expression within only immune cells from blood samples, circulating cytokines may be released by multiple sources, therefore serum levels are not specific to activated immune cells.

FRAUD IN AN ONLINE SURVEY STUDY OF PARENTS OF ADOLESCENTS AND YOUNG ADULTS WITH CANCER: WHAT WE LEARNED AND WHAT YOU SHOULD KNOW

Aliza A. Panjwani, MA¹, Katherine J. Roberts, Ed.D., M.P.H.², Rebecca Cipollina, BA³, Tracey A. Revenson, Ph.D.⁴¹Graduate Center, City University of New York, New York, NY; ²Teachers College Columbia University, Mountain Lakes, NJ; ³Rutgers University- New Brunswick, Piscataway, NJ; ⁴Hunter College & The Graduate Center, City University of New York, New York, NY

BACKGROUND: Online data collection is becoming an increasingly common and often viable option when targeting hard-to-reach populations. However, concerns call into question the validity of survey data (e.g., fraudulent respondents or duplicate submissions). We sought to identify hoax submissions in a sample of *parents* of adolescents and young adults with cancer (AYAs), determine if instating security precautions prevented subsequent fraudulent responses, and evaluate differences in demographics and distress outcomes between valid and non-valid respondents.

METHOD: The online survey study was designed to understand the experiences of a hard-to-reach population: *parents* of AYAs with cancer. Survey links were posted on the Facebook page and Twitter account of a social advocacy organization for AYAs with cancer. Original survey: Participants who completed the survey received a \$20 Amazon monetary compensation. Relaunch survey: Multiple protections were added, including a raffle.

RESULTS: With the initial survey, we noticed an unrealistic surge of participants (~310 parents) in the first three weeks of recruitment, which alerted us to potential fraud. Examination of the responses using a five-step hierarchy of post-survey criteria left only 11% (34) with complete and usable data. In the relaunched survey, we developed protocols to screen for eligibility pre-survey, added security features to the survey, and used a five-step hierarchy to identify fraudulent responses. Thirty-six additional surveys from parents of AYAs with cancer were collected, of which all (100%) were deemed valid. All valid completed surveys (n=70) were compared to fraudulently completed surveys (n=95). The fraudulent sample appeared more diverse (e.g., 62% male; 50% Native-Hawaiian/Pacific Islanders and African Americans); whereas, the valid sample was homogenous (92.5% women; 100% White) and similar to that in published studies. Most importantly, compared to valid respondents, fraudulent respondents had higher anxiety, depression, and post-traumatic stress (all p 's < .001).

CONCLUSIONS: Our data suggest that without a stringent protocol of security measures, study findings could indicate significantly different outcomes than what is actually present. It is critical for researchers collecting online data to add protections for screening and eligibility pre-survey, within survey, and post-survey to increase the validity of their research.

UNDERSTANDING DEPRESSION SUBTYPES AMONG ADULT ONCOLOGY PATIENTS VIA LATENT PROFILE ANALYSIS

Rebecca Saracino, PhD

Memorial Sloan Kettering Cancer Center, New York, NY

Background: Depression remains poorly managed in oncology patients, in part because of the difficulty of reliably screening and assessing for depression in the context of medical illness. For example, whether or not somatic items actually skew our ability to flag “true” depression, or represent meaningful indicators of depression subgroups, remains to be determined. Additionally, subthreshold depressive disorders may represent clinically meaningful subgroups among those with cancer diagnoses. This study implemented latent profile analysis (LPA) to characterize depressive symptom profiles of patients in the cancer setting.

Method: Depressive symptoms were assessed using the PHQ-9, Endicott Criteria, and CES-D in a group of ambulatory outpatients with cancer; only those participants who scored a 1 or more on depressed mood, anhedonia, or suicidal ideation were included in these analyses (N=295). LPA was utilized to characterize the underlying latent depressive symptom profiles and to determine the best fitting model. Chi-square tests examined clinical and demographic differences between classes.

Results: Participants were 54% female (n = 160), predominately White (85%; n = 251), 10% identified as Hispanic (n = 28), and mean age was 63 years old (SD = 11.5). Multiple cancers were represented with lung (12%; n = 34), ovarian (11%, n = 32), and prostate (10%; n = 28) representing the largest groups. LPA supported a 4-class model as the best fit: anhedonia-somatic (Class 1; 17%, n = 49), low energy-depressed mood (Class 2; 23%, n = 68), mild symptom (Class 3; 43%, n = 126), and major depression (Class 4; 18%, n = 52). Those in the Class 3 were more likely to be married men; participants in Classes 2 and 4 were more likely to report past or current treatment for depression; Classes 1 and 4 reported worse self-rated health status.

Conclusions: LPA results demonstrated 4 distinct symptom profiles of depression varying by predominate symptom pattern and on several key demographic and clinical characteristics; these differences would not have been identified without the unique capabilities of LPA. These results illustrate the need for researchers and practitioners to focus on varying phenotypes of depressive symptoms in the cancer setting. Future studies should examine whether the depressive symptom classes identified demonstrate reliability within an oncology sample over time and whether or not they warrant distinct treatments.

HEALTHY BEHAVIORS FOR CHRONIC DISEASE MANAGEMENT:
A STUDY OF BEHAVIOR MODIFICATION AND ACCULTURATION
AMONG LATINOSTailisha Gonzalez, MPH, MS¹, Bo Katic, MPH, MPA², Leonell Pagan, PhD³,
Anna Divney, DrPH⁴, Sandra E. Echeverria, MPH, PhD²¹CUNY Graduate School of Public Health and Health Policy, Brooklyn, NY;
²CUNY Graduate School of Public Health and Health Policy, New York, NY;
³Hunter College, New York, NY; ⁴CUNY School of Public Health, New York,
NY

Hypertension, type II diabetes, and hypercholesterolemia are leading chronic diseases in the United States. In 2016, the Centers for Disease Control and Prevention (CDC) reported that about half of all adults, 117 million people, had one or more chronic conditions and one in four adults had two or more. These conditions disproportionately affect Latinos in the U.S. We examined the association between language, an acculturation proxy, and adoption of recommended healthy behavior modifications among Latino adults sampled in the 2011–2014 waves of the National Health and Nutrition Examination Survey. The study population included participants who were 20 years of age or older and who self-reported prior physician diagnosis with hypertension, hypercholesterolemia or diabetes (N=1,196). We examined the adoption of three healthy behaviors- namely, weight loss in past year, leisure time physical activity (LTPA), and smoking cessation for 1 or more years- identified by the CDC to successfully manage all three chronic health conditions. A total score of behavior change was created and those with scores of 4 or higher were categorized as 'high motivation' behavior change adopters. Log binomial models were fit to estimate prevalence ratios (PR), accounting for the complex survey design of NHANES. More than half of our study participants reported hypercholesterolemia (66.7%) and hypertension (62.3%), and 29% reported having diabetes. The most salient positive health behavior adopted was smoking cessation (83%), while less than half met leisure time physical activity recommendations or attempted to lose weight. Crude models showed that Latinos who spoke English exclusively were significantly more likely to report positive behavior change than Latinos who only/ mostly spoke Spanish (PR: 1.30, CI: 1.06, 1.60), with comparable estimates observed for bilingual study participants and in fully adjusted models. Our findings provide new evidence on behavioral patterns for Latinos living with chronic health conditions and show that increased English language use is associated with improved health behaviors, raising intriguing questions on acculturation-related processes and health.

ADOLESCENT EXERCISE AND DIETARY CHANGE RELATED TO
PROS AND CONSNathan L. Baumann, MA, Marie Tate, BA, Andrea L. Paiva, PhD, Colleen A.
Redding, PhD

University of Rhode Island, Kingston, RI

Health behaviors such as diet and exercise in adolescence are important for establishing and maintaining health across the lifespan. Early intervention for maladaptive health behaviors in adolescence is an opportunity to help shape health behaviors into adulthood. Previous research, using the Transtheoretical Model, has shown pros and cons contribute to the process of change in health behavior in adults. The current study examines concrete effects of pros and cons on amount of fruit and vegetable (FV) intake and physical activity (PA) in an adolescent sample.

The present study examined two mediational models, (1) pros and cons of FV consumption and the amount of servings per day at time one (T1) and time two (T2) and (2) pros and cons of PA and how much PA is done at T1 and T2. Participants included 4,158 middle school students ($M_{age} = 11.4$, $SD = .69$) in the northeast, 52.2% were females and 65% were Caucasian. Participants were recruited through an intervention program, Project BEST. All measures were collected through a self-report survey, and pros and cons of FV and PA were collected at T1 only and constructed by summing four items per construct.

The mediational model used pros and cons as IVs, servings of FV/amount of PA T1 as mediators, and servings of FV/amount of PA T2 as DVs. The indirect mediation model fit was acceptable for FV ($= 4.37$, $p > .05$, $CFI = .99$, $RMSEA = .02$). The amount of explained variance for servings of FV T1 was a small ($= .03$) and at T2 was medium ($= .15$). Pros FV was a significant predictor of servings of FV T1 ($\gamma = .29$, $p < .05$) while cons FV was not significant ($\gamma = .007$, $p > .05$). Servings of FV T1 was predictive of servings T2 ($\Gamma = .016$, $p < .05$). When applied to PA the fit was also acceptable for the indirect mediational model, ($= 13.1$, $p < .05$, $CFI = .99$, $RMSEA = .04$). The amount of explained variance for amount of PA T1 was small ($= .03$) and at T2 was medium ($= .19$). Pros PA and cons PA were significant predictors of the amount of PA at T1 ($\gamma = .19$, $p < .05$; $\gamma = .017$, $p > .05$). PA at T1 was predictive of PA at T2 ($\Gamma = .015$, $p < .05$).

The pros and cons of FV and PA appear to predict the amount of servings per day and activity per day at time point one. The amount of FV consumed and PA done at T1 is predictive of the amount done at T2. This supports the idea that pros and cons contribute to the level of activity in the health behaviors of FV intake and amount of PA. However, it does not fully account for the level of activity in the health behaviors. The support for the contribution of pros and cons has clinical implications for assessment and intervention in FV and PA in adolescents.

Learning Objectives: After attending this session, participants will have an increased understanding of the role of pros and cons in the process of change in health behaviors.

After attending this session, participants will be able to discuss the role of increasing pros and decreasing cons in health behavior change for adolescents.

EXECUTIVE FUNCTION PREDICTS MEMBERSHIP IN LATENT CLASSES OF MULTIPLE HEALTH RISK BEHAVIOR ACROSS EARLY ADOLESCENCE

Mary Ann Pentz, PhD¹, Christopher Warren, PhD (c)¹, Chih-Ping Chou, Ph.D.², Donna Spruijt-Metz, MFA, PhD², Nathaniel R. Riggs, PhD³¹University of Southern California Keck School of Medicine, Los Angeles, CA; ²University of Southern California, Los Angeles, CA; ³Colorado State University College of Health and Human Sciences, Fort Collins, CO**Background:** Early adolescence is a pivotal developmental period where lifelong patterns of multiple health risk behavior (MHRB) begin to solidify. Previous research has demonstrated that MHRB like substance use, sedentary behavior, consumption of high-calorie/low-nutrient (HCLN) foods, and insufficient sleep, tend to co-occur.**Objective:** To ascertain how clustering of MHRB may change across the late-elementary school years and its determinants.**Methods:** Study data were gleaned from the school-based Pathways to Health MHRB prevention trial administered from 4th-6th grade (N=709) in 75 classrooms and 24 schools. Trial participants were 50% female, 21% eligible for free lunch, 33% White and 25% Hispanic. The following constructs were assessed via validated survey measures at 4th, 5th, and 6th grade: cigarette use, alcohol use, sedentary behavior, insufficient physical activity, insufficient sleep (<9 hrs/night), consumption of HCLN foods, executive function.**Results:** At 4th grade: evaluation of BIC, Lo Mendell-Rubin (LMR) and parametric bootstrap (PB) tests found a 2-class model demonstrated the best fit whereas at 6th grade a 3-class model fit best. At 4th grade, members of class 1 (N=502) reported significantly more alcohol use, sedentary behavior, HCLN food intake, and cigarette use relative to class 2 (N=207). At 6th grade members of the riskiest class—class 1 (N=42) reported significantly more substance use and less sleep than members of either class 2 (N=536) or class 3 (N=131). Class 2 members, in turn, reported significantly greater sedentary behavior, less PA, greater HCLN intake and less sleep than class 3 (the least risky class). EF was significantly associated with membership in less risky classes (p<.001) at 4th and 6th grades adjusting for gender, SES, White ethnicity, Hispanic ethnicity and program vs. control group participation via the 3-step procedure.**Conclusion:** These data suggest EF is a key predictor of multiple clustered drug use and obesogenic behaviors during the late-elementary school years. While drug use and obesogenic behaviors are highly associated at 4th grade, comprising a single latent class of MRHB, by 6th grade, MHRB exhibit divergent clustering, with a subset of individuals with high rates of obesogenic behavior, also reporting substance use initiation and greater rates of insufficient sleep. These findings suggest that health promotion interventions should address EF and consider simultaneous targeting of MHRBs.

INTEREST IN LIFESTYLE ADVICE AT LUNG CANCER SCREENING: DETERMINANTS AND PREFERENCES

Claire Stevens, MSc¹, Samantha Quaipe, PhD¹, Samuel Smith, PhD², Charlotte Vrinten, MSc¹, Jo Waller, PhD², Rebecca J. Beeken, PhD²¹University College London, London, England, United Kingdom; ²University of Leeds, Leeds, England, United Kingdom; ³UCL, London, England, United Kingdom**Background:** Lung cancer screening has been identified as a 'teachable moment' at which to deliver cessation advice to smokers, who also more commonly engage in other cancer risk behaviours. Little is known about how this advice would be received by lung screening attenders, or whether advice about other behavioural cancer risk factors would be acceptable within this setting.**Methods:** We carried out a population-based survey of English adults aged 50–75 years who self-identified as current smokers or recent quitters, and indicated they would participate in lung cancer screening if invited (n=459). We assessed willingness to receive lifestyle advice (smoking, diet, weight, physical activity, and alcohol consumption) at lung screening. Additional items assessed whether advice should be provided in the event of an abnormal screening result, the potential impact of advice on screening uptake, and preferred timing of advice.**Results:** Overall, 64% (n=292) of the sample were willing to receive lifestyle advice at lung screening. A greater proportion of the sample were willing to receive advice in a scenario where the screening results required further investigation (83%, n=381; p<0.01). However, 14% (n=64) indicated the provision of lifestyle advice at lung screening would make them less willing to attend. Non-White ethnicity and greater cancer risk factor awareness were associated with willingness to receive advice (p<0.05). Half of current smokers (51%; n=113) were willing to receive smoking cessation advice. Interest in dietary advice was expressed by 47% (n=84) of people not consuming five portions of fruits and vegetables each day, and interest in advice about weight was expressed by 43% (n=50) of people with a BMI >25. One third of physically inactive people (32%; N=59) were willing to receive advice about increasing their physical activity, and one in five people identified as problematic drinkers (17%; N=16) were willing to receive advice about reducing alcohol consumption. There was a preference for advice to be delivered at the screening appointment (38%, n=108) over other time points during the screening process.**Conclusions:** Lung screening may offer an opportunity to deliver not only smoking cessation advice, but also advice about other behavioural cancer risk factors. Future work should consider how to deliver effective interventions in this setting to support multiple behaviour change for this high risk group, while monitoring screening uptake.

THE COMPLEX HOSPITALIZED PATIENT: HOW PSYCHOLOGISTS MIGHT PLAY A ROLE IN IMPROVING CARE

Lauren R. Pudalov, Psy.D.¹, Marc T. Swogger, Ph.D.², Marsha Wittink, MD, MBE²¹Cleveland Clinic, Cleveland, OH; ²University of Rochester Medical Center, Rochester, NY

In primary care settings, where multimorbidity is increasingly the norm, there is a recognition that integrated care can improve outcomes. Behavioral interventions that target multiple conditions are an essential component of integrated care, but can be a challenge to implement. Herein we describe our initial efforts to integrate psychological/behavioral services for inpatients on an inpatient medicine psychiatry unit. The Medicine in Psychiatry unit uses a multidisciplinary approach to improve outcomes among patients with acute medical illness and underlying behavioral health needs. While the structure of the unit provides many advantages for patients with multimorbidity, including daily medical rounds with social workers and psychiatric consultants, it does not use a systematic approach for psychosocial evaluation and intervention. Our study was developed to assess opportunities for integrating behavioral health services into the multidisciplinary team. Our mixed-methods approach included observation of daily rounding which informed a 21-item survey completed by clinicians. We report findings from our study and discuss areas of overlap between unit needs and widely available behavioral health services including specific clinical services (e.g., Brief Motivational Interventions, psychological testing, behavioral modification), ongoing consultation (e.g., patient behavioral concerns, diagnostic presentations, discharge planning for patients with complex needs), and staff trainings (e.g., verbal and physical aggression, personality disorders). Implications for program development and interdisciplinary training opportunities will be discussed.

UPTAKE OF AN INCENTIVE-BASED HEALTH PORTAL FOR EMPLOYEE HEALTH: PROCESS EVALUATION OF CHANGE4LIFE

Matthew Kwan, PhD¹, Katie Ross, MA², Marc Mitchell, PhD³¹McMaster University, Hamilton, ON, Canada; ²Niagara Health, Hamilton, ON, Canada; ³Western University, London, ON, Canada

Background: The workplace is recognized as an important setting for health-related interventions (Brown et al., 2013), and evidence from systematic reviews (Mitchell et al., 2012) suggest that financial health incentives, such as paying people to exercise or lose weight, may promote healthy behaviours and improve health outcomes. While there is limited evidence to support the sustained effects of incentive-based intervention, incentives targeting self-regulatory behaviours (e.g., self-monitoring) have been theorized to drive exercise maintenance. Best Life Rewarded (BLR) is an incentive-based health and wellness platform that rewards individuals for managing and improving their own health, enabling users the opportunity to self-monitor, set goals, and action plan. The purpose of the current study was to examine the uptake of BLR offered to a large health organization in Southern Ontario, which is oftentimes underutilized.

Method: Change4Life was officially launched to 6,072 eligible employees, with 869 individuals signing up to the program in the first year (representing about 14% of the total eligible employee population). All enrollees were encouraged to complete a health risk assessment and incentivized for doing so. Participants accrued points for tracking diet, cholesterol, blood sugar, and syncing Fitbit devices. A total of 384 participants (*M* age = 45.5 years) completed the health risk assessment, with the majority being female (90%), married (57%), and having at least a college diploma (84%).

Results: Overall users reported being in good to excellent health (82%), were predominantly non-smokers (93%), and indicated a good to excellent diet. Interestingly, however, only one-third of users were meeting recommended physical activity levels and/or daily consumption of fruit and vegetables. Usage data also suggests that only 27% of participants did not engage with Change4Life beyond one month, and only 15% sustained engagement for more than three months.

Discussions: Overall, 14% uptake from an organizational wellness program was positive. Unfortunately the usage was not sustained long-term, with the vast majority of participants ceasing engagement within the first 30 days. Future work will begin to assess the impact of behaviour change among users of Change4Life.

WOMEN'S USE OF GUIDED IMAGERY DURING A MULTI-BEHAVIOR INTERVENTION FOCUSED ON STRESS, FOOD CRAVINGS, AND EXERCISE

Peter R. Giacobbi, Ph.D., Kylie Phillips, M.S., Samantha Shawley, MPH, Richard Nolan, B.S., Kelsey Giacobbi, B.S., Ranjita Misra, Ph.D, CHES, FASHA, FESG West Virginia University, Morgantown, WV

Introduction: Finding ways to help individuals modify diet and exercise behavior is important given that a large proportion of adults in most developed countries are overweight or obese. Psychological stress has been implicated in the regulation of diet and exercise while guided imagery has shown promise addressing all three health behaviors. However, few multi-behavior studies have address these behaviors simultaneously using guided imagery.

Objectives: The purpose of this short report was to describe the experiences of 29 overweight or obese women ($M_{age} = 44$) who completed a multi-behavior guided imagery intervention that simultaneously targeted psychological stress, food cravings, and physical activity behavior.

Design: Qualitative

Procedures: Participants co-created tailored guided imagery scripts with health coaches for daily use as part of the 5-week intervention. Post-intervention semi-structured interviews were transcribed verbatim and content analyzed for common conceptual themes.

Results: The results showed that 83% or 24 participants stated they would continue using guided imagery.

Conclusions: Guided imagery has the potential to address multiple health behaviors and our results shed light on the use of tailored scripts to manage or lose weight in overweight and obese women.

ORAL HEALTH NEEDS AND BARRIERS TO DENTAL CARE AMONG SMOKERS CALLING STATE TOBACCO QUITLINES

Paula R. Blasi, MPH¹, Melissa L. Anderson, MS², Ella E. Thompson, BS¹, Jennifer C. Nelson, PhD³, Terry Bush, PhD⁴, Sheryl Catz, PhD⁵, Jennifer B. McClure, PhD¹¹Kaiser Permanente Washington Health Research Institute, Seattle, WA; ²Kaiser Permanente WA Health Research Institute, Seattle, WA; ³Kaiser Permanente Washington Health Research Institute, Seattle, WA; ⁴Optum (formerly Alere Wellbeing), Seattle, WA; ⁵UC Davis, Sacramento, CA

Smokers are at increased risk of oral disease. Those eligible for care through state-funded tobacco quitlines may be at particular risk given their lower socioeconomic status, which could limit access to dental care and also contribute to lower adherence to recommended routine oral self-care. To better understand the oral health needs and barriers to dental care among quitline callers, we surveyed smokers enrolled in the Oral Health 4 Life trial at baseline. All participants (*n*=718) had at least some natural teeth, had not seen a dentist in the past 6 months, were eligible for cessation treatment through the Oregon (OR), Nebraska (NE) or Louisiana (LA) quitlines, and met other study requirements. Participants were racially diverse (58% White, 29% Black, and 13% other or multiple races). Nearly 87% had an annual household income under \$40,000, 15% had a college degree, and 12% lived in a rural area. Participants smoked an average of 19 cigarettes per day, and 71% rated their oral health as "fair" or "poor." Less than half met the American Dental Association's recommendations for twice-daily teeth brushing (48.3%), and only 27% flossed daily. Most (80.2%) had not seen a dentist in more than a year, and 28% had not seen one in more than five years. Reported oral health problems include stained or discolored teeth (79.8%), toothaches/sensitive teeth (61.8%), bleeding gums (37.1%) and difficulty eating/chewing (32.9%). Most (71.4%) reported three or more oral health problems, and these individuals were more likely to be non-elderly (72.6% for ages 18–64 vs. 48.3% for ages ≥65; *p*=0.02) and White (76.3% vs. 64.6% for non-White; *p*<0.01). Reported barriers to dental care include cost (78.5%), a lack of dental insurance (75.1%), fear or nervousness (35.3%), and viewing other health concerns as more important (26.5%). Less common were access-related barriers such as an inability to find a dentist (19.3%) or difficulty getting to a clinic (12.3%). Cost was a particular barrier for LA residents (81.6%) compared to residents of OR (71.9%) or NE (68.1%; *p*<0.01). About three-quarters of low-income residents (<\$40K annually) also reported cost and insurance barriers. This study confirms that smokers who are eligible for free services through state-funded quitlines are an important target group for oral health intervention, highlighting an important opportunity to partner with quitlines to better address the oral health needs of these high-risk smokers.

A QUALITATIVE STUDY OF THE ROLE OF EMOTIONAL REGULATION IN WEIGHT LOSS MAINTENANCE

John Spencer Ingels, MA, Samuel Zizzi, Ed.D.

West Virginia University, Morgantown, WV

Participants have found success using behavioral lifestyle interventions to lose weight, but maintaining these losses remains a challenge for many (Peirson et al., 2015). The role of emotions in the process of lifestyle change may provide a clue to how some are able to maintain their success over longer periods of time while others regain weight (Bennett, Greene, & Schwartz-Barcott, 2013). The following research questions guided this project: 1) how do individuals working to lose weight perceive the impact emotions have on their long-term success, and 2) What strategies do more or less successful participants use to regulate their emotions? Semi-structured interviews were conducted by phone with 21 participants in an insurance-subsidized weight management program. Participants who completed a minimum of 18-months in the program were split into three groups based on weight change at 18-months: regain, moderate weight loss of 3–6%, and significant weight loss >7%. Those in the regain group had at one point in the program achieved an average weight loss of over 6%, similar to the moderate weight loss group, thus this group was classified regain. Interviews were transcribed and coded following thematic analysis. Codes were then organized by weight loss group to display differences across participants in their perspectives of the role of emotions during their weight loss journey. Four broad themes emerged: awareness of emotional impact, emotional regulation strategies, role of support, and the impact of personal attitude. The majority of maintainers spoke about the large impact of emotions and the need for the development of new strategies to regulate their emotions to be successful. Maintainers reported using a variety of strategies to regulate emotions, with exercise being the most commonly reported. Finally, maintainers differed from those who regained weight in that they spoke of a change in attitude as an important part of their success. A focus on long-term outcomes and breaking down goals into small steps were two common attitude changes. Conversely, participants who regained weight at 18-months described feeling stuck when talking about their experience in the program. From these findings, we present a conceptual model connecting the role of emotions, attitude, and behavioral regulation within weight loss to guide practice. Awareness of emotional impact is central to the model, driving changes in attitude and the development of new self-regulation strategies for participants who were able to maintain loss at 18-months. Tools to increase awareness, encourage attitude change, and develop improved self-regulation strategies will be discussed.

AN ONLINE MULTIPLE HEALTH BEHAVIOUR INTERVENTION TO PREVENT CHRONIC DISEASE RISK AMONG AUSTRALIAN ADOLESCENTS: STUDY PROTOCOL

Katrina E. Champion, BA Psych(Hons), PhD¹, Nicola C. Newton, PhD², Frances Kay-Lambkin, BSc(Psyc)Hons PhD³, Cath Chapman, PhD², Louise Thornton, PhD⁴, Tim Slade, PhD⁴, Katherine Mills, PhD⁵, Matthew Sunderland, PhD⁶, Bonnie Spring, PhD¹, Steve Allsop, PhD⁷, Belinda Parmenter, PhD², David Lubans, PhD³, Maree Teesson, BSc Psych(Hons), PhD², Leanne Hides, PhD (Clin Psych)⁸, Judith Bauer, BSc, GradDipNutriDiet, MHlthSc, PhD⁹

¹Northwestern University, Chicago, IL; ²UNSW Sydney, Sydney, New South Wales, Australia; ³University of Newcastle, Callaghan, New South Wales, Australia; ⁴University of New South Wales, Randwick, New South Wales, Australia; ⁵University of NSW, Sydney, N/A, Australia; ⁶Centre for Research Excellence in Mental Health and Substance Use, Sydney, New South Wales, Australia; ⁷Curtin University, Perth, Western Australia, Australia; ⁸University of Queensl, Brisbane, Queensland, Australia; ⁹University of Queensland, Surfers Paradise, Queensland, Australia

Chronic diseases, such as cardiovascular diseases, diabetes and cancers, are a leading cause of death and disability worldwide. Six behavioural risk factors (smoking, alcohol use, poor diet, physical inactivity, sedentary behaviour and poor sleep) have been identified as strong determinants of chronic disease risk among Australians. Alarming, 74% of young Australians (aged 12–17 years) have consumed alcohol, 23% have used tobacco, 85% do not meet physical activity guidelines, 80% do not meet guidelines for sedentary behaviour, 25% do not get adequate sleep and 95% do not eat enough fruit and vegetables. Not only are these behaviours risk factors for disease and mortality, in the short-term they are associated with obesity and mental health problems. These six risk factors (the “Big 6”) commonly emerge early in life and co-occur as clusters. Therefore, early and effective prevention is critical.

This study seeks to develop and evaluate a two-tiered eHealth multiple health behaviour intervention to concurrently target the Big 6 risk behaviours among Australian adolescents. We will utilise established frameworks for primary and secondary prevention to reduce or delay the risk factors for chronic disease, and intervene early where early signs of risk factors have already emerged. A cluster randomised controlled trial (RCT) will be run in 80 schools (8000 13-year-olds) across three Australian states in 2019. The RCT will evaluate the effectiveness of the two-part intervention: 1) A ‘universal’, online school-based prevention program and accompanying smartphone application (‘app’) targeting the Big 6 behaviours delivered to Year 8 students (*Healthy Lifestyles program – primary prevention*), and 2) An early intervention booster app delivered to students who remain at-risk of chronic disease as they progress through high school (*Healthy Lifestyles program – secondary prevention*).

The co-development process of the interventions and the study design will be outlined. Results from initial end-user consultation and focus testing will also be presented. This will be the first evaluation of a two-tiered eHealth intervention that concurrently targets six key lifestyle risk factors among adolescents, *prior to the onset* of chronic disease. Addressing the Big 6 during adolescence will not only improve the health of young Australians in the short term, but also carries enormous potential to enhance their capacity to lead healthy adult lives.

CHANGES IN HEALTHY GOAL COMMITMENT AND AUTOMATICITY DURING A TECHNOLOGY-ASSISTED MULTIPLE HEALTH BEHAVIOR INTERVENTION

Tammy Stump, PhD¹, Bonnie Spring, PhD¹, Donald Hedeker, Ph.D.², Juned Siddique, DrPH³, Angela F. Pfammatter, PhD³

¹Northwestern University, Chicago, IL; ²University of Chicago, Chicago, IL; ³Northwestern University Feinberg School of Medicine, Chicago, IL

Current research is mixed concerning whether changes in multiple diet and activity health behaviors should be initiated simultaneously or sequentially. While focusing on simultaneously changing two or more health behaviors may energize commitment to a general goal of living a healthy lifestyle, a sequential approach to behavior change may reduce burden and help individuals focus attention on specific behaviors, leading to the formation of stronger habits. The present study examined these competing mechanisms during a technology-assisted multiple health behavior change intervention. Participants (n=212) were randomly assigned to one of three 3-month treatments. In the simultaneous (SIM) condition, participants were instructed to increase fruit and vegetable consumption (FV), increase physical activity (PA), and decrease sedentary leisure screen time (SED) at the start of the intervention. Sequential (SEQ) condition participants received instruction to increase FV and decrease SED at the start of the intervention, and then additionally, after six weeks, received instruction to increase PA. Participants in a contact-matched control condition completed stress management training. During the intervention, all participants received weekly study calls and self-monitored their behavior using a smartphone application, with assessments at baseline, 3, 6, and 9 months.

The main analyses (previously reported) of this intervention indicated that health behaviors, which were poor at the start of the intervention, improved in, and did not differ between, the SIM and SEQ conditions. For all behaviors, self-reported automaticity (a measure of habit strength) improved between baseline and the 3- and 9-month follow-ups (Bs=.44-.75, $p<.05$). For most behaviors, the extent of improvement was comparable across treatments. However, for sedentary behavior, participants receiving either SIM or SEQ treatment tended to increase automaticity to a greater extent than controls (B=.52, $p=.06$). For all behaviors, better performance at the end of treatment was correlated with greater automaticity ($r_s=.27-.38$, $p<.05$). Healthy goal commitment was high at baseline and decreased slightly over time in all conditions. These results suggest that technology-assisted health interventions, whether involving sequential or simultaneous prescriptions, can strengthen healthy habits.

ILLNESS BEHAVIORS MEDIATE THE LINK BETWEEN SOCIAL SUPPORT AND FUNCTIONAL DECLINE IN THE SWEDISH ADOPTION TWIN STUDY OF AGING

Brittany L. Bannon, Ph.D.¹, Anna K. Dahl Aslan, Ph.D.², Nancy L. Pedersen, Ph.D.³, Chandra A. Reynolds, Ph.D.⁴

¹University of Utah, Salt Lake City, UT; ²School of Health and Welfare, Jönköping University, Jönköping, Jonkopings Lan, Sweden; ³Karolinska Institutet, Stockholm, N/A, Sweden; ⁴University of California, Riverside, Riverside, CA

Background: Social connections in late-life are associated with functional health, well-being, and survival. Although there is an abundant literature on social relationships and health, research on the mechanisms linking the two has primarily focused on primary, preventive health behaviors (diet, exercise) or disease management (adherence). The role of illness behaviors (IB) (perceptions, evaluations, and responses to illness) as a pathway linking social support to late-life functional health is not understood.

Aim: We evaluated the extent to which IB trajectories mediate the association between social support availability (from friends and family) and functional decline across 6 questionnaires (Qs) (1987–2010) in the Swedish Adoption Twin Study of Aging.

Method: Analyses included 1,314 individuals (29–96 years, M_{age} baseline= 60.26; $SD=13.20$; 57% female). Family and friend support were self-reported composites from the first Q. Illness behavior measures were CFA-derived factor scores across the first 4 Qs; higher scores reflected greater somatic complaints, medication use, pain limitations, and perceived illness complications. Functional difficulties were measured from a composite of 7 activities of daily living (ADLs) across 6 Qs. Longitudinal mediation models in a latent growth curve framework evaluated whether illness behavior trends across age mediated the association between social support availability and functional trajectories. Analyses were adjusted for data dependency, sex, SES, and comorbidity.

Findings: Greater social support predicted reduced IB levels at age 60 ($p<.0001$; $d=.08$), but not IB change. Higher IB levels at age 60 predicted subsequent ADL difficulty at age 75 ($p<.0001$) but not ADL change afterward. Conversely, lower IB levels at age 60 partially explained the association between greater support and reduced ADL difficulty at age 75 ($p<.0001$), accounting for more than half of the total relationship. The only significant indirect effect was through functional status rather than change. Lastly, there was a separate unmediated path from a linear increase in IB to accelerated ADL difficulty after age 75 ($p=.011$; $d=1.25$ across 5 years).

Conclusion: Illness behavior levels in late-life represented a significant mediating pathway linking support availability to subsequent improvements in functional status. Although illness behavior change did not play a mediating role, its association with accelerated functional decline suggests a health process distinct from social support.

MULTIPLE HEALTH BEHAVIORS AND ALL-CAUSE MORTALITY AMONG U.S. ADULTS

Seung Hee Choi, PhD¹, Manfred Stommel, PhD²¹Michigan State University, East Lansing, MI; ²Michigan State University, Alexandria, VA

Introduction: While some risk health behaviors occur together, the impact of multiple health behaviors on mortality has not been fully examined in the literature. Using a nationally representative sample of U.S. adults, this study was aimed to examine the impact of multiple health behaviors on all-cause mortality.

Methods: National Health Interview Survey (NHIS) data from 1997 through 2005 were linked to the National Death Index (NDI) with a follow-up to December, 31, 2011. The primary dependent variable was all-cause mortality; the predictors included four multiple risk health behaviors (current smoking, heavy drinking, physical inactivity, and obesity). Confounding variables included demographics, socio-economic status, and health insurance. The analyses included U.S. residents who were 30 years old and older (N=180,875, Population Estimate: 205 million). The primary statistical analysis relied on fitting Cox proportional hazards models.

Results: Among the U.S. population of adults, 22.3% engaged in at least two risk behaviors. Engaging in all multiple health behaviors was related to 2.6 times elevated mortality risks compared to zero risk behavior, albeit these risks varied by socio-demographic variables. Mortality risks also varied by the combinations of risk behaviors. When the combinations included smoking, the mortality risks were high. When the combinations include obesity, the mortality risks were low.

Conclusions: Clustering of four risk health behaviors was associated with more than two-times higher mortality risk compared to zero risk behavior. Multiple health behavior interventions addressing more than one risk behavior simultaneously, especially including smoking, will save millions of lives in the U.S.

PARTICIPANTS EXPERIENCES IN A CULTURALLY APPROPRIATE PEER SUPPORT PROGRAM FOR AFRICAN AMERICANS WITH TYPE 2 DIABETES

Florence Okoro, PhD, MScN, RN¹, Shelby D. Veri, B.S.B.A.²¹School of Nursing, University of North Carolina at Charlotte, Charlotte, NC; ²The University of North Carolina at Charlotte, Charlotte, NC

Background and Purpose: Specific ways in which peer support recipients describe their experiences of support received from a trained peer supporter in a culturally appropriate peer support program are poorly understood. Our central question was: “What are the defining features of a culturally appropriate peer support program for African Americans with type 2 diabetes?” We explored participants experiences related to: assistance with daily disease management, emotional support, linkage to clinic care and community resources, and ongoing support. We used qualitative interpretive descriptive approach.

Method: Data were gathered through semi-structured interviews with 20 low-income African Americans with type 2 diabetes who were participating in a peer support program. Interviews captured participants’ background and experiences with the peer supporter in providing culturally appropriate support. We coded all data deductively using predetermined codes found in peer support literature and inductively to identify emergent themes.

Results: We identified three themes: 1) healthy cooking, healthy eating, reading food labels and exercise. 2) ‘she will call’ 3) emotional support was a by-product of the support activities.

Discussion: Our findings mirror the broader literature on what constitutes culturally appropriate peer support programs for ethnic minorities. The information and knowledge transfer were tailored to the specific needs of the target population, taking into consideration their cultural beliefs and language requirement. Culturally appropriate peer support program complementing diabetes medical management may be a means of reaching the hardly reached low income ethnic minorities and thus help to close the health disparity gap affecting this population.

Conclusion: We suggests the inclusion of culturally appropriate peer support programs to complement diabetes management as a targeted plan to improve diabetes clinical care and ultimately, diabetes outcome.

SBIRT AT A LEVEL 1 TRAUMA CENTER: EVALUATING THE CURRENT STANDARD OF CARE AND IDENTIFYING AREAS FOR IMPROVEMENT

Kelly Gilrain, PhD¹, Alexa Hays, MS², William M. Skelton, MA, MS³, Rachel Gerofsky, MS³, Jennifer Petrongolo, MA, MSW⁴, Steven Ross, MD, FACS, FCCM³, Cori E. McMahon, PsyD⁵

¹Cooper University Hospital, Division of Hospital Medicine, Camden, NJ; ²Drexel University, Philadelphia, PA; ³Cooper University Hospital, Camden, NJ; ⁴LaSalle University, Camden, NJ; ⁵Tridium, Inc., Wayne, PA

Unhealthy alcohol use causes many of the injuries that bring people to trauma centers and this patient population is at considerable risk for alcohol-related trauma recidivism. As part of the American College of Surgeons Committee on Trauma accreditation requirements, Level 1 trauma centers are required to have a mechanism to identify patients whose drinking is unhealthy and to provide an intervention. Screening, Brief Intervention and Referral to Treatment (SBIRT) is a comprehensive, evidence-based approach that uses alcohol screening to provide early intervention and treatment to those with risky alcohol use.

In 2014, the Behavioral Medicine Consultation-Liaison (CL) service at Cooper University Hospital (CUH) implemented an SBIRT-based standard of care (SOC). The alcohol use disorders screening test (AUDIT) was chosen as the tool to assess alcohol use with newly admitted trauma patients. Brief intervention (BI) is provided to those with a positive screen. The CL provider is trained in motivational interviewing to determine need and desire for behavior change. The BI includes education on the effects of alcohol use and talking about strategies to manage use and cut down (or eliminate use), avoid certain risks (e.g., drinking and driving), and seek help from community referrals. Follow-up consists of a phone survey in which patients are rescreened with the AUDIT and asked about changes to drinking patterns, re-hospitalizations and alcohol-related treatment. The current study aims to evaluate the effectiveness of the SOC at CUH and provide recommendations for its continued improvement.

Trauma patients ($n = 464$, 75.8% male, 58.0% White) with elevated alcohol levels ($M = 187.67$) were referred to the CL service per the SOC. Initial AUDIT scores were significantly related to alcohol levels on admission ($r = .18$, $p < .001$). At follow-up, patients reported modifying the way they drink and seeking treatment for alcohol (71% and 26%, respectively). A paired samples t -test found significantly reduced AUDIT scores ($t(55) = 4.63$, $p < .001$, $r = .53$) for those who completed the SOC. Fourteen patients reported hospitalizations since the initial visit; only two were alcohol-related. Additional data is anticipated and will be included in future analyses.

This evaluation found significant reductions in AUDIT scores and positive changes in alcohol consumption patterns in the year following initial hospital admission, which provides sufficient evidence for continued use of this SOC. To improve future effectiveness, modifications to enhance fidelity to the SBIRT model are recommended, such as instituting additional training for hospital providers, utilizing technology for more standardized screenings, incorporating additional evidence-based components into the BI (e.g., mindfulness training), and publicizing our work to educate and engage professionals from other institutions about SBI services.

THE CROSSOVER EFFECT OF PREDICTING INTENTIONS OF MEETING CARDIO AND MUSCLE STRENGTHENING PHYSICAL ACTIVITY RECOMMENDATIONS

Paul Branscum, PhD, RD¹, Grace Fairchild, MS²

¹Miami University, Oxford, OH; ²University of Oklahoma, Norman, OK

Research that focuses on predicting and changing physical activity oftentimes focuses on aerobic physical activity (PA), while ignoring muscle strengthening PA. According to the Centers for Disease Control and Prevention, while a little over half (50.2%) of US adults meet recommendation for aerobic PA, less than one-third (29.6%) meet muscle strengthening recommendations. Both types of physical activity are modifiable determinants of health that if done in the appropriate amounts, can greatly reduce health risks, specifically from chronic diseases, and improve one's quality of life. Promoting aerobic and muscle strengthening PA together would be ideal for a multiple health behavior change intervention, given their inherent similarities (i.e. both can be performed in a single workout session and require similar equipment). Yet, the two behaviors should be studied and intervened upon independently, because they have different recommendations, and different skills are needed to perform them. When interrelated health behaviors are studied together, a crossover effect can also be evaluated, through which one behavior can be examined by theory-based determinants of the other interrelated behavior (i.e. intentions towards aerobic PA may predict intentions towards muscle strengthening PA). The purpose of this study was to examine the crossover effect for predicting both types of PA, using constructs of the Integrative Model of Behavioral Prediction for both behaviors. Undergraduate students ($n=392$) completed an online survey evaluating each type of PA, and its theoretical determinants (intentions, attitudes, perceived norms, and perceived behavioral control (PBC)). Two stepwise multiple linear regression models were run for both types of PA. The first (base) model used the behavior's own behavioral determinants to predict intentions. The second (omnibus) model added behavioral intentions from the other type of PA to the base model. Results from the first set of models indicated that attitudes, perceived norms and PBC predicted a significant amount of variance of intentions [aerobic (46.2%); muscle strengthening (53.9%)] for both PA groups. Results from the omnibus set of models showed that adding behavioral intentions from the interrelated PA behaviors moderately improved the amount of variance explained [aerobic (57.1%); muscle strengthening (60.9%)]. Overall, the IM was found to be a robust framework for predicting the intentions of aerobic and muscle strengthening PA. When testing the crossover effect of behavioral determinants, all models moderately improved, which provides implications for promoting aerobic and muscle strengthening PA.

THE IMPACT OF THE WORKSITE HEART HEALTH IMPROVEMENT PROJECT (WHHIP) ON CARDIOVASCULAR RISK FACTORS AMONG LONG-TERM CARE STAFF

Kelly Doran, PhD, RN, Barbara Resnick, PhD CRNP

UMB, Baltimore, MD

Worksite health promotion is an effective way to engage otherwise difficult to access populations (e.g., unhealthy, low-income, minority individuals) in health promotion interventions aimed at reducing cardiovascular disease risk. This presentation will discuss the findings from an 18-month cluster randomized control trial that tested the impact of the Worksite Heart Health Improvement Project (WHHIP) on cardiovascular risk factors among long-term care staff ($n=98$). The WHHIP included a 9-month exercise, nutrition, and stress management intervention implemented during paid work time that was rooted in the social ecological model and social cognitive theory. Participants were followed for an additional 9-months to preliminarily assess long-term adherence. Subjective data collection was assessed via survey and included the following concepts: mood, dietary intake, sleep quality, and sleep duration. Objective data collection included: physical activity engagement, body mass index, blood pressure, and total cholesterol. There was a significant positive treatment effect for mood ($p = .013$), sleep quality at 9-months ($p=.029$), diastolic blood pressure at 18-months ($p = p=.022$) at 18-months. There was a trend towards decreased dietary sodium intake at 6-months ($p=.084$) and dietary fat ($p=.087$) at 9-months. While both groups reduced their BMI, the education only group lost significantly more weight overtime ($p = .045$). We concluded that the WHHIP improved some cardiovascular disease risk factors but further improvement in outcomes were limited by overwhelmingly high reports of job stress. Job stress limited participation in the intervention activities, impacted engagement in healthy behaviors, and resulted in high rates of employee turnover. Our presentation will also include lessons learned from implementing the WHHIP as well as next steps, which resulted from end of study focus groups.

THINKING BEYOND SEX DIFFERENCES IN HEALTH: THE ROLE OF GENDER IN HEALTH-PROMOTING AND HEALTH-RISK BEHAVIORS

Rebecca Delaney, Ph.D.¹, JoNell Strough, Ph.D.²¹University of Utah School of Medicine, Salt Lake City, UT; ²West Virginia University, Morgantown, WV

Background: Most prior research examining gender differences in health has examined a person's self-reported sex. Other aspects of gender, such as personality traits stereotypically associated with masculine (e.g. forceful, dominant) and feminine (e.g. affectionate, understanding) gender roles, have received less attention. NIH highlights that gender can influence health through pathways above and beyond physiology, including health behaviors. However, few studies have examined how gender-typed traits influence behaviors (e.g. interpersonal strategies, healthcare utilization) known to impact health and have been shown to differ between men and women. Studying psychological dimensions of gender may add to understanding factors beyond sex that influence behavior change, and offer a nuanced perspective to understanding sex differences in health behaviors.

Aim: To assess the extent to which men and women's endorsements of gender-typed traits (masculinity and femininity) predicted health behaviors, and whether sex moderated these associations.

Method: Participants were 486 middle-aged and older adults (40–79 years old; $M = 55.57$; 54.5% female) recruited from Amazon Mechanical Turk to complete an online survey. Composite measures of stereotypical masculine and feminine traits, interpersonal strategies (e.g. interdependence, social support), health-promoting behaviors (e.g. physical activity, nutrition), and health-risk behaviors (e.g. alcohol use), were assessed. A path analysis in SPSS Amos was computed, where gender-typed traits were entered as predictors of health behaviors.

Findings: Model fit was acceptable ($\chi^2(5) = 10.17$, $R^2 = .15-.37$, CMIN/df = 2.04; CFI = .99; RMSEA = .05). A multi-group analysis that evaluated path value differences between men and women, revealed no moderation. The model was the same for men and women ($\Delta\chi^2(12) = 16.89$, $p = .15$). For men and women, gender-typed traits were found to be significantly and differentially associated with behaviors. For example, greater endorsement of stereotypical masculine traits predicted less interdependence and more health-risk behaviors. Whereas, greater endorsement of stereotypical feminine traits predicted greater interdependence and fewer health-risk behaviors.

Conclusion: Future studies should assess psychological aspects of gender and diversity within men and women's gender identification to better understand the development and prevention of a range of health behaviors, which in turn can inform changes in a healthcare context.

ADVERSE CHILDHOOD EXPERIENCES, EXECUTIVE FUNCTION, AND WEIGHT LOSS IN AMERICAN INDIANS: RESULTS FROM POWER-UP

Misty Hawkins, PhD¹, David Gahn, MD², John Chaney, PhD¹, William Lovallo, PhD³¹Oklahoma State University, Stillwater, OK; ²Cherokee Nation, Tahlequah, OK; ³University of Oklahoma Health Sciences Center and VA Medical Center, Oklahoma City, OK

Background: Adverse childhood experiences (ACEs) are repeatedly shown to predict negative biopsychosocial health outcomes, including adult obesity. American Indian (AI) communities have been shown to have high rates of both ACEs and obesity. Despite these lines of evidence, little work has been done to examine how ACEs relate to weight loss and executive function (EF) indicators, which may be critical to self-regulation and weight control. The Pilot of Weight Reduction in an Underserved Population (POWER-UP) trial addresses these gaps by examining ACEs and EF indicators as they relate to one another and weight loss success in an AI sample participating in an open weight loss pilot trial.

Methods: 48 overweight/obese AI adults (aged 43.3 ± 10.3 years, 85% female; baseline BMI = 36.8 ± 4.4 kg/m²) enrolled in a 6-month open weight loss trial (Identifier: NCT02786238). ACEs and EF were measured at baseline using the Adverse Childhood Experiences Scale and the NIH Cognition Toolbox, respectively. Specific domains of EF were working memory (WM), inhibitory control (IC), and cognitive flexibility (CF). The primary outcome was percent weight loss (%WL) at post-treatment. For %WL, we utilized an intent-to-treat approach with last weight carried forward for all participants.

Results: Greater ACEs were associated with lower CF ($\beta = -0.47$, $p = .015$) with a trend toward lower IC ($\beta = -0.23$, $p = .13$) after adjusting for age, gender, and baseline body mass index (BMI). ACEs were not related to WM ($\beta = 0.14$, $p = .483$). Lower CF predicted less %WL ($\beta = .33$, $p = .032$), whereas IC ($\beta = .18$, $p = .270$) and WM were unrelated to %WL ($\beta = -.08$, $p = .620$) adjusting for the above covariates. Adding ACEs as a covariate to the model attenuated the CF-%WL relationship ($\beta = .22$, $p = .316$). ACEs did not show direct effects on %WL ($\beta = -.07$, $p = .746$).

Conclusion: In an American Indian sample, adverse child experiences were related to poorer executive function, particularly cognitive flexibility. In turn, poorer cognitive flexibility was related to poorer weight loss outcomes. The role of ACEs in health may be related to their impact on cognitive function indicators essential to self-regulation behaviors.

CHRONIC STRESS AND IMPULSIVITY LEVELS SYNERGISTICALLY PREDICT 18-MONTH INCREASES IN VISCERAL FAT

Hiba Aboussleiman, BA¹, Alison R. Hartman, BA¹, Samantha Schleicher, BA², Kirstin Aschbacher, Ph.D.¹, Elissa S. Epel, Ph.D.³, Ashley E. Mason, Ph.D.⁴¹University of California, San Francisco, San Francisco, CA; ²University of Maryland School of Medicine, Rockville, MD; ³UCSF, San Francisco, CA; ⁴University of California San Francisco, San Francisco, CA

Objective: To examine baseline chronic stress, indexed each as an objective status (i.e., caregiving for a child with an autism spectrum disorder [ASD] diagnosis versus caring for a healthy neurotypical child) and as a subjective experience (i.e., perceived stress levels), as well as impulsivity levels serve as predictors of changes in visceral fat among healthy mothers of young children in an observational, longitudinal, 18-month study. We sought to examine these factors both synergistically and individually.

Methods: We examined these associations in a prospective cohort of 113 adult women (age $M \pm SD$: 42.83 ± 4.70 ; BMI $M \pm SD$: 24.86 ± 4.32 ; 74% ($n=84$) White) who were either chronically stressed mothers caring for a child with an ASD diagnosis ('caregivers' $n=72$ participants) or lower stress mothers caring for a healthy child ('controls' $n=41$). Caregivers and controls were matched by age, ethnicity/race, and body mass index (BMI). Participants completed self-report assessments of subjective chronic stress (perceived stress scale; PSS) at baseline. We objectively assessed impulsivity using the Behavioral Analog Risk Task (BART) at baseline. We assessed visceral fat at each baseline and 18-month follow-up using bioelectrical impedance (ViScan).

Results: The interaction of baseline objective stress (caregiver versus control) and impulsivity predicted 18-month change in visceral fat such that greater impulsivity was associated with greater 18-month increases in visceral fat among caregivers ($\beta=.426$, $p=.008$), but not among controls ($\beta=-.013$, $p=.918$). The direction of findings and pattern of significance remained in both unadjusted models and after accounting for covariates. The interaction of baseline perceived stress (PSS) and impulsivity did not predict 18-month change in visceral fat ($p=.906$). Neither type of stress (caregiver status or perceived stress) nor impulsivity level independently predicted 18-month changes in visceral fat.

Conclusions: The combination of high objective chronic stress and high impulsivity may increase risk for visceral fat gain over time and therefore may identify an at-risk population requiring tailored intervention geared toward obesity prevention.

DOES WEIGHT LOSS REDUCE WEIGHT STIGMA? RESULTS FROM A LONG-TERM WEIGHT LOSS MAINTENANCE TRIAL

Rebecca L. Pearl, PhD

Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA

Background: Weight loss is associated with improvements in quality of life and some psychosocial outcomes. However, the impact of weight loss on weight stigma is largely unknown. The current study investigated the effects of weight loss, achieved with behavioral weight loss (BWL) counseling and pharmacotherapy, on perceived and internalized weight stigma.

Methods: Participants were 137 adults with obesity (85.5% female, 68.1% black, mean BMI = 40.8 ± 5.9 kg/m²) enrolled in a weight loss maintenance trial. All participants attended a 14-week meal replacement program accompanied by weekly group BWL sessions (Phase 1). Participants were then randomized to receive lorcaserin or placebo and attended 16 weight loss maintenance sessions over an additional 52 weeks (Phase 2, 66 weeks of total treatment). Participants completed the Public Distress (PD) subscale of the Impact of Weight on Quality of Life – Lite (IWQOL-Lite) scale and the Weight Bias Internalization Scale (WBIS) at baseline, randomization (i.e., before the start of Phase 2), and weeks 38 and 66. The IWQOL-PD is a measure of perceived weight stigma (e.g., the extent to which participants perceive discrimination from others due to their weight), and the WBIS is a measure of internalized weight stigma (i.e., the extent to which patients self-stigmatize due to their weight). Height was measured at baseline and weight was measured at all study visits. Nested mixed models with residual maximum likelihood were used to determine the effects of weight change from baseline to week 66 on changes in perceived (IWQOL-PD) and internalized (WBIS) weight stigma. Baseline demographic variables were included as covariates in all analyses.

Results: Changes in weight stigma did not differ by treatment condition, so data were collapsed across groups. Linear and quadratic models with variance component structure were fitted to determine the effects of weight change on changes in IWQOL-PD and WBIS scores, respectively. Results showed that change in weight over time did not significantly predict changes in scores on the IWQOL-PD [$F(1, 134.81) = .08$, $p = .78$] or WBIS [$F(1, 293.19) = 1.18$, $p = .28$].

Conclusion: Weight loss did not significantly predict changes in weight stigma among patients with obesity enrolled in a long-term weight loss maintenance trial. Targeted interventions are needed to reduce internalized weight stigma and related distress in individuals with obesity.

WEIGHT STIGMA AND PROVIDER COMMUNICATION WITH PATIENTS WITH OBESITY

Sean M. Phelan, PhD MPH¹, Rebecca Puhl, Ph.D.², Somnath Saha, MD³, Diana J. Burgess, PhD⁴, Michelle van Ryn, PhD³¹Mayo Clinic, Rochester, MN; ²University of Connecticut, Hartford, CT; ³Oregon Health & Sciences University, Portland, OR; ⁴Minneapolis VA Healthcare System/University of Minnesota, Minneapolis, MN

Many healthcare providers have negative attitudes about higher-weight patients. The impact of these attitudes on provider behavior and communication quality in medical encounters is not known. We enrolled 120 advanced medical students from a single US medical school and measured their attitudes and beliefs about higher-weight patients and their perceptions of normative attitudes about weight among doctors. One to three months later, we video recorded them providing care for a standardized patient with higher weight. We evaluated patient centered communication in the encounter using several coding strategies. We conducted multivariate regression to assess the effect of attitudes and beliefs on patient-centered behavior. Students who expressed more dislike for providing care for higher-weight patients were rated as less friendly and observers were less likely to report that they would recommend them to family or friends. Student perception that negativity toward higher-weight patients was normative among healthcare providers was associated with lower observers' ratings of the providers': interest in caring for the patient, friendliness, engagement, respectfulness, and interactivity; as well as lower likelihood of performing behaviors consistent with person-centered care. These findings underscore the importance of intervening upon the attitudes of medical trainees as well as physicians and other role-models to trainees.

COMMUNICATION BETWEEN PATIENT AND PRIMARY CARE PHYSICIAN AFTER LIFESTYLE MODIFICATION

Jocelyn Remmert, B.A.¹, Savannah Roberts, B.S.¹, Adam G. Tsai, MD, MSCE², Meghan Butryn, Ph.D.¹

¹Drexel University, Philadelphia, PA; ²Kaiser Permanente Colorado, Denver, CO

Introduction: Many primary care physicians (PCPs) have negative views of people with overweight/obese BMIs, which may lead to negative interactions and barriers to health behavior change. It is unknown if those conversations are more positive or supportive after a patient engages in lifestyle modification (LM) and incurs significant weight loss. This study surveyed adults after LM to examine patients' perspectives of their relationship with their PCPs.

Methods: Adults (n=145) who had seen their PCP in the past year were surveyed at the end of 18 months of LM. On average, participants last saw their PCP 4.2 months before the 18-month assessment (18-month M weight loss=11.9%). The survey included Likert scale questions (strongly disagree to strongly agree).

Results: During the last appointment, most PCPs provided general encouragement about weight control (90%), but few provided specific feedback on change in medical parameters (12%). Several participants noted their PCPs had negative reactions to their weight loss or current weight, including "my PCP told me to stop losing weight," and, "I bragged about the weight loss I achieved and my doctor told me I was still obese." There was large variation in patient response to that appointment: 68% of participants reported feeling more motivated to work on weight control, but 32% reported their feelings did not change or they were more discouraged. Participants varied in their response to "my primary care physician understands my barriers to weight control," with 42% indicating that they "neither agree/disagree" to "strongly disagree," and 58% agreeing to some degree.

Conclusion: There is wide variation in communication between PCP and patient after weight loss. Most PCPs were generally supportive, but few offered specific feedback on how weight loss positively affected other objective measurements of health. Also, a few were unsupportive or did not understand the benefits of a significant weight loss independent of current BMI. Additionally, many felt their PCP did not understand the difficulties of weight loss. Potentially, factors such as PCP weight stigma or limit of PCP knowledge of weight control explain this aspect of the relationship. Overall, these results show variation in communication and the relationships between PCP and patient after weight loss, and future studies should continue to examine how these relationships change over time and how that change may affect engagement in health behavior change.

SEASONAL PATTERNS OF WEIGHT GAIN IN WEIGHT-LOSS TREATMENT SEEKING ADULTS

Margaret Fahey, Master of Arts¹, Robert C. Klesges, PhD², Mehmet Kocak, PhD³, Gerald Talcott, PhD⁴, Jiajing Wang, MS³, Rebecca Krukowski, PhD³

¹University of Memphis, Memphis, TN; ²Department of Public Health Sciences University of Virginia School of Medicine, Charlottesville, VA, VA; ³University of Tennessee Health Science Center, Memphis, TN; ⁴University of Virginia, San Antonio, TX

Background: Research suggests adults gain more weight in fall and winter compared to summer months, and that this seasonal pattern, perhaps, is affected by sociodemographic factors (i.e., race, gender, BMI, age). Weight patterns in weight-loss treatment seeking adults are currently unknown.

Methods: Active duty military personnel (n=248) engaged in a 12-month program adapted from the Look AHEAD intensive lifestyle intervention. Participants were evenly distributed by gender and BMI category (50.8% female, 56.05% obese) and had a mean age of 34.6 years. Participants were reasonably diverse, 65.7% Caucasian, 19.8% African American, and 14.5% Other race category. BMI category (i.e., overweight, obese) was calculated from baseline in-clinic weight and height using the standard formula. Participants received an e-scale and asked to self-weigh daily. Average weight was computed across each calendar season [i.e., fall (Sept. 1-Nov.30), winter (Dec. 1- Feb. 28), spring (March 1- May 31), summer (June 1- August 31)]. Season weight was compared to subsequent season weight by race, gender, BMI, and age. Final regression models controlling for intervention enrollment season, previous season weight, and significant covariates examined weight change and are subsequently reported.

Results: On average, participants gained .97 lbs. from fall to winter, lost .79 lbs. from winter to spring, gained .89 lbs. from spring to summer, and lost 1.21 lbs. from summer to fall. There were no seasonal differences in age or race. However, those classified as obese gained more weight from fall to winter compared to those classified as overweight ($p=0.006$), and this BMI category difference was greater in men ($p=0.001$). In addition, from winter to spring, men lost more weight ($p=0.001$), and from spring to summer, women gained more weight ($p=0.033$). No BMI category differences were observed in these two season changes. From summer to fall, no differences by covariates in weight change were observed.

Conclusions: Among adults in a weight loss intervention, regardless of time from enrollment and influencing covariates, seasonal weight patterns were exhibited similarly to those in the general population. Further, seasonal weight change was influenced by gender and BMI, but, not by race or age.

THE EFFECTS OF LOSS OF CONTROL EATING ON OVERWEIGHT AND OBSESSIVE INDIVIDUALS WITH CLINICALLY SIGNIFICANT EMOTIONAL EATING

Megan N. Parker, B.S.¹, Stephanie Manasse, PhD¹, Jennifer L. Barney, M.S.², Emily Wyckoff, B.A.³, Adrienne Juarascio, Ph.D.¹¹Drexel University, Philadelphia, PA; ²Utah State University, Logan, UT; ³University of Connecticut, Storrs, CT

Emotional eating (EE; defined as eating in response to negative mood states) contributes to the onset and maintenance of obesity. EE is not considered a disordered eating behavior in and of itself, however, it is conceptually akin to loss of control eating (LOC; feeling like one cannot stop eating or control what or how much one is eating) which can similarly be triggered by negative emotions. EE and LOC appear to serve similar functions (e.g. as maladaptive coping strategies for distracting from or numbing out from negative emotions) and can be barriers to successful weight loss. Given the conceptual and functional overlap between EE and LOC eating, one might expect that individuals may have co-occurring EE and LOC. However, few studies have assessed for both behaviors, and therefore little is known about the frequency of LOC in individuals with EE. Because LOC is a more severe disordered eating we may expect that individuals with both EE and LOC are more disordered (eg. higher levels of eating pathology, emotion dysregulation, and poorer treatment outcomes). However, to date, no study has tested this.

In the current study, we used data from a small proof of concept study that evaluated emotion-focused treatment approaches for individuals with clinically significant EE (N= 54) and 1) determined the frequency of LOC eating in an overweight and obese sample with clinically significant EE 2) examined if individuals with EE+LOC have greater eating pathology and emotion dysregulation than individuals with EE alone and 3) examined if the presence of LOC impacts outcome from an emotion-focused treatment workshop. At baseline 52% (n=28) of individuals with EE had also experienced at least one LOC episode in the past month. Consistent with expectations the EE+LOC group reported more EE episodes ($t=2.35$, $p=.02$). Presence of LOC was associated with higher global eating pathology ($t=2.37$, $p=.02$), greater difficulty controlling impulses when distressed ($t=3.43$, $p<.001$, $pF(1,52)=7.22$, $p=.01$). Findings indicate that there is a group of overweight and obese individuals who frequently experience EE along with more severe LOC. For overweight and obese individuals with EE, co-occurring LOC is associated with higher levels of eating pathology and higher emotion dysregulation that can result in poor outcomes in emotion-focused treatments. Future studies should also assess for LOC within overweight and obese individuals who experience clinically significant EE.

THE GEM INTERVENTION PROTOCOL: A TECHNOLOGY-ASSISTED WEIGHT-LOSS INTERVENTION IN PRIMARY CARE SETTINGS

Sandra Wittleder, PhD¹, Adefunke K. Ajenikoko, B.S.², Nicole Harris-Hollingsworth, EdD, MCHES³, Jeannette M. Beasley, PhD⁴, M. Diane McKee, MD⁵, Paul A. Meissner, MSPH³, Colin D. Rehm, Ph.D.⁶, Lorena Velastegui, B.A.⁷, Judith Wylie-Rosett, EdD, RD⁵, Melanie Jay, MD, MS⁸¹New York University School of Medicine, New York, NY; ²NYU Langone Health, New York, NY; ³Montefiore Health System, Bronx, NY; ⁴NYU Department of Medicine, New York, NY; ⁵Albert Einstein College of Medicine, Bronx, NY; ⁶Montefiore Medical Center, Bronx, NY; ⁷Albert Einstein School of Medicine and Montefiore, Bronx, NY; ⁸New York University School of Medicine, Brooklyn, NY

Background: Over one-third of American adults have obesity and are at increased chronic disease risk. Although Medicare reimburses physicians' 5As (Assess, Advise, Agree, Assist, Arrange) counseling patients with obesity, barriers to providing it include competing demands and low perceived competency. A technology-assisted, 5A-based weight management intervention to engage patients in setting behavioral goals may facilitate integration of obesity counseling in primary care.

Methods: We developed the Goals for Eating and Movement (GEM) protocol and algorithms for 5As weight management and conducted a pilot RCT (N=45) to evaluate the feasibility of implementing a technology assisted GEM intervention. The GEM intervention includes: 1) the online GEM tool via tablet, 2) health coach counseling and goal setting, 3) addressing barriers to participating in intensive weight management programs (e.g., the Veteran's Affairs MOVE! program and the Diabetes Prevention Program), and 4) follow-up telephone coaching. In a cluster-randomized control trial, we are evaluating the GEM intervention in two NYC healthcare systems (the VA New York Harbor Healthcare System Manhattan Campus) and Montefiore Health System Medical Groups (4 Bronx, NY sites) among both English and Spanish-speaking patients. Primary care (PC) teams were randomized (16 teams, 28 providers) to the GEM intervention or EUC (enhanced usual care). Providers in the GEM arm receive training in brief counseling and support. Patients (N=512) are recruited via mail and phone calls. Eligibility criteria include: age 18 – 69 years, obese or overweight with a comorbidity (e.g., arthritis, sleep apnea or hypertension), PC physician visit in the last two years, and no physical/mental health or other contraindications.

Results: We hypothesize that GEM patients will lose 2.2 kg more than EUC patients and that a higher percentage will have clinically significant weight loss (>5%). We will also examine whether the intervention improves clinical outcomes (e.g., blood pressure and waist circumference), improves behavioral outcomes (e.g., physical activity and dietary intake), and increases engagement in intensive lifestyle programs.

Conclusions: The GEM intervention utilizes the patient-centered medical home (PCMH) model of care while linking patients to existing evidence-based programs. This RCT will determine the effectiveness of the GEM intervention in a diverse patient population.

A DAILY DIARY STUDY OF INTERNALIZED WEIGHT BIAS AND ITS PSYCHOLOGICAL, EATING AND EXERCISE CORRELATES

Robert Carels, Ph.D., MBA, Reid Havka, B.A., Jennifer Selensky, B.S., Chelsey Solar, M.S., Ed.S., James Rossi, M.A., Julia Caroline Miller, M.A.

East Carolina University, Greenville, NC

Introduction: The current investigation extends EMA and daily diary weight stigma research in the area of internalized weight bias (IWB). Over the course of a month, utilizing daily diary methodology, this investigation examined the relationship between these common weight-related negative experiences and mood, coping, body appreciation, exercise behaviors, and eating behaviors.

Methods: The study sample consisted of 66 individuals (85% female) with $M_{BMI}=36.2$, $SD_{BMI}=6.4$ (range 25.5 – 59.5). Participants completed a daily diary each evening for 30 days and wore a Fitbit. Participants reported on internalized weight bias, mood, coping, body appreciation, exercise behaviors, and eating behaviors.

Results: Both within and between subjects IWB were significantly related to positive affect, negative affect, several coping responses, body appreciation, several eating behaviors, and the urge to avoid exercise.

Discussion: This investigation provides evidence that IWB experiences have daily impacts on psychological well-being, coping, eating, and exercise behaviors. Also, this study raises awareness about the upsetting internal experiences or personal reminders about weight that people with overweight/obesity commonly experience and its potential impact on psychological well-being.

ACCEPTANCE-BASED VERSUS STANDARD BEHAVIORAL TREATMENT FOR OBESITY: WEIGHT LOSS, REGAIN AND QUALITY OF LIFE ACROSS 3 YEARS

Evan Forman, Ph.D.¹, Meghan Butryn, Ph.D.¹, Stephanie Manasse, PhD¹, Ross D. Crosby, Ph.D.²¹Drexel University, Philadelphia, PA; ²Neuropsychiatric Research Institute, Fargo, ND

Acceptance-based behavioral treatments (ABTs; i.e., approaches that fuse behavioral strategies with tolerance of difficult internal experiences and loss of pleasure, mindful decision making and commitment to valued behavior) have been recognized as potential enhancements to the efficacy of gold standard behavior treatment (SBT) for weight loss. However, few full randomized controlled trials of these treatments have been conducted, and results have varied in terms of whether ABT's superiority was evidenced at post-treatment or at a later follow-up period and also in terms of whether certain variables moderated the treatment effect. The NIH-funded Mind Your Health Project randomly assigned overweight and obese participants ($n = 190$) to 25 sessions of either SBT or ABT over the course of 1 year. At post-treatment, ABT produced significantly greater percent weight loss (13.3%) than did SBT (10.2%). More recently collected data reveal that the superiority of ABT persisted at 1-year (7.6% versus 5.8%; linear effect $p = .04$) and (at trend) 2-year follow-ups (4.7% vs 3.3%; $p = .06$). Effects at post-treatment, but not 1 and 2-year follow-up, were moderated by baseline impulsivity. Moderators previously identified (depression, susceptibility to food cues) did not significantly impact the treatment effect. Of note, quality of life improved at faster rates and was better sustained in the ABT compared to SBT group ($p = .02$), even when controlling for weight losses. Overall, results suggest that infusing standard behavioral treatment for weight loss with acceptance-based strategies enhances weight loss and quality of life, that the benefits of ABT are experienced by most identified subgroups, and that these benefits are largely sustained (though not widened) into the very long term.

ACCESS TO HEALTHCARE, DEMOGRAPHICS AND KNOWLEDGE IN WILLINGNESS TO CONSIDER BARIATRIC SURGERY AMONG SOUTHERN BLACKS AND WHITES

Irma Corral, PhD, MPH, Hope Landrine, PhD, Jukelia Bess, BA

Brody School of Medicine, East Carolina University, Greenville, NC

Bariatric surgery is an effective intervention for morbid obesity. Although African-Americans (AAs) have a higher prevalence of morbid obesity than Whites, they are less likely than Whites to have the surgery. This disparity reflects AAs' lower access to healthcare and lower knowledge of and willingness to consider the surgery. Studies have focused on demographic and healthcare variables, with few studies of knowledge or of willingness. This preliminary study is the first to explore the role of demographic, healthcare, and knowledge variables in willingness to consider bariatric surgery. Participants were a random, household sample of 1670, southern, AA and White adults. They completed a brief, anonymous survey on weight/height (used to calculate BMI), demographics (race, age, education, income), and access to healthcare (health-insurance, a regular doctor, a usual source of care). A random subsample of $N=552$ (293 AA, 259 Whites) also received three knowledge and one willingness questions about bariatric surgery: Have you ever heard of bariatric surgery; Do you know anyone who has had bariatric surgery; Did you know that bariatric surgery results in long-term weight loss and can cure other health problems such as diabetes; If you are currently obese or become obese, would you ever consider having bariatric surgery. Univariate analyses revealed that a significantly larger percentage of obese AAs, compared to obese Whites, had never heard of the surgery, didn't know anyone who'd had it, and didn't know its health benefits, but there were no racial differences in willingness to consider the surgery. The logistic regression for the sample as a whole predicting willingness to consider the surgery revealed that current obesity and knowledge of the health benefits were the sole predictors; race, other demographic variables, and healthcare variables did not contribute. The same regression for Whites found that knowing someone who'd had the surgery was the sole predictor of willingness to consider the surgery. The same regression for African-Americans revealed that current obesity and knowledge of the health benefits were the only predictors of willingness to consider the surgery. These preliminary findings suggest that Whites' willingness to consider bariatric surgery might be enhanced by stories/blogs by those who have had the surgery, whereas African-Americans' willingness might be enhanced by information on the additional health benefits of the surgery.

ADAPTING A BEHAVIORAL WEIGHT LOSS INTERVENTION FOR FACEBOOK DELIVERY: A PILOT SERIES AMONG LOW INCOME, POSTPARTUM WOMEN

Valerie Silfee, PhD¹, Andrea Lopez-Cepero, M.S.¹, Stephenie Lemon, Ph.D.², Monica Wang, ScD, MS³, Milagros C. Rosal, MS, PhD¹

¹University of Massachusetts Medical School, Worcester, MA; ²UMass Worcester Prevention Research Center, Worcester, MA; ³Boston University School of Public Health, Boston, MA

Background: Efforts to translate evidence-based weight loss interventions, such as the Diabetes Prevention Program (DPP), to low income, postpartum women are limited by poor intervention attendance and high attrition rates. Strategies that improve engagement and retention in this population are needed to maximize the reach of evidence-based weight loss interventions.

Purpose: To adapt a DPP-based weight loss intervention (Fresh Start) for Facebook delivery and to evaluate the feasibility of the Facebook-delivered intervention among low-income postpartum women through a series of three iterative pilot studies.

Methods: This study comprised of three single group pilot studies where feasibility outcomes iteratively informed changes from one pilot to the next. We paralleled the in-person program to Facebook delivery by translating the protocol to a content library to be delivered in a Facebook feed. Low income postpartum women were recruited from Women, Infants, and Children (WIC) clinics in Worcester, MA. Participants were enrolled into a 16-week weight loss intervention delivered entirely via Facebook. During the first eight weeks, Facebook intervention posts were delivered two times per day with additional coaching. For the following 8 weeks, posts were delivered once per day without additional coaching. Outcome measures were collected at baseline and 16-week follow-up and included changes in weight as well as feasibility outcomes including retention, engagement (defined by likes, comments, and posts), and acceptability.

Results: Pilot 1 ($n = 27$) had a retention rate of 89% and 62% engaged in the group during the 8-week coached phase. Mean weight loss was 2.6 pounds ($SD = 8.64$) and 75% reported being satisfied with the program. Pilot 2 ($n = 24$) had a retention rate of 83% and 55.2% engaged in the group during the 8-week coached phase. Mean weight loss was 2.5 pounds ($SD = 9.23$) and 80% were satisfied with the program. Pilot 3 ($n = 16$) had a retention rate of 88% and 67% engaged in the group during the 8-week coached phase. Mean weight loss was 7.0 pounds ($SD = 11.6$) and 64.3% were satisfied with the program.

Conclusions: Findings demonstrated that a Facebook-delivered intervention was acceptable and could be feasibly delivered to reach low-income, postpartum women. Future research is needed to evaluate the efficacy of a Facebook-delivered weight loss intervention compared to traditional interventions among low income, postpartum women.

COMPARATIVE EFFECTIVENESS TRIAL OF AN OBESITY PREVENTION INTERVENTION IN EFNEP AND SNAP-ED: PRIMARY OUTCOMES

Joanna Buscemi, Ph.D.¹, Lara Blumstein, MS², Angela Odoms-Young, PhD², Melinda Stolley, PhD³, Linda Schiffer, MS, MPH⁴, Jennifer McCaffrey, PhD, MPH, RD⁵, Marian L. Fitzgibbon, IL²

¹DePaul University, Chicago, IL; ²University of Illinois at Chicago, Chicago, IL; ³Medical College of Wisconsin, Milwaukee, WI; ⁴University of Illinois at Chicago, Oak Park, IL; ⁵University of Illinois, Urbana, IL

The Expanded Food and Nutrition Education Program (EFNEP) and the Supplemental Nutrition Assistance Program-Education (SNAP-Ed) are USDA-funded nutrition education programs offered to low-income families which can provide an ideal platform for dissemination of obesity prevention interventions for young children. The current trial tested the comparative effectiveness of an adapted evidence-based obesity prevention intervention delivered through EFNEP and SNAP-Ed by trained peer educators versus the standard curriculum delivered by the programs. Data were collected on sociodemographic, anthropometric, and behavioral variables for children and parents at baseline and post-intervention (6 weeks). One-hundred fifty-three child-parent dyads were enrolled ($n = 103$ in the Intervention group; $n = 53$ in the Standard group). Children participating in the trial were 2–5 years old, 55% female, 37% African American and 36% Latino. Parent/caretaker ages ranged from 20–74 ($M = 34.4$; $SD = 9.2$), and 81% were mothers. Forty-one percent of the children and 69% of parents enrolled were overweight/obese. Retention at 6 weeks post-intervention was 86% for children (83% in the Intervention group and 92% in the Standard group) and 79% for parents (78% in the Intervention group and 82% in the Standard group). Random intercept mixed models comparing 6-week mean changes on anthropometric and health behavior variables between groups were tested adjusting for age, sex, race (white, other), parent's education (<high school, high school graduate, Bachelor's degree), parent's employment (full- or part-time, other), parent's marital status (married or living with partner, other), and SNAP participation in the last 6 months. There were no differences in the child BMI z-score by groups ($p = 0.27$). However, there were small, but statistically significant differences in parent BMI by group (mean BMI change Intervention group = -0.20 ; $SD = 0.10$; mean BMI change Standard group = 0.29 ; $SD = 0.15$; $p = 0.01$). There were improvements in child physical activity in the Intervention group versus the Standard, but these improvements were not statistically significant ($p = 0.13$). Although the trial was feasible, in that we were able to successfully train peer educators to deliver the obesity prevention intervention to both parents and children, parent participation and retention was challenging, even in well-known community settings. Results from this trial can inform future dissemination efforts of evidence-based programs for underserved families.

DAILY EATING DURATION, MORNING VS. EVENING INGESTIONS, FOOD CHOICES, BINGEING, AND BMI: COMPARISON OF BOOMERS AND MILLENNIALS

Raymond C. Hawkins, II, Ph.D.¹, Alma Rodriguez, BA², Johnny Jones, BA³, Katherine Soon, BA³¹Fielding Graduate University & The University of Texas at Austin, Austin, TX; ²The University of Texas at Austin, Austin, TX; ³Psychology Dept., The University of Texas at Austin, Austin, TX

Recent research (e.g., Gill & Panda, 2015) has emphasized the importance of daily eating duration, morning vs. night eating, and time restricted feeding on healthy food choices and obesity management. The purpose of the present study was to extend our investigation of changes in binge eating prevalence to exploring time of eating using a standardized measure called the POES (“Periodicity of Eating and Sleeping”) scale, using undergraduate samples of “Baby Boomers” (1977, N=277, 198 females, 79 males) and “Millennials” (2004–2005, N=266, 203 females, 63 males; 2009, N=179, 104 females, 75 males) who completed the Binge Scale (BS), the Height-Weight Questionnaire, and two weekday and two weekend days of food diaries from which POES scores, food choices, numbers of meals and snacks, and self-statements were independently and reliably calculated by research assistants. These cross-sectional convenience samples were obtained by the first author at the same university over the different time periods. Although average daily eating duration (Median = 11 hrs) decreased slightly but significantly across the cohorts, it was not significantly associated with BMI, weight concern, or binge eating. Binge eating was reported more frequently by women than men, and Millennial women’s scores on the BS were significantly lower than Boomer women’s scores. Overall, students with an “owl” eating pattern (i.e., ingestions after 9 PM) (31% of the sample) consumed significantly more sugar drinks and sweets, and had more negative self-statements about what they ate, while those with a “lark” pattern (ingestions before 9 AM) (19% of the sample) ate significantly more fruits and veggies. Eating after 9 PM was significantly more prevalent for the 1977 “Boomer” cohort than the Millennial cohorts. Finally students who reported binge eating ate significantly more snacks, had higher POES scores on the Eating subscale, more negative self-statements, more ingestions after 9 PM, and ate more sweets compared with those who did not report any bingeing. We present a social ecological life contextual model that considers the possible contributions of both person factors (e.g., biological factors related to weight history and undergraduates’ changed attitudes about disordered eating as coping behavior) and contextual factors (e.g., changes in availability of nutritious food choices, eating environments, culture, and exercise options, particularly for women).

DETERMINANTS OF INTENTIONS IN TAKING A DIRECT-TO-CONSUMER GENETIC TEST FOR THE OBESITY GENE: A TEST OF THE INTEGRATIVE MODEL

Yue Dong, PhD(c)¹, Paul Branscum, PhD, RD²¹The University of Oklahoma, Norman, OK; ²Miami University, Oxford, OH

Several studies have suggested that providing individuals with personalized genetic information helps to mediate changes in their behaviors and increase adherence to risk-reducing behaviors. Concurrently, advances in genetic testing technologies, such as next-generation sequencing, have dramatically reduced the cost and time of genetic testing, which makes direct-to-consumer genetic testing (DTC-GT) services more availability and affordability. There are a limited number of studies evaluating the attitudes consumers have toward taking a DTC-GT, and of the studies that have been published, few are rooted in a theoretical framework. The purpose of this study was to evaluate the determinants of DTC-GT for obesity related genes, using the Integrative Model of Behavioral Prediction (IMB). Overall, 291 college students completed an online survey evaluating each psychosocial construct related to the IMB (intentions, attitudes, perceived norms and perceived behavioral control (PBC)). Determinants of behavioral intentions (attitudes, perceived norms, and PBC) were evaluated using a linear regression model. Determinates of attitudes, perceived norms and PBC were evaluated using salient beliefs, which were derived from an elicitation study. Results showed that perceived norms ($\beta=0.614$), attitudes ($\beta=0.214$) and PBC ($\beta=0.121$) accounted for 64.2% of the variance of intentions, with perceived norms having the strongest influence on intentions. Pressure from a significant other or spouse was found to have the strongest association with perceived norms ($r=0.64$; $p=0.001$). The IMB appears to be an effective model for explaining students’ intentions for receiving a DTC-GT. Health practitioners should operationalize behavior change techniques and strategies that target the IMB’s core constructs, with special emphasis on perceived norms, using the salient beliefs evaluated in this study.

EATING IN THE ABSENCE OF HUNGER RELATES TO LOSS-OF-CONTROL EATING, HEDONIC HUNGER, AND WEIGHT GAIN IN NORMAL-WEIGHT WOMEN

Emily H. Feig, PhD¹, Amani D. Piers, B.S.², Tanja Kral, PhD³, Michael Lowe, PhD²¹Massachusetts General Hospital, Boston, MA; ²Drexel University, Philadelphia, PA; ³University of Pennsylvania, Philadelphia, PA

Introduction: Eating when not in an energy deprived state likely contributes to weight gain, and in some cases, is a feature of disordered eating. Work on the concept of hedonic hunger suggests that there are individual differences in the strength of hedonically-motivated appetite in the absence of energy need. Measuring this behavior in normal weight individuals could help identify those at risk for weight gain and/or disordered eating behavior. The present study measured eating in the absence of hunger (EAH) and its relationship with weight change and self-report measures related to appetite and eating behavior.

Method: Participants were 46 normal-weight young women (M age = 21 years, M body mass index (BMI) = 22 kg/m²). Two-thirds of participants were selected to be at risk for weight gain, with above average body dissatisfaction, a history of dieting, and/or a baseline weight at least 5 lbs below their highest ever weight. EAH was assessed after a standardized lunch of pasta with pesto sauce consumed to self-reported fullness, and was defined as the total number of calories consumed from several salty and sweet snack foods. Participants also completed the Power of Food Scale, Eating Loss of Control Scale, Three Factor Eating Questionnaire – Disinhibition Subscale, and Dutch Eating Behavior Questionnaire – Emotional Eating Subscale, and their weights were measured at 0, 2, 4, 6, and 12 months.

Results: Participants consumed, on average, 188 calories in the absence of hunger ($SD = 140$, range 18 – 488 calories). EAH was positively associated with hedonic hunger ($p < 0.01$, $R^2 = 0.18$), loss of control eating ($p < 0.01$, $R^2 = 0.29$), and weight gain over two months ($p < 0.01$, $R^2 = 0.19$), controlling for baseline BMI. In contrast, EAH was unrelated to emotional eating, disinhibition, and longer-term weight change. Amount of the lunch entrée consumed was unrelated to weight change or self-report measures.

Conclusions: EAH, which previously has mainly been assessed in children, was significantly associated with short-term weight gain, drive to overconsume foods, and loss of control over eating in a sample of normal-weight young women. EAH appears to be a useful laboratory test to capture a propensity toward overeating in adults as well as children. EAH may be an important behavioral phenotype to identify young adults at risk for weight gain and/or disordered eating, and may be a target for intervention.

HAPPY HOLIDAYS? INVESTIGATING THE RELATIONSHIP BETWEEN HOLIDAY SEASON AND BEHAVIORAL WEIGHT LOSS OUTCOMES

Jocelyn Remmert, B.A., Stephanie Kerrigan, M.S., Alexandra Convertino, B.S., Christine C. Call, A.B., Evan Forman, Ph.D., Meghan Butryn, Ph.D.

Drexel University, Philadelphia, PA

Introduction: The winter holiday season (Thanksgiving to New Years') provides many potential barriers to weight control, evidenced by the average 0.5–1 kg gained during each holiday season by US adults. However, unknown is whether weight loss efforts are affected by these barriers when one attempts to engage in active behavioral weight loss (BWL) during this period. To address this gap, this study examined differences in weight loss (WL) between participants whose BWL treatment overlapped with the holidays and those whose treatment did not.

Methods: Adult participants with overweight or obese BMIs ($n=637$) were weighed at each treatment session during the initial weight loss period (0–6 months). ANCOVAs and multilevel modeling in R Studio were utilized.

Results: At six months there was a significant difference in percent WL between participants whose treatment overlapped with the holidays ($n=258$, $WL = 8.02\%$) and participants whose treatment did not ($n=379$, $WL = 10.60\%$), $F(1,633)=28.76$, $p<0.001$. Participants whose treatment overlapped with the holidays lost weight at significantly slower rates during the holiday season compared to those who treatment did not overlap. Exploratory analyses revealed that participants who encountered the holidays primarily during months 2–3 ($n=149$, $WL=9.04\%$) lost significantly more weight at 6 months as compared to participants who encountered the holidays primarily during months 5–6 ($n=109$, $WL=6.63\%$), $F(1,254)=12.22$, $p=0.001$.

Conclusions: Participants whose treatment overlapped with the holiday season during the first six months of BWL lost approximately 2.5% less weight as compared to participants whose treatment did not overlap with the holiday season, attributable to a slower rate of weight loss during the holiday season specifically. Additionally, reaching the holidays later in treatment was associated with the lowest weight loss, suggesting that the barriers present during the holiday season may be even more difficult to overcome as motivation or accountability decrease. Overall, additional resources are needed for managing the holiday season during BWL, such as additional self-monitoring, increased social support, and more specific planning. Future directions include randomizing treatment timing to determine if these differences are due to holiday-related barriers or due to participant characteristics that may affect choice of treatment timing.

HEALTHY HABITS MEDIATE THE EFFECTS OF CONSCIENTIOUSNESS ON SUSTAINED WEIGHT LOSS MAINTENANCE

Joshua Gold, M.A.¹, Jeremy Burrus, PhD², Lucas Carr, PhD¹

¹University of Iowa, Iowa City, IA; ²ACT, Iowa City, IA

Background: High levels of conscientiousness (e.g., the personality trait associated with self-discipline, orderliness, and adherence to social norms) have been shown to protect against excess weight gain, but less is known about how this trait affects successful weight loss maintenance or potential mechanisms that could be mediating this relationship. The purpose of this study will be to determine if daily health-related lifestyle choices (i.e. food quantity and temptations, consistent meal and sleep timing, exercise adherence, and psychosocial health and stress coping) mediate the relationship between conscientiousness and successful weight loss maintenance.

Methods: We recruited a national sample of participants ($N=954$) from Amazon's M-Turk crowdsourcing marketplace who indicated they had attempted to lose weight at least once over the past 3 years. Within this sample, 32.7% of participants ($N=312$) indicated they were successful at maintaining their weight loss for a year or longer. Conscientiousness was measured with the 60-item Cherynshenko Conscientiousness Scale and health behaviors were assessed with the 26-item Healthy Lifestyle & Personal Control Questionnaire that focused on five factors (dietary healthy choices, dietary harm avoidance, daily routines, organized physical exercise, social/mental balance). Direct and indirect effects of conscientiousness on successful weight loss maintenance were tested within a path model in Mplus v7.0 while accounting for demographic differences.

Results: High conscientiousness was significantly associated with being a successful weight loss maintainer ($\beta = .129$, $p < .000$). Additionally, greater daily health-related lifestyle choices was also significantly associated with successful maintainer status ($\beta = .364$, $p < .000$). Lastly, a significant indirect effect emerged where frequency of daily health-related lifestyle choices partially mediated the relationship between conscientiousness and successful weight loss maintenance ($B = .087$, 95% CI = .058 to .117).

Conclusions: Higher levels of conscientiousness were associated with an increased likelihood of maintaining successful weight loss for a year or more. Furthermore, this relationship was partially mediated by the frequency of daily healthy habits. Improving our understanding of how personality traits, and in particular conscientiousness, influence weight loss maintenance may allow for enhanced tailoring in future weight loss maintenance interventions.

ONTRACK: CAN A SMARTPHONE-BASED JUST-TIME ADAPTIVE INTERVENTION IMPROVE WEIGHT LOSS OUTCOMES?

Evan Forman, Ph.D., Stephanie Goldstein, MS, Zoe Zhang, PhD, Meghan Butryn, Ph.D., Adrienne Juarascio, Ph.D., Stephanie Manasse, PhD, Gerald Martin, B.A.

Drexel University, Philadelphia, PA

Lack of success in weight loss programs can be largely attributed to dietary lapses, i.e., specific instances of in adherence to dietary recommendations. Lapses have been linked to a select group of internal and external cues, suggesting that lapse prediction and prevention are possible, given sufficient data. As such, we created an smartphone-based Just-in-Time Adaptive Intervention (JITAI) system called OnTrack that gathers lapse predictor data via repeated mini-surveys, uses machine learning to predict lapse behavior with increasing accuracy, and delivers tailored, interventions at moments of high risk that are designed to prevent lapses from occurring. In preliminary work, OnTrack's machine learning model has proven to have good predictive power, participants have rated interventions highly and have demonstrated decreases in lapses and weight. However, its incremental efficacy over and above an established weight loss program is unknown. As such, the current study (current $n = 57$; projected $n = 160$ by March) is randomizing overweight participants to receive either: the app-based Weight Watchers program alone (WW), or WW plus OnTrack (WW+OT). Preliminary data suggests an advantage of the WW+OT condition (Weight Loss $M=5.3\%$, $SD=4.1\%$) over WW ($M=4.4\%$, $SD=3.3\%$), but the number of completers ($n=16$) is not yet sufficient to perform statistical testing. Perceived effectiveness of OT was moderate (4.71/7) and equivalent to WW (5.68/10). However, ratings of specific OT intervention usefulness were low ($M=3.4/10$) for the initial set of 16 users. Follow-up interviews revealed that risk alerts did not feel personalized leading us to discover--and correct--algorithm errors. Overall, the first RCT of a dietary-lapse-focused JITAI is offering tentative support of its efficacy, though more reliable and complete results await the full 160 participants completing the trial.

PARTICIPANT AND CLINICIAN PERCEPTION OF CHALLENGES DURING BEHAVIORAL WEIGHT LOSS TREATMENT

Meghan Butryn, Ph.D.¹, Leah Schumacher, M.S.¹, Diane Rosenbaum, Ph.D.², Alexandra Convertino, B.S.¹, Fengqing Zhang, Ph.D.¹¹Drexel University, Philadelphia, PA; ²Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA

Behavioral weight loss treatment has a strong focus on identifying factors that can make lifestyle modification challenging, yet information on perception of such barriers is limited. This is the first study designed to compare participant and clinician perceptions of weight control challenges, as well as the first to examine how clinician perceptions relate to weight loss concurrently and predictively. Behavioral weight loss participants ($n = 320$) were given a checklist of weight control challenges and asked to select the three factors most relevant to their weight control. Clinicians delivering this group-based intervention independently completed a checklist for each participant they treated, identifying the three challenges they perceived as most relevant to that specific participant's weight control. Checklists were completed at month 3. Weight was measured at months 0, 3, and 12; participants received 28 treatment sessions during this time. Kappa values indicated low rates of agreement between participants and clinicians, with the lowest agreement ($\kappa < 0$) for endorsement of hunger, support, or mood. Clinician endorsement of motivation, effort, nutrition knowledge, planning, or keeping track was associated with lower participant weight loss at 3 months (all $ps < .001$), while clinician endorsement of good tasting food ($p = .001$), support ($p = .04$), or social factors ($p < .001$) was associated with greater 3-month weight loss. These eight factors each initially predicted 12-month weight loss ($p < .05$), but were not significant once 3-month weight loss was added as a covariate. Participant endorsement of motivation ($p = .002$) or keeping track ($p = .001$) as a challenge was associated with lower 3-month weight loss, while endorsement of good tasting food was associated with greater weight loss ($p = .02$). Consistent with the pattern of clinician results, these items (as well as social factors) predicted 12-month weight loss ($ps < .05$), but were not significant once 3-month weight loss was covaried. In summary, clinician perception of what makes weight control challenging for a given participant was typically inconsistent with that participant's understanding of his or her weight control challenges, but was strongly associated with weight loss. Future research should explore whether treatment efficacy might be improved if clinician or participant perceptions were shaped to have greater consistency. Further research on participant phenotypes also is warranted.

PARTICIPANT EXPECTATIONS OF A WEIGHT LOSS PROGRAM: A MULTI-METHOD APPROACH

John Spencer Ingels, MA, Adam H. Hansell, B.A., Samuel Zizzi, Ed.D.

West Virginia University, Morgantown, WV

Millions of people in the US would benefit from lowering their weight through weight management programs, yet little is known about their expectations of such programs beyond weight loss itself. This project used a multi-method approach to answer the following research questions: what do participants expect to gain from participating in a weight management program, how do expectations differ across BMI status, and across weight loss outcomes? Participants were selected from a 2-year weight management program run through the state of WV Public Employees Insurance Agency. Two methods were used in addressing participant expectations: 1) quantitative analysis of baseline survey responses, and 2) qualitative analysis of interviews conducted with participants after completing 18-months in the program. The first method analyzed responses from a baseline survey that asked participants to list "what do you hope to get out of the program?" The following themes were created from analyzing participants responses: weight loss, improved appearance, improved family time, improved health, improved lifestyle, improved mood, and education. Responses were quantified across 1,339 participants by coding 1 for the presence of each theme. An ANOVA found significant differences in response frequency across BMI classes for general health $F(3, 1332) = 8.65, p < 0.00$; improved family time $F(3, 1,332) = 7.49, p < 0.00$; and appearance $F(3, 1,332) = 5.01, p < 0.01$. Post-hoc analysis revealed that participants of all 3 obesity classes were more likely to expect health improvements than those who were overweight (BMI 25–29.9); those with class III obesity (BMI >40) were more likely to expect improved family time than those who were overweight or class I obese (BMI 30–34.9); and individuals with class III obesity were less likely to expect improved appearance when compared to overweight participants. The second method involved 22 interviews focused on understanding participants' expectations and their strategies for measuring progress after completing at least 18-months of the program. Thematic analysis of the transcripts revealed 6 expectations: weight loss, improved fitness, improved health, improved mood, advice, and support to develop new habits. Participant measurement themes were related to expectations (e.g. measuring weight). Finally, a comparison of responses across three subgroups of weight success at 18-months (regained weight, lost 3–6%, and lost over 7%) revealed an increased number of participants focused on mood improvement in the groups that lost weight. In conclusion, both methods revealed a rich and diverse range of expectations, beyond just weight loss, and evidence points to expectations differing across BMI classes. Further implications of these results for practitioners and program development will be discussed.

RECRUITING HISPANIC ADULTS FOR A FEASIBILITY AND ACCEPTABILITY BEVERAGE INTERVENTION

Luis A. Valdez, PhD, MPH¹, Benjamin Aceves, MPH, MA², Kristin Morrill, B.S.³, Erika Rodriguez-Guzman⁴, Guadalupe Ballesteros⁵, Cynthia Thomson, PhD, RD³, Iman A. Hakim, MBBCH; PhD, MPH⁶, Melanie Bell, PhD¹, Jessica A. Martinez, PhD⁷, David O. Garcia, PhD⁸

¹The University of Arizona, Tucson, AZ; ²University of Arizona, Mel and Enid Zuckerman College of Public Health, Tucson, AZ; ³University of Arizona, Tucson, AZ; ⁴Mel and Enid Zuckerman College of Public Health, Tucson, AZ; ⁵University of Arizona/ Mel and Enid Zuckerman College of Public Health, Tucson, AZ; ⁶Mel & Enid Zuckerman College of Public Health at University of Arizona, Tucson, AZ; ⁷University of Arizona Cancer Center, Tucson, AZ; ⁸The University of Arizona / Mel and Enid Zuckerman College of Public Health, Tucson, AZ

Background: Hispanic adults have a higher prevalence of obesity-related comorbidities and related metabolic abnormalities relative to other racial/ethnic groups in the U.S. The consumption of select beverages (i.e. green tea and Mediterranean lemonade) rich in bioactive dietary constituents may modify lipids, insulin/glucose and hemoglobin A1c in this at-risk group. Sparse research has assessed if Hispanic adults can be efficiently recruited into beverage intervention studies.

Purpose: To evaluate recruitment strategies for engaging obese Hispanic adults into a beverage intervention focused on examining changes in cardiometabolic health.

Methods: Fifty Hispanic adults (18–64 years; BMI ≥ 30 kg/m²) were recruited for an 8-week randomized, controlled beverage intervention study of three beverages: Mediterranean lemonade, Green Tea, or flavored water control. Face-to-face recruitment efforts occurred at a swap meet, community health clinics, worksites, and governmental facilities frequented by the Hispanic community in Tucson, AZ. Family/friend referrals, printed advertisements, and social media comprised additional outreach efforts. Recruitment effectiveness was determined by the number of adults who enrolled in the study relative to those who expressed interest, participated in screening, and were eligible.

Results: Recruitment took place over 6 months. A total of 287 Hispanic adults expressed interest in participating in the study, of which 222 (age: 43.4 ± 10.3 yrs; BMI: 33.0 ± 6.3 kg/m²; 21% male) completed screening for eligibility. Face-to-face recruitment yielded the most participants (86%; n=192) with the swap meet alone yielding 44% (n=97) followed by worksites (18%; n=40), community health clinics (17%; n=37), and government facilities 8% (n=18). Family referrals (8%; n=18), online outreach (3%; 6) and response to flyers (3% n=6) comprised the remainder of participant screenings. In total, 46% (n=102) of those screened were eligible for the study; the primary reason for ineligibility was self-reported BMI.

Conclusions: Face-to-face recruitment in community settings appears to be an effective strategy to engage this underrepresented group in research given the yield of interested participants deemed eligible. Efforts to evaluate this approach targeting other racial/ethnic groups and health behaviors are needed.

SOCIAL CAPITAL AND OBESITY AMONG ADULTS LONGITUDINAL FINDINGS FROM THE MONTREAL NEIGHBOURHOOD NETWORKS AND HEALTHY AGING PANEL

Yun-Hsuan Wu, PhD¹, Spencer Moore, MPH, PhD², Laurette Dube, PhD³

¹McGill Centre for the Convergence of Health and Economics, Montreal, PQ, Canada; ²University of South Carolina, Columbia, SC; ³McGill University, McGill Centre for the Convergence of Health and Economics, Montreal, PQ, Canada

Curbing the worldwide increase in obesity requires upstream social interventions that modify the environment in which obesity emerges. Recent studies have suggested that social capital and networks may influence a person's risk of obesity. Yet, few longitudinal studies have assessed whether social capital and networks reduce obesity risk in adult populations. In this study, the analytical data come from three waves (2008, 2010, and 2013) of the Montreal Neighborhood Networks and Health Aging Panel (N = 2606). Self-reported height and weight were used to calculate body mass index (BMI) with obesity defined as a BMI >30. Name and position generator instruments captured network measures of social capital, including: (1) upper reachability, (2) range, (3) diversity and (4) the number of kin ties. Questions on generalized trust and participation were used to assess cognitive and structural dimensions of social capital. Separate random effects logistic regression was used to examine the association among social network characteristics, social capital, and obesity. We found the greater the number of kin ties in a person's network, the greater the risk of obesity (OR: 1.33, 95% CI: 1.08 – 1.62). Adults with higher network diversity (OR: 0.83, 95% CI: 0.72 – 0.96) and high generalized trust (OR: 0.52, 95% CI: 0.35 – 0.77) were at a lower risk of obesity. The current study confirmed that higher network capital and trust were protective against obesity, while having kin ties was not. Disentangling the multidimensional role that social capital plays can lead to more effective interventions to reduce obesity.

THE ANIMO STUDY: A GENDER- AND CULTURALLY-SENSITIVE WEIGHT LOSS INTERVENTION FOR HISPANIC MALES

David O. Garcia, PhD¹, Luis A. Valdez, PhD, MPH², Benjamin Aceves, MPH, MA³, David P. Campas, B.S. in Public Health², Julio C. Loya, BSN, RN, CMS-RN⁴, Melanie D. Hingle, PhD, MPH, RDN⁵, Kyle Humphrey, MS⁶, Melanie Bell, PhD², Marylyn McEwen, PhD, RN⁷, Steven P. Hooker, Ph.D.⁸

¹The University of Arizona / Mel and Enid Zuckerman College of Public Health, Tucson, AZ; ²The University of Arizona, Tucson, AZ; ³University of Arizona, Mel and Enid Zuckerman College of Public Health, Tucson, AZ; ⁴University of Missouri Sinclair School of Nursing, Marana, AZ; ⁵University of Arizona, Tucson, AZ; ⁶University of Arizona, Seattle, WA; ⁷The University of Arizona College of Nursing, Tucson, AZ; ⁸Arizona State University, Phoenix, AZ

Background: Hispanic males have the highest rates of overweight and obesity compared to males of other racial/ethnic groups. While weight loss can significantly reduce obesity related health risks, Hispanic males are grossly underrepresented in weight loss research. Our work addresses a critical gap by informing how tailored intervention strategies improve weight management in this health disparate population.

Purpose: This pilot randomized controlled study compared a 12-week gender- and culturally-sensitive weight loss intervention (GCSWLI) to a waist-list control (WLC) in sedentary, overweight/obese Hispanic males.

Methods: Fifty Hispanic males (age: 43 ± 11 years; BMI: 34 ± 5 kg/m²; 58% Spanish monolingual) were randomized to one of two groups: GCSWLI (n=25) or WLC (n=25). GCSWLI participants attended weekly in-person individual sessions guided by a trained bilingual Hispanic male lifestyle coach, were prescribed a daily reduced calorie goal with a specific focus on reducing/modifying the types of food and liquids consumed (e.g., alcohol/sugar sweetened beverages), and 225 minutes of moderate-intensity physical activity (PA) per week. Additional GCSWLI features included a free gym membership and optional spouse/significant other attendance at intervention sessions. The WLC were asked to maintain their usual dietary intake and PA habits during the 12 weeks. GCSWLI participants continued with 12 weeks of follow-up including bi-weekly phone calls. Estimates of weight lost were obtained using a linear mixed effects model with categorical time and random intercepts.

Results: Between June-August 2016, 143 men expressed interest in participation; 35% (n=50) completed baseline measures and were randomized. Forty-three of 50 participants completed 12-week assessments, an overall attrition rate of 14% (GCSWLI: n=5, 20% vs. WLC: n=2, 8%). At week 12, using intention-to-treat, the mean weight loss in the GCSWLI was -6.3 kg (95% CI [-8.4, -4.1]) compared to -0.8 kg (95% CI [-2.8, 1.2]) for WLC (difference = -5.5 kg, 95% CI [-7.6, -3.4], $p < 0.001$). At week 24, weight loss in the GCSWLI was maintained (-6.4 kg, 95% CI [-8.6, -4.3]).

Conclusion: The GCSWLI appears to be a feasible strategy to engage Hispanic males in weight loss/management. Our pilot study indicates preliminary evidence of efficacy, though due to the small sample size, confirmation of these findings are needed in a larger study.

THE QUALITY OF NUTRITION AND PHYSICAL ACTIVITY ENVIRONMENTS OF CHILD CARE CENTERS IN THREE SOUTHERN STATES

Temitope Erinosh, PhD¹, Amber E. Vaughn, MPH, RD¹, Derek Hales, PhD², Stephanie Mazzucca, PhD³, Dianne S. Ward, EdD⁴

¹University of North Carolina at Chapel Hill, Chapel Hill, NC; ²University of North Carolina at Chapel Hill, Chapel Hill, NC; ³Washington University at St. Louis, Clayton, MO; ⁴Gillings School of Global Public Health, Chapel Hill, NC

Purpose: In early childhood when diet and physical activity (PA) behaviors are established, a significant proportion of U.S. children attend child care. Little is known about the nutrition and PA environments of child care centers in the south, where child obesity levels are highest. This study assessed the quality of nutrition and PA environments of child care centers in three southern states and examined differences by rural versus urban location, participation in the Child and Adult Care Food Program, and Head Start status.

Methods: The sample included 354 centers that enroll children aged 2–5, including 97 centers from Mississippi, 103 from Kentucky, and 154 centers from Georgia. Center directors and preschool teachers completed the Environment and Policy Assessment and Observation self-report tool (EPAO-SR) that assesses nutrition and PA environments of child care centers. Items on the tool were scored to capture six nutrition domains (foods provided at lunch, beverages provided at lunch, feeding environment, feeding practices, nutrition training/education, nutrition policy) and five PA domains (active play opportunities, outdoor play environment, PA practices, PA training/education, PA policy). The domains were then summed to create a combined nutrition and PA score (range=0–45); higher scores indicated that a greater number of best practices were met, which translated to higher-quality environments. Data analysis was performed in SAS and statistical significance was set at $p < 0.05$.

Results: Fifty-nine percent were rural centers versus 41% that were urban. Seventy-five percent participated in the Child and Adult Care Food Program, 73% received child-care subsidies, and 23% were Head Start centers. Overall, the centers had an average combined nutrition and PA score of 23.62 (± 4.70) out of 45. These scores did not differ between rural and urban centers (mean=23.51 \pm 4.85 versus 23.78 \pm 4.50, $p=0.60$). However, centers in the Child and Adult Care Food Program had higher nutrition and PA environment scores than non-participating centers (mean=24.18 \pm 22.06 versus 22.06 \pm 4.61, $p < 0.01$).

Conclusions: Findings highlight the vital role of federal programs play in supporting healthy nutrition and PA in child-care. Efforts are needed to increase enrolment in the Child and Adult Care Food Program. Providing nutrition and PA training and technical assistance to centers might also help.

TIME-VARYING DISTRESS TOLERANCE AND ITS ROLE IN PROBLEMATIC EATING BEHAVIOR: A STUDY USING ECOLOGICAL MOMENTARY ASSESSMENT

Stephanie Manasse, PhD¹, Ross D. Crosby, Ph.D.², Helen B. Murray, BA¹, Evan Forman, PhD³¹Drexel University, Philadelphia, PA; ²Neuropsychiatric Research Institute, Fargo, ND; ³Drexel University, Phila., PA

A growing body of literature supports the maintaining role of distress tolerance (i.e., the ability to withstand negative affect) in dysregulated eating behaviors that contribute to overweight, obesity, and binge eating. However, extant literature is fraught with limitations including: (1) reliance on retrospective self-report, and (2) the assumption that distress tolerance is a trait, rather than state (i.e., time-varying), construct. Using ecological momentary assessment is one method for addressing these limitations. In an ongoing study, treatment-seeking adults with clinically significant loss-of-control (LOC) eating ($n=15$, projected $n=20$) completed a smartphone-delivered EMA protocol for two weeks. Six times per day, participants answered questions regarding their current levels of negative affect, distress tolerance, and degree of LOC eating. We used generalized linear models and generalized estimating equations to examine: (1) time-varying nature of momentary distress tolerance; (2) ability of distress tolerance at time 1 (T1) to predict episodes of LOC at time 2 (T2); and (3) interaction between momentary negative affect and distress tolerance at T1 in predicting LOC at T2. We found distress tolerance, on average, decreased throughout the day, even when accounting for negative affect ($p = .03$). T1 distress tolerance did not significantly predict T2 LOC ($ps > .05$). At lower levels of momentary distress tolerance, feeling more guilty, bored, or sad was associated with later LOC eating ($ps = .01-.04$). Overall, our results support the value of assessing distress tolerance on a momentary level, as it may be a state, rather than trait variable. Additionally, it appears to moderate the prospective relation between negative affect and binge eating. Targeting distress tolerance in treatment may be beneficial in preventing LOC episodes (and therefore reducing risk for overweight, obesity, and continued binge eating) increasing a patient's ability to tolerate uncomfortable feelings, especially boredom, guilt or sadness. Future research should further examine the role of emotion-specific distress tolerance in dysregulated eating behavior.

WEIGHT CHANGE MEDIATES CHANGE IN DEPRESSION: RESULTS FROM THE TRACK STUDY

Christina M. Hopkins, BS¹, Dori Steinberg, PhD, RD², Gary Bennett, PhD¹¹Duke University, Durham, NC; ²School of Nursing, Durham, NC

Depression remains one of the most disabling mental illnesses in the United States, particularly for low-income communities who lack access to treatment. Obesity and depression are frequently comorbid, resulting in compounded risk of cardiovascular disease. Behavioral weight loss programs have demonstrated reductions in depression, but it is currently unknown whether amelioration of depressive symptoms is due to weight reduction or simply time and attention. We investigated the mediating effect of weight reduction on change in depressive symptoms in a behavioral weight control program.

The Track program was delivered within a network of community health centers in North Carolina. Participants ($n=351$) received 1 year of behavioral weight loss treatment delivered digitally. Treatment included automated weekly self-monitoring prompts via mobile technologies, daily self-weighing, and counseling calls from registered dietitians; half of participants received enhanced usual care. Depression was measured using the PHQ-8 at baseline and 12 months. Anthropometric measurements were collected in clinic.

Participants were 68.1% female and 50.7 (SD = 8.9) years old, with a mean BMI of 35.9 (SD = 3.9) kg/m². Participants who received the intervention lost significantly more weight than the control group (adj. $M_{diff} = -3.8$ kg; 95% CI, -5.1 to -2.5 kg; $p < .0001$). There was no significant effect of intervention group on change in depression; both groups experienced significant reductions in depression (intervention: $p < .001$; control: $p = .004$). In those who received the intervention, there was a significant effect of weight change on depression, such that those who lost more weight showed greater reduction in depressive symptoms [$F(6,148) = 23.73$, $p < .001$].

Weight losses were dichotomized to assess differential depression change when comparing those who lost any weight to those who maintained or gained weight. Participants in the intervention group who maintained or gained reported an increase in depressive symptoms ($M=.3$, $SD=4.4$) while those who lost weight reported a decrease in depressive symptoms ($M=-1.8$, $SD=3.9$; $p=.011$). Mediation analyses revealed that the effect of intervention status on depression is mediated by weight change ($b = -.56$, $SE = .17$, 95% CI = $-.94, -.27$).

Digitally-delivered behavioral weight control can reduce depressive symptoms, but this effect is mediated by successful weight loss. Future work should investigate the clinical significance of this reduction in depression and assess whether depressive symptoms continue to remit in the event of weight regain.

WHO ARE THE SUPERTRACKERS? UNDERSTANDING PREDICTORS AND OUTCOMES OF ENGAGEMENT IN A DIGITAL HEALTH WEIGHT LOSS INTERVENTION

Dori Steinberg, PhD, RD¹, Melissa C. Kay, PhD, MPH, MS, RD², Gary Bennett, PhD³¹School of Nursing, Durham, NC; ²Duke Global Digital Health Science Center/Duke University, Carrboro, NC; ³Duke University, Durham, NC

Objective: Self-monitoring engagement is the most reliable predictor of weight loss. The most successful interventions are those that help participants become “supertrackers;” those who consistently engage in self-monitoring throughout the intervention. Yet, we know little about who is most likely to achieve supertracker status, particularly among low-income groups. The current analysis examines predictors and weight outcomes of supertrackers among patients enrolled in a digital health weight loss intervention (Track) within community health centers.

Methods: We conducted a 12-month randomized controlled trial comparing the Track intervention to usual primary care for weight loss. The intervention included weekly self-monitoring of diet and physical activity goals via automated text messages or interactive voice response calls, daily self-weighing via a connected e-scale, and 18 counseling phone calls with a dietitian. Using data from our intervention platform, we operationalized self-monitoring engagement as proportion of days or weeks in which participants self-monitored behavioral goals and weight. Supertrackers are participants that tracked behaviors for at least 80% of weeks and weighed at least 5 days per week over 12 months.

Results: Intervention participants (n=170) were on average 50.9 years old and obese (BMI: 36.0 kg/m²). Most were female (69%) and non-Hispanic Black (54%), and 53% had an income ≤ \$25,000/y. Intervention participants completed a median of 93.2% (IQR: 54%-100%) of weekly self-monitoring and weighed on average 2.9 (2.0) days/week; 25% of participants (N=43) were supertrackers. Supertrackers lost significantly more weight at 12 months compared to those who tracked less often [mean difference: -4.6kg (95%CI: -7.0, -2.4); p=.0001]. There were no baseline differences in supertracker status by gender, race/ethnicity, employment, marital status, education, income, use of social services, diagnoses of hypertension, diabetes, or depression, stress, quality of life, smartphone ownership or use of health apps. However, at baseline, a greater proportion of supertrackers were more likely to have high levels of obesity (>35 kg/m²) [70% vs 51%; p=.034] and be weighing at least weekly [42% vs 21%; p=.008] compared to those who tracked less often.

Conclusions: The Track intervention achieved high levels of engagement, and only a limited number of factors predicted supertracker status. This suggests that high engagement can be achieved for most groups. It remains evident, however, that high levels of self-monitoring lead to significantly greater weight losses. Continued efforts to boost engagement rates are needed.

FOCUS GROUPS TO INFORM THE DEVELOPMENT OF A NUTRITIONAL INTERVENTION IN THE FIRE SERVICE

Mercedes Sotos-Prieto, PhD¹, Carolyn Muegge, MPH², Vanessa Kleinschmidt, MPH², Kara Johnson, MS (c)², Elizabeth A. Beverly, PhD³, Steven M Moffatt, MD², Stefanos N Kales, MD, MPH, FACP, FACOEM⁴¹Ohio University, Athes, OH; ²National Institute for Public Safety Health, Indianapolis, IN; ³Ohio University Heritage College Osteopathic Medicine, Athens, OH; ⁴Harvard Chan School of Public Health, Boston, MA

Cardiovascular disease (CVD) is the leading cause of on-duty deaths among US firefighters. A poor diet and firehouse traditions of large portion sizes, second helpings and leftovers contribute to obesity, which is steadily increasing in the fire service and is strongly associated to CVD. Because most risk factors are modifiable through lifestyle and firefighters spend a significant amount of time together in the firehouse, including time spent preparing and consuming meals and snacks, a worksite intervention trial was designed to encourage adoption of the Mediterranean-style diet. Prior to the start of the trial focus group sessions were conducted to assess firefighter and firefighter spouse/partner's perceptions toward food and nutrition behaviors and inform the “Feeding America’s Bravest” worksite intervention trial. Specifically we wanted to learn about: (1) perceptions and behaviors toward food and nutrition behaviors, (2) current attitudes and beliefs toward a healthy diet and lifestyle, (3) platforms for learning (4) key obstacles to eating a healthy diet and (5) willingness to change to a Mediterranean eating style from a sample of firefighters and their spouses or partners (hereafter referred to as “partners”).

Four semi-structured focus group discussions (2 firefighter and 2 partner), facilitated by a trained moderator, were held at a professional research center in Indianapolis, Indiana. A purposive sampling process was used to ensure that groups contained both sexes, a geographic distribution of firefighters from the department, and a mix of length-of-service. Participants were recruited one at a time until a group was full. The goal of the selection process was to select 11 participants and seat 8. Transcripts were coded and analyzed via content and thematic analyses. The results revealed that firefighters (mean age = 47, n=17) and their spouse/partners (mean age=46, n=16) report that their eating behaviors and food choices were predominantly affected by schedules, firehouse tradition (such as large portion sizes, volume of food, desserts and snacks, leftovers), quality of life (general sense of well-being), and cost of food. These findings inform that fire service nutrition interventions need to consider family and firefighter work schedules and cultural expectations of the fire service (timing, portion size, meal structure, quantity and content). Tools and resources to improve diet should minimize cost and maximize time.

THE IMPACT OF INJUSTICE APPRAISALS ON PAIN AND PSYCHOSOCIAL OUTCOMES IN AN INPATIENT SPINAL CORD INJURY REHABILITATION PROGRAM

Monima Anam¹, Alexandra Wike, PhD², Ashley Garner, PhD², Liza Nowlin, BS², Tori Wheelis, PhD², Kimberley Monden, PhD³, Adriel Boals, PhD², Zina Trost, PhD⁴

¹University of Alabama at Birmingham, Lagrange, GA; ²University of North Texas, Denton, TX; ³Craig Hospital, Dallas, TX; ⁴University of Alabama Birmingham, Birmingham, AL

Perceived injustice -- belief that one's pain/injuries are undeserved and attributable to error or negligence--has been found predictive of negative physical and psychosocial outcomes following acute injury and in the context of chronic health conditions. Individuals who sustain spinal cord injury (SCI) face multiple physical and psychological challenges that may contribute to injustice appraisals; however, to date, almost no studies have addressed the role of injustice perception following SCI. The current study examined the relationship between injury-related injustice perception and physical and psychosocial outcomes among patients receiving inpatient rehabilitation following recently acquired SCI. Of the sample ($n=77$; 24 female; mean age = 48.1 years), 45 sustained cervical and 28 sustained thoracic-level injuries, respectively. In addition to injury-related and sociodemographic variables, participants completed measures of current pain intensity, perceived disability across life domains following discharge, and depressive symptomatology. Perceived injustice was significantly positively associated with perceived disability ($r = .44$), depressive symptoms ($r = .41$), and current pain report ($r = .23$, marginal). In regression analyses, level of perceived injustice significantly accounted for variance in level of perceived disability and depression beyond that accounted for sociodemographic variables, type of injury (cervical/thoracic, traumatic/nontraumatic) and pain intensity. The study is among the first to examine the role of injustice appraisals in the context of SCI as well as inpatient rehabilitation for major trauma. Findings are consistent with existing evidence regarding the deleterious impact of elevated injustice appraisals across a multiple pain/injury conditions (e.g., whiplash, fibromyalgia, chronic musculoskeletal pain) and suggest that interventions targeting injustice appraisals and related psychological factors (e.g., blame, anger) may be warranted following SCI. Future studies are encouraged to examine the longitudinal impact of injustice cognitions following acute SCI hospitalization and rehabilitation.

ASSOCIATIONS BETWEEN MINDFULNESS, DEPRESSION, AND ANXIETY SYMPTOMS IN PEOPLE WITH MIGRAINE

Lauren A. Rosenberg¹, Talia G. Korn², Elizabeth K. Seng, Ph.D.³

¹Ferkauf Graduate School of Psychology, Yeshiva University, New York, NY; ²Stern College for Women, Yeshiva University, Miami, FL; ³Ferkauf Graduate School of Psychology, Yeshiva University; Albert Einstein College of Medicine, Bronx, NY, USA; Montefiore Medical Center, Bronx, NY, USA, Bronx, NY

Objective: Migraine is a painful, prevalent, and disabling neurologic condition that is comorbid with both depression and anxiety. Higher depression and anxiety symptoms have been associated with poor quality of life, disability, and disease severity in people with migraine. Mindfulness techniques have been shown to reduce depression and anxiety symptoms in other populations. The purpose of the present study is to determine if mindfulness is associated with depression and anxiety symptoms in people with migraine.

Method: Thirty-eight (35 woman, 3 men; M age = 39.7, $SD = 14.2$; 86.8%, $n = 33$ Caucasian, non-Hispanic; 89.5%, $n = 34$ with a college graduate degree or higher) people with migraine recruited from flyers and neurology offices in a large urban area were recruited to participate in a randomized clinical trial to evaluate Mindfulness-Based Cognitive Therapy for migraine. Participants completed a series of baseline questionnaires, including the PROMIS Depression and PROMIS Anxiety measures to assess depression and anxiety symptoms, and the Five Facet Mindfulness Questionnaire (FFMQ) to evaluate mindfulness. The FFMQ includes five subscales: observing, describing, acting with awareness, non-judging of inner experience, and non-reactivity to inner experience. Pearson correlations evaluated relationships between depression and anxiety symptoms, and the FFMQ subscales.

Results: In this sample, participants demonstrated broadly average levels of depression symptoms ($M = 53.8$, $SD = 6.7$) and anxiety symptoms ($M = 56.7$, $SD = 6.8$). FFMQ total scores were not significantly associated with depression symptoms ($p = .115$) or anxiety symptoms ($p = .124$). However, higher scores on the non-reactivity to inner experiences subscale were associated with lower depression symptoms ($r = -.34$, $p = .041$), and higher scores on the non-judging of inner experiences subscale were associated with lower anxiety symptoms ($r = -.33$, $p = .049$).

Conclusion: These findings suggest that certain components of mindfulness may be associated with psychiatric symptoms in people with migraine. Specifically, non-reactivity was associated with lower depression symptoms, and non-judging was associated with lower anxiety symptoms in people with migraine. Future studies should continue to evaluate the impact of mindfulness components on psychiatric symptoms and other outcomes in people with migraine.

CLASSIFYING CHRONIC PAIN PATIENTS BY VALUES AND ACCEPTANCE

Eric Kruger, DPT/M.S.¹, Kevin Vowles, PhD¹, Lance McCracken, PHD²

¹University of New Mexico, Albuquerque, NM; ²King's College London, London, England, United Kingdom

Pain acceptance and values-based action are two interconnected behavioral processes that appear important to the treatment of chronic pain. Both are emphasized in Acceptance and Commitment Therapy (ACT)—an empirically supported treatment for chronic pain. Acceptance entails engaging in activities despite pain and refraining from impractical attempts to avoid pain. Value-based action means acting in alignment with verbally stated meaningful purposes and is most effectively pursued with acceptance. The present study explored the interconnectedness of acceptance and values in a sample of individuals with chronic pain ($n = 1196$) by using latent profile analysis to determine if meaningful sub-groups (classes) of individuals can be identified based on measures of pain acceptance and values-based action. Analyses indicated that a three-class solution was optimal, which included a class high in both acceptance and values, low in both acceptance and values, and a values discrepancy group, which was characterized by low acceptance and large discrepancy between values importance and success. Significant differences were observed between the classes across measures of pain, fear avoidance, depression, and physical and psychosocial disability. Overall, the high acceptance and values class had the highest levels of functioning and the values discrepancy class had the lowest levels, with the low acceptance and values group falling in the middle. By evaluating both acceptance and values-based action together, the interconnectedness of these processes is better understood and their importance to ACT is further supported.

EXAMINING THE RELATIONSHIP BETWEEN DRIVING OUTCOMES AND PERCEIVED INJUSTICE AMONG INDIVIDUALS WITH CHRONIC LOW BACK PAIN

Albatoool H. Alnojeidi, MSH, PT¹, Joshua Seward², Deanna D. Rumble, PhD¹, Maegan Gates¹, Nina Attridge, PhD³, Despina Stavrinou, PhD¹, David J. Moore, PhD⁴, Zina Trost, PhD⁵

¹University of Alabama at Birmingham, Birmingham, AL; ²The University of Alabama at Birmingham, Pell City, AL; ³Loughborough University, Loughborough, England, United Kingdom; ⁴Liverpool John Moores University, Liverpool, England, United Kingdom; ⁵University of Alabama Birmingham, Birmingham, AL

Studies consistently link elevated pain-related injustice perception with poor physical and psychosocial outcomes among individuals with acute injury or chronic musculoskeletal pain. Perceived injustice has been conceptualized as a cognitive appraisal reflecting the severity and irreparability of pain/injury-related loss, as well as externalized blame and unfairness. There is likewise strong theoretical and empirical support for the relationship between anger and injustice appraisals. Recent research has highlighted the deleterious impact of perceived injustice specifically among individuals with chronic low back pain (CLBP), which is among the most prevalent and disabling pain conditions in the US and worldwide. Given the well-established association between anger and problematic driving outcomes, the current study sought to examine the relationship between perceived injustice, anger-related variables, and driving outcomes among individuals with CLBP ($n=315$; 159 female, Mean age = 35.16 years). Participants completed the Injustice Experience Questionnaire (IEQ) with reference to their CLBP, and measures of recent anger experience, characteristic anger responses while driving, and the extent to which their back pain exacerbated anger responses while driving. Participants also completed standard measures of driving errors/violations associated with collision involvement. In line with previous findings, individuals who endorsed higher CLBP-related injustice perception reported higher average pain intensity, pain-related disability (p 's < .001), and recent anger (p < .001). Higher perceived injustice ratings likewise showed significant positive association with both characteristic driving-related anger and anger responses when driving in pain (p 's < .001). Critically, higher injustice and anger scores were associated with more driving errors/violation and higher incidence of collision. Given the prevalence of CLBP and central role of driving behavior in both daily function and possible injury, the current preliminary analyses support the value of further examining the association between pain-related anger, injustice appraisals and driving-related outcomes.

EXPLORING THE ROLE OF PAIN CATASTROPHIZING IN DRIVING BEHAVIOR AMONG INDIVIDUALS WITH CHRONIC LOW BACK PAIN

Joshua Seward¹, Maegan Gates², Deanna D. Rumble, PhD², Nina Attridge, PhD³, Despina Stavrinou, PhD², David J. Moore, PhD⁴, Zina Trost, PhD⁵

¹The University of Alabama at Birmingham, Pell City, AL; ²University of Alabama at Birmingham, Birmingham, AL; ³Loughborough University, Loughborough, England, United Kingdom; ⁴Liverpool John Moores University, Liverpool, England, United Kingdom; ⁵University of Alabama Birmingham, Birmingham, AL

Chronic low back pain (CLBP) is among the most prevalent, disabling, and costly conditions worldwide. Recent research has found that, in addition to traditionally-examined domains of daily living, individuals with CLBP report significant pain interference in driving-related activity. Although driving represents one of the most common and instrumental daily activities in the United States, few studies to date have examined the interface between chronic musculoskeletal pain and driving experience. In the context of CLBP, prior research has supported that pain catastrophizing – a negative orientation to pain experience characterized by pain magnification, rumination, and helplessness – contributes to negative physical and psychological outcomes through such mechanisms as maladaptive attentional bias toward pain. The current study examined the association between pain catastrophizing and driving-related physical and psychological outcomes among 315 participants with CLBP (159 female, Mean age=35.16 years, SD=10.52). Participants rated the extent to which driving exacerbated their current pain intensity as well as the extent to which pain while driving increased their distractibility, impatience, and irritability at other drivers and passengers. Collisions during the previous three years were also recorded. Participants completed the Pain Catastrophizing Scale (PCS) and Experience of Cognitive Intrusion of Pain Scale (ECIP; adapted to driving) -- previously associated with pain catastrophizing. In line with existing research, participants with higher PCS scores reported higher average pain intensity and disability/daily pain interference (r 's=.26-.85, all p 's < .01). Higher PCS scores were also associated with greater pain experience while driving as well as greater increase in negative affective/behavioral responses (distractibility, impatience, irritability) when driving in pain (r 's=.37-.50, all p 's < .01). Notably, higher pain catastrophizing was significantly positively associated with cognitive intrusions by pain while driving (r = .80, p < .01). Further, analyses revealed that, in comparison to participants without a collision history, participants who had experienced a vehicle collision in the past three years reported higher pain catastrophizing and cognitive intrusions by pain when driving. Current findings highlight the potential mechanisms by which pain cognitions and attentional capture may contribute to heightened risk conditions when driving.

MULTI-SCALED MEASURES OF PAIN EXPERIENCE IN YOUNG ADULTS WITH SICKLE CELL DISEASE

Ashley Walton, PhD Psychology¹, Juan Quiroz, PhD Computer Science and Engineering², Richardson Michael, PhD Psychology³, Lori Crosby, PsyD⁴, Adam Kiefer, PhD Psychology⁴, Anthony Chemero, PhD Philosophy⁵, Susan Murphy, PhD Statistics¹

¹Harvard University, Cambridge, MA; ²Sagobrush, Reno, NV; ³Macquarie University, Cincinnati, OH; ⁴Cincinnati Children's Hospital, Cincinnati, OH; ⁵University of Cincinnati, Cincinnati, OH

Daily experience of pain can lead to long-term disability, particularly for individuals with Sickle Cell Disease (SCD). Inheritance of this genetic disorder leads to changes in hemoglobin causing the stiffening and distorting of red blood cells into the shape of "sickles". This sickling blocks or partially restricts blood flow to different parts of their bodies, resulting in both chronic and acute pain. Current developments in mobile technology provide new tools for understanding and managing SCD pain outside the clinical setting, where characteristics of pain can be captured using self-report measures administered using mobile applications on patients' smart phones. However, self-report can be burdensome for patients and have potential iatrogenic effects. Mobile technology can capture characteristics of pain experience through the passive recording of physiological measures including movement and heart rate variability. Therefore, this project aimed to capture these passively recorded physiological signals across different reported pain intensities in order to identify measures that can be used as indicators of SCD pain experience. Four young-adult patients with SCD recruited from Cincinnati Children's Hospital Medical Center wore wristbands that recorded their heart rate, skin conductance, temperature, and movement (accelerometer data) for four consecutive days. They also used a mobile application to report their pain intensity, pain location, pain descriptors, happiness, stress and fatigue. The pattern-recognition techniques of machine learning were used to identify regularities in the physiological signals in relationship to the reported pain intensities. For example, statistical features from sliding windows of the accelerometer data were extracted to build personal models to predict the pain intensity for each patient. The Linear Regression, Multi-layer Perceptron and Random Forest classification algorithms significantly predicted pain intensity for two of the four patients. Future work will focus on the development of mobile health interventions that can leverage changes in physiological signals to provide adaptive support for pain management that is responsive to the momentary needs of individuals with SCD within their everyday lives.

PRE-SURGICAL BIOPSYCHOSOCIAL CORRELATES OF LUMBAR FUSION OUTCOMES AMONG UTAH WORKERS' COMPENSATION PATIENTS

Julie Murray¹, Scott DeBerard, PhD¹, Seth Seifert¹, Cassie Dance², Jessica Gundy Cuneo, Ph.D.³

¹Utah State University, Logan, UT; ²Utah State University, Department of Psychology, Logan, UT; ³University of California San Diego, Sonoma, CA

Lumbar fusion surgery is an increasingly prevalent and costly procedure in the U.S. Outcomes following this surgery can be quite variable. There has been an effort to identify pre-surgical biopsychosocial variables that may predict lumbar fusion outcomes. Identification of such variables are particularly important for informing patient screening and selection procedures. The present purpose was to examine how pre-surgical demographic, health status, and compensation variables correlated with post-surgical outcome variables. Participants were 110 Utah workers' compensation patients (average age = 42.7 yrs., 77.3% male) who underwent lumbar fusion surgery from 1987–2007 and were at least two-years post-surgery at time of follow-up. A retrospective cohort design was utilized consisting of a review of pre-surgical records and a postsurgical telephone survey. Presurgical variables included: age at time of injury, number of levels fused, smoking status, amount of pain prior to surgery, depression history, assignment to a nurse case manager, and litigation status. The outcome measures were assessed at least 2-years post-surgery and included disability status, Roland-Morris Disability Questionnaire (RMDQ) total score, and Short-Form-36 Physical and Mental Health Composite Scores (PCS/MCS). Correlational analyses revealed that smoking, higher amount of pain prior to surgery, depression, assignment of a case manager, and litigation were all consistently statistically significant correlates of outcomes. Linear regressions were conducted in which pre-surgical variables were used to predict outcomes. Statistically significant amounts of variance were accounted for in disability status ($R^2 = 0.21$), RMDQ total ($R^2 = 0.26$), SF-36 MCS ($R^2 = 0.19$) and SF-36 PCS scores ($R^2 = 0.31$). The benefits of integrating pre-surgical predictors of outcomes into lumbar fusion patient selection protocols are discussed.

PSYCHIATRIC HISTORY, OPIOID USE, PAIN, AND POST-OPERATIVE OUTCOMES IN LIVING KIDNEY DONORS

Heather Bruschwein, PsyD¹, Shaina Gulin, PhD², Marci Loiselle, Ph.D.³, Terra Rose, Psy.D.⁴, Jaclyn Jacobs, MS, CRC⁵, Lacey Clement, MA⁶, Harendra Arora, MBBS⁷, Rebekah Nash, MD, PhD⁸, Amy Woodard, RN, BSN, CNN, CCTC⁹, Tomasz Kozlowski, MD⁷

¹University of North Carolina, Charlottesville, VA; ²University of North Carolina Chapel Hill, Chapel Hill, NC; ³University of North Carolina at Chapel Hill, Chapel Hill, NC; ⁴University Of North Carolina, Chapel Hill, Chapel Hill, NC; ⁵University of North Carolina at Chapel Hill, Philadelphia, PA; ⁶University of North Carolina at Chapel Hill, Carrboro, NC; ⁷University of North Carolina, Chapel Hill, NC; ⁸University of North Carolina Hospitals, Psychiatry Department, Chapel Hill, NC; ⁹UNC Center for Transplant Care, UNC Hospitals, Apex, NC

Psychiatric characteristics such as depression and anxiety predict worse post-surgical pain severity and management. This study of living kidney donors (LDs) explores the effect of psychiatric history on opioid medication use, subjective pain, length of stay (LOS), and post-donation emergency department (ED) visits. These relationships were studied in LDs undergoing traditional peri-operative pain management (pre-ERAS group; n=86) and in LDs with an enhanced recovery after surgery (ERAS; n=10) protocol to reduce opioid use in all care phases. LDs in both groups (n=96, age_{yr} = 45.3, 55.2% female, 72.9% Caucasian) underwent standard medical, surgical, psychological and social assessment. Total morphine milligram equivalents (MME) per stay was significantly higher in the pre-ERAS group ($M=256.7$, $SD=140.2$) compared to the ERAS group ($M=153.2$, $SD=88.9$); $t(94)=2.3$, $p=0.25$. The ERAS group had significantly shorter LOS ($M=3.5$ days, $SD=.53$) than the pre-ERAS group ($M=4.4$ days, $SD=.99$); $t(94)=2.9$, $p=.004$. There was no difference in pain ratings between the groups; $t(94)=.79$, $p=.43$. For both groups, pain explained a significant proportion of variance in LOS [$R^2=.18$, $F(1, 94)=20.24$, $p < .001$], with higher pain associated with longer LOS; $B=.24$, $t(94)=4.5$, $p<.001$. 9 of 86 (10.5%) pre-ERAS LDs required ED treatment for pain within 2 weeks after discharge, compared to 0 ERAS donors. LOS explained a significant amount of variance in post-donation ED treatment [$R^2=.05$, $F(1, 94) = 4.62$, $p<.05$, with greater LOS associated with more ED visits; $B=.10$, $t(94)=2.2$, $p<.05$. LDs with a psychiatric history (21.9% of overall sample) had the same LOS compared to LDs without such history ($M=4.3$ days). LDs with a psychiatric history did not have significantly higher pain ($M=7.1$ highest pain, $SD=1.6$) than those without a psychiatric history ($M=7.7$ highest pain, $SD=1.7$); $t(94)=1.4$, $p=.16$, and also did not have more post-donation ED visits; $t(94)=-.77$, $p=.45$. LDs with a psychiatric history did not receive more MME ($M=228.31$, $SD=94.6$) compared to LDs with no psychiatric history ($M=250.9$, $SD=149.4$); $t(94)=.66$, $p=.51$. Results showed that carefully screened donors with a psychiatric history had no differences in outcomes than donors without a psychiatric history. Higher pain was associated with longer LOS, with longer LOS related to more post-surgical ED visits. Preliminary findings indicate successful shortening of LOS and reduced opioid use after implementation of ERAS.

RACE AND SEX DIFFERENCES IN PAIN SENSITIZATION AMONG PATIENTS WITH CHRONIC LOW BACK PAIN

Samantha M. Meints, Ph.D., Victor Wang, M.D., Robert R. Edwards, Ph.D.

Brigham and Women's Hospital, Chestnut Hill, MA

There is evidence that chronic low back pain (CLBP) involves changes in the CNS resulting in pain augmentation. Further, race and sex disparities in the prevalence and experience of low back pain may be related to differences in pain sensitization. Catastrophizing may also influence pain sensitization in CLBP patients. The current study aims to examine race and sex differences in pain sensitization among CLBP patients and the role of catastrophizing as a potential mediator of those differences. Participants were 324 Black and non-Hispanic White adults (27% Black, 47% female) with idiopathic CLBP. Participants completed a series of questionnaires followed by a battery of quantitative sensory testing (QST) using weighted pinprick stimulators and a rapid cuff inflator to induce mechanical punctate pain and deep muscle pressure pain, respectively. Results of 2 (race) X 2 (sex) analyses of covariance indicated a significant effect of race for all QST variables such that, compared to White participants, Black participants reported greater mechanical punctate pain intensity ratings ($p<.01$) and aftersensations ($p<.01$) as well as deep muscle pressure pain ratings ($p<.01$) and aftersensations ($p<.01$). Further, Black participants required less cuff inflation to produce moderate pain ($p<.01$) and demonstrated greater temporal summation for both mechanical punctate pain ($p<.01$) and deep muscle pressure pain ($p<.01$). There were also main effects of sex for mechanical punctate aftersensations and inflation pressure needed to produce moderate pain. Compared to males, female participants rated mechanical punctate aftersensations as more painful ($p<.01$) and required less cuff inflation to produce moderate pain ($p<.01$). Results of mediation analyses indicated that catastrophizing mediated the race differences in temporal summation of deep muscle pain, cuff inflation pressure needed to produce moderate pain, and mean cuff pain intensity ratings. That is, Black participants endorsed greater catastrophizing which was associated with greater temporal summation of deep muscle pain, less pressure required to produce deep muscle pain, and greater cuff pain intensity ratings. These findings are consistent with the literature indicating that Blacks and females experience heightened pain sensitization compared to Whites and males, respectively. While catastrophizing may play a role in pain sensitization among CLBP, a more nuanced understanding of this relationship is warranted.

THE SOCIAL CONSTRUCTION AND LANGUAGE OF PAIN AMONG WOMEN MANAGING KNEE OSTEOARTHRITIS PAIN

Erica Anderson, MSC¹, Angelina Vickers, MSC², Torre Anderson¹, Warren Feaster, AS³, Bridgett Rahim-Williams, MA, MPH, PhD⁴¹Bethune-Cookman University, Daytona Beach, FL; ²Healthy Start, Daytona Beach, FL; ³Bethune Cookman University, Daytona Beach, FL; ⁴Bethune-Cookman University, Daytona Beach, FL

Introduction: The experience of knee OA pain is a shared and socially constructed phenomenon. For individuals living with and managing symptomatic knee OA, expressions of pain reflect biopsychosocial dimensions affecting health-related quality of life. The aim of this study was to explore the socially-constructed experiences of knee OA and pain among women managing the disease.

Methods: Four focus groups were conducted to examine the narrative experience of living with and managing doctor-diagnosed knee OA pain among middle and older-aged women; ages 51- 72. Diagnosis of knee OA ranged from six months to 20 years. Sixteen women participated in the focus groups; nine African American and seven non-Hispanic Whites. Sessions were held for approximately one hour each, audio-taped, text transcribed verbatim, and coded for content analysis with NVivo software. Cross-verification was conducted to examine and confirm textual data for emergent themes (pain avoidance, pain sensitivity, coping mechanisms, etc.) and conceptual constructs.

Results: Ratings of pain ranged from 10 at its mildest, and 100 at its worst. The time of day, weather and physical activity affected the quality of the pain. Pain descriptors included: “throbbing,” “can’t take it anymore”, “frustrating,” as “something you don’t want to think about, but makes you think about it all the time”, “emotional”, and “to be without pain is a blessing”; makes one “happy”. When in pain, “pain makes you cry, you get pissed, sad, and tired”. Pain “is always there”. Treatments for pain included both biomedicine and alternative remedies. African American women reported using more complementary and alternative treatment methods (tea-tree oil, blue emu, heat/ice packs, etc.) compared to non-Hispanic White women who reported more biomedicine use (hyaluronic acid, meloxicam, tramadol, etc.). Women from both ethnic groups were supportive of knee joint replacement, but AA women were less likely to undergo the invasive procedure.

Conclusion: Women managing knee OA pain have commonalities in the experience of living with the degenerative disease. Understanding the qualitative dimensions of knee OA pain holds promise for individualized precision medicine for improved pain treatment; thus, reducing pain health disparities and increasing health-related quality of life.

TREATMENT OF CHRONIC PAIN AND COMORBID PTSD WITHIN A PAIN REHABILITATION PROGRAM: EXAMINING FUNCTIONAL OUTCOMES & PTSD SYMPTOMS

Matthew Schumann, PhD¹, Keith Gascho, Jr., MA², Daniel Luedtke, BA², Wesley Gilliam, PhD²¹Mayo Clinic, Albert Lea, MN; ²Mayo Clinic, Rochester, MN

Introduction: Patients who experience both chronic pain and post-traumatic stress disorder (PTSD) report greater pain, affective distress and disability when compared to those with either chronic pain or PTSD alone. As many as three quarters of patients who initiate care for PTSD have significant chronic pain issues. Conversely, 20 to 37% of persons presenting for chronic pain care have PTSD. These reports suggest that rather than being distinct disorders, chronic pain and PTSD may be intricately connected and mutually maintaining each other. While there is empirical evidence that individuals with comorbid chronic pain and PTSD can benefit from interdisciplinary pain rehabilitation programs (IPRP) in terms of pain outcomes, there is a dearth of evidence demonstrating PTSD symptomology is responsive to such a treatment approach. This study sought to examine treatment outcomes among patients enrolled in a three-week IPRP with chronic pain and a provisional PTSD diagnosis.

Methods: Outcome data for 62 patients completing treatment at the Mayo Clinic 3-week IPRP between January 2016 and December 2017 with a provisional diagnosis of PTSD were examined. A provisional PTSD diagnosis was established based on the National Center for PTSD scoring recommendations for the PTSD Checklist for DSM-5 (PCL-5). Within-subjects ANOVAs were used to examine pre- to post-treatment changes on pain specific self-report outcomes (e.g., pain severity, interference, catastrophizing, depressive symptoms) and performance-based outcomes (e.g., aerobic capacity, trunk strength), as well as self-report PTSD symptomatology.

Results: For pain outcomes, significant improvements were detected for all self-report (F 's > 55.18 , p 's η^2 's $> .48$) and performance-based measures (F 's > 27.72 , p 's $< .001$, η^2 's $> .32$). Participants also endorsed significantly lower total PCL-5 scores from pre- to post-treatment, $F = 26.55$, $p < .001$, $\eta^2 = .36$. In addition, only 29 patients continued to meet provisional PTSD diagnosis at post-treatment (i.e., 47.3% reduction in diagnosis across treatment).

Conclusions: This study suggests that IPRPs can facilitate functional and psychological improvement for patients with chronic pain and likely comorbid PTSD. Additional research is needed to understand the mechanisms of change for these patients as a means to identify evidence-based approaches to facilitate functioning.

DISTRESS TOLERANCE AND PAIN EXPERIENCE IN YOUNG ADULTS WITH CURRENT PAIN

Andrew H. Rogers, B.A.¹, Jafar Bakhshaie, M.D., M.A.¹, Nubia A. Mayorga, B.S.¹, Joseph W. Ditre, Ph.D.², Michael J. Zvolensky, Ph.D.¹¹University of Houston, Houston, TX; ²Syracuse University, Syracuse, NY

Pain, and pain-related problems affect a significant portion of the United States population (Nahin, 2015) and cause significant disability. Importantly, emotional distress has been associated with more severe and disabling pain experience (Craig, 1994). One transdiagnostic factor that may be particularly important in this context is distress tolerance, reflecting the perceived capacity to withstand distress related to affective, cognitive, and/or physical states (Simons & Gaher, 2005). Previous research has examined pain tolerance as a predictor of pain experience. However, although pain tolerance and distress tolerance are similar, they are distinct constructs (Asmundson, Peluso, Carleton, Collimore, & Welch, 2011). Therefore the current study sought to explore distress tolerance in relation to pain intensity, pain disability, and past-3 month frequency of pain disability in a sample of young adults.

Participants ($N = 1,577$, 79.9% female, $M_{age} = 22.17$, $SD = 5.24$) reporting bodily pain were recruited for a survey based study at a large southwestern university. Participants completed the Distress Tolerance Scale (Simons & Gaher, 2005), the Graded Chronic Pain Scale (Von Korff et al., 1992), the Short Form General Health Survey (Stewart, Hays, & Ware, 1988), and reported on their drug and alcohol use. Two-step stepwise multiple linear regressions were conducted using SPSS Version 24 for pain intensity and pain disability, and a negative binomial regression was conducted for the past-3 month frequency of pain disability variable.

In predicting pain intensity, distress tolerance was a significant predictor ($B = -0.05$, $SE = 0.01$, $p < 0.001$, $\Delta R^2 = 0.012$). Additionally, distress tolerance significantly predicted pain disability ($B = -0.083$, $SE = 0.01$, $p < 0.001$, $\Delta R^2 = 0.03$). Finally, distress tolerance was a significant predictor of days with pain disability ($B = -0.007$, $SE = 0.002$, $p = 0.005$).

Results from the study indicated that distress tolerance was significantly associated with pain outcomes. Specifically, lower tolerance for distress was associated with greater pain complaints and disability. Clinically, it may be important to assess and target distress tolerance in the context of pain treatment to lessen the negative impact of pain experiences. Overall, the current study provides initial empirical evidence that distress tolerance may be important to understanding more severe and disabling pain experiences among young adults experiencing current pain.

GREATER PAIN DISCLOSURE AT PREOPERATIVE VISITS PREDICT LOWER SELF-REPORTED PAIN AT POSTOPERATIVE VISITS

Robert Wright, MA, Kate Sweeny, PhD, Megan Robbins, PhD

University of California, Riverside, Riverside, CA

Preoperative visits provide a time for the patient to discuss diagnoses and concerns with a surgeon. This visit is meant to inform the patient about what will happen surrounding the surgery and assuage any fears that may arise. A common fear about surgical procedures is pain, yet little is known about the role of disclosing pain in preoperative visits. To explore how discussing pain at the preoperative visit was related to postoperative self-reported pain, 147 general surgery, preoperative clinic visits were audio recorded and transcribed. Forty-eight patients returned for their postoperative visit, which was recorded. Self-reported pain was assessed just prior to both visits with the surgeon. The preoperative and postoperative visit transcripts were analyzed using a software program with a validated pain-specific dictionary, which provides a proportion of pain related words to total words spoken. Patients' pain word use at the preoperative visit predicted lower self-reported pain at the postoperative visit, controlling for preoperative self-reported pain and self-reported worst pain since the operation ($\beta = -.32$, $p = .04$). Further, pain word use at the preoperative visit was not related to preoperative self-reported pain ($r = .04$, $p = .67$) and postoperative pain word use was not related to postoperative self-reported pain ($r = -.12$, $p = .55$). This finding adds to the importance of the patient/surgeon interaction. Further, this study highlights the growing importance to focus on preoperative techniques in preventing postoperative pain. These findings underscore the importance of providing the patient with the opportunity to discuss their pain, and concerns surrounding it, at preoperative visits, as they were associated with less pain after the surgery.

HISPANIC ETHNICITY, ETHNIC ATTITUDES, AND CHRONIC PAIN CARE: A VIRTUAL PATIENT INVESTIGATION

Nicole Hollingshead, Ph.D.¹, Leslie Ashburn-Nardo, Ph.D.², Jesse Stewart, Ph.D.², Gerardo Maupomé, Ph.D.³, Adam T. Hirsh, PhD⁴¹Dept of Family Medicine / The Ohio State University, Columbus, OH; ²Dept of Psychology / IUPUI, Indianapolis, IN; ³Dept of Cariology, Operative Dentistry and Dental Public Health / School of Dentistry / Indiana University, Indianapolis, IN; ⁴Indiana University - Purdue University Indianapolis, Indianapolis, IN

Previous research has found Hispanic American (HA) patients are less likely than Non-Hispanic White (NHW) patients to receive opioid medications, but little is known about the potential influence of patient ethnicity on clinicians' use of integrated treatments for chronic pain. This is striking, given that HAs represent the fastest growing demographic group in the U.S., HAs are at high risk for chronic pain, and clinical guidelines recommend an integrated approach to chronic pain care. To address this gap, we recruited medical students (N=97) to make decisions regarding pain assessment and treatment (referral to pain specialist, mental health counseling, and physical therapy [PT]) for 8 computer-simulated patients. Patient vignettes included a video and text description of a HA or NHW patient reporting chronic low back pain. Patient ethnicity was manipulated in the video; clinical information and pain expression was similar across vignettes. Participants also completed measures assessing their attitudes towards out-group members and rated their emotional reactions (e.g., hostility, disdain, warmth) when providing care to HA and NHW patients. Paired samples t-tests indicated that, on average, participants made statistically equivalent assessment and treatment decisions for HA and NHW patients ($ps > 0.10$). Surprisingly, participants reported more negative attitudes when providing care to NHW patients than HA patients ($t(96) = 2.92, p = 0.004, d = 0.33$). Pearson correlations indicated that more negative attitudes towards HAs was associated with lower pain assessment ratings ($r = -0.25, p = 0.008$) and lower likelihood of referring HA patients to a pain specialist ($r = -0.21, p = 0.03$); participants' attitudes towards NHW patients were not significantly associated with their assessment or treatment decisions for these patients ($ps > 0.10$). These data suggest that, in the aggregate, medical students make similar pain assessment and integrated care decisions for HA and NHW patients with chronic low back pain. Nevertheless, the results suggest that providers' negative attitudes about HA patients may contribute to disparate care delivered to these already vulnerable patients. This is one of the first experimental investigations of ethnic differences in integrated chronic pain care, the results of which raise the possibility that interventions targeting provider attitudes may reduce disparities and improve care for HA patients.

HOW DO ADOLESCENT BOYS AND GIRLS PERCEIVE SYMPTOMS OF ENDOMETRIOSIS AMONG PEERS?

Jhumka Gupta, SCD, MPH¹, Lauren F. Cardoso, MSW², Courtney Harris, N/A³¹GEORGE MASON UNIVERSITY, FAIRFAX, VA; ²University of Pennsylvania, Cambridge, MA; ³George Mason University, Fairfax, VA

Background: Symptoms of endometriosis, including debilitating pelvic pain, back and nerve pain, irregular menstruation, and painful sex, often begin in adolescence. Yet, research on the experience of these debilitating pain symptoms among young people is scarce. Of particular concern is the influence of adolescent girls' social context. Research with adult women that their social environment (e.g. intimate partners, friends, family members, healthcare providers) plays a critical role in shaping their experiences of endometriosis. Understanding contextual factors among adolescents is important given their developmental stage and sensitivity to the beliefs and behaviors of others.

Objectives: To qualitatively examine how, among adolescents, endometriosis and painful symptoms suggestive of endometriosis, is perceived at the family, peer/school, and community/society levels.

Methods: Eight focus groups were conducted with an ethnically diverse sample of boys and girls (N=54) residing in New York City. Vignettes were utilized to elicit participants' perceptions of factors that may shape girls' experiences of seeking help for endometriosis pain.

Results: Five major factors, which operated at multiple levels of the social environment, were identified: distrust of healthcare providers, stigma, lack of endometriosis knowledge, inequitable gender norms, and invisibility of pain and menstrual symptoms. These factors were perceived to impact girls' social, educational, and emotional well-being.

Conclusions: Findings underscore the importance of understanding the social environment of girls with symptoms of endometriosis and educating and engaging their peers, family, and school personnel to create a supportive, informed social climate. Efforts should include stigma reduction campaigns targeted towards female and male adolescents.

INJUSTICE PERCEPTIONS PREDICT FUTURE FUNCTIONING IN CHILDREN WITH CHRONIC PAIN: A 12-MONTH FOLLOW-UP

Megan M. Miller, M.S.¹, Amy E. Williams, PhD², Eric L. Scott, PhD³, Zina Trost, PhD⁴, Adam T. Hirsh, PhD¹¹Indiana University - Purdue University Indianapolis, Indianapolis, IN; ²Indiana University School of Medicine, Indianapolis, IN; ³University of Michigan, Ann Arbor, MI; ⁴University of Alabama Birmingham, Birmingham, AL

Pain-related injustice, or the perception of one's pain as unjust, has been identified as an important cognitive-emotional factor in the pain experience of children. Recent studies have found pain-related injustice predicted unique variability in physical disability and in emotional, social, and school functioning – over and above that of pain catastrophizing – in a pediatric chronic pain sample. Additionally, pain-related injustice, but not catastrophizing, partially mediated the relationships between pain intensity and stress, disability, and quality of life. Because the literature has been largely cross-sectional in nature, little is known about the temporal relationship between injustice perceptions and pain-related functioning in children and adolescents. The purpose of the current study was to examine the extent to which baseline levels of perceived injustice predicted pain-related functioning 12 months later among children and adolescents with chronic pain. The sample consisted of 81 pediatric chronic pain patients (mean age = 14.2 years, 74% female) presenting to an outpatient university-based pain clinic. Patients completed measures at their initial clinic visit and at a 12-month follow-up appointment. The measures assessed current pain intensity (NRS), perceptions of injustice (IEQ, completed at baseline only), functional disability (FDI), pain catastrophizing (PCS-C), and quality of life (PedsQL). Baseline perceived injustice was significantly associated with follow-up scores on measures of functional disability ($r = .35, p < .05$), and quality of life ($r = -.37, p < .05$). In hierarchical regression analyses, after controlling for baseline pain intensity and catastrophizing, baseline perceived injustice accounted for an additional 5% of the variance in 12-month quality of life ($p < .05$) but did not account for significant additional variance in 12-month functional disability ($p > .05$). These findings suggest that injustice perceptions have prognostic value in predicting future pain-related functioning, which may indicate a need for new interventions that specifically target injustice perceptions early in the pain experience of children and adolescents.

PAIN RELIEF INTERVENTION USING MBCT IN END STAGE RENAL DISEASE (PRIMER): A FEASIBILITY PILOT STUDY

Emanuela Offidani, PhD¹, Carla Boutin Foster, MD²¹Weill Cornell Medicine, New York, NY; ²SUNY Downstate, Brooklyn, NY

Background: Pain is a relevant yet underestimated problem in end stage renal disease. Although helpful, pain medications have been shown to cause several side effects. Psychological distress is also extremely common in patients with end stage renal disease and may worsen the perception of pain. Mindfulness Based Cognitive Therapy has been proved effective in reducing both distress and pain in individuals with different medical conditions. The overarching goal of PRIMER is to explore the feasibility of a Mindfulness Based Cognitive Therapy intervention to reduce pain in dialysis patients. Main aim of the study is to determine: a) Feasibility of recruitment; b) Feasibility of delivering the intervention chair-side at the dialysis facility while the participant is ongoing treatment; c) Acceptability of the intervention.

Methods: PRIMER is a cluster controlled feasibility trial comparing usual care and 8 weeks of individual 1-hour session of MBCT, with nested qualitative research to evaluate patients' satisfaction and suggestions to improve the intervention. Participants were 20 patients with ESRD who were receiving hemodialysis, recruited from two different locations of the Rogosin Institute (New York, NY, USA) to avoid contamination between intervention and usual care. Main outcomes of the study to establish feasibility and acceptability were: a) eligibility rates; b) acceptance rates; c) dropout rates; d) number of sessions attended; e) number of weeks needed to complete 8 sessions.

Results: In the controlled site, 17 patients were approached. Of these, 13 were eligible to participate in the study (eligibility rate 76.5%) and a total of 8 (acceptance rate 61.5%) enrolled in our study. In the intervention site, 75 patients were approached. Of these, 54 were eligible to participate (eligibility rate 72%, 95%CI:5.41–9.32) and a total of 12 (acceptance rate 22%, 95%CI:1.12–3.78) patients enrolled in the intervention. In regard of feasibility and acceptability of the intervention, 2 of the 12 patients enrolled dropped out after the second session (dropout rate 16%, 95%CI:0.2–6.02). The 10 patients who remained in the study completed all the sessions. Specifically, 1 patients completed the 8 sessions in 12 weeks, 1 in 11 weeks, 2 in 9 and 6 in 8 weeks (89 total weeks required instead of 80).

Conclusion: Overall, we obtained mixed results. On one hand, our pilot showed the feasibility of delivering the intervention at chair side and its acceptability with only two patients dropping out and the other patients completing all the sessions. On the other hand, we failed to enroll eligible patients. Difficulties in enrolling medical patients are not new, however this population proved to be particularly challenging to engage. Future studies should investigate barriers to participations and include components of motivational/engagement interviewing during recruitment.

PERSONALITY ATTRIBUTES AND MIGRAINE IMPACT ASSOCIATED WITH MIGRAINEURS' EMERGENCY CARE

Joseph Patrick. McNabb, Student¹, Daniel Hernandez Altamirano, Student², Paige Barrette, Student³, Amrita Bhowmick, MPH⁴, Amy Wachholtz, PhD¹¹University of Colorado Denver, Denver, CO; ²University of Colorado Denver, Thornton, CO; ³University of Colorado Denver, Denver, CO; ⁴Health Union, LLC, Chapel Hill, NC

Introduction: Migraines are a common presentation in emergency care center (ECC) (i.e., emergency room or urgent care) settings. Previous studies have found that migraineurs visit ECCs for severe headache episodes or lack of treatment options. However, little research has examined ECC visit frequencies in relation to migraineur personality attributes and perceived migraine impact (PMI). It was hypothesized that migraineurs who have more negative personality attributes and greater PMI, visit ECCs more frequently.

Methods: ECC visits, personality attributes, PMI (e.g. 'I feel embarrassed about having migraines': 5 point Likert Scale), and demographics were collected on 4,502 US adult migraine participants in the 2015 Migraine.com survey. Composite ECC visit groups included: no visits (58.1%), 1–3 visits (26.7%), 4–6 visits (8.8%), and >7 visits (6.4%).

Results: Participants were primarily middle age (M=47.5 years; SD=10.2), women (95.5%), between 3–4 migraines per months (M=3.7; SD=1.2). Linear regression showed that participants with more ECC visits describe themselves as: lonely ($\beta=.047$, $p<.00$), unreliable ($\beta=.054$, $p<.00$), depressed ($\beta=.097$, $p<.00$), angry ($\beta=.081$, $p<.00$), and helpless ($\beta=.081$, $p<.00$). Using ANOVA, PMI significantly differed among the groups ($F(3,4498)=158.8$, $p<.00$), with greater PMI equating to more frequent ECC visits.

Discussion: Our study found a positive relationship between ECC visits and negative personality attributes. Indicating that a population of frequently visiting ECC migraineurs, who also have a strong likelihood of having negative personality attributes, are improperly using ECCs. Conventional emergency treatments are intended to treat isolated headache emergencies (i.e., with medications like opioids and NSAIDs) and emergent mental health issues. Yet, the target population is using ECCs to treat ongoing migraine disorders and mental health issues. Thus, we suggest ECCs screen migraineurs for mental issues (e.g., screening for words like 'lonely', 'unreliable', 'depressed', 'angry', or 'helpless') to identify migraineurs who frequently seek emergency migraine treatments. Once identified, ECCs can refer patients to more appropriate treatment including pain management psychologists. Advantages of this empirically-supported approach include: (1) implementing long-term migraine treatment strategies (2) reducing the chances of ECC facilitated drug dependencies, and (3) reducing unnecessary migraineur ECC visits.

SELF-PERCEPTIONS AND GENDER-ROLE STEREOTYPES OF PAIN IN PHYSICIANS AND DENTISTS

Danielle M. Wesolowicz, M.S., Jaylyn F. Clark, M.S., Jeff Boissoneault, Ph.D., Michael E. Robinson, Ph.D.

University of Florida, Gainesville, FL

Introduction: Research suggests that women are seen to be more sensitive and willing to report pain, and less able to endure pain compared to men. Such stereotypical views among healthcare providers may influence clinical decision making, with some studies suggesting providers of both genders see women as more likely to exaggerate their pain. A provider's perception of their own pain experience may affect their assessment of a patient's pain. Further, providers may act more empathic towards members of their own in-group (e.g., same gender); for example, both male and female providers are more likely to prescribe analgesics to patients of their same gender. Thus, the goal of this study was to determine how healthcare providers perceive their own gender-related pain attributions.

Methods: 169 practicing physicians and dentists (80 physicians, 40% women) were recruited to participate in an online study on assessment and clinical decision making in pain management. Participants completed a demographic questionnaire and the Gender Role Expectations of Pain (GREP) Questionnaire, which asks participants to rate their own willingness to report pain, sensitivity to pain, ability to endure pain compared to the typical man and the typical woman.

Results: A MANOVA was run for each pair of GREP questions related to willingness, sensitivity, and endurance of pain. Compared to their same sex, both men and women rated themselves as more willing to report pain ($F_{(1,165)}=5.692$, $pd=.182$), and female providers rated themselves as more willing to report pain compared to other women, but not men ($F_{(1,165)}=12.323$, $pd=.546$). For pain sensitivity, female providers rated themselves as less sensitive to pain than other women, and male providers rated themselves as more sensitive to pain than other men ($F_{(1,165)}=4.347$, $pd=.327$). No effects of provider sex on endurance were found.

Discussion: These findings suggest healthcare providers have differential stereotypical views of gender-related differences in pain in relation to themselves and when compared to members of the same sex. Female providers viewed other women as less willing to report and more sensitive to pain than themselves, and male providers viewed other men as less willing to report and less sensitive to pain than themselves. Perception of pain in patients can be influenced by a provider's own experience of pain, and differential views of the pain experience in patients based on the patient's sex may influence clinical decision making. Future work can refine the effects of social learning history and other psychosocial factors that contribute to gender and provider differences in pain management decisions.

THE CHRONIC PAIN MANAGEMENT SHARED MEDICAL APPOINTMENT: INTEGRATION OF OPIATE OVERDOSE EDUCATION

Delilah O. Noronha, Psy.D.¹, Elizabeth Oliva, Ph.D.²¹Department of Veterans Affairs, Palo Alto, Palo Alto, CA; ²VA Palo Alto Health Care System, menlo park, CA

BACKGROUND: In May 2014, in an effort to prevent opioid-related mortality, the Veterans Health Administration (VHA) launched a national Opioid Overdose Education and Naloxone Distribution (OEND) program that targeted two patient populations: (1) patients prescribed opioids and (2) patients with opioid use disorders (Oliva et al., 2017). OEND includes education on opioid overdose prevention, recognition, and response, including provision of naloxone. Naloxone is a lifesaving medication that has an excellent safety profile (e.g., is inert unless opioids are in the system) and if administered in a timely manner and in sufficient amount, it can reverse an opioid overdose and prevent death. These aspects have led to naloxone distribution to laypersons that includes FDA-approved layperson naloxone formulations (e.g., auto-injector and nasal spray). Notably, there is a tremendous amount of support for OEND within VHA with the recent Comprehensive Addiction and Recovery Act of 2016 (Public Law 114-198) eliminating copay requirements for Veterans receiving OEND (eliminates copays for both education as well as the medication) as well as a "Free-to-Facilities" naloxone initiative that provides naloxone—paid for by VHA Pharmacy Benefits Management Services—to be dispensed to VHA patients without the medical center incurring the cost of naloxone. With regards to patients prescribed opioids, as many patients receive opioids in primary care settings, there is increasing interest in understanding how to feasibly implement OEND in primary care. One promising approach is integration into Shared Medical Appointments (SMAs). SMAs are an effective way to educate patients within Primary Care settings. SMAs are group visits that typically are focused on chronic condition management (e.g. diabetes, insomnia). SMAs are unique to the primary care setting and are differentiated from mental health or psychoeducational classes as they include the following components: prescriber intervention, education and individualized treatment planning. For the purposes of this program evaluation, our primary care clinic sought to integrate OEND into a chronic pain SMA. The SMA is offered weekly however it is utilized as a one time or PRN visit that is facilitated by a health psychologist, MD or PharmD, and a registered nurse. The goals of this program evaluation are to examine the feasibility and acceptance of naloxone education and distribution within a chronic pain SMA.

METHOD: To examine feasibility, this program evaluation will describe the process by which OEND was integrated into a chronic pain SMA. This information can help inform future efforts to integrate OEND into primary care settings. To examine acceptability, we will examine how many patients accept an offer of a naloxone prescription after being trained in OEND during the SMA. To examine differences in pain and depression self-report between patients prescribed opiates and those who are not, we provide descriptive data for 283 patients who attended the SMA between July 2014 and July 2017. This chronic SMA did provide psychoeducation on risks of opiates use and reviewed universal precautions but did not provide OEND training and naloxone prescription. This data was not complete as only a portion of data were not entered into the data base thus the total number of patients who attended the SMAs during this time frame is greater than sample presented in this program evaluation.

RESULTS: Feasibility—While the chronic pain SMA was initiated in 2009, in 2016 the clinic began discussion of how to integrate OEND into their primary care setting. The health psychologist who chairs the primary care pain program reached out to the VHA National OEND Coordinator and facilitated discussion with the primary care clinic pain committee. The committee decided that integration into the chronic pain SMA was a promising approach and that a clinical pharmacist and clinical psychologist trained in OEND would be best suited to lead the SMA. In the summer of 2017 the process was operationalized and OEND was integrated into an existing chronic pain SMA. Notably, this chronic pain SMA is a mixed group of some of which do and do not receive opioids from VHA. In September 2017, 9 of 15 patients accepted naloxone kits at the chronic pain SMA which integrated the OEND training (See table 1). Acceptability—Among the 15 patients that attended the SMA with integrated OEND training (3 were prescribed opioids by VHA; and 5 others had risk factors for accidental overdose for themselves or someone else), 9 accepted naloxone prescription. With regard to differences in self-report measures among patients prescribed opiates and those who are not between 2014–2017—When patients who attended were divided into those who had active prescriptions for opiates and those who did not, the two groups were similar in their PEG and PHQ-9 scores (See tables 2 and 3). **DISCUSSION:** These results suggest that an SMA approach to OEND in primary care is feasible and acceptable to patients. Notably, even patients who were not receiving opioids from VHA were interested in a naloxone prescription

(at least one of these patients was considering seeking opioids outside of VHA). These findings build upon previous work in this area that found that the majority of patients receiving opioids for ≥ 3 months (including patients receiving opioid substitution treatment as well as prescription opioids for pain) were interested in obtaining naloxone (Tiffany et al. 2015). Our preliminary findings suggest that OEND may be an intervention to offer broadly to patients with pain conditions. Given that patients with pain conditions—including those who do as well as those who do not receive opioids from their primary care provider—may seek opioids from other places and/or have conditions that may increase risk for overdose (e.g., sedative prescriptions, sleep apnea, etc.), universal OEND training may be warranted to increase awareness about risk for overdose and ways to mitigate risk. With regard to PHQ-9 and PEG scores, both patients who do and do not receive opioids appear to have similar scores across these measures. Thus SMAs for patients, regardless of opiate use status, may be helpful as these appointments may also assist in identifying and addressing other risk factors and assist in comprehensive treatment planning. For example, a patient in pain who is not using opiates may be experiencing depression which can be addressed as part of his/her pain management plan that is developed in the SMA. This program evaluation demonstrates the following: 1) patients may accept naloxone kits regardless if they are actively using opiates and 2) patients appear to have similar self-perceptions of pain and depression regardless of use of opiates and 3) it is feasible to integrate OEND training into an existing primary care SMA.

THE IMPACT OF AGE OF MIGRAINE ONSET ON SYMPTOMOLOGY AND DIAGNOSIS DELAY

Paige Barrette, N/A¹, Joseph Patrick. McNabb, Student², Daniel Hernandez Al-tamirano, Student³, Amrita Bhowmick, MPH⁴, Amy Wachholtz, PhD²

¹University of Colorado Denver, Highlands Ranch, CO; ²University of Colorado Denver, Denver, CO; ³University of Colorado Denver, Thornton, CO; ⁴Health Union, LLC, Chapel Hill, NC

Introduction: Migraines are a common disorder and considered one of the most disabling diseases. Even with a high prevalence rate, migraines are still misdiagnosed especially in the pediatric population who often present with atypical symptoms. This study aimed to examine symptomology variances among age of migraine onset groups as well as the time from migraine onset until a formal diagnosis was made; hypothesizing that childhood onset have a longer time until diagnosis and a wider spectrum of symptoms compared to adulthood onset.

Method: 4,502 adult participants were recruited from an online migraine specific website. An adaptive retrospective self-report survey included questions on demographic characteristics, migraine incidence, symptomology, diagnosis and treatments. Composite variables were generated that examined the age of migraine onset and time until diagnosis. Cohorts were formed based on migraine symptom onset age: childhood (0–12 years), adolescent (13–18 years), and adulthood (19+ years). Data were analyzed using one-way ANOVA and regression analysis based on age of onset cohort.

Results: Symptoms were significantly different among onset age groups with childhood onset experiencing higher rates and variety of symptoms such as Alice in Wonderland Syndrome ($p < .00$, $\eta^2 = 0.123$), Moderate/Severe Nausea ($p < .00$, $\eta^2 = 0.108$), Vomiting ($p < .00$, $\eta^2 = 0.122$) and Sensitivity to Smell ($p < .00$, $\eta^2 = 0.156$). Atypical symptoms were more often experienced in childhood onset while “typical” symptoms (e.g. photophobia, phonophobia) were more often found in adult onset. Diagnostic timelines showed that 27.8% of childhood onset reported 15+ years between symptom onset and diagnosis compared to 5.7% in the adult onset group. 23.9% of the adult onset reported less than six months between symptom onset and diagnosis compared to 7% in the childhood onset.

Discussion: This study uniquely allowed us to capture a population of migraineurs who experienced migraine symptoms in childhood but may not have been diagnosed immediately. These findings show a negative correlation between age of migraine onset and length of time until a diagnosis is received. The variance in experienced symptoms among age cohorts could explain the negative correlation. Common diagnostic tools and symptom markers used for adults may be insufficient or inaccurate for pediatric diagnostics. Further understanding of these symptom differences may decrease diagnostic delays in the pediatric population.

THE LONGITUDINAL EFFECTS OF SYMPTOM DURATION AND SELF-EFFICACY ON PAIN AND FUNCTION IN WOMEN WITH FIBROMYALGIA

Charles Van Liew, GCAS, MA, MA¹, Gabriel Leon, B.S.², Mikayla Neese, B.S.¹, Terry Cronan, Ph.D.³¹Grand Canyon University, Phoenix, AZ; ²Grand Canyon University, Peoria, AZ; ³San Diego State University, San Diego, CA**Objective:** To determine whether the effects of symptom duration on fibromyalgia physical impairment are moderated by symptom self-efficacy.**Method:** Participants included 572 females who were members of a large health maintenance organization that had a diagnosis of fibromyalgia syndrome (FMS) and met inclusion criteria for the study. Age, symptom duration, history of physical, sexual, and emotional abuse, fibromyalgia-specific self-efficacy (Arthritis Self-Efficacy Scale adapted for FMS [ASES]), depression (Centers for Epidemiological Studies Depression Scale [CES-D]), fibromyalgia physical impairment (Fibromyalgia Impact Questionnaire [FIQ]), and pain (McGill Present Pain Index [PPI]) were measured five times across 18 months.**Results:** Linear regressions were performed to predict baseline FIQ and PPI cross-sectionally. Of primary interest was a hypothesized interaction between ASES and symptom duration, which was significant in relation to FIQ but not PPI. Multilevel mixed models were performed to determine whether the same pattern existed longitudinally controlling for baseline symptom duration as an effect of time and ASES. The interaction was significant in the models for both FIQ and PPI.**Conclusion:** These results suggest that the effects of age and symptom duration on FMS are unique, and that self-efficacy plays a crucial role in moderating disease course (measured by symptom duration or time) in FMS.

THE ROLE OF SELF-COMPASSION IN FUNCTIONING AMONG THOSE WITH CHRONIC PAIN

Karlyn A. Edwards, B.A., Melissa Pielech, M.S., Eric Kruger, DPT/M.S., Graham Ford, M.S., Kevin Vowles, PhD

University of New Mexico, Albuquerque, NM

Previous research has shown that self-compassion is associated with improved functioning and health outcomes among multiple chronic illnesses, such as inflammatory bowel disease, celiac disease, and cancer. However, the role of self-compassion, and particularly the use of the Self-Compassion Scale, has been understudied in those with chronic pain. The present study seeks to understand the association between self-compassion and important measures of functioning within a chronic pain sample. Treatment-seeking individuals (N= 343) that were mostly White (97.9%) and female (71%) with chronic pain completed a battery of assessments that included the Self-Compassion Scale (SCS), as well as measures of pain-related fear, depression, disability, pain acceptance, success in valued activity, and use of adaptive pain coping strategies. Cross-sectional multiple regression analyses that controlled for age, sex, average pain intensity in the last seven days, and pain duration, revealed that self-compassion did account for a significant and unique amount of variance in all measures of functioning (r^2 range: .060 – .321, all $p < .001$). Inspection of beta weights indicated that higher self-compassion was associated with lower pain-related fear, depression, and disability, as well as greater pain acceptance, success in valued activities, and utilization of adaptive pain coping strategies. These findings suggest that self-compassion may be a relevant adaptive process in those with chronic pain. Further, it is possible that improving self-compassion over the course of treatment may be of benefit to those with chronic pain.

VARIATIONS IN MIGRAINE TREATMENT METHODS USED BY SOCIOECONOMIC STATUS GROUPS

Daniel Hernandez Altamirano, Student¹, Joseph Patrick. McNabb, Student², Paige Barrette, Student³, Amrita Bhowmick, MPH⁴, Amy Wachholtz, PhD²¹University of Colorado Denver, Thornton, CO; ²University of Colorado Denver, Denver, CO; ³University of Colorado Denver, Littleton, CO; ⁴Health Union, LLC, Chapel Hill, NC**Introduction:** Previous research suggests that lower SES individuals have an increased migraine risk yet may face limited treatment options. Analyzing what treatment methods migraineurs use in relation to their SES may reveal treatments that are underutilized by certain SES brackets. It was hypothesized that lower SES brackets used less treatment methods.**Method:** SES, demographics, migraine, and treatment data were collected on 3549 adult US-based participants in the 2015 Migraine.com survey. Annual income levels were organized to establish SES: <\$30k(19.4%), \$30k-50k(18.6%), \$50k-75k(22.5%), \$75k-100k(15.3%), and \$100k+(24.2%).**Results:** Several treatment methods had significant differences within SES brackets such as acute prescription medication($F(4,3544)=13.0$, $p=.00$), with less use in <\$50k ($p<.05$); onabotulinum toxin A($F(4,3544)=13.6$, $p=.00$), with less use in <\$50k ($p<.05$); head-based TENS units($F(4,3544)=3.8$, $p<.05$), with \$30k-50k using less than higher SES group ($p<.05$); unprescribed substances (eg, THC, alcohol; $F(4,3544)=8.6$, $p=.00$), with <\$30k using more ($p<.05$); complementary and alternative medicine(CAM; $F(4,3544)=9.8$, $p=.00$), with less use in <\$75k ($p<.05$); and rescue prescription medications ($F(4,3544)=4.8$, $p<.05$), with more use in \$100k+ ($p<.05$); OTC medication showed no SES differences($p=ns$). Preventative medications only had differences between the <\$30k and \$100k+ SES groups($F(4,3544)=1.9$, $p<.05$).**Discussion:** Migraineurs earning <\$30k are more likely to self-medicate using illicit drugs, alcohol, or marijuana. As prescribers increase efforts to educate migraineurs on better treatment options such as pain management psychotherapy, we may reduce self-medicating among lower-SES migraineurs. TENS units may also provide a future treatment option that has efficacy with minimal likelihood of abuse. Low SES migraineurs are less likely to be prescribed rescue medications (e.g., opioids). Efforts to increase preventative medications (e.g., beta blockers) and CAM among low-SES has long-term treatment potential and less risk of abuse. It may also be worth exploring and identifying CAM treatments that are used among the lowest SES group that may include treatments not traditionally assessed by CAM studies. While CAM efficacy varies depending on the treatment, the risk of secondary gains is low. Identifying underutilized treatments in SES brackets can lead to discussions for treatments not previously explored, increasing migraineurs' treatment options.

ENHANCEMENTS IN CARDIOVASCULAR FITNESS AND COGNITIVE, SOCIAL, AND EMOTIONAL FUNCTION FOLLOWING EXERCISE IN OLDER ADULTS

Casey K. Gardiner, MA¹, Sophie YorkWilliams, MA², Genevieve Bennett, B.A.³, Timothy Helmuth, BA⁴, Audrey Davis, BA¹, Gregory Giordano, MS⁵, Angela Bryan, PhD⁶

¹University of Colorado Boulder, Boulder, CO; ²University of Colorado Boulder Boulder, Boulder, CO; ³University of Colorado Boulder, Denver, CO; ⁴University of Colorado, Boulder, Broomfield, CO; ⁵University of Colorado Boulder, Loveland, CO; ⁶University of Colorado Boulder, BOULDER, CO

Physiological and neurocognitive changes experienced as a result of increasing age may influence socio-emotional functioning and economic behaviors, yet the mechanisms through which these changes occur are not well understood. Studies have also shown that aerobic exercise may protect against age-related cognitive decline in other domains. The FORCE trial is designed to test the hypothesis that aerobic exercise will enhance social, emotional and economic functioning in older adults, including testing the potentially differential effects of exercise intensity on physiological and psychosocial outcomes. Sedentary adults ($n = 84$) aged 60 and over (range 60 – 88, $M = 69.73$) were randomly assigned to one of two 16-week supervised exercise interventions: low intensity continuous training (LICT) or moderate intensity continuous training with interval training (MICT+IT). At baseline and the end of the intervention, participants completed a maximal exercise test (i.e., VO_{2max} testing) and a battery of measures assessing cognitive, social, emotional, and economic function.

Participants increased their maximal exercise capacity from pre- to post-intervention [$F(1,82) = 16.16, p < .001$], and this effect was qualified by a time X condition interaction [$F(1,82) = 12.13, p = .001$], such that those completing MICT+IT had greater gains in cardiorespiratory fitness than those completing LICT. Importantly, aerobic fitness, cognitive function, and well-being were related over time. Performance on a measure of executive function improved from pre- to post-intervention [$F(1,74) = 12.38, p = .001$]. Following the intervention, stronger aerobic fitness was associated with higher performance on a measure of economic function [$r(82) = .285, p = .009$], and there was a trending relationship between executive and economic function [$r(79) = .201, p = .08$]. Enhancements in maximal exercise capacity from pre- to post-test were associated with decreased depressive symptoms at post-test [$r(82) = -.281, p = .01$]. These findings highlight the synergistic relationships between physiological, cognitive, socio-emotional, and economic function in older adults. Importantly, they indicate promise for interventions including moderate intensity exercise with interval training among older adults, and the results suggest that salutary effects of physical exercise can be achieved even if it is started later in life.

A SYSTEMATIC REVIEW AND META-ANALYSIS OF THE OUTCOME EXPECTANCY CONSTRUCT IN PHYSICAL ACTIVITY RESEARCH

Lauren Connell, PhD¹, Jessica A. Emerson, MS², Dr. Ryan E. Rhodes, PhD³, David Williams, Ph.D.⁴

¹The Miriam Hospital and Alpert School of Medicine at Brown University, Providence, RI; ²Brown University, East Providence, RI; ³University of Victoria, Victoria, BC, Canada; ⁴Brown University School of Public Health, Providence, RI

BACKGROUND: Cognition-based theories dominate health behavior change research, including physical activity research. Beliefs about the consequences of behavior (e.g. outcome expectancies, perceived benefits and barriers) are a common feature of such theories. It is important to examine whether the literature supports the outcome expectancy construct as a predictor of behavior.

AIM: This study reviewed observational (i.e. non-intervention) reports of longitudinal associations between outcome expectancy beliefs and physical activity in adults. Studies were eligible if (a) the target behavior was a form of physical activity, (b) beliefs about the consequences of physical activity behavior were measured, and (c) beliefs were measured at a time point prior to physical activity.

METHODS: Literature searches were conducted in November 2016 in seven relevant databases. This search yielded 3,380 references, 873 of which underwent full-text review by two independent coders. Of these, 23 observational studies met the inclusion criteria. Random effects meta-analysis produced an overall effect of outcome expectancy on physical activity across all studies.

RESULTS: The 23 studies were published between 1989 and 2016, with sample sizes ranging from 19 to 1,193. Studies assessed different types of positive and negative outcome expectancy beliefs including those related to weight, health, time commitment, affect, enjoyment, social, physical and self-evaluative beliefs. Looking across all types of beliefs, a positive association was identified ($r = 0.13$; 95% CI [0.037, 0.221]). Examining only those studies which assessed positive beliefs about physical activity, a positive association was identified ($r=0.18$; 95% CI [0.118, 0.237]), and within studies which assessed negative beliefs, a negative association was identified ($r= -0.11$; 95% CI [-0.204, -0.010]).

CONCLUSIONS: The results indicate a small effect size for the association between outcome expectancy beliefs and physical activity in the context of observational studies. Many studies were not included in the meta-analysis due to an explicit lack of reporting of non-significant effects. Given the number of studies failing to report non-significant associations, and the potential number of studies never published due to non-significant results, this small effect size may be an overestimation of the effect. Findings raise questions about the extent to which outcome expectancies influence physical activity behavior.

CORRELATES OF MUSCLE-STRENGTHENING ACTIVITIES AMONG LATINAS ENROLLED IN A FAITH-BASED PHYSICAL ACTIVITY INTERVENTION

Tanya J. Benitez, PhD, MSW¹, Nanette Lopez, PhD, MS/MS², Jessica Haughton, MPH, MA³, Bess H. Marcus, Ph.D.⁴, James F. Sallis, PhD⁵, Noe Crespo, PhD³, Lilian Perez⁶, Elva Arredondo, PhD³

¹University of California San Diego, La Jolla, CA; ²University of Southern California, San Diego, CA; ³San Diego State University, San Diego, CA; ⁴Brown University, Providence, RI; ⁵UC, San Diego, La Jolla, CA; ⁶National Cancer Institute, Arlington, VA

Introduction: Despite the health benefits of regular physical activity (PA), only 12.2% of Latinas meet the national guidelines for both aerobic and muscle-strengthening PA. Increasing evidence indicates that engaging in muscle-strengthening PA can produce greater health improvements than aerobic alone, including improvements in insulin sensitivity, HbA1c, blood pressure, and reducing mortality risk. While most PA interventions in Latinas have focused primarily on increasing aerobic PA, there is a need to help Latinas achieve the full PA guidelines. The purpose of this analysis was to examine correlates of muscle-strengthening PA among participants enrolled in *Fe en Acción*, a randomized controlled trial of a faith-based intervention promoting aerobic and muscle-strengthening PA in Latina adults.

Methods: Using baseline data from *Fe en Acción*, we examined the association between behavioral/psychosocial factors and participants' level of muscle-strengthening PA (i.e., engaging in strength PA one day/week or none at all vs meeting the national guidelines of ³2 days/week). Independent samples T-tests were used to examine associations between continuous variables (demographics, social support, behavioral strategies, self-efficacy, diet) and muscle-strengthening activities. Differences in categorical variables (marital status, employment, acculturation, health status) and levels of muscle-strengthening PA were assessed using Chi-Square tests.

Results: Participants (N = 436) were Latina women (77% married) ages 18–65 (44.4 ± 9.6 years) who were recruited from Catholic churches in San Diego, California. At baseline, 3.2% (n = 14) reported performing muscle-strengthening PA on one day/week and 19% (n = 83) met the national guidelines for muscle-strengthening PA. Participants who performed muscle-strengthening PA on ³2 days/week reported significantly higher social support for PA (M = 1.65 vs 1.23, t(429) = -3.14, p = .002), use of behavioral strategies for PA (M = 4.80 vs 2.86, t(404) = -6.44, p < .001), consumption of fruits (M = 3.77 vs 3.33, t(427) = -2.37, p = .018), and lower barriers to PA (M = 21.51 vs 25.35, t(238) = 2.21, p = .028) compared to those who did not meet the national guidelines for muscle-strengthening activities.

Conclusion: The same psychosocial variables commonly associated with aerobic PA were also significantly related to muscle-strengthening PA among Latinas. One implication is that similar strategies can be used to promote both types of PA.

PSYCHOSOCIAL OUTCOMES FOLLOWING A RANDOMIZED PILOT TRIAL TO REDUCE SITTING TIME IN OLDER ADULTS WITH OBESITY

Theresa E. Matson, MPH¹, Anne D. Renz, MPH¹, Melissa L. Anderson, MS², Mikael A. Greenwood-Hickman, MPH¹, Jennifer B. McClure, PhD¹, Dori E. Rosenberg, PhD, MPH¹

¹Kaiser Permanente Washington Health Research Institute, Seattle, WA; ²Kaiser Permanente WA Health Research Institute, Seattle, WA

Introduction: Sedentary behavior is characterized by prolonged periods of sitting and is associated with poor health and higher risk of mortality, independent of physical activity. Older adults with obesity spend more time sitting than any other demographic, making them particularly vulnerable to health consequences. Behavioral theories suggest that psychosocial factors are important for promoting changes in physical activity, and these constructs are often the target of interventions. However, little is known about the relationship between psychosocial factors and sitting time. Therefore, we assessed whether psychosocial factors were impacted after participation in a 12-week sedentary behavior reduction intervention (I-STAND) for older adults.

Methods: Adults (n = 60) age 60–89 with a BMI ≥ 30 kg/m² were randomized to I-STAND or a healthy living control group. I-STAND participants received 6 health coaching sessions, a study workbook, a Jawbone UP band to prompt breaks from sitting, and activPAL feedback on sitting time. At baseline and 12-week follow up, participants completed a survey with scales measuring psychosocial factors: perceived benefits (6 items) and barriers (4 items), self-efficacy (9 items), and habit strength (10 items) regarding sitting time. Validated measures do not currently exist for older adult sitting time, so psychosocial scales were modified from other health behaviors (e.g., physical activity). Responses were scored on a 5-point Likert scale and averaged for analyses. Linear regression assessed associations between group assignment and average score for each psychosocial scale at 12-week follow up, adjusting for baseline scores.

Results: At 12-week follow up, I-STAND participants had higher self-efficacy (β=0.35, 95% CI: 0.09–0.61, p<0.01) and reduced habit strength (β=0.23, 95% CI: 0.03–0.43, p=0.02) compared to control participants. There were no differences in perceived benefits or perceived barriers to reducing sitting time.

Conclusions: A sedentary behavior reduction intervention for older adults improved confidence to reduce sitting time and reduced the strength and automaticity of sedentary habits in this pilot study, however the effects were small. More research is needed to understand whether these psychosocial constructs translate to changes in sitting time.

THE RELATIONSHIP BETWEEN MODERATE-TO-VIGOROUS PHYSICAL ACTIVITY AND TIME-ON-TASK ON ACADEMIC ACHIEVEMENT

Amanda N. Szabo-Reed, Ph.D.¹, Erik A. Willis, PhD, MPH², Jaehoon Lee, Ph.D.³, Charles H. Hillman, Ph.D.⁴, Richard Washburn, PhD⁵, Joseph Donnelly, ED.D.⁶

¹University of Kansas Medical Center, Lenexa, KS; ²Cancer Prevention Fellowship Program, Division of Cancer Prevention, Metabolic Epidemiology Branch, Division of Cancer Epidemiology & Genetics, National Cancer Institute, Rockville, MD; ³Texas Tech University, Lubbock, TX; ⁴Northeastern University, Boston, MA; ⁵University of Kansas Medical Center, Lawrence, KS; ⁶University of Kansas Medical Center, Kansas City, KS

Objective: To determine the impact of classroom-based physical activity and time on task (TOT) following activity on academic achievement.

Methods: Seventeen elementary schools were cluster randomized to a 3-yr. classroom based physical activity intervention ($n=9$) or non-active control ($n=8$). Classroom teachers were trained to deliver academic instruction using moderate-to-vigorous physical activity (MVPA) with a target of 100+ min./wk.⁻¹. Duration and intensity of active lessons and time spent on task pre and post lesson were assessed by direct observation across 3 yrs. Academic achievement in math, spelling, and reading (Wechsler Individual Achievement Test-III) was assessed at baseline and repeatedly each spring for 3 yrs. Multilevel modeling was utilized to estimate (linear) change in academic achievement over the study period, the effect of time spent in MVPA (percent), or TOT post-lesson (percent), and their interaction on academic achievement, controlling for dependency among observations and covariates including age, gender, race, free or reduced lunch, BMI (percentile), and aerobic fitness (PACER).

Results: Children ($n=319$ intervention and $n=314$ control) were 7.57 ± 0.58 years old, 50.6% girls, 81.4% White, and 28.4% receiving free/reduced meals at baseline. Multilevel modeling revealed that spending more time in MVPA (percent) was associated with higher math ($p<.05$) and spelling scores ($p<.001$), but not reading scores when controlling for age, gender, race, free/reduced meals, BMI and aerobic fitness. With regards to covariates, math scores were significantly higher in boys when compared to girls ($p=.036$). Students receiving free/reduced meals had significantly lower scores in reading, spelling, and math when compared to students who did not (all $p<.01$). Greater aerobic fitness was significantly associated with higher scores in math and spelling (all $p<.05$). Age, gender, race, and BMI on were not significantly associated with academic achievement. TOT was not associated with academic achievement scores.

Conclusion: These findings suggest that participating in MVPA delivered in the form of physically active classroom lessons were associated with better achievement in math and spelling in elementary school children. Future studies should continue to evaluate the influence of physical activity in the classroom and TOT behaviors and its impact on academic achievement to determine the sustainability of physical activity's effect on classroom behavior.

ACCELEROMETER MEASURED SEDENTARY TIME, SELF-REPORTED PHYSICAL FUNCTION AND QUALITY OF LIFE IN AFRICAN AMERICAN OLDER ADULTS

Neha P. Gothe, MA, PhD

University of Illinois at Urbana Champaign, Urbana, IL

Purpose: Sedentary time has been increasingly recognized as a distinct health risk behavior. The purpose of this study was to determine the associations between accelerometer measured sedentary, light and moderate-vigorous physical activity (PA) and self-reported physical function and quality of life among older adult cohorts.

Methods: African American older adults ($N=110$, Mage: 64.7 ± 5.7 ; males =14) completed the Late-life Function and Disability Instrument (LLFDI) and the SF-36 health related quality of life. Sedentary time and PA were assessed objectively using a 7-day accelerometer wear period and scored using the NHANES cut-offs for sedentary (<100), light (101–2019) and moderate-vigorous PA (>2020 activity counts/minute).

Results: Within the younger cohort ($N=55$, Mean age=60.07), sedentary time significantly correlated with the LL-FDI, total disability frequency ($r=-.49$, $p<.001$) and limitation ($r=-.28$, $p=.04$). MVPA was associated with the LL-FDI subscales within the older cohort ($N=55$, Mean age=69.47) but not in the younger cohort. Both light PA and MVPA were associated with total function score on the LLFDI for the younger cohort. On the SF-36, sedentary time ($r=-.32$, $p=.02$) and MVPA ($r=.32$, $p=.01$) were associated with general health for the younger cohort, whereas light PA was associated with physical functioning ($r=.28$, $p=.04$) and general health ($r=.36$, $p=.01$) within the older cohort.

Conclusion: Although sedentary time and light PA were not significantly different between the two cohorts of older adults, it showed unique associations with self-reported physical function and quality of life within the younger (< 64.5 yrs) and older (> 64.5 yrs) participants. Examining sedentary time and light PA along with MVPA can provide significant information for designing future health and PA interventions within different cohorts of older adult populations.

ASSOCIATIONS BETWEEN SLEEP AND ACTIVITY: EVALUATING BETWEEN- AND WITHIN-PERSONS RELATIONSHIPS

Stephanie Kerrigan, M.S.¹, Bradley Appelhans, PhD²

¹Drexel University, Philadelphia, PA; ²Rush University Medical Center, Chicago, IL

Physical activity (PA) and sleep are important predictors of overall health. Prior research suggests a bidirectional relationship between sleep and activity, with most research focused on the sleep-related benefits of increased PA. The potential influence of sleep on PA has received less attention. Using data from an observational study of community adults, the present analysis: (1) tested the between-person associations between sleep parameters and activity (average counts per minute, and counts per minute during morning [7am-12pm], afternoon [12pm-5pm], and evening [5pm-10pm] windows), (2) examined the within-person relationship between activity and sleep on the preceding night, and (3) examined the within-person relationship between sleep and activity the preceding day. Daily sleep actigraphy and accelerometer data were available on 729 participant-days across 169 participants (age: $M=44 \pm 13$; 82.0% female; 65.4% ethnic minority). Controlling for age, sex, and weekday/weekend, higher average PA was associated with increased average sleep latency ($p = .02$) and decreased average sleep efficiency ($p = .04$), but not average total sleep time. Increased sleep latency was associated with greater evening activity ($p = .01$) and decreased sleep efficiency was associated with increased afternoon ($p = .03$) activity. Within-persons, increased total activity was predicted by increased sleep latency ($p = .05$) and decreased efficiency ($p < .01$) and total sleep time ($p = .03$) during the night prior. Within-persons, sleep latency, efficiency, and total sleep time were not predicted by total activity. Collectively, poorer sleep predicted increased activity on the following day, whereas sleep was not predicted by PA within-persons. It may be that other measures of activity, e.g., bouts of cardiovascular activity, predict sleep while total activity does not. Future research should explore whether other activity behaviors help to explain sleep-activity relationships, whether prescribed changes in PA behaviors alter sleep outcomes, and what explains the negative relationship between sleep and activity.

EFFECTS OF GENETIC RISK AND SOCIAL ENVIRONMENTAL FACTORS ON PHYSICAL ACTIVITY IN AFRICAN-AMERICANS ADULTS

Cody M. King, Student¹, Tyler McDaniel, M.S.², Dawn K. Wilson, Ph.D.,
FSBM², Raines M. Waggett, Student², Sandra Coulon, Ph.D.³

¹Clemson University, Clemson, SC; ²University of South Carolina,
Columbia, SC; ³Medical University of South Carolina, Charleston, SC

Given current national trends in health disparities, it is important to examine factors that may promote physical activity (PA) in underserved (low-income, minority) populations. Genetic and environmental neighborhood risk likely interact to influence PA, though these effects have not been studied as a function of the neighborhood context in underserved African-American communities. This study specifically expands on prior research by using an established measure of genetic risk shown to be dependent on environmental conditions in healthy adults (Li et al., 2010), in order to understand potential gene-by-environment effects in African-American populations. The purpose of the present study was to examine the effects of genetic risk for obesity (using the Li Index) and social environmental factors (walkability, neighbor social support for walking) on moderate-to-vigorous (MV) PA in African-American adults who took part in the Positive Action for Today's Health (PATH) trial, an environmental intervention to increase walking. Buccal swabs were used to collect genetic data and twelve single nucleotide polymorphisms (SNPs) were genotyped using an established obesity-risk Li index. MVPA was assessed using 7-day accelerometry estimates. Regression analyses were conducted to examine the relationship between genetic risk and environment factors on MVPA after controlling for intervention and community. The sample included 223 participants (59% female; BMI $M=31.0$, $SD=7.4$; age $M=51.7$, $SD=15.6$). On average participants completed less than one year of college (68%) and had less than \$25,000 annual family income per year (65%). The overall regression model for PA was significant ($F [11, 211] = 10.44$, $p < 0.05$), and accounted for approximately 32% of variance. The genetic Li Index was a significant predictor of MVPA ($B = -26.90$, $SE = 13.15$, $p < 0.05$), and lower genetic risk was associated with greater MVPA overall. Additionally, neighborhood social support ($B = 4.26$, $SE = 2.37$, $p=0.07$) and places for walking and cycling ($B=5.25$, $SE = 2.80$, $p=0.06$) were marginally significant for predicting MVPA, and may also be important factors to consider in future investigations. Continued research is needed to better understand the potential mechanisms underlying these genetic and social environmental environmental effects which may inform community-based interventions and policy efforts for promoting PA in underserved African-American communities.

EXERCISE PRESCRIPTION FOR BREAST CANCER SURVIVORS TAR- GETING CARDIOVASCULAR HEALTH INDICATORS: A SYSTEMATIC REVIEW

Kate Dibble, M.A., Linda Pescatello, PhD, FACSM, FAHA

University of Connecticut, Storrs, CT

Breast cancer is the most common cancer among women affecting 1 in 8 women, with an estimated 252,710 new cases in 2017. Advances in early detection and treatment have resulted in a 10-year survival rate of 80%. Yet, survivors remain at increased risk for long-term cardiovascular disease (CVD) complications due to these treatments. Physical activity is an important treatment component for certain types of cancer including breast cancer and CVD. The purpose of this study was to conduct a systematic review of the cardiovascular health benefits of exercise among breast cancer survivors who had undergone treatment. A literature search was conducted to locate 367 articles relevant to breast cancer survivorship, physical activity, and indicators of cardiovascular health. Inclusion criteria were studies examining breast cancer survivors that completed treatment within 10 years; including an aerobic, resistance, or concurrent exercise intervention; and investigating cardiovascular health indicators. A total of 23 randomized controlled trials qualified, all following the American College of Sports Medicine (ACSM) recommendations of at least 30–60 minutes/day of moderate-to-vigorous intensity exercise for at least 5 days/week. No intervention included solely resistance regimens. Eleven interventions involved aerobic exercise only (47.8%), 12 combined aerobic and resistance (52.1%), and one combined aerobic and flexibility (4.3%) training. All samples consisted of breast cancer survivors aged 18+ yr from a variety of ethnic/racial groups [Caucasian ($n=15$, 65.2%), African American ($n=2$, 8.6%), Asian ($n=1$, 4.3%); Latina ($n=3$, 13%); Not reported ($n=2$, 8.6%)]. Length of the exercise interventions varied widely from 8 weeks to 3 years and measured cardiorespiratory function baseline, post-intervention, and at intervals (dependent on the length of intervention). Aerobic-only ($n=11$) and aerobic-combination intervention reported significant improvements in peak oxygen consumption, blood pressure, resting HR, forced vital capacity, and expiratory volume. Out of the 12 concurrent interventions, 7 (58.3%) reported improvement in cardiovascular health (VO_2 max, cholesterol, BMI, etc.), 3 (25%) noted enhanced muscle strength and endurance, and 2 (16.7%) improvements in fasting glucose. Data are currently being extracted and analyzed regarding the influence of different types of physical activity on treatment-related CVD indicators. Adherence to the ACSM exercise recommendations for breast cancer survivors resulted in improved cardiovascular health benefits that may have a favorable impact on survivorship.

EXERCISE SELF-EFFICACY GROWTH TRAJECTORIES AFTER 20 HOURS OF COGNITIVE TRAINING

Tiffany Bullard, B.S.¹, Jason D. Cohen, B.S.², Daniel Palac, MA³, Arthur Kramer, PhD⁴, Edward McAuley, PhD¹, Sean P. Mullen, PhD¹

¹University of Illinois at Urbana-Champaign, Urbana, IL; ²University of Illinois at Urbana Champaign, Champaign, IL; ³University of Illinois at Urbana-Champaign, Champaign, IL; ⁴Northeastern University, Boston, MA

Exercise self-efficacy (SE) is one's perception of his or her own ability to regularly exercise. It has been well-established that exercise SE has a tendency to be inflated at the start of an exercise program, and drop at the end. To date, no randomized controlled trials have been designed to change SE through multimodal cognitive training (CT). The aim of the CORTEX trial was to increase exercise adherence for middle-aged adults through enhancing SE and self-regulation via a 20-hour CT program, relative to an attention control (health-related videos) group. All participants were then provided a 4-mo membership to a local fitness facility. A latent growth curve model (LGCM) was used to examine how exercise SE changed at crucial points of the program, assessed via the composite score of the *Exercise Self-Efficacy Scale* at the start of CT (m0), the start of the exercise program, after a month of exercise, and at program end (m5). When collapsed across all participants, irrespective of group, the slope was not significant, although SE decreased from program start ($M_0 = 82.96$) to end ($M_5 = 67.19$). However, group did have a significant impact on slope ($\beta = -3.32, p = .04$). To further explore this, we tested a second LGCM allowing for group differences and found the model fit the data ($\chi^2(13) = 17.12, p = .19, CFI = 0.972, SRMR = 0.068$). The CT and video group showed mean differences from baseline ($M_0 = 82.35$ vs. 83.59 , respectively) to program end ($M_5 = 68.86$ vs. $M_5 = 54.38$), with the CT group having a significant but less severe decline (slopes = -3.20 vs. $-6.37, p < .01$). Unlike the video group, the CT group showed an increase in exercise SE after CT, followed by less decline after the first month of exercise. A positive relationship was found between class attendance and SE change, indicating that smaller declines in SE were associated with higher class attendance in both groups; however, the CT group effect on this relationship was nearly twice the video group effect ($\beta = 4.27$ vs. $2.18, p < .01$). Consistent with prior research, exercise SE appears to decline at the start of an exercise program in the absence of intervention. Further declines are expected at program end in anticipation of non-supervised, fully self-regulated exercise. Future mind-body interventions should be designed to optimize the recalibration of SE levels and reserves, to prevent or attenuate these expected decreases in SE, at critical periods before, during and after an exercise program.

GOALS MATTER: EXERCISING FOR REVITALIZATION INCREASES AUTONOMY AND FUTURE EXERCISE BEHAVIOR AMONG PARENTS

Emily L. Mailey, PhD¹, Deirdre Dlugonski, PhD², Michelle Segar, PhD, MPH, MS³

¹Kansas State University, Manhattan, KS; ²East Carolina University, Greenville, NC; ³University of Michigan, Ann Arbor, MI

Objective: Many parents exhibit high levels of inactivity. Further research is needed to understand the goals that drive sustained exercise participation in this population. The purpose of this study was to examine the relationship between changes in parents' exercise goals, autonomous and controlled motivation, and exercise behavior across one year.

Methods: Mothers ($n=150$) and fathers ($n=46$) of children under age 16 completed the Exercise Motivations Inventory-2, the Behavioral Regulation in Exercise Questionnaire-2 and the Godin Leisure Time Exercise Questionnaire at baseline and one year later. A path analysis tested a model whereby changes in exercise goals (stress management, revitalization, positive health, ill-health avoidance, weight management, and appearance) were associated with changes in leisure-time exercise via changes in autonomous and controlled motivation.

Results: Increases in revitalization goals were associated with increases in autonomous motivation ($\beta=0.33, p<.05$), whereas increases in appearance goals were associated with decreases in autonomous motivation ($\beta=-0.18, p<.05$). Changes in weight-related goals were positively associated with changes in both autonomous ($\beta=0.29, p<.05$) and controlled motivation ($\beta=0.18, p<.05$). Changes in health-related goals were not associated with changes in either autonomous or controlled motivation. Changes in autonomous but not controlled motivation were positively associated with changes in exercise behavior ($\beta=0.26, p<.05$). Tests of indirect effects of goals on exercise behavior (via autonomous motivation) were significant only for revitalization goals (positive effect= $0.08, p=0.02$) and appearance goals (negative effect= $-0.05, p=0.03$).

Conclusions: Only revitalization goals were positively associated with both autonomous motivation and exercise behavior over time. These findings support recent calls to "rebrand exercise" as a means to improve daily well-being. By adopting exercise goals related to revitalization, as opposed to appearance, weight, or health, parents appear to be more likely to prioritize exercise because they value the immediate positive experiences it provides for themselves and their families. Thus, exercise promotion messages targeting parents should highlight the "feel-good" effects of exercise that are immediately noticeable and facilitate autonomous motivation, as opposed to appearance goals that may ultimately undermine autonomous motivation and behavior.

GROUP VIDEO CONFERENCING FOR EXERCISE DELIVERY IN YOUNG ADULTS WITH DOWN SYNDROME

Lauren T. Ptomey, PhD, RD, LD

University of Kansas Medical Center, Kansas City, MO

Between 250,000 and 400,000 individuals in the United States are diagnosed with Down syndrome (DS). Nearly all adults with DS will develop Alzheimer's disease (AD) pathology starting in their thirties. Recent studies suggest that increased physical activity (PA) may be important for maintaining components of cognition, including memory. However, PA rates of adults with (DS) are low, and effective strategies for increasing PA are limited. The purposes of this study were to assess the feasibility of group-based exercise sessions delivered remotely to young adults with DS and to evaluate changes in cognitive function after completion of a PA intervention. Participants were randomized to attend 30-minute group exercise sessions 1 or 2 times a week for 12 weeks. The exercise sessions were delivered via video conferencing on a tablet computer to groups of 5–8 participants. Groups were formed based on mutual time availability. The sessions were led by a health educator who was a specialist in adapted physical education and experienced in working with adults with DS. The 1 session/week and 2 sessions/week groups were conducted separately but led by the same health educator. Sessions consisted of a 5-minute warm-up, 20 minutes of MVPA (i.e., 3–6 METs), and a 5-minute cool-down period. The MVPA was comprised of aerobic based exercises such as walking and jogging to music, dancing, as well as strength based exercises such as vertical jumps, bicep curls, and squats. Exercise intensity increased progressively across the first 6 weeks of the intervention, then remained steady weeks 7–12. Cognitive function, was measured at baseline and end of study using the Cantab Dementia Battery for iPads, the specific variables measures were two paired associates learning variables, which assess the cognitive domain of memory, PALTEA and PALFAMS. Twenty-seven participants (27.9 ± 7.1 years of age, 40.7% female) enrolled and completed the 12-week intervention. On average participants attended 89.5% of the group exercise and 83.5% of the individual support sessions. there were no significant differences in exercise session attendance between those randomized to 1 ($89.9 \pm 8.8\%$) or 2 sessions/week ($88.8 \pm 7.7\%$; $p=0.790$). Participants randomized to 1 session/week averaged 26.6 ± 3.0 mins/week of MVPA from the group exercise session. Participants randomized to 2 sessions/week averaged 57.7 ± 15.3 mins/week of MVPA from the group exercise sessions. Participants in the 2 sessions/week group significantly improved their performance on the two paired associate learning variables ($p=0.046$ and 0.011). Group-based exercise sessions delivered remotely may be a feasible approach for delivering exercise to adults with DS, and increased exercise may have positive changes on memory.

INFLUENCE OF SCHOOL INTERVENTION ON PARENT'S PHYSICAL ACTIVITY PERCEPTIONS, SUPPORT AND BEHAVIOR

Erica M. Thomas, M.Ed.¹, Erin E. Centeio, Ph.D.², Noel Kulik, Ph.D., CHES², Nate McCaughtry, PhD²¹Wayne State University, St. Clair Shores, MI; ²Wayne State University, Detroit, MI

Regular physical activity (PA) is important for health, yet most children do not meet the recommended guidelines of 60 minutes per day. School-based interventions have been deemed the most universally applicable and effective way to counteract low PA. Parental support and role modeling of PA is consistently associated with children's participation in PA. Using Social Cognitive Theory as a guide, the purpose of this study is to determine the effects of a school PA intervention on parents' support for PA (SS_{tot}), perception of school PA (PA_{per}), and self-report PA behavior (PA_{beh}). Data was collected via surveys prior to the intervention in September (T1) and in May (T2). Parents who have children in 4th grade in six urban elementary schools participated in the survey ($N=217$; mothers =80%, African American=52%, $M_{age}=36$). SS_{tot} consisted of 4 sub-categories (Logistic (LS), Modeling (MS), Community Resource (CRS), and Restricting Sedentary Behavior (RSB)). As a measurement of program engagement, the survey contained 4 questions on a scale from 1-none to 5 -a lot: "How much do you know about the program" ($M=3.3+/-1.22$), "How much have you engaged in the program" ($M=2.5+/-1.38$), "How important is promoting health at school" ($M=4.75+/-0.56$), and "To what degree has the program affected your family's lifestyle" ($M=3.5+/-1.19$). Paired-samples t-tests with a Bonferroni correction were conducted to compare all variables at T1 and T2. There was a significant difference in the scores for T1 and T2 for: SS_{tot} ($M_D=2.13$; $t(216)=3.38$ $pD=.52$); $t(215)=2.94$ $pD=.64$); $t(216)=2.82$ $pD=.76$); $t(215)=4.18$ $pbeh$ ($M_D=7779$); $t(115)=3.66$ $pper$ ($M_D=.40$); $t(186)=1.32$, $p=.19$, or RSB ($M_D=.35$ $t(216)=1.1$, $p=.27$). Results from this study show: 1) Parent's total, logistic, modeling and community support improved over time, 2) Parents did not improve their support of restricting access to sedentary behaviors, and 3) Parents viewed PA as an important part of the school day before the intervention. This study is significant because it shows school-wide interventions have the potential to increase parental support and PA behaviors, which in turn could impact children's PA levels. Furthermore, it highlights that parents may not realize the detrimental effects of sedentary behavior at home, despite knowing the importance of PA.

LOWER SELF-COMPASSION PREDICTS INCREASED FREE-LIVING PHYSICAL ACTIVITY IN COLLEGE-AGED UNIVERSITY STUDENTS

Fawn A. Walter, M.S.¹, David Ede, Jr., B.S.², Joel W. Hughes, PhD²¹Kent State University, Stow, OH; ²Kent State University, Kent, OH

Introduction: Self-compassion, an attitude of self-kindness, mindfulness, and a sense of common humanity, has been related to numerous health behaviors¹ and appears to be an important factor in health across multiple domains.^{2,3,4} However, little research has examined the association of self-compassion with objective health measures. High levels of free-living physical activity are an important health behavior, as more sedentary behavior has been related to an increased risk of both fatal and non-fatal cardiovascular disease.⁵ This study examined the relationship between self-compassion and free-living physical activity (step count) in college-aged students.

Methods: The sample (N = 94) was aged 19.51 ± 1.75 , 79.8% female, and 77.7% Caucasian. Participants completed the Self-Compassion Scale (SCS), which measures three facets on continuums, including self-kindness, common humanity, and mindfulness. Participants wore an accelerometer for a 10-hour period during a standard weekday and step counts were obtained. Hierarchical linear regressions were performed to determine whether self-compassion explained variability in free-living physical activity (step count) after controlling for age and sex.

Results: The mean SCS score was 3.11 ($SD = .69$), and mean step count was 8385.9 ($SD = 3250.78$). After controlling for demographic variables, the SCS composite was negatively associated with step count (see Table 1).

Discussion: Contrary to the hypothesis, in this sample of college-aged students, poor self-compassion predicted increased step count. In other words, increased free-living physical activity was predicted by higher levels of self-judgment, isolation, and over-identification. The results from this study, which included an objective measure of physical activity, contradict previous research supporting the association between self-compassion and increased self-reported physical activity.¹ These findings challenge previous research using self-report methodology. It is possible that those lower in self-compassion engage in more free-living physical activity, but still exercise less. However, future research should verify this finding and seek potential mechanisms.

METHODS FOR AN MHEALTH APPROACH TO PREVENT WEIGHT REGAIN BY REDUCING SEDENTARY BEHAVIOR IN OLDER ADULTS: THE EMPOWER TRIAL

Jason Fanning, PhD¹, Barbara J. Nicklas, PhD², W. Jack Rejeski, PhD³¹Wake Forest School of Medicine, Winston Salem, NC; ²Wake Forest School of Medicine, Winston-Salem, NC; ³Wake Forest University, Winston-Salem, NC

Background: The promotion of “spontaneous physical activity” (SPA) across the intensity spectrum and throughout the day may be useful for promoting lasting weight loss. SPA interventions build activities into daily life while minimizing time sitting. Because SPA interventions are less aversive to older adults relative to structured exercise, early evidence suggests they may be more sustainable. There is a need to understand the impact of SPA interventions on long-term maintenance of weight loss, and to identify methods for intervening on movement patterns among older adults across the day.

Purpose: The “Empowered with Movement to Prevent Obesity and Weight Regain” (EMPOWER) study aims to compare the effects of 3 interventions on weight loss over 6 months, and on the prevention of weight regain during a 12-month follow-up period. Interventions include (1) A treadmill-based walking intervention (EX); (2) A SPA intervention; and (3) a combined EX+SPA condition.

Methods: During the first 6 months, participants attend weekly group weight loss sessions, and those in the EX conditions engage in a combination of supervised and home-based walking 4 times weekly, progressing to 40–50 minutes at 65–70% heart rate reserve. Those in the SPA intervention receive self-regulation skill training and an individualized daily step goal that is monitored using a study app that places emphasis on movement throughout the day. Throughout the intervention, all participants have access to a condition-specific app paired with a Fitbit. Activity data are imported into the app in near real time, and participants access data in both summary form (e.g., transitions, steps) and on a unique “daily timeline”. This graphical feedback bar provides insight into minute-level movement patterns. Sedentary minutes are colored blue, and for those in the EX conditions, movement minutes are colored teal, while sustained bouts of at least 10 minutes are colored green. Participants aim to achieve one green bout most days per week, and bout duration is tailored by the exercise leader. Movement is colored green for those in the SPA conditions, who aim to minimize periods of sustained blue (sitting) by frequently standing and moving. Participants gain access to a number of evidence-based app tools meant to improve self-efficacy and social connection. For instance, “mastery badges” highlight mastery experiences, and are released as when in-app goals are met. Participants work toward cooperative goals (e.g., standing out of all of the seats in the local football stadium), and have access to in-app group messaging.

Conclusion: The EMPOWER interventions utilize popular technologies integrated into an evidence- and theory-based package with the goal of evaluating the effect of the promotion of SPA on weight loss and on preventing weight regain following intentional weight loss.

MHEALTH PHYSICAL ACTIVITY INTERVENTION INCREASED EXERCISE TASK SELF-EFFICACY AMONG SEDENTARY ADULTS

Celia Ching Yee Wong, MPhil¹, Elizabeth J. Lyons, PhD, MPH², Zakkoyya H. Lewis, PhD³, Maria Swartz, PhD, MPH⁴, Eloisa Martinez, Bachelor of Science in Psychology⁵

¹University of Houston, Houston, TX; ²The University of Texas Medical Branch, Galveston, TX; ³Beachbody, Santa Monica, CA; ⁴University of Texas Medical Branch, Missouri City, TX; ⁵UTMB- Galveston, Texas City, TX

Purpose: Interventions targeting self-efficacy can increase physical activity, which is in turn associated with positive health outcomes. Though mHealth interventions using mobile apps and telephone counseling have shown promise for increasing activity, little is known about their possible mediating constructs such as self-efficacy. In particular, self-efficacy to perform active behaviors (task self-efficacy) may be affected differently than self-efficacy to overcome barriers to being active (barrier self-efficacy). Therefore, this study aimed to examine the effects of a mHealth intervention on task and barrier self-efficacy for physical activity.

Methods: Sedentary, overweight adults (N = 40) were randomized to a 12-week intervention or wait list control. Participants (87.5% female, with mean age 47.80 years (SD = 12.55) and mean BMI 33.22 kg/m² (SD = 12.40)). Participants in the intervention condition were given a mobile device loaded with a physical activity app (Zombies, Run!) and weekly brief phone counseling sessions. The app promoted self-monitoring and virtual rewards, while the phone counseling emphasized problem solving and action planning. Assessments occurred at baseline and 12 weeks, using validated measures (responses between 0 – 100). Data were analyzed using analyses of covariance controlling for baseline values and using the intent to treat principle.

Results: At the 12-week assessment, participants in the intervention group reported significantly higher levels of task self-efficacy as compared to the wait list controls (81.39 ± 15.51 vs. 69.26 ± 20.34, p = .02). However, no significant group differences were observed in barrier self-efficacy (56.56 ± 24.96 vs. 47.78 ± 18.52, p = .34).

Conclusions: Our results suggested that mHealth interventions may differentially impact task and barrier self-efficacy for exercise. The increased task self-efficacy in the intervention group may be related to virtual rewards and encouragement in the app building confidence to perform physical activity. It is unclear why the intervention group did not experience significant improvement in barrier self-efficacy despite counseling on problem solving. This finding may suggest measurement insensitivity and/or a gap between brainstorming potential solutions to barriers and building confidence in addressing them. Future studies should explore more sensitive measures of barrier self-efficacy and alternative ways to promote barrier self-efficacy.

PHYSICAL ACTIVITY AND SEDENTARY OBJECTIVELY MEASURED IN ADULT CANADIANS WITH CHRONIC DISEASE: A CROSS-SECTIONAL STUDY

Gabriel Hains-Monfette, Baccalaureate¹, Paquito Bernard, Pr²

¹Université du Québec à Montréal, Montréal, PQ, Canada; ²Université du Québec à Montréal, montreal, PQ, Canada

Objectives: The aim of this research is to compare objective physical activity and sedentary behaviors between canadian adults with and without chronic disease, and to examine physical activity and sedentary behaviors between adults with multiple chronic diseases.

Methods: Data were obtained from Canadian Health Measure Survey (CHMS) (2007–2013). Physical activity and sedentary were measured using accelerometry in Canadians aged between 18 and 69 years. Data are presented as daily mean time spent in moderate and vigorous intensity physical activity (MVPA), light physical activity (LPA), sedentary, as well as steps accumulated per day. Pregnant women, participants with functional limitation were not included. Four self-reported chronic diseases were available (i.e., fibromyalgia, diabetes, heart diseases, cancer) in CHMS. The chronic obstructive pulmonary disease was determined with spirometry measures. Among 8380 participants, those with 1, 2, 3 or more were compared with participants without chronic disease. A weighted ANCOVA regression model incorporating age, sex, body mass index, accelerometer wearing time, marital status, smoking status, education level and income was carried out.

Results: Distribution across healthy participants, those with one chronic disease, two and three or more were 74.5%, 21%, 4% and 0.5%, respectively. Participants with two or three and more chronic diseases spent significantly less time in MVPA (min/day) (M=11.6, SE=1.6; M=7.4, SE =1.6) and LPA (M=182.7, SE=7.2; M=160.8, SE=14.5) and had lower daily steps count (M=6272, SE=308; M=5339, SE=542) compared with healthy adults (MVPA-M=22.8, SE=0.6; LPA-M=216.1, SE=1.8; Steps-M=7972 SE=82) or with one chronic disease (MVPA-M=17.6, SE=0.8; LPA-M=210.5, SE=3.4; Steps-M=7598, SE=163). However, sedentary time (min/day) did not differ between the groups, ranging from 442 (SE=3.9) to 486 (SE=33.6).

Conclusion: Our findings highlight the importance of targeting interventions promoting physical activity towards adults with multiple chronic diseases. We found no evidence that canadian adults with one chronic disease were less active in comparison to healthy adults.

PHYSICAL ACTIVITY PROGRAMMING AND COUNSELING PREFERENCES AMONG CANCER SURVIVORS: A SYSTEMATIC REVIEW

Jaime Wong, B.A., Edward McAuley, PhD, Linda Trinh, PhD

University of Illinois at Urbana-Champaign, Urbana, IL

Background: Physical activity (PA) participation and adherence among cancer survivors is low, despite research indicating numerous physical, psychological and emotional health benefits of exercise. Tailoring exercise programs specific to the PA preferences in cancer survivors has merit for increasing PA participation and adherence to accrue these benefits.

Purpose: This systematic review aims to identify and differentiate exercise programming and counseling preferences of adult cancer survivors across various cancer survivor groups.

Methods: PubMed, SPORTDiscus, Scopus, PsycINFO, EMBASE, Web of Science and CINAHL were electronically searched (inception to Sept 2016) and articles were identified using PRISMA guidelines. Two reviewers independently assessed identified articles to determine eligibility and then individually performed a quality assessment on all final studies. Extracted and analyzed data included participant characteristics, interest in exercise counseling and programming, as well as specific exercise and counseling preferences (e.g. location, timing, intensity).

Results: Thirty-two articles were included in this systematic review. Most studies assessed mixed cancer survivor groups; however, breast cancer and lung cancer were the two most studied individual cancer survivor groups. Most cancer survivors felt able and interested in participating in a PA program, though starting a PA program after or before treatment was preferred. Walking was the strongest PA modality preference, and most cancer survivors preferred moderate intensity PA. Cancer survivors also indicated preferences for home-based PA that could take place in the morning. Slight preferences were found towards physical activity counseling delivered by a fitness expert from a cancer center. Studies were found to be of moderate to high quality based on the Appraisal Tool for Cross-Sectional Studies (AXIS).

Conclusion: Cancer survivors have an interest in participating in PA programs with walking as the primary modality. Additionally, morning-based PA programs that can be tapered to home-based programs are desirable. Many cancer survivors felt interested and able to participate in PA, and therefore designing PA programs that are tailored to cancer survivors is integral for optimizing recruitment and adherence, as well as enhancing health outcomes in cancer survivors.

PILOT STUDY OF A YMCA-BASED EXERCISE PROGRAM TO INCREASE EXERCISE ENJOYMENT AND PARTICIPATION AMONG WOMEN WITH OBESITY

Lucia A. Leone, PhD¹, Leah Vermont, BS¹, Laura Anderson, PhD¹, Leonard H. Epstein, PhD¹, Rocco Paluch, MA¹, Gary Bennett, PhD²¹University at Buffalo, Buffalo, NY; ²Duke University, Durham, NC

Background: Women with obesity are less likely to engage in regular exercise than non-obese women. Possible reasons for this disparity may be that they less likely to enjoy exercise and more likely to report that they only exercise when trying to lose weight. While women with obesity report interest in social exercise programs that foster better health, most publically available exercise programs targeted to this population focus on weight-loss. There is a need for behavior-change programs for women with obesity that focus on exercise enjoyment rather than weight-loss, and which include opportunities for exercise in a supportive community setting.

Method: Using Social Cognitive Theory as a guide and working with women from the target population and the YMCA, we developed a novel exercise program designed to increase exercise participation among women with obesity through increased enjoyment. The Fit & Fab program, based at the YMCA, included special exercise classes and weekly behavior-change focused group sessions open only to study participants. We recruited women ages 18–64 with a BMI of 30 or higher (N=49) and randomized them to receive either a 3-month YMCA membership (control group, n=24) or a membership plus access to the 3-month Fit & Fab exercise program (intervention group, n=25). Women wore accelerometers for 7 days and completed a survey at baseline and during the last week of the program.

Results: Participants on average were 49.0 years old (SD=10.9) and had a BMI of 38.7 (SD=3.8). Preliminary accelerometer data indicated a trend that change in vector magnitude (raw activity counts per day) was higher for the intervention group (294,624, SD=327,362) compared to the control (100,039, SD 364,938) ($p = 0.07$). We also found that women in the intervention group visited the YMCA more times ($p < 0.0001$) on average over 12 weeks (23.4 times) than women in the control group (9.7 times). Average Physical Activity Enjoyment Scale (PACES) scores at baseline were 80.3 (out 119); at follow-up the intervention group scored significantly higher ($p = 0.04$) on the PACES exercise enjoyment scale (98.1, SD=17.5) compared to women in the control group (85.5, SD=20.5).

Conclusion: An enjoyment-focused exercise intervention was able to increase exercise participation in a high-need population. If we can demonstrate that the Fit & Fab program has an effect on longer term exercise participation and health outcomes, this intervention has the potential to be scaled up through YMCAs across the country.

PROMPTS TO INCREASE PHYSICAL ACTIVITY AT POINTS-OF-CHOICE BETWEEN STAIRS AND ESCALATORS: WHAT ABOUT ESCALATOR CLIMBERS?

John Bellettiere, PhD, MPH, MA¹, Benjamin Nguyen, MPH², Sandy Liles, MPH³, Vincent Berardi, PhD⁴, Citlali Alvarado, N/A⁵, Marc A. Adams, PhD, MPH⁶, Jacqueline Kerr, PhD⁷, Melbourne F. Hovell, PhD, MPH⁸

¹University of California, San Diego, La Jolla, CA; ²Center for Behavioral Epidemiology & Community Health, San Diego, CA; ³Center for Behavioral Epidemiology and Community Health, San Diego State University, San Diego, CA; ⁴Chapman University, San Diego, CA; ⁵Center for Behavioral Epidemiology and Community Health, Fallbrook, CA; ⁶Arizona State University, Phoenix, AZ; ⁷UCSD, San Diego, CA; ⁸San Diego State University, San Diego, CA

Background: Since 1980, many studies have evaluated the efficacy of stair-use prompts to increase physical activity by diverting ascenders from escalator to stair use, but nearly all studies combined escalator standing (a *non-active* ascent method) with escalator climbing (an *active* ascent method).

Purpose: This presentation addresses the often-overlooked assessment of climbing up escalators in stair use studies. Ultimately, we assessed the degree to which stair-use prompts led to increased total physical activity—i.e., stair use + escalator climbing.

Methods: At a stairs/escalator point of choice at the San Diego International Airport, we systematically alternated days with sign prompts and days without sign prompts. We video-recorded passersby who ascended either stairs or escalators. Staff reviewed and coded video-recordings of 13,544 participants taken on 20 days spread over five months, and we compared the odds of using the stairs, standing on the escalator, and climbing the escalator on the 10 days with signs vs. the 10 days without signs. Multivariable models were adjusted for age, sex, ethnicity, body shape, shoe type, luggage, and pedestrian traffic volume.

Results: On days without signs, the proportion of stair use (3.6%) was lower than escalator climbing (20.4%) and escalator standing (76.0%). Sign prompts increased the multivariable odds of stair use by 125% (OR=2.25; $p < .001$) when escalator standing and climbing were combined as a comparison (the analytic approach used by nearly all other point-of-choice prompt stair use studies). Comparing the three modes of ascent on days with signs, the proportion of escalator standing did not change significantly while stair use increased to 6.9% ($p < .001$) and escalator climbing decreased to 18.4% ($p = .003$). As an exploratory analysis to assess changes in total physical activity, we combined stair use and escalator climbing into an “active ascent” mode and found that sign-prompts increased the multivariable odds of *active ascent* versus *passive ascent* (escalator standing) by only 15% (OR=1.15; $p = .002$).

Conclusions: Stair use prompts accomplished their intended effect by increasing stair use roughly 125%, an outcome similar to that of many other stair studies. However, the increase in total physical activity was more modest (15%), partly because escalator climbing, a physical activity not targeted by the intervention, decreased. One possible explanation for these findings is that ascenders already disposed to climbing the escalator shifted to stair use in the presence of signs, leading to increased stair use, but little change in total physical activity. Sign prompts specifically designed to increase escalator climbing, as well as stair use, might have a larger impact on total physical activity.

SOURCE-ORIENTATION IN INTROJECTED REGULATION FOR LEISURE-TIME EXERCISE

Kimberly R. More, B.A. (Hons), M.S.¹, L. Alison. Phillips, B.A., M.A., Ph.D.²

¹Iowa State University, Ames, IA; ²Psychology Department, Iowa State University; War Related Illness and Injury Study Center, Veterans Affairs, New Jersey Health Care System, Ames, IA

Self-Determination Theory (SDT) is widely used to predict behavior change. To extend the reach of SDT research into effective interventions for promoting exercise (Chatzisarantis & Hagger, 2009; Silvia et al., 2008), more foundational work is required. Namely, the literature is conflicting regarding the relationship between introjected regulation and exercise (Teixeira et al., 2012). This may be due to introjected regulation being an umbrella construct—the dimensions of which have yet to be defined. In an academic domain (motivation and behavior), research has distinguished between avoidance and approach introjected regulation (Assor et al., 2009). We propose these dimensions may predict engagement in leisure-time exercise and that there may be a further distinction in *source* of feelings of introjection—namely, one’s self versus others. From a SDT perspective, we hypothesized the following to be related to exercise engagement from strongest to weakest: self-approach (exercising to feel pride in oneself), self-avoidant (to avoid self-guilt), other-approach (to gain pride from how others see one), and other-avoidant (to avoid feeling guilty for letting others down). 336 undergraduates reported on regulations at baseline and exercise activity at the two-week follow-up. EFA resulted in a three-factor solution accounting for 73.25% of the variation in introjected regulation scores: self-avoidance, other-avoidance, and a general approach factor. Correlation analysis revealed that self-avoidance ($r(334) = .18$, $p r(334) = .15$, $p r(321) = .13$, $p B = 44.50$, $t(2.40)$, $p = .02$) and none of the predictors were uniquely related to exercise at follow-up. Results suggest that it is theoretically important to distinguish between approach vs avoidance introjected regulation and the source of avoidance introjected regulation. However, these distinctions may not explain conflicting relationships between introjected regulation and exercise in the literature.

THEORETICAL CONSTRUCTS & PHYSICAL ACTIVITY CHANGE IN BREAST CANCER SURVIVORS IN A TECHNOLOGY-BASED PHYSICAL ACTIVITY PROGRAM

Lauren S. Weiner, BA¹, Sandahl H. Nelson, MS², Sheri J. Hartman, PhD³¹UC San Diego, La Jolla, CA; ²University of California, San Diego, San Diego, CA; ³University of San Diego, California, La Jolla, CA

Introduction: Wearable activity trackers support theory-based techniques proven to enhance the success of physical activity interventions. Few studies in breast cancer survivors have examined the relationship of theoretical constructs to physical activity change in a technology-driven intervention.

Methods: Sedentary breast cancer survivors randomized to the physical activity intervention arm of a 12-week randomized controlled trial received a Fitbit One activity tracker and tailored feedback based on Fitbit data. Participants received additional support via phone and email. An ActiGraph GT3X+ accelerometer was worn for 7 days at baseline and week 12 to measure change in moderate-to-vigorous physical activity (MVPA). Theoretical constructs of self-efficacy as well as cognitive and behavioral processes of change were measured at weeks 2 and 10. Paired t-tests examined change in MVPA from baseline to Week 12 and changes in theoretical constructs from week 2 to 10. Multivariate linear regression models controlled for ActiGraph wear time and examined 1) associations between change in theoretical constructs and change in MVPA, and 2) associations between Week 2 scores on measures of theoretical constructs and change in MVPA.

Results: Participants (n=38) were a mean of 58 years (SD=11.3), BMI of 26.4 kg/m² (SD=5.9), and diagnosed 2.5 years ago (SD=1.4); 63% had Stage I disease and 53% received chemotherapy. Participants increased MVPA a mean of 14.7 min/day (SD=13.7; t=6.59, p<.0001). Self-efficacy significantly improved from week 2 to 10 (t=3.80, p<.001) but there were no significant changes in cognitive (t=-.33, p=.74) or behavioral processes (t=-1.48, p=.15). The association between change in self-efficacy and change in MVPA was not significant (b=-2.79, p=.49). However, higher scores on the theoretical constructs at week 2 were related to greater improvements in MVPA: self-efficacy b=7.35, p=.03; cognitive processes b=8.30, p=.04; behavioral processes b=9.49, p=.01.

Conclusion: While the intervention increased self-efficacy, change in self-efficacy was not related to change in MVPA. Lower scores early on were associated with less success in the intervention. Theoretical variables may help identify subgroups of survivors who need more intervention support. With the growing role of wearable activity trackers, additional studies are needed to better understand how established theories operate in this emerging intervention modality to facilitate behavior change in breast cancer survivors.

USING FITNESS TECHNOLOGY AND WALKING CAMPAIGNS TO INCREASE PHYSICAL ACTIVITY AMONG OLDER BLACK WOMEN IN GIRLTREK

Carmen Harris, MPH¹, Jylana Sheats, PHD, MPH²¹GirlTrek, Washington DC, DC; ²Tulane University School of Public Health & Tropical Medicine Dept. of Global Community Health and Behavioral Science, New Orleans, LA

GirlTrek is a public health non-profit which currently supports and encourages over 110,000 African-American women across the U.S. to change their lives and their communities through the daily habit of walking. GirlTrek shares free, culturally-relevant, monthly health campaigns and challenges to increase daily walking and healthy eating habits, reduce stress, and encourage social support and cohesion among African-American women located in predominately African-American communities in the U.S. In October 2016, GirlTrek staff conducted a pilot study of 82 African-American women to determine if Fitbit technology and a walking competition campaign would be a feasible method to track and encourage walking behavior among older GirlTrek participants.

Methods: Participants were recruited from highly active GirlTrek walking teams in New Orleans, Louisiana, Jackson, Mississippi, and Atlanta, Georgia. During the U.S. Surgeon General's "Step It Up" Campaign, GirlTrek participants were encouraged to increase daily walking habits by any amount for two weeks in October 2016. Participants used their own Fitbit wearable device or downloaded the free Fitbit app to their smartphones to track their daily walking habits. Participants completed a post-campaign survey and shared 4 weeks of Fitbit activity and dietary data via Fitbit's export data option.

Results: Sixty-five percent of participants were age 46 or older, 84% were classified as overweight or obese, 98% owned a smartphone, and 68% used a Fitbit or other wearable activity tracking device to track their activity prior to the walking campaign. During the two-week campaign when participants were encouraged to increase their daily walking habits, 82% of participants walked at least 150 minutes per week compared to 61% one week prior to the campaign. In addition, 78% of the participants reported being encouraged by their walking team members to eat well and drink water. Finally, 77% of the participants reported they planned to continue using the Fitbit technology to monitor activity after the campaign.

Conclusion: Fitness technology coupled with GirlTrek's monthly health-promoting campaigns and walking challenges could play a critical role in assessing and increasing physical activity as well as encourage healthy eating habits among older African-American women.

WHAT ARE THE BIDIRECTIONAL ASSOCIATIONS BETWEEN SYMPTOMS AND PHYSICAL ACTIVITY IN DAILY LIFE FOR THOSE WITH MULTIPLE SCLEROSIS?

Anna Kratz, PhD¹, Nora Fritz, PhD², Tiffany Braley, PhD¹, Eric L. Scott, PhD¹, Emily Foxen-Craft, PhD¹, Susan Murphy, PhD¹

¹University of Michigan, Ann Arbor, MI; ²Wayne State University, Detroit, MI

Individuals with multiple sclerosis (MS) typically experience a complex symptom burden and are less physically active compared with other clinical populations. Because increased physical activity offers many potential benefits in terms of decreased symptom burden and improvement and maintenance of physical functioning, there is a need to identify factors that are related to physical activity in MS. Severity of symptoms, such as fatigue and pain, is negatively associated with physical activity in MS in cross-sectional research. However, it is unclear how physical activity and symptoms correlate bi-directionally on a day-to-day basis in persons with MS. The objective of this study was to determine the temporal within-person associations of pain, fatigue, depressed mood, and cognitive dysfunction with physical activity in MS. Community dwelling ambulatory adults with MS (N=107) were recruited and completed 7 days of home monitoring. Continuous physical activity data (assessed via wrist-worn accelerometer) and concurrent ecological momentary assessment (5X/day) of pain, fatigue, depressed mood, and cognitive dysfunction were collected as participants went about daily life. Correlational analyses of cross-sectional (aggregated) values indicated that symptoms were not significantly related to physical activity over the duration of the home monitoring period (all $r < 0.16$). In contrast, results of multilevel models indicated that fatigue and depressive symptoms demonstrated bi-directional temporal associations with physical activity, whereas pain and cognitive dysfunction did not. Moments of higher than usual fatigue ($B = -5.83$, $p = 0.001$) and depressed mood ($B = -4.12$, $p = 0.03$) were followed by decreased physical activity. In contrast, periods of higher than usual physical activity were associated with subsequent declines in fatigue ($B = -0.001$, $p = 0.02$) and depressed mood ($B = -0.0007$, $p = 0.02$). Interestingly, this negative association between preceding physical activity and subsequent fatigue was only observed in the morning and evening, but not midday. Physical activity is dynamically related to fatigue and depressed mood on a moment-to-moment basis in MS; interestingly, physical activity did not demonstrate similar temporal associations with either pain or cognitive function. Efforts to increase physical activity in MS must incorporate a focus on how symptoms affect and are affected by activity, with particular attention to fatigue and depressive symptoms.

WORKING OUT WITH F.I.D.O. (FREQUENCY, INTENSITY, DURATION, & OUTCOMES) - A FEASIBILITY RANDOMIZED CONTROLLED TRIAL

Dr. Ryan E. Rhodes, PhD¹, Clarise Lim, MSc²

¹University of Victoria, Victoria, BC, Canada; ²Behavioral Medicine Lab - University of Victoria, Victoria, BC, Canada

Objective: Dog owners have been shown to walk more per week compared to non-dog owners; however, 60% of dog owners are still not walking their dogs at intensities sufficient to reap health benefits. The aim of this study was to evaluate the feasibility, acceptability, and efficacy of a 9-week feasibility randomized controlled trial involving a program of six weekly scheduled instructor-led group dog walks supplemented with theory-based strategies to encourage increased dog walking among dog owners in Greater Victoria, BC.

Methods: This study was based on the multi-process action control (M-PAC) framework and utilized an open parallel randomized controlled trial design involving experimental and waitlist-control group participants. Quantitative data was collected using pedometers and self-report measures. A program evaluation survey was administered upon the completion of the study. Primary outcomes examined the feasibility and acceptability of the program; secondary outcomes analyzed pedometry and self-report moderate-to-vigorous physical activity (MVPA) data; and tertiary outcomes observed changes in participants' perceptions of M-PAC constructs. Percentage calculations were used to obtain primary outcomes, and analysis of covariance (ANCOVA; controlling for baseline) was performed to examine secondary and tertiary outcomes to explore the direction of effects. Eligibility: Male and female adults aged 18+ living in Greater Victoria, BC, who owned at least one healthy and friendly dog aged six months and above, who were not meeting recommended guidelines of 150 minutes of MVPA per week, and who were medically cleared to participate.

Results: Feasibility outcomes included 74 interested responses, 23% recruitment rate ($n = 17$), 94% retention rate ($n = 16$), and 94% adherence rate ($n = 15$). Program participants were overall (very) satisfied with the program – worksheets (62.5%), instructor (100%), various program logistics (75% to 100%). Total weekly step counts and average daily step counts, MVPA dog walking, and MVPA with dog increased at end-of-program and follow-up, resulting in large effect sizes when compared to the waitlist-control group. MVPA dog walking and total MVPA (with + without dog) exceeded recommended guidelines at follow-up. Positive changes across time were observed for dog responsibility and M-PAC constructs of affective judgments, opportunity, planning, identity, and habit, resulting in medium and large effect sizes when compared to the waitlist-control group.

Conclusions: This six-week group dog walking program is overall feasible, acceptable, and is efficacious in encouraging increased dog walking and MVPA among dog owners. It is recommended for the full trial to refine/modify initial recruitment strategies and eligibility criteria (e.g., reimburse medical/veterinarian clearance costs, offer various options of program delivery).

COMPARISON OF COLLEGE STUDENTS AND OLDER ADULTS IN HAPPINESS INTERVENTION

Elizabeth Orsega-Smith, PhD¹, Erica Rathie, Bachelor of science², Jennie L. Turner, Master of Science¹, Katie E. Greenawalt, Master of Science³, Stephen Goodwin, PhD¹

¹University of Delaware, Newark, DE; ²University of Delaware, Wilmington, DE; ³University of Delaware, Lancaster, PA

Introduction: College students and older adults are at risk populations for poor mental health issues including depression. Among adults 18 and older, 6.7% have experienced at least one depressive episode per year. Positive psychology interventions can enhance subjective wellbeing and reduce depression. However, a comparison of these programs in older adults and college students has not been widely examined. The present study sought to evaluate and compare an intervention with the goals of enhancing happiness levels and overall mental wellbeing in the older adult and college populations.

Methods: The Art of Happiness classes were conducted in senior centers and at a university as a one credit undergraduate course. Each class examined a different topic including defining happiness, stress management, reflecting on happiness, compassion and human connection, forgiveness, transforming suffering, mindfulness, and humor. Pre and post questionnaires assessed participant subjective happiness, stress, life satisfaction, depression, and general demographic information. Repeated Measures GLM was used to examine group by time effects.

Results: The 32 older adult participants who completed the course were mostly married (43.8%), female (87.5%) and Caucasian (90.6%), with an age range of 53–84 years of age. There were 16 college students between 20–24 years of age mostly female (53.6%), and upperclassmen (87.6%). The results revealed a significant effect of time in both groups for depression (p

Conclusion: Programs like “The Art of Happiness,” which emphasize aspects of wellbeing may have the potential to buffer the older adult population and college students against poor mental health by improving subjective happiness and overall mental wellbeing. This may lead to incorporating these types of programs into both college curriculum and senior centers as part of their healthy lifestyle curriculum in order to improve their overall quality of life as they embark on different stages of their lives.

RACIAL AND INCOME DISPARITIES IN THE HEALTH-RELATED QUALITY OF LIFE AMONG SMOKERS WHO ATTEMPT TO QUIT

Yu Hsiang Kao, PhD¹, Michael Celestin, PhD¹, Qingzhao Yu, PhD², Sarah Moody-Thomas, PhD², Tung Sung Tseng, PhD¹

¹Louisiana State University Health Sciences Center, New Orleans, LA; ²LSU Health Sciences Center, New Orleans, LA

Background: It has been established that smoking is associated with worse health-related quality of life (HRQoL). However, little is known about the association between HRQoL and race among smokers with quit attempts at different income levels.

Objective: To assess racial and income disparities in HRQoL among smokers who have made a quit attempt.

Methods: This study applied a cross-sectional study design using data from the 2017 LSU Tobacco Control Initiative patient survey conducted at eight Louisiana public hospitals. We extracted 1,108 interviewees responding to HRQoL measures including the EuroQol 5D, which consists of five dimensions and result in an index score adjusted by U.S. population-based preference weights. We classified smoking status into four groups: never smokers, former smokers, current smokers with a quit attempt, and current smoker without a quit attempt. Multivariate linear regressions compared the HRQoL between African Americans and Caucasians.

Results: The sample consisted of predominately African American (59%), female (66%), low income (71%), and never smokers (41%). Bivariate analyses showed significant differences in income and smoking status between African Americans and Caucasians (P=.006 and P<.001). Moreover, African Americans had a significantly higher average HRQoL than Caucasians (P<.001). Controlling for age, sex and education, race, income and smoking status were significantly related to HRQoL in multivariate analyses (all P<.001). Analyses stratified by race and income found that among low-income African Americans, smokers with a quit attempt had a lower average HRQoL than either never smokers (P<.001) or smokers without a quit attempt (P=0.006).

Conclusion: The findings reveal racial disparity in the HRQoL. Moreover, low-income African American smokers who made a quit attempt had a lower HRQoL. Cessation interventions may focus on lower income African American smokers who made a quit attempt to reduce disparities in smoking and HRQoL.

RESILIENCE AND PSYCHOLOGICAL FLEXIBILITY IN PERSONS WITH SCI: MALLEABLE TRAITS?

Brigid Waldron-Perrine, PhD¹, Robin Hanks, PhD², Anna Kratz, PhD³

¹Wayne State University School of Medicine/Rehabilitation Institute of Michigan, Detroit, MI; ²Wayne State University School of Medicine/Rehabilitation Institute of Michigan, Detroit, MI; ³University of Michigan, Ann Arbor, MI

Many persons with spinal cord injury (SCI) thrive despite physical changes, but there is little research examining positive factors that impact rehabilitation success. This study explored contributions to resilience, defined as the ability to adapt and thrive in the face of hardship. Psychological flexibility, the ability to tolerate negative thoughts and feelings in the context of engaging in valued activities, is theoretically related to resilience, but as yet unexplored as a contributory factor. Acceptance and Commitment Therapy, which augments psychological flexibility, has been effective in a number of chronically and/or traumatically affected patient populations. It was adapted to an 8-session, 1–2 hour weekly group format, completed by 12 individuals in two diverse urban locations.

Method: 117 participants (mean age = 46.3, SD=15.3; 65% male; 63% Caucasian) who had sustained a SCI at least one year prior were recruited via medical center registries. A survey design was employed and included the Resilience, Depression and Positive Affect banks of the SCI-QOL measurement system (Tulsky et al., 2015) and the Cognitive Fusion Questionnaire (Gillanders et al., 2014).

Results: Linear regression revealed that the overall model accounted for 71% of the variance in resilience ($F(3, 113) = 93.652, p < .001$). Positive emotion, absence of negative emotion and extent of *cognitive fusion* (i.e., entrenchment in unhelpful thoughts) were each uniquely predictive of resilience ($p < .001$). Whereas absence of negative emotion accounted for less than 2% of unique variance, experience of positive emotion uniquely accounted for 8%, and absence of cognitive fusion uniquely accounted for 4%.

Consistent with expectations, 91% of completers of a pilot ACT intervention with emphasis on reduction of cognitive fusion reported the intervention was “a great deal of help” with regard to “minimizing thoughts/feelings getting in the way” (9% stated “some help”), and 75% reported “a great deal of help” with regard to “getting meaning from my experiences” (25% reported “some help”).

Discussion: Improvement in the quality of life for those with SCI requires better understanding of the principles of positive psychology (i.e., a focus not on symptoms or problems in coping, but positive approaches to coping) within this unique population. By uncovering the mechanisms by which individuals with SCI cope well with their barriers, such as emphasis on the experience of positive emotion and minimal cognitive fusion, we can move towards delivery of innovative rehabilitation programs and standards for delivery of psychological care that are supportive of positive coping. A shift in the thinking in SCI psychological rehabilitation from deficits to attributes and facilitation of underlying positive characteristics in coping with SCI will ultimately improve participation and well-being in the SCI population.

A QUALITATIVE STUDY OF PREPAREDNESS FOR END-OF-LIFE CARE IN TERMINAL CANCER PATIENTS: THE ROLE OF RELIGIOUSNESS/SPIRITUALITY

Allen C. Sherman, Ph.D.¹, Stephanie Simonton-Atchley, Ph.D.¹, Cindy Mikeal, Ph.D.¹, Kendra M. Anderson, Ph.D.², Issam Makhoul, MD³, Sarah E. Harrington, MD⁴, Konstantinos Arnaoutakis, MD³, Laura F. Hutchins, MD³, Fade Mahmoud, MD³, Natasa Milojkovic, MD³, Suen Y. James, MD⁵

¹Behavioral Medicine, Winthrop P. Rockefeller Cancer Institute, University of Arkansas for Medical Sciences, Little Rock, AR; ²Department of Neurology, University of Texas Health Science Center-Houston, Houston, TX; ³Medical Oncology, Winthrop P. Rockefeller Cancer Institute, University of Arkansas for Medical Sciences, Little Rock, AR; ⁴Palliative Care, Winthrop P. Rockefeller Cancer Institute, University of Arkansas for Medical Sciences, Little Rock, AR; ⁵Otolaryngology, Winthrop P. Rockefeller Cancer Institute, University of Arkansas for Medical Sciences, Little Rock, AR

The extent to which patients feel prepared for end-of-life (EOL) care may have significant implications for treatment decisions, healthcare expenditures, and quality-of-life. The concept of “preparedness” has drawn growing interest, but little is known about factors that might influence these perceptions. Religious or spiritual (R/S) involvement often becomes more salient at the end of life, and these commitments might be expected to affect patients’ sense of preparedness. This qualitative study examined associations between religious/spiritual (R/S) factors and preparedness, among cancer patients with terminal illness. We explored whether particular R/S functions might propel or impede perceptions of readiness for managing the myriad challenges of EOL care. Individual interviews were conducted with cancer patients with end-stage disease. Average age was 63.7, most participants were Christian, and the sample included diverse malignancies. Enrollment continued until data saturation. Thematic coding of transcripts was completed by 3 investigators, using NVivo 11 software. Four major themes emerged. Patients perceived that their readiness for EOL care was enhanced by R/S involvement, because it provided them with: (1) spiritual/emotional comfort; (2) a restored sense of control (e.g., part of God’s plan); (3) support from the congregation (e.g., instrumental and emotional assistance); and (4) spiritual guidance (e.g., repentance and redemption). Findings suggest that R/S involvement may assist some cancer patients in feeling more ready to manage the demands of EOL care, by serving several specific functions (i.e., comfort, control, support, and guidance). These results offer a critical foundation for further research in this area. Participants focused on the salutary effects of R/S involvement on emotional and spiritual aspects of preparedness for EOL care. There were few spontaneous narratives concerning religious struggle or alienation, or on the impact of R/S factors on other important domains of EOL preparedness (e.g., managing difficult treatment decisions, financial planning, interactions with the healthcare team). Additional investigations would be helpful to further explore these areas as well.

COGNITIVE BEHAVIORAL THERAPY FOR MS-RELATED FATIGUE EXPLAINED: A LONGITUDINAL MEDIATION ANALYSIS

Lizanne van den Akker, PhD¹, Heleen Beckerman, PhD¹, Hans Knoop, PhD², Gijs Bleijenberg, PhD³, Joost Dekker, PhD¹, Vincent de Groot, MD, PhD¹¹VU University Medical Center, Amsterdam, Noord-Holland, Netherlands; ²Academic Medical Center, Amsterdam, Noord-Holland, Netherlands; ³Radboud University Medical Centre, Nijmegen, Noord-Holland, Netherlands

Background Cognitive behavioral therapy (CBT) effectively reduces fatigue in patients with multiple sclerosis (MS). Little is known about the process of change during and after CBT. **Purpose** To investigate which psychological factors mediate change in fatigue during and after CBT in patients with MS. **Methods** Ninety-one patients (44 in CBT, 47 in the control intervention) were included in a trial on the effectiveness of a 16 week CBT treatment for MS-related fatigue. Patients were assessed at baseline, 8, 16 and 52 weeks. Mediation was analyzed in two separate mediation models, one for mediation during treatment and one for mediation post-treatment. Proposed mediators were: change in illness cognitions, general self-efficacy, coping styles, daytime sleepiness, concentration, physical activity, fear of disease progression, fatigue perceptions, depression and physical functioning. Mediators were analyzed separately according to the product-of-coefficients approach. Confidence intervals were calculated with a bootstrap procedure. **Results** During treatment, improvement in fatigue brought on by CBT was mediated by improved fatigue perceptions, increased physical activity, less sleepiness, less helplessness, and improved physical functioning. Post-treatment worsening of fatigue was mediated by reduced physical activity, reduced concentration, and increased sleepiness. **Conclusion** These results suggests that focusing on improving fatigue perceptions, physical activity, sleepiness, helplessness, and physical functioning may further improve the effectiveness of CBT for fatigue in patients with MS. Maintenance of treatment effects may be obtained by focusing on improving physical activity, concentration and sleepiness.

DO YOU NEED TO KNOW THAT YOUR LIFESTYLE BEHAVIORS ARE “GOOD FOR YOU” IN ORDER FOR THEM TO AFFECT YOUR WELL-BEING?

Sandra J. Winter, PhD, MHA¹, Vidhya Balasubramanian, MS¹, Haley Hedlin, PhD², Catherine Heaney, PhD, MPH³¹Stanford University School of Medicine, Palo Alto, CA; ²Stanford University, Palo Alto, CA; ³Stanford, Stanford, CA

Background: This study examined the associations of self-reported diet, physical activity (PA) and sleep with well-being, and the extent to which these associations are mediated by participants' perceptions of these lifestyle behaviors.

Methods: Participants (n=597, mean age=45.1 ± 17.3, women=73%, years of education=16.0 ± 3.9, marital status-married=45%, never married=32%, other=23%) completed the Stanford WELL for Life on-line survey that included questions about 10 domains of wellbeing: social connectedness, lifestyle behaviors (including diet, PA, and sleep), physical and emotional health, stress/resilience, purpose and meaning, sense of self, finances, spirituality/religiosity, and creativity. For each domain, a score from 0–10 was created. Within the lifestyle domain, a sub-domain score from 0–10 was created for each lifestyle behavior. An overall wellbeing score was created by summing the 10 domain scores. Participants were also asked if their current diet, PA and sleep influenced their wellbeing. Linear regression analyses were conducted, controlling for age, gender, education and marital status.

Results: All three lifestyle behaviors were positively and statistically significantly related to well-being. A 10% improvement in the diet domain score was associated with a 2.4 % increase in the overall wellbeing score (95% CI 1.78, 2.97), a 10% improvement in the PA domain score was associated with a 1.3% increase in the overall wellbeing score (95% CI 1.02, 1.66), and a 10% improvement in the sleep score was associated with a 2.18% increase in the overall wellbeing score (95% CI 1.70, 2.66). When the perceived influence variables were added to the models, these associations were attenuated but still statistically significant. For diet, the increase in well-being decreased from 2.4% to 1.8%, with most of the explanation due to people who perceived their diets as harmful to their well-being. For PA, the increase in well-being decreased from 1.34% to .92%, with most of the explanation due to people who perceived their PA as contributing to their well-being. There was no statistically significant association between the perceived influence of sleep and wellbeing.

Conclusion: On average, participants in this study who reported healthier diet, PA and sleep behaviors also reported higher levels of wellbeing. These associations were partially mediated by participants' reports of the influence of these lifestyle behaviors on their well-being. However, a sizable portion of each of the associations was independent of participants' awareness. Implications for intervention and future research will be discussed.

EFFECTS OF DEPRESSION ON THE QUALITY OF LIFE AMONG FIBROMYALGIA PATIENTS

Mathew Mansoor, B.A.¹, Lauren Mckinley, B.A.², Terry Cronan, Ph.D.³¹San Diego State University, El Cajon, CA; ²San Diego State University, 92182, CA; ³San Diego State University, San Diego, CA

Fibromyalgia Syndrome (FMS) is a chronic pain condition characterized by symptoms that include widespread musculoskeletal tenderness, fatigue, cognitive impairment, and altered mood. Those suffering from FMS often report experiencing depression and a lower quality of life. The purpose of the present study was to determine whether depressed and non-depressed FMS patients differed over time in their mood, helplessness, self-efficacy, and health status. Participants were part of an intervention study examining the effects of social support and education, in which no intervention effects were found. Participants were 492 patients with a physician's diagnosis of FMS, which was confirmed by trained research assistants. Participants completed the Center for Epidemiologic Studies Depression Scale (CESD), Profile of Mood States, Arthritis Self-Efficacy Scale, Arthritis Helplessness Index, and the Fibromyalgia Impact Questionnaire at entry into the study and at a 1-year post-assessment. Participants scoring 19 or above on the CESD were categorized as depressed and those who scored below were categorized as non-depressed. A series of 2 (Depression Status: Not Depressed, Depressed) X 2 (Time: Baseline, One-year post-assessment) repeated measures analyses of variance were performed on each of the measures. Significant differences were found for depression status, time, and for the interaction for all analyses. Depressed participants had significantly greater improvements over time in mood, $F(1, 490) = 139.85, p < .001$, helplessness, $F(1, 490) = 11.04, p = .001$, self-efficacy, $F(1, 490) = 23.28, p < .001$, and health status, $F(1, 490) = 30.44, p < .001$ than non-depressed participants. These findings suggest that clinically depressed FMS patients are more likely to have improved changes in their mood, self-efficacy, helplessness levels, and health status than those who are not depressed. One possible explanation for these findings is that depressed people benefit from attention more than non-depressed people. Another possible explanation is that depressed participants' scores regressed toward the mean on the four measures assessed. Future researchers should develop interventions that target depression among FMS.

EXAMINING THE MOMENTARY EFFECTS OF SOCIAL AND ACTIVE LEISURE ON AFFECTIVE WELL-BEING IN CAREGIVERS

Matthew Zawadzki, Ph.D.¹, Brent T. Mausbach, PhD², Amanda Small, B.A.¹¹University of California, Merced, Merced, CA; ²University of California, San Diego, La Jolla, CA

Leisure engagement is an important component in daily life with beneficial effects on long-term health. Yet the possible mechanisms for how leisure has positive health effects remain to be identified and tested. One possibility is that leisure promotes positive, and reduces negative, affect. Over time, greater affective well-being can predict health given its associations with beneficial self-care and health behaviors. The first aim of this study is to test the in-the-moment associations of leisure with affect. The second aim is to compare social and active dimensions of leisure to test if leisure done in varied ways has different relationships with affect. These aims were tested in a sample of adult caregivers ($n = 25$; age $M=62.71$; 92.0% female; 80.0% white; caregiving hours per week $M=58.61$) who indicated at least three depression symptoms. For leisure, participants were provided with a list of 20 common leisure activities and indicated the frequency of each activity since the last assessment (Pleasant Events Scale-AD). Affect was assessed with 20 mood adjectives that fall into a positive or negative subscale (Positive and Negative Affect Schedule). Leisure and affect were assessed 4 times a day for 14 consecutive days; multi-level models tested the relationships between leisure and positive and negative affect over time. Testing Aim 1, the more frequently a person did leisure in a moment, the more positive ($b = 1.40, SE = .36, p < .001$) and less negative ($b = -.17, SE = .08, p < .05$) that person's affect was compared to moments with less frequent leisure. Testing Aim 2, leisure activities were coded as being social (e.g., having meals with friends or family) or non-social (e.g., watching television), and as being active (e.g., going on outings) or non-active (e.g., reading or listening to stories). Results indicated higher positive affect and lower negative affect in moments when the leisure was either more social or more active. In sum, findings point to a possible mechanism for leisure's associations with long-term health: when leisure is done more frequently, affective well-being is greater compared to moments with less frequent leisure, particularly when that leisure is social or active. With opportunities for leisure likely being limited among caregivers for this chronically stressed population, these results may suggest a way to optimize leisure experiences among this group.

IMPACT OF ORAL HEALTH STATUS AND ORAL HYGIENE PRACTICES ON QUALITY OF LIFE AMONG LOW-INCOME SENIORS

Judy A. Johnston, MS, RD, LD¹, Milan Bimali, PhD², Susan Parsons, PhD, RN³, Adam F. Lukens, D.D.S.⁴¹University of Kansas School of Medicine - Wichita, Wichita, KS; ²University of Kansas School of Medicine-Wichita, Wichita, KS; ³Wichita State University, Wichita, KS; ⁴Wichita Sedgwick County Oral Health Coalition, Wichita, KS

Associations exist between poor oral health status (POHS) and multiple health conditions among the elderly: localized infection and pain, increased risk of respiratory infections, under-nutrition, and unplanned weight loss. POHS has also been associated with challenges in ability to eat, speak clearly, and socialize, negatively impacting quality of life. A large proportion of older adults are unable to follow recommended teeth and denture hygiene practices due to limited income and lack of dental insurance. The goal of this research was to assess the oral health status of low-income seniors, as well as their oral health quality of life and self-care habits.

Data were collected from residents of low-income senior housing communities (LISHC) in a large Midwestern community. An oral health assessment was completed by Extended Care Permit Dental Hygienists. Nursing students collected the Oral Health Care Access and Behaviors and Oral Health Impact Profile (OHIP14). All data were collected on-site in March/April, 2017. Incentives were provided. Descriptive analyses were conducted, including risk ratios.

163 participants were recruited from 10 LISHCs. The average age of participants was 73 years; 80% females; 87% Caucasians; 92% single (never married, divorced or widowed); and 79% had high school degree or higher. 84% had Medicare enrollment; 35% had Medicaid enrollment; and 21% had dental insurance. 84% had some or all natural teeth and 29% reported denture use. 23% missed brushing teeth at least once a week; and 17% reported not cleaning denture at least once per week. 43% reported to be diabetic; and 48% reported to have had pneumonia. 22% had root fragments; 43% reported mild or severe inflammation on the Loe and Sliness Gingival Index. 88% had normal tooth mobility; and 49% were in need of dental care either urgently or within few weeks. Direct/unadjusted comparison showed that risk of eating discomfort was 12% higher among those with untreated root decay compared to those without untreated root decay; 87% higher among patients with painful mouth-ache compared to those without painful mouth-ache. Risk of embarrassment was 26% lower among denture users compared to those who did not use denture.

Findings from this study provide an overview of oral health status among low income uninsured seniors living in assisted housing. Preliminary findings suggest that quality of life could be impacted by the oral health status among our study population.

SEEKING AND ATTAINED MEANING-IN-LIFE: ASSOCIATIONS WITH PSYCHOSOCIAL OUTCOMES AMONG BREAST CANCER SURVIVORS

Allen C. Sherman, Ph.D.¹, Stephanie Simonton-Atchley, PhD¹, Angela Pennisi, MD², Daniella Ochoa, MD³, Rhonda Henry-Tillman, MD⁴, Laura F. Hutchins, MD², Issam Makhoul, MD²¹Behavioral Medicine, Winthrop P. Rockefeller Cancer Institute, University of Arkansas for Medical Sciences, Little Rock, AR; ²Medical Oncology, Winthrop P. Rockefeller Cancer Institute, University of Arkansas for Medical Sciences, Little Rock, AR; ³Surgical Oncology, Winthrop P. Rockefeller Cancer Institute, University of Arkansas for Medical Sciences, Little Rock, AR; ⁴Breast Oncology, Winthrop P. Rockefeller Cancer Institute, University of Arkansas for Medical Sciences, Little Rock, AR

Perceptions of meaning have garnered increased attention as a potential resource for patients struggling with the burdens of cancer. Different dimensions of meaning appear to have distinct health correlates. This preliminary cross-sectional study examined how sought and attained global meaning are related to a range of psychosocial outcomes among breast cancer survivors. To overcome limitations in previous research, we carefully selected indices of meaning that avoided confounding with study endpoints (e.g., well-being). It was hypothesized that a stronger sense of attained meaning in life would be related to more favorable outcomes, whereas a protracted search for meaning well into the survivorship phase might be tied to poorer outcomes. Participants were nonmetastatic breast cancer survivors enrolled in a larger study, who were assessed a minimum of 6 months since completion of treatment (except endocrine therapy) and who were in married/committed relationships. Mean age was 58.1 years, mean time since diagnosis was 3.4 years, and 70.1% were receiving endocrine therapy. They completed validated measures of global meaning (Meaning in Life Q). Outcomes included emotional distress (Brief Symptom Inventory anxiety and depression), adjustment to cancer (Illness Cognition Questionnaire), body image (Body Image Scale), and illness-related stress (single item). In bivariate analyses, attained meaning was significantly associated with more favorable scores on all 6 outcomes (all p 's < .04). Conversely, greater search for meaning was related to worse emotional distress, illness-related helplessness, and body image difficulties (all p 's < .05). In multiple regression analyses that accounted for current endocrine therapy and any significant clinical or demographic covariates, attained meaning remained significantly associated with less distress ($\beta = -.49$, $p = .001$), less illness-related helplessness ($\beta = -.40$, $p = .01$), greater illness-related benefits ($\beta = .43$, $p = .008$), less body image disturbance ($\beta = -.39$, $p = .01$), and less illness-related stress ($\beta = -.48$, $p = .003$). In contrast, greater search for meaning was significantly associated with greater helplessness ($\beta = .45$, $p = .004$) and body image disturbance ($\beta = .46$, $p = .004$), and marginally greater emotional distress ($\beta = .31$, $p = .054$). Results of this preliminary study underscore the importance of evaluating discrete domains of perceived meaning, which have distinct associations with psychosocial outcomes. Seeking and found global meaning merit further attention in larger investigations using longitudinal designs.

SELF-EFFICACY TO COMMUNICATE ABOUT SEX AND INTIMACY IN WOMEN TREATED FOR CANCER: AN INSTRUMENT DEVELOPMENT STUDY

Elizabeth Arthur, RN MS CNP¹, Celia Wills, PhD RN², Usha Menon, PhD RN FAAN³¹The Ohio State University College of Nursing, Westerville, OH; ²The Ohio State University, Columbus, OH; ³University of Arizona, Tucson, AZ

Background and Purpose: The sequelae of cancer treatment can negatively impact women's sexual wellbeing. Self-efficacy (confidence in one's ability to perform the steps of a designated task) is a component of Social Cognitive Theory, a key theory guiding health behavior interventions. Research on interventions for improving sexual wellbeing after cancer treatment reveals that self-efficacy is a key factor. The purpose of this study was to refine the Self-Efficacy to Communicate about Sex and Intimacy (SECSI) scale.

Methods: The initial self-efficacy instrument was developed from a comprehensive review of the literature and clinical experience with cancer survivors. A panel of four international content experts in self-efficacy scale development, women's sexual health, and partner communication after cancer treatment provided feedback about relevance, clarity and comprehensiveness of items using a standardized tool. Next, twenty adult women cancer survivors provided feedback via semi-structured cognitive interviews, as well as sociodemographic and clinical characteristics data. Each participant was asked questions regarding comprehension, clarity, and relevance of a random selection of items from the 25 item instrument. Data collection ended based on saturation of responses (no substantively new information being gathered) for all candidate scale items.

Results: Cognitive interview feedback was coded into seven categories: 1) irrelevant or unimportant, 2) didn't understand the question, 3) off-putting, 4) redundant, 5) not related to cancer, 6) makes assumptions, and, 7) wording too general and not consistent with (explained) intent. Based on the coded feedback, the research team revised wording of items and structure of the instrument. The final instrument is a 10-item list of statements scored on a Likert-type response scale and summed for a total score ranging from 0 to 40 regarding a woman's level of confidence in her ability to communicate with her partner about sex and intimacy in the context of cancer treatment.

Conclusions: Self-efficacy is an important predictor of behavior, and should be a focus of future study of sexual adjustment in survivorship. This study fills a need for development and validation of a standardized measure of self-efficacy for communication about sex and intimacy. The next step is to evaluate psychometric performance of the refined scale (internal consistency and test-retest reliability; construct validity).

WELL-BEING ACROSS THE LIFE COURSE

Naina Ahuja, BS¹, Sandra J. Winter, PhD, MHA², Catherine Heaney, PhD, MPH³, Rajani Kaimal, MS⁴, Haley Hedlin, PhD¹¹Stanford University, Palo Alto, CA; ²Stanford University School of Medicine, Palo Alto, CA; ³Stanford, Stanford, CA; ⁴Quantitative Sciences Unit (QSU), Stanford Department of Medicine, Palo Alto, CA

Background: The concept of wellbeing and how it changes across the life course is not clearly understood. The literature shows inconsistent results in terms of the association between age and wellbeing, partially due to different conceptualizations of wellbeing. In this study, we used a broad, multi-faceted 10 domain measure of wellbeing to investigate the following research questions: how is age associated with overall wellbeing?; how is age associated with each of the constituent domains of wellbeing?; and to what extent does age modify the contribution of the constituent domains to wellbeing?

Methods: 618 participants responded to the online Stanford WELL for Life Scale (SWLS score ranges from 0–100). The sample was predominantly female (75% female) and relatively highly educated (51% with 17+ yrs of education). Using previously established age categorizations (young adult: 18–35 yrs; middle aged: 36–55 yrs; older adults: 55+ yrs), linear regression was used to investigate the research questions.

Results: The association of age with wellbeing, after adjusting for education and gender, was positive and statistically significant ($p < 0.001$). Compared to the referent age group of 18–35 yrs, the estimated mean wellbeing score of a male with 17+ yrs of education was higher in the age group 36–55 yrs by 1.22 (95% CI 1.12–3.56) and was higher by 5.06 (95% CI 2.87–7.26) in the age group 55+ yrs. Age was also significantly associated with each of the constituent domains of wellbeing with the exception of exploration/creativity. Unexpectedly, participants aged 55+ yrs had higher scores on the constituent domains of wellbeing than in the two younger age groups. In only the lifestyle domain was the association between the domain and wellbeing statistically significantly modified by age. The lifestyle domain includes diet, sleep, physical activity, binge drinking and smoking. A unit increase in lifestyle score increased the wellbeing score by 2.97 (95% CI 1.97–3.97) in ages 18–35 yrs, but by 5.38 in ages 36–55 yrs (95% CI 4.03–6.73) and by 5.03 (95% CI 3.63–6.43) in ages 55+ yrs.

Conclusion: These results contribute to the growing literature finding higher than expected levels of wellbeing among older adults: older adults score higher on the SWLS compared to young adults and middle-aged adults. In addition, the results also added to the existing literature on older adults reporting a stronger sense of self and purpose and meaning. However, unexpectedly, older adults in our sample report being more socially connected and experiencing a higher level of physical health (measured here as having more vitality and energy). Further investigation is needed to explore these unexpected results.

24-HOUR HEALTH BEHAVIOR: DAILY INTERACTION OF SLEEP AND WAKING HEALTH BEHAVIORS

Michael P. Mead, MS, Allison Engwall, BS, Leah A. Irish, PhD

North Dakota State University, Fargo, ND

The consideration of health behaviors within a 24-hour context provides an important model for health promotion and intervention efforts. Although sleep has been shown to be associated with waking health behaviors, including exercise, alcohol consumption, caffeine use, and napping, research investigating the directional influence of night and day is scant and inconsistent. The current study sought to extend the literature by examining the daily, bidirectional relationships between sleep and waking health behaviors. Baseline data from a parent study were used for analyses. Participants ($N=384$) were college students who completed two weeks of a baseline assessment in which their objective sleep quality was assessed via Actigraphy and various waking health behaviors were self-reported via a bedtime sleep diary. Mixed linear models were used to test the daily, direct effects of waking health behaviors on subsequent night's sleep. Alcohol consumption was significantly associated with greater total sleep time (TST) and sleep onset latency (SOL), but predicted fewer awakenings ($p's < .05$). Drinking caffeine after 2PM significantly predicted less TST and longer SOL ($p's < .001$). Napping longer than 30 minutes was associated with greater SOL, wake after sleep onset (WASO), and number of awakenings ($p's < .05$). Mixed linear models were also used to test the daily, direct effects of sleep on next day health behavior. Longer TST significantly predicted less alcohol and caffeine consumption the following day ($p's < .001$). Contrary to expectation, more nighttime awakenings significantly predicted less alcohol and caffeine consumption the following day ($p's < .001$). Lastly, greater sleep efficiency significantly predicted less time spent napping the following day ($p=.036$). These results indicate that sleep and waking health behaviors hold a significant, bidirectional influence on one another and provide evidence for a 24-hour model of health behavior. Greater understanding of the temporal relationships between nocturnal and waking health behaviors can help identify targets for intervention and improve effective allocation of public health resources.

CHASING Z'S: SLEEP QUALITY AND BEDSHARING IN TEEN MOMS

Lauren E. Boddy, M.A., Nancy A. Hamilton, Kansas

University of Kansas, Lawrence, KS

Sleep is disrupted during pregnancy and the postpartum period (PPP) for adult women, and infant sleep location affects maternal sleep quality and may increase risk for infant mortality. However, little is known about sleep and co-sleeping practices of adolescent mothers, particularly low income, ethnically diverse populations. To fill that gap, data were gathered from a small sample of primiparous, pregnant adolescents, aged 15–19 years ($M=17.7$ yrs; $SD=1.4$ yrs), participating in a larger, longitudinal pilot study testing the feasibility of a multiple health behavior change intervention. The teens completed 2 home visits; they reported on demographics, completed the Pittsburgh Sleep Quality Index (PSQI) and 7 days of twice-daily sleep diaries (pre- and postpartum). Pre-partum (week 31): pregnant adolescents completed a standard sleep diary (quality, duration, etc.) and answered questions about bedsharing intentions ("Where [and why] do you plan for your baby to sleep once s/he is born?"). Postpartum (week 5 PPP): teen moms completed a standard sleep diary and reported on where the baby slept each night. Pre-partum results: The PSQI total score exceeded the "poor sleep" cut-off for 50% of teen moms, and 70% reported elevations on sleep disturbance. The modal problem was difficulty breathing. Average sleep duration varied greatly across moms (within-person means, range: 3-13hrs). Most (83%) mothers reported pre-partum intention to co-sleep (crib/bassinet in mother's room), and one indicated intention to bedshare (mother and baby on same sleep surface). Reasons for chosen infant sleep location include distance/access (70%), unprepared for baby (17%), and safety concerns (17%). Postpartum results: Again, average sleep duration varied greatly across moms (within-person means, range: 3-10hrs), with a varied list of disturbances (e.g., use bathroom, feel hot, pain). All mothers (100%) reported bedsharing for at least part of the night on at least one night, with a majority (80%) on 4+ nights. Reasons for PPP bedsharing: post-feeding/changing (80%), comfort baby (80%), feel close to baby (60%), safety concerns (40%), and other (20%). This is one of the first studies to focus on pre- and post-partum sleep and mother-infant bedsharing within the teen mom population. These findings have important implications for the care of teens and their families, including their medical and psychological teams, especially given the known risks of sleep disruption and bedsharing.

CPAP TITRATION NON-COMPLETION: A PREDICTIVE CORRELATIONAL STUDY

Katelijne F. Acker, PhD, RN¹, Elizabeth Restrepo, PhD, RN²¹Texas A&M University - Corpus Christi College of Nursing and Health Sciences, Corpus Christi, TX; ²Texas Woman's University College of Nursing, Denton, TX

Background: Sleep loss is a global public health burden with far-reaching social, economic, and health consequences. Obstructive sleep apnea (OSA) causes fragmented sleep and OSA prevalence in adults, 30–70 years of age, approximates 26%. About 30% of those who are diagnosed with OSA drop the recommended CPAP treatment before initiation. In this study, the concept of *CPAP adherence* was expanded to include titration study completion as the first act of adherence. This study targeted a group that is rarely studied: the non-adherers.

Participants: Consecutively sampled, CPAP-naïve, newly diagnosed OSA patients ($N=155$) completed a battery of questionnaires the evening of their diagnostic polysomnography, before receiving educational information.

Methods: A predictive correlational study, using logistic regression, was conducted. Using valid and reliable surveys, cognitive concepts assessed were: (a) risk perception, (b) outcome expectancy, (c) self-efficacy, (d) locus of control, (e) health value, and (f) beliefs about OSA and CPAP. Physiological data were gathered from diagnostic sleep study results. Titration completion was assessed 90 days after diagnosis.

Results: Lower perceived risk scores ($OR=0.28$, $p=.028$), maladaptive beliefs about OSA and CPAP ($OR=0.87$, $p=.033$) and lower internal LOC scores ($OR=0.88$, $p=.045$) contributed significantly to titration non-completion prediction. The final regression model explained about 35 % of the variance in titration non-completion and 83.2 % of cases were correctly classified. Approximately 24 % of the participants did not complete a titration study within 90 days. Respiratory disturbance index (RDI) was implicated in titration non-completion prediction.

Conclusion: Participants' maladaptive beliefs about OSA and the CPAP treatment, and their lack of understanding of the risks associated with OSA, influence titration non-completion, even when measured before OSA diagnosis.

'I WAS PARANOID MILLIPEDES WERE IN MY BED...' AND OTHER REASONS YOUNG ADULTS VOLUNTARILY RESTRICT THEIR SLEEP

Allison Engwall, BS, Michael P. Mead, MS, Leah A. Irish, PhD

North Dakota State University, Fargo, ND

Approximately 32% of young adults report short sleep duration (< 7 hours/night). Much of the research to date has focused on inadequate sleep occurring as a result of sleep problems (e.g., sleep disorders, delayed sleep phase syndrome) or specific behaviors (e.g., technology use). The present study takes a broad approach to explore the prevalence of and reasons for voluntary sleep restriction in a sample of 272 undergraduates. Each morning for 2 weeks participants were asked, "Last night, what prevented you from going to bed when you wanted?", producing 3601 nights of data. Of these, participants indicated that their sleep had been restricted and provided reasons on 2088 nights (58%). Responses were coded and collapsed into 4 general categories: work/school-related restriction (e.g., work, homework), social-related restriction (e.g., time spent with family or friends), restriction due to sleep difficulties (e.g., illness, noisy environment), or activity-related restriction (e.g., technology use, sports, eating). Results indicated that sleep restriction was common and variable. Only 4% of participants reported no sleep restriction over the study period, whereas approximately 70% of participants reported sleep restriction on more than half of the nights, including 18% who reported sleep restriction every night. The reasons given for sleep restriction were reported at similar rates, with frequencies ranging from 21–31% of restricted nights. Further, almost 2/3 of participants reported reasons for their sleep restriction that represented 3 or more categories, suggesting that, for many, sleep restriction is the result of a complex rather than singular cause. Although actigraphy-assessed total sleep time was shorter on nights that participants reported sleep restriction, the difference between restricted and non-restricted nights was relatively small (10–16 minutes), and average total sleep time did not reach the recommended 7 hours even on unrestricted nights. Taken together, these findings provide novel insight into the obstacles to healthy sleep. Our findings show that, among young adults, sleep restriction is common, results from multiple causes, and contributes to shorter sleep duration. Efforts to improve sleep health in young adults, therefore, might consider time management to promote healthy sleep.

ASSOCIATIONS AMONG SLEEP, BODY MASS INDEX, WAIST CIRCUMFERENCE AND RISK OF TYPE 2 DIABETES AMONG US CHILDBEARING WOMEN

Lydi-Anne Vézina-Im, PhD¹, Theresa A. Nicklas, DrPH¹, Tom Baranowski, PhD¹¹Baylor College of Medicine, Houston, TX

Objective. Women of childbearing age present an important group for understanding sleep and few studies have focused on this population. To our knowledge, no study has investigated the associations among sleep, overweight/obesity and risk of type 2 diabetes (T2D) among childbearing age women in the National Health and Nutrition Examination Survey (NHANES). We hypothesized that sleep duration and quality will be negatively associated with body mass index (BMI), waist circumference (WC) and 2-hour oral glucose tolerance test (OGTT).

Methods. Data were from NHANES, 2005-2008. The study population consisted of 18-44 year old women. Pregnant women and those diagnosed with sleep disorders were excluded. Sleep duration and quality were self-reported by women. Sleep quality was measured using three indicators: latency, disturbances and daytime dysfunction (Cronbach $\alpha=0.81$). BMI, WC measurements and a 2-hour 75 g OGTT were performed by trained NHANES staff. To assess the associations between sleep and BMI, WC and 2-hour OGTT, three linear regression analyses with survey weights were computed for each outcome: 1) an unadjusted analysis, 2) one adjusted for demographic variables only (partially adjusted analysis: age, ethnicity and education) and 3) one adjusted for demographics and variables associated with obesity/T2D (fully adjusted analysis: depression, total energy intake, moderate- and vigorous-intensity physical activity, screen time, smoking, alcohol, antidiabetic and obesity treatment medications).

Results. Total sample consisted of 2388 childbearing age women. The average sleep duration was 7 hours per night and the average score for sleep quality was 8 on a scale from 0 to 23, indicating an overall good sleep quality. Only sleep duration was significantly associated with BMI and WC in the unadjusted ($\beta = -0.12$; $p = 0.0001$; $R^2 = 0.02$ and $\beta = -0.13$; $p < 0.0001$; $R^2 = 0.02$) and partially adjusted ($\beta = -0.10$; $p = 0.0015$; $R^2 = 0.05$ and $\beta = -0.11$; $p = 0.0002$; $R^2 = 0.06$) models, but was no longer significant in the fully adjusted model ($p > 0.05$). Neither sleep duration nor quality were significantly associated with 2-hour OGTT in any of the models (all $p > 0.05$).

Conclusions. Targeting sleep duration and sleep quality alone would not likely contribute to significantly lowering BMI, WC or risk of T2D in US childbearing age women. Additional studies, especially longitudinal ones, with both self-reported and objective measures of sleep are needed to confirm the present findings.

SELF-REPORTED SLEEP DURATION AND CORTISOL REACTIVITY TO SOCIAL EVALUATIVE THREAT

Kevin Jordan, Ph.D.¹, Matthew R. Cribbet, Ph.D.², Timothy Smith, Ph.D.³, Megan Barclay, MS¹, Katie Niehus, BA¹, Anna Gernand, BS¹, Ari Feinstein, BS¹¹Indiana State University, Terre Haute, IN; ²Texas Tech University, Lubbock, TX; ³University of Utah, Salt Lake City, UT

Insufficient sleep is reliably associated with increased risk for depression, diabetes, cardiovascular disease and premature mortality. Activation of the hypothalamic pituitary adrenal (HPA) axis during stress, especially stress that involves social evaluative threat, represents one mechanism linking short sleep duration with adverse health outcomes. Empirical studies have produced inconsistent results when testing associations between short sleep and HPA axis activation when stressed. These inconsistent findings may be due to the fact that the most widely used social evaluative stressors involve both threats to status (e.g. achievement and influence) and acceptance (e.g. inclusion and connection with others). The current study addressed prior inconsistent results by evaluating the content of social evaluative stress through experimental manipulation of status and acceptance threats. Ninety-seven healthy participants ($M_{age} = 22.8$ years; 48% female) rested quietly for 10 minutes and then participated in a modified Trier Social Stress Test (TSST) that included 1 of 4 conditions (status threat, acceptance threat, combined status and acceptance threat, or control condition). Following the modified TSST, participants rested quietly for 5-minutes. Prior night sleep duration, minutes since awakening and height and weight were assessed prior to baseline. Salivary cortisol was measured at baseline, 5 minutes after conclusion of the stress task, and 10 minutes later. Reactivity was calculated as task minus baseline value. In multiple regression analyses controlling for age, gender, race, BMI and minutes since awakening, sleep duration was negatively associated with cortisol reactivity during the combined status and acceptance threat condition ($\beta = -.31$, $t = -2.74$, $p < .01$), the status condition ($\beta = -.27$, $t = -2.52$, $p < .05$) but not the acceptance condition ($\beta = -.20$, $t = -1.89$, $p = .06$). For the control condition, sleep duration was unrelated to cortisol reactivity ($\beta = -.13$, $t = -1.23$, $p = .22$). In the current study, short sleep duration was associated with HPA axis activation during both the combined threat and status threat conditions. These results replicate prior associations between short sleep and HPA axis activation to social stress and suggest that threats to status may be particularly impacted by short sleep duration. Ultimately, these findings may have implications for future studies linking short sleep duration and health through stress pathways.

SLEEP IN YOUNG ADULTS: PRE-SLEEP TECHNOLOGY USE, AROUSAL, AND HYGIENE IN RELATION TO SLEEP DISTURBANCE AND INSOMNIA SYMPTOMS

Christine E. Smith-Mason, MA¹, Virginia Gil-Rivas, Ph.D.²¹University of North Carolina at Charlotte, Chicago, IL; ²UNC Charlotte, Charlotte, NC

Introduction: The importance of a good night's sleep to health outcomes is well-documented in clinical sleep research. Less is known about patterns of sleep behavior in non-clinical populations. Young adults are the fastest growing group reporting poor sleep. This, in part, may be related to the increase in the use of electronic devices prior to sleep (Gradisar et al., 2015; Levinson et al., 2017). This study examined relationships among pre-sleep technology use, arousal, and sleep hygiene with sleep disturbance and insomnia symptoms.

Participants: Young adults (N=249) from diverse backgrounds (63.7% White; 8.1% Hispanic); 68.7% female; age range 18–24 years ($M=19.06$; $SD=1.45$).

Procedure: Self-administered electronic survey. Demographics, sleep quality (PSQI – Buysse et al., 1989), insomnia severity (ISI – Morin et al., 1987), pre-sleep technology use (NNSF, 2011), pre-sleep arousal (PSAS – Nicassio et al., 1985), sleep hygiene (SHI – Mastin et al., 2010), and sleep-related worry (Sunnhed & Jansson-Fröjmark, 2014). All scales indicated strong internal reliability ($\alpha = 0.76 - 0.93$).

Results: Surprisingly, poor-quality sleep (PSQI > 5) was reported by 88.8% of participants and 35% met the criteria for subthreshold or clinically significant insomnia symptoms. Females were more likely than were males to report poor sleep quality [$t(247)=-2.03$, $p < 0.05$]. The majority (83%) used three or more electronic devices in the hour before sleep, with 95.2% reporting sleeping with their mobile phones on or next to their beds, and 25.8% reporting regular awakenings during the night due to cell phone alerts. Correlations were observed in expected directions. Regression analyses indicated that female gender, sleep related worry, and pre-sleep arousal were significant predictors of sleep quality ($R^2=.38$, $p<.01$) and insomnia symptoms ($R^2=.30$, $p<.01$). Furthermore, number of devices and pre-sleep laptop use predicted pre-sleep arousal ($R^2=.06$, $p<.05$).

Conclusion: Technology use prior to bed and reports of poor quality sleep were overwhelmingly endorsed. Findings suggest that the relationship between technology use and sleep among young adults is complex. However, device usage in the hour prior to sleeping was associated with pre-sleep arousal and sleep-related worry, which have demonstrated relationships with poor sleep among clinical samples. Future research will benefit exploring the directionality and causality of these associations.

6:15 PM-7:15 PM

THE EFFECTS OF APP-DELIVERED CBT FOR INSOMNIA ON SLEEP QUALITY, DYSFUNCTIONAL BELIEFS, AND SLEEP HYGIENE

Julia Leonard, B.A., Angela B. Duncan, Ph.D.

Washburn University, Topeka, KS

Sleep quality is correlated with physical and mental health (Ohayon et al., 2017). Cognitive Behavioral Therapy for Insomnia (CBT-I) is an evidence-based strategy to improve sleep quality; however, shortage of qualified providers, logistical issues such as cost, travel, and time, privacy concerns, and a desire to resolve symptoms on one's own limit access to CBT-I. Compared to traditional face to face or web-based delivery of CBT-I, app-delivered CBT-I may be an efficacious alternative capitalizing on the portability, privacy, and accessibility of mobile phones. Interventions involving smart phones, including mobile apps, are readily accessible as smartphone usage has steadily increased with over three-quarters (77%) of American adults currently owning smartphones, an increase from 64% in 2015 (Pew Research, 2017). The present study examined the effectiveness of the CBT-I Coach for educating participants about the importance of healthy sleep practices, dysfunctional beliefs about sleep, and targeting sleep quality among participants ($N=25$, mean age $M=22$, $SD=8.867$) from a midsize Midwestern University. Participants completed surveys assessing sleep quality (PSQI; Buysse, Reynolds, Monk, Berman, & Kupfer, 1989), dysfunctional beliefs about sleep (DBAS; Morin, Vallieres, & Ivers, 2007), and sleep hygiene behaviors (SHPS; Yang, Lin, Hsu, & Cheng, 2010). Participants completed sleep diaries every day over a 4-week time period before and during their use of the CBT-I Coach app. When pre- and post-test measures of sleep quality (pre-test $M=7.52$, $SD=3.36$; post-test $M=5.6$, $SD=2.42$), beliefs about sleep (pre-test $M=4.76$, $SD=1.71$; post-test $M=4.01$, $SD=1.24$), and sleep hygiene behaviors (pre-test $M=3.53$, $SD=0.89$; post-test $M=3.04$, $SD=0.69$) were compared, a significant improvement was found across all factors (PSQI $t(24) = -3.842$, $p=.001$; DBAS $t(24) = -2.995$, $p=.006$; SHPS $t(24) = -3.783$, $p=.001$). Findings suggest that app-delivered CBT-I can aid in improvement of sleep quality and target both the cognitive and behavioral components of sleep supporting both feasibility and efficaciousness of app-delivered treatment. This is especially important for those who do not have sleep difficulties that are severe enough for them to seek more formalized treatments and for those who cannot access face-to-face treatment due to personal and logistical barriers.

6:15 PM-7:15 PM

ASSESSMENT OF SELF-REPORTED SLEEP PROBLEMS AND PHYSICAL HEALTH SYMPTOMS IN ADULT PSYCHIATRIC INPATIENTS

Lauren Straine, M.A.¹, Matthew C. Sullivan, B.A.¹, Stacy E. Cruess, Ph.D.², David Wheeler, Ph.D.³, Dean G. Cruess, Ph.D.¹¹University of Connecticut, Storrs, CT; ²Natchaug Hospital, Hartford Healthcare, Mansfield, CT; ³Natchaug Hospital, Hartford Healthcare, Mansfield Center, CT

Sleep is an important determinant of physical and mental health. Despite evidence that psychiatric inpatients may be at increased risk for both poor sleep and clinically significant physical symptoms, the relationship between these variables is not well understood in this population. The goal of this study was to assess the relationship between sleep problems and physical health symptoms in a sample of adult psychiatric inpatients, and evaluate the utility of a brief sleep disturbance measure as a predictor of physical health symptom severity.

Ninety-five adults were assessed upon admission to an inpatient psychiatric hospital. Demographic and medical information were extracted via chart review. Participants completed the PROMIS Sleep Disturbance Measure – Short Form, the PROMIS Depression Measure – Short Form, the DSM-5 Cross-Cutting Symptom Measure (CCSM), and the Patient Health Questionnaire – Physical Symptoms measure (PHQ-15). PHQ-15 scores were dichotomized to reflect low versus medium/high severity of physical symptoms. A hierarchical binomial regression was conducted predicting severity of physical symptoms from sleep disturbance scores, while controlling for gender, depression scores, presence of psychotic symptoms, number of medications prescribed, number of psychiatric diagnoses, and whether the participant was undergoing detoxification during hospitalization.

Fifty percent of participants reported medium/high levels of physical health symptoms, and 41% of participants reported moderate/severe levels of sleep disturbance. A positive screen on the CCSM Somatic Symptoms domain was a significant predictor of more severe physical symptoms ($\exp(\beta) = 3.096$, $p = 0.036$, 95%CI [1.07, 8.93]). When sleep disturbance scores were added, the model accounted for significantly more variability in physical symptom severity ($\Delta R^2 = 0.096$, $\chi^2 = 9.202$, $p = 0.002$), and the CCSM Somatic Screener was no longer a significant predictor ($\exp(\beta) = 2.730$, $p = \text{n.s.}$, 95%CI [0.88, 8.47]). Sleep disturbance scores independently predicted a significant share of physical symptom severity ($\exp(\beta) = 1.112$, $p = 0.005$, 95% CI [1.03, 1.20]).

A significant proportion of psychiatric inpatients in this sample reported moderate/high levels of physical health symptoms and poor sleep, and greater sleep disturbance was a significant predictor of somatic symptom severity. The brief PROMIS Sleep Disturbance Measure was a better predictor of physical health symptoms among psychiatric inpatients than the CCSM alone.

INCREASED SLEEP EFFICIENCY THROUGH HEAT THERAPY AND EXERCISE

Jonathan North, B.S.¹, Jason Cohen, B.S.², Daniel Palac, MA³, Tiffany Bullard, B.S.⁴, Madhura Phansikar, M.A.⁴, Brett J. Wong, Ph.D.⁵, Sean P. Mullen, PhD⁴¹University of Illinois Urbana-Champaign, Monticello, IL; ²University of Illinois at Urbana-Champaign, Champaign, IL; ³University of Illinois at Urbana-Champaign, Champaign, IL; ⁴University of Illinois at Urbana-Champaign, Urbana, IL; ⁵Georgia State University, Atlanta, GA

Regular physical activity is widely accepted as a viable form of behavioral medicine for the prevention and treatment of cardiovascular disease (e.g., reducing blood pressure). Recent evidence also indicates heat therapy (saunas, heated blankets, warm baths, and infrared therapy) can elicit benefits similar to physical activity. Both heat therapy and exercise interventions can independently improve sleep quality but the additive effects of combined interventions are unclear. In a pilot randomized control trial participants received 14 weeks of supervised, regular (3x/week) moderate intensity aerobic activity (50 minutes) followed by either sessions in a same-sex steam-room located in a locker-room ($n=21$) or time-matched quiet seated rest in a lobby of a fitness facility ($n=20$). Participants were recruited via electronic advertisements and subsequently screened for depression, cognitive impairment, and untreated pre-hypertension (auto-BP device confirmed 120–139 mmHg systolic blood pressure [BP] / 80–89 mmHg diastolic BP). A battery of psychosocial questionnaires (including the Pittsburg Sleep Quality Index [PSQI]) was assessed at baseline and month 4 follow-up. Participants were mostly non-Hispanic White (73.2%) women (58.5%), with a college/advanced degree (75.6%). At baseline, the majority were overweight or obese (BMI $M=32.92$, $SD=8.28$) and non-smokers (24.4% had a history of smoking or currently smoke). In an exploratory analysis, a univariate test of our hypothesis showed no difference between groups in PSQI composite score change. Similarly, change from pre- to post intervention in sleep efficiency (self-reported sleeping hours / hours spent in bed) was not statistically significant (86.41% vs. 84.31%). However, after adjusting for treatment dose (total visits), and factors known to impair sleep (depression, BMI), we found a significant group effect indicating improvement in sleep efficiency in favor of the steam group ($p = .02$, $\eta^2 = .14$). Specifically, participants in the steam condition were 7.68% more efficient. After adjusting for smoking history/current smoking status and overall program compliance with American Heart Association recommendations for alcohol consumption (less than or equal to 1 alcoholic beverage per day), the group effect was attenuated somewhat ($p = .06$, $\eta^2 = .10$). There were no statistically significant differences between steam and rest groups in session attendance (30.62 vs. 36.60 sessions; overall compliance = 80%) or frequency of evening sessions (61.90% vs. 65.00% sessions held after 5pm). Together, these findings add to the growing literature on the benefits of heat therapy as a standalone or adjuvant therapy with other evidence-based treatments (exercise) for improving sleep efficiency.

SHORT SLEEP DURATION AND BEHAVIORAL RISK FACTORS FOR PREMATURE MORBIDITY AND MORTALITY

Matthew R. Cribbet, Ph.D.¹, Jenny M. Cundiff, Ph.D.¹, Jennifer M. Taber, PhD²¹Texas Tech University, Lubbock, TX; ²Kent State University, Kent, OH

Behaviors such as smoking, alcohol use, physical inactivity, and poor diet are established risk factors for increased morbidity and early mortality, and there is now convincing evidence that short sleep duration is as well. These risk factors are often examined in isolation; however, their aggregation may better reflect risk for poor health outcomes. This secondary data analysis had two aims: 1) to understand whether health behaviors vary more between people or between days; and 2) to examine whether and how these health behaviors aggregate with short sleep duration. To test these aims, a community sample of 213 participants recruited for the Pittsburgh Cold Study 3 ($M_{age}=30.13$ years; 57% male; 66% White) completed a health behavior diary and wore a wrist actigraph for 14 consecutive days. Health behaviors were quantified as the daily number of cigarettes smoked ($M=3.81$), alcoholic drinks consumed ($M=3.49$), fruits and vegetables consumed ($M=10.48$), and minutes exercising ($M=26.13$). Wrist actigraphy data were used to categorize sleep duration ($M=5.87$ hours) as short (6 hours, $n=75$). To test the first aim, multilevel modeling assessed the proportion of variance between people versus within days. In multilevel models, we found that levels of physical inactivity, fruit and vegetable consumption and alcohol were more a function of the day than the person (% of variance accounted for within person was 76%, 74% and 64% respectively; $p=.06$). To test the second aim, a principal components analysis revealed a two-factor solution among short sleepers, alcohol consumption and smoking comprised 1 component and physical inactivity and fruit and vegetable consumption comprised a second component (all loadings greater than .66; accounting for 61% of cumulative variance). Among adequate sleepers, smoking and fruit and vegetable consumption comprised 1 component and physical inactivity and alcohol consumption comprised a second component (all loadings > absolute value of .63; accounting for 57% of variance). These results suggest that most health behaviors are a function of day rather than person, and that both healthy and unhealthy behaviors aggregate among short sleepers, but are less likely to aggregate among those obtaining adequate sleep. These findings help us better understand the potential aggregation of behavioral risk factors with short sleep.

SLEEP DIFFICULTIES INTERACT WITH AGE IN PREDICTING COGNITIVE PERFORMANCE AMONG PATIENTS WITH HEART FAILURE

Kristie Harris, M.S.¹, Jocelyn D. Shoemake, M.P.H.², Laura Boxley, Ph.D.³, Charles F. Emery, Ph.D.⁴¹Warren Alpert Medical School of Brown University, Providence, RI; ²The Ohio State University, Columbus, OH; ³Ohio State University Wexner Medical Center, Columbus, OH; ⁴Ohio State University, Columbus, OH

Background: Impaired cognitive function is common among patients with heart failure (HF), with deficits observed across several domains, including executive functioning, attention, and memory. Older age is also associated with increasing cognitive impairment. Sleep disturbance is common in HF patients and is generally more common in older adults. This study was designed to evaluate the influence of age (and education) on cognitive functioning in HF patients, and to determine the degree to which self-reported sleep difficulties influence the relationship. It was hypothesized that older age and lower education would be associated with worse cognitive performance in HF patients, and that self-reported sleep difficulties would moderate these relationships.

Methods: Thirty-three patients with HF (mean age = 56.4 ± 9.9 years; age range = 38 to 75 years; 21 males; mean education = 14.1 ± 3.0 years) referred for comprehensive neuropsychological evaluation completed the California Verbal Learning Test (CVLT) and the Trail Making Test (TMT). The CVLT assesses verbal learning and memory and provides subscale scores for short and long delay, free and cued recall, and recognition. The TMT is comprised of two parts, A and B, measuring visual search, attention, and motor functioning, as well as higher-order executive functioning. Patients also completed an intake questionnaire detailing demographics (i.e. age, gender, education level) and presence of sleep difficulties (yes/no). Hierarchical regression analyses were performed to predict performance on the CVLT and TMT from age and education level, as well as the interaction of those variables with self-reported sleep difficulty.

Results: Neither age nor education level was associated with CVLT or TMT performance ($ps > .05$). However, there was a significant interaction of sleep difficulty with age in predicting performance on each CVLT subscale (range of β s = -16.68 to -15.63, all $p < .05$, range of Model R^2 s = 0.27 to 0.29, all $p < .03$) and TMT part B ($\beta = -13.08$, $p = .04$, Model $R^2 = 0.17$, $p = .13$), reflecting that endorsement of sleep difficulties worsened the relationship of older age to poorer cognitive performance in HF.

Conclusions: These data underscore the importance of sleep disturbances among patients with HF. In these patients, the negative effects of illness and older age are exacerbated by difficulty sleeping, particularly in the domains of verbal learning, memory, and executive functioning. Thus, addressing sleep complaints among patients with HF may be beneficial both for physical health and for cognitive functioning.

SLEEP DURATION AND METABOLIC CONDITIONS AMONG US OLDER ADULTS: ANALYSIS OF THE NATIONAL HEALTH INTERVIEW SURVEY

Jolaade Kalinowski, Ed.D., M.A.¹, Azizi Seixas, PhD, MS, MA², Shawn Youngstedt, Ph.D.³, Tamar Shochat, M.D.⁴, Valerie Newsome, Ph.D.⁵, Girardin Jean-Louis, PhD⁶

¹NYU School of Medicine, New York, NY; ²NYU Langone Health, New York, NY; ³Arizona State University, Phoenix, AZ; ⁴University of Haifa, Haifa, Hefa, Israel; ⁵New York University School of Medicine, New York, NY; ⁶New York University, New York City, NY

BACKGROUND: Metabolic conditions are on the rise among older adults. Sleep behavior may modify risk of metabolic conditions. We hypothesized that age may moderate associations between sleep duration and metabolic conditions. It is unclear whether the relationship between duration and metabolic syndrome is stronger with morbidity in comparison to younger vs. older adults. This study explored associations between sleep and metabolic conditions among white and black older and younger adults.

METHODS: Data were collected from the 2004–2013 National Health Interview Survey (NHIS). We established an unhealthy cohort (reporting at least one of four conditions: obesity, dyslipidemia, diabetes, and hypertension) and healthy cohort (none). Morbidity burden was defined as: 1 (1/4 conditions) to 4 (4/4 conditions). We defined recommended sleep (7–8 hours), short sleep (< 6 hours) and long sleep (> 9 hours). Sex, race, exercise, smoking and alcohol use were covariates. Students T-tests and ANOVA were used for group mean comparisons (18-65-younger vs. 66-85-older). A logistic regression adjusting for age, SES, education, smoking, alcohol use, BMI, exercise, hypertension, diabetes, dyslipidemia was performed in a step-wise model to test associations between sleep duration and morbidity.

RESULTS: Among older adults, 56.4% were female and 81.7% were white. Among younger adults, 52.0% were female and 76.5% were white. Sleep duration was longer for older adults (7.49 ± 0.01) compared with younger adults (7.08 ± 0.01) ($p < .01$). Among the healthy cohort ($N=15765$), 20% reported short sleep and 7% reported long sleep. Among the unhealthy cohort ($N=49,675$), 30.2% reported short sleep and 9% reported long sleep. Older adults were less likely to report short sleep [OR=0.92, 95% CI=0.89–0.95, $p < 0.01$], but were more likely to report long sleep [OR=1.89, 95% CI=1.80–1.98, $p < .01$]. Unhealthy older adults had two-fold greater odds of reporting long sleep ($p=0.01$), but were not significantly more likely to report short sleep (5% lower odds; $p=0.09$), relative to unhealthy younger adults. Older adults were less likely to be short sleepers, but were more likely to be long sleepers.

CONCLUSION: Study results show age differences in sleep duration and that age has a significant effect on the association between sleep duration and metabolic conditions. Compared to younger adults, older adults were at an increased risk for long sleep and at a decreased risk for short sleep. Future studies should explore this relationship further.

SLEEP IN CARDIAC PATIENTS: MEASUREMENT STRUCTURE AND PREDICTION OF HEALTH FUNCTIONING OVER 6 MONTHS

Biing-Jiun Shen, Ph.D.¹, Jonathan JL Tan, B.A.¹, Hung Yong Tay, M.S.²

¹Nanyang Technological University, Singapore, N/A, Singapore; ²Singapore Heart Foundation, Singapore, N/A, Singapore

BACKGROUND: Sleep problems appear common and associated with health outcomes among cardiac patients. Nevertheless, few studies have examined the measurement structure of sleep among cardiac patients and whether different sleep dimensions may be associated with health functioning. This study aims to (1) employ confirmatory factor analysis (CFA) to examine the measurement structure of the Pittsburgh Sleep Quality Index (PSQI) among cardiac patients, and (2) investigate whether different sleep dimensions would predict physical and mental health functioning over a 6-month period.

METHODS: Participants were 223 cardiac patients (mean age = 63.0 [SD = 8.5]; 19% women) from a community-based cardiac rehabilitation program, among whom 166 also completed a follow-up at 6 months. Participants completed the PSQI and a cardiac-specific quality-of-life measure assessing both physical health and mental health functioning. The CFA was applied to evaluate the 1-, 2-, and 3-factor structure of the PSQI. Hierarchical multiple regression analyses were conducted to examine whether the sleep dimensions derived would predict physical and mental health functioning at the baseline and at 6 months. All regression models were adjusted for age, gender, education level, body mass index, and months in rehabilitation. For models predicting 6-month health functioning, the baseline health functioning was also included as a covariate in order to examine predictors of change.

RESULTS: On the basis of the PSQI scores, 68% of the patients reported sleep disturbances. The CFA of the PSQI demonstrated that the 2-factor solution fitted the data most optimally ($\chi^2 [8] = 14.01$, $p = .08$; CFI = .98; RMSEA = .07), with a sleep efficiency factor (sleep duration and habitual sleep efficiency) and a sleep quality factor (subjective sleep quality, latency, disturbances, and daytime dysfunction). The single-factor structure showed a poor fit ($\chi^2 [9] = 53.48$, $p < .01$, CFI = .88; RMSEA = .17), and the 3-factor structure did not show a better fit than the 2-factor one. Cross-sectionally, after controlling for covariates, both sleep quality and sleep efficiency were significantly associated with better physical health (sleep quality $\beta = .45$, sleep efficiency $\beta = .17$, $ps < .01$) and mental health function (sleep quality $\beta = .43$, sleep efficiency $\beta = .17$, $ps < .01$). At 6 months, after controlling for baseline health functioning ($\beta_s = .64$ to $.74$ in models, all $ps < .001$) and other covariates, only higher sleep quality independently predicted increased physical health ($\beta = .13$, $p < .05$) and mental health functioning ($\beta = .11$, $p < .05$), whereas sleep efficiency ($\beta_s = .05$ and $.01$, respectively, $ps > .10$) did not.

CONCLUSIONS: Findings highlighted the importance of evaluating sleep and assessing different sleep components among cardiac patients. Sleep quality appeared to be a better predictor of greater improvement of both physical and mental health functioning over time.

6:15 PM-7:15 PM

SUMMERTIME SLEEP VARIABILITY AMONG URBAN MINORITY YOUTH: DIFFERENCES BETWEEN UNSTRUCTURED AND STRUCTURED SETTINGS

Laura M. Nicholson, BA¹, Carolyn Bates, M.A.¹, Amy Bohnert, Ph.D.²¹Loyola University Chicago, Chicago, IL; ²Loyola University of Chicago, Chicago, IL

Summertime has emerged as a high-risk period for short sleep (Nixon et al., 2008) and weight gain (Von Hippel & Workman, 2016). A lack of daily structure during the summer months may contribute to weight gain via obesogenic behaviors, including disrupted sleep (Brazendale et al., 2017). Summer programming though may provide structure that can address concerns about disrupted sleep. This study will be the first to compare sleep variability (e.g. night-to-night fluctuations in sleep timing) among a sample of urban, minority youth when engaged in summertime programming (structured) versus no programming (unstructured). Relations between sleep variability and body mass index (z BMI) will also be examined.

Participants were 77 urban, minority girls ages 10–14 ($M=11.8$, $SD=1.01$) enrolled in a community-based summer program. Data were collected prior to the start of programming (unstructured; T1) and during the final week of programming (structured; T2). Sleep was measured using Actigraph GT3X Tri-Axis Accelerometer. Inclusion criteria were 3 or more weekday nights of sleep data. Using standard procedures, nightly variability (NV) was characterized for three indices: (1) sleep onset (SO), (2) sleep duration (SD), and (3) wake time (WT) by creating difference scores from night to night (e.g. [night1 - night2] [night2 - night3], etc.) then averaging these differences (Suh et al., 2012).

Participants recorded large fluctuations in all indices of NV across both structured and unstructured settings. In the unstructured setting, SO was at 12:15AM (NV= 1 hr 6 min), WT at 9:02AM (NV=1 hr 9 min), and SD was 8 hr 49 min (NV=1 hr 41 min). In the structured setting, participants exhibited a shift to earlier sleep schedules (reflected in both earlier SO and WT), but similar nightly sleep variability. Specifically, SO was 11:09PM (NV=1 hr 11 min), WT was 7:39AM (NV=1 hr 11 min), and SD was 8 hr and 32 min (NV=1 hr 38 min). During the unstructured setting, WT variability was inversely related to z BMI ($b=-.37$, $t(48)=-2.74$, pz BMI). None of the NV indices were associated with z BMI during the structured setting. These discrepant findings suggest the need for further investigation of sleep timing, its variability, and contribution to excess weight gain during the summertime.

THE EFFECTS OF DAILY CAFFEINATED ENERGY DRINK USE AND CAFFEINE ABSTINENCE ON SLEEP AMONG YOUNG ADULTS

Kristina Murani, B.A.¹, Claire E. Lunde, B.A.², Kathleen C. Gunthert, Ph.D.², Laura M. Juliano, Ph.D.²¹American University, Silver Spring, MD; ²American University, Washington, DC

Caffeine is the most widely used psychoactive drug in the world and is the primary active ingredient in Energy Drinks (EDs). Controlled research has shown that caffeine disrupts planned sleep, with greater effects observed at greater doses and when taken closer to bedtime. Given the popularity of EDs, understanding the effects of caffeinated EDs on sleep among young adults under naturalistic conditions is of great importance. This study investigated the effects of normal dietary doses of caffeine (200 mg) taken early in the day (before 3pm) on sleep functioning in a sample of young adults. The effects of caffeine abstinence on sleep were also evaluated. Thirty-six (44% female) light caffeine consumers participated in the 6-week within-subjects study. One week of baseline monitoring (week 1) was followed by one week of placebo ED ingestion (week 2), three weeks of caffeinated ED ingestion (weeks 3–5), and another week of placebo ED ingestion (week 6). Participants completed measures three times per day, including total sleep time (TST), sleep onset latency (SOL), and subjective sleep quality. Statistical analyses involved running a series of hierarchical linear models. The effects of caffeinated EDs were examined by comparing placebo weeks (weeks 2 and 6) to caffeine weeks (weeks 3–5). Caffeine abstinence effects were assessed by comparing week 2 (placebo) to week 6 (placebo after three weeks of caffeine). The last three days of week 5 (caffeine) were compared to the first three days of week 6 (placebo) when the greatest caffeine withdrawal effects were expected. Total sleep time was significantly less during caffeine weeks compared to placebo weeks ($\gamma_{10} = -19.80$, $p < 0.006$). Placebo ED ingestion after three weeks of daily caffeine resulted in shorter SOL compared to the first placebo week ($\gamma_{10} = -4.43$, $p < 0.059$) demonstrating a caffeine withdrawal effect. Acute caffeine abstinence (first three days of week 6 compared to last three days of week 5), produced greater TST ($\gamma_{10} = 52.28$, $p < 0.009$), shorter SOL ($\gamma_{10} = -5.47$, $p < 0.05$), greater sleep quality ($\gamma_{10} = 0.234$, $p < 0.038$), and feeling more rested ($\gamma_{10} = 0.218$, $p < 0.041$). This study is among the first to show a direct causal link between caffeinated ED consumption and sleep disturbance among young adults. These findings call for further investigation of the effects of caffeine on young adults and have implications for the regulation of caffeine content in EDs and other products.

THE IMPACT OF SLEEP QUALITY ON COLLEGE STUDENTS' APPETITIVE BEHAVIOR

Emily P. Midgette, B.A.¹, Matthew Whited, PhD, Licensed Psychologist², John T. Freeman, M.A.², Jordan Ellis, MA², Ansley Taylor Corson, MA²

¹East Carolina University, Vanceboro, NC; ²East Carolina University, Greenville, NC

Introduction: Sleep disturbance is a common problem among the college student population, with as many as 73% reporting at least occasional sleep difficulties. Lack of sleep amplifies the brain's reactivity to rewarding stimuli; however, it is unknown if students with poor quality sleep experience subsequent sensitivity to the hedonic aspects of the food environment, which could result in overeating. Symptoms of depression could also play a role. Investigating the poorly understood factors that influence reward-based eating is important for the development of interventions designed to improve college student health.

Method: 1,525 undergraduates participated in an online survey regarding college student health. Participants completed the Power of Food Scale (PFS), the Pittsburgh Sleep Quality Index (PSQI) and the Patient Health Questionnaire – 9 (PHQ-9). We examined the association between subjective sleep quality and the appetitive drive to consume easily-accessible, highly palatable foods (the PFS) and examined the indirect effect of depression on this relationship using the PROCESS macro. We controlled for possible covariates including gender and race/ethnicity in all analyses.

Results: Regression analyses were used to examine the mediating effect of depressive symptoms on the relationship between subjective sleep quality and appetitive behavior. Results indicated that sleep quality was a significant predictor of depression ($b = 0.44$, $SE = 0.02$, $p < 0.05$), and that depression was a significant predictor of appetitive behavior ($b = 0.51$, $SE = 0.09$, $p < 0.05$). After accounting for depressive symptoms as a mediator, sleep quality had a significant direct effect on appetitive drive ($b = 0.24$, $SE = 0.07$, $p < 0.05$). The indirect effect of depression on this relationship was tested using the bootstrapping estimation method with 5000 samples. The results indicated that the indirect effect of depression was significant ($b = 0.22$, $SE = 0.04$, $CI = 0.14, 0.31$).

Discussion: Results found that subjective sleep quality was significantly associated with appetitive drive, and that depression was a significant partial mediator of this relationship. These results suggest that poor quality sleep could increase consumption of high-calorie foods among college students, partially due to depressive symptoms. Future studies should focus on determining if the influence of disturbed sleep on appetitive drive results in unhealthy eating behaviors, and utilize longitudinal data.

THE MODERATING ROLE OF THE NEIGHBORHOOD ENVIRONMENT FOR CHILDREN'S PHYSICAL ACTIVITY OVER TIME

Natalie Colabianchi, MA, PhD¹, Morgan Clennin, MPH², Marsha Dowda, PhD², Kerry McIver, PhD², Rodney Dishman, PhD², Dwayne Porter, PhD², Russell Pate, PhD²

¹School of Kinesiology, University of Michigan & Institute for Social Research, University of Michigan, Ann Arbor, MI; ²University of South Carolina, Columbia, SC; ³University of Georgia, Athens, GA

Introduction: Evidence to support the association between the neighborhood environment and physical activity levels has increased in recent years. A number of studies have examined whether the association between aspects of the neighborhood environment and physical activity varies by demographic characteristics. Fewer studies have gone beyond demographic characteristics and examined specific individual and interpersonal psycho-social characteristics that may interact with environmental characteristics to predict physical activity.

Methods: Over a thousand fifth grade students from 21 elementary schools were enrolled. Participants were followed from elementary to middle school and measured again in 6th and 7th grades. Participants were asked to complete a questionnaire, had anthropometric measurements taken, and received an accelerometer to assess physical activity each year. The student's parent/guardian also completed a questionnaire each year. Two methods were used to assess attributes and features of the neighborhood environment: a windshield survey of each participant's street segment and audits of the physical activity resources in the neighborhood. Growth curve analyses with total physical activity as the dependent variable were completed adjusting for race, gender, neighborhood socio-economic status, and children nested in schools.

Results: Two significant three-way interactions (i.e., time*neighborhood environment* individual and interpersonal psycho-social characteristics) were found. There was a significant three-way interaction between time, neighborhood environment and child reported equipment in the home as well as a significant three-way interaction between time, neighborhood environment and parent-reported parent support for physical activity. In addition, there was a significant two-way interaction between child-reported perception of parental support for physical activity and time as well as a significant two-way interaction between child-reported perception of parental support for physical activity and neighborhood environment. There were two additional variables with a significant interaction with time including self-schema for physical activity and child-reported perception of parental encouragement for physical activity.

Conclusions: This study found significant moderating effects of the neighborhood environment in the relationship between individual and interpersonal psycho-social characteristics and physical activity over time. Simultaneously considering the neighborhood environment and individual and interpersonal psycho-social characteristics can help improve our understanding of the reasons for declines in physical activity over time and provide information to help develop interventions to maintain physical activity levels in children.

COMT VAL158MET (RS4680) GENOTYPES MODERATE THE ASSOCIATION BETWEEN CAREGIVER STRESS AND THE CORTISOL AWAKENING RESPONSE

Beverly Brummett, PhD¹, Rong Jiang, PhD², Abanish Singh, PhD², Elizabeth Hauser, PhD³, Michael Babyak, PhD², Ilene Siegler, PhD², Redford Williams, Jr., MD²

¹Duke University Medical Center, Department of Psychiatry, CHAPEL HILL, NC; ²Duke University Medical Center, Department of Psychiatry, Durham, NC; ³Duke Molecular Physiology Institute, Duke University Medical Center, Durham, NC

Background: *COMT* Val158Met (rs4680) genotypes have recently been shown to be associated with cortisol response to psychological stress. Caregiving is a recognized stressor that is associated with numerous health outcomes, with neuroendocrine functioning considered one likely mediator.

Methods: We examined allelic variation in *COMT* Val158Met (rs4680) as a moderator of the association between stress of caregiving for a relative with Alzheimer's Disease or other dementia and the salivary cortisol awakening response (CAR) in 158 adult caregivers and 155 controls. General linear models were used to test whether the association between caregiver stress and CAR differed across rs4680 (Met/Met, Val/Met, Val/Val) genotypes.

Results: Homozygous Met allele caregivers displayed the largest CAR, while Met allele homozygotes who were not caregivers displayed the lowest CAR ($p = 0.006$). In contrast, Val/Val homozygotes displayed an essentially opposite pattern of response.

Conclusions: The finding for Met allele homozygotes is consistent with prior observations that the Met allele is associated with poorer emotional control. The reverse pattern among Val/Val homozygotes is less well explained by prior research. Replication and extension of this work will be required to elucidate the interpretation of this finding.

EFFECTS OF REJECTION SENSITIVITY ON PHYSIOLOGICAL STRESS REACTIVITY, DEPRESSION, RELATIONSHIP SATISFACTION & HEALTH

David R. Moore, PhD¹, Jill B. Nealey-Moore, PhD¹, Jamie C. McGovern, PhD², Courtney Covington, MA Candidate³

¹University of Puget Sound, Tacoma, WA; ²University of Kansas Medical Center, Kansas City, KS; ³University of Washington, Tacoma, School of Social Work, Tacoma, WA

Rejection sensitivity (RS), the tendency to over perceive rejection from others and react strongly, has been linked to a number of negative relational, psychological, and neuroscientific variables. Less is known about the physiological effects of RS, particularly cardiovascular reactivity in response to interpersonal stressors and associations with physical health. This study examined the effect of rejection sensitivity on relationship satisfaction, depression, physical health, and physiological reactivity during a conflict task with a romantic partner. Physiological and self-report data were collected from 74 college-aged dating couples, where dyads were categorized as high or low in RS, based on composite scores on the Rejection Sensitivity Questionnaire -Short version (RSQ-SF; Downey & Feldman, 1996). Consistent with hypotheses, the study replicated previous findings linking high rejection sensitivity to lower relationship satisfaction ($p < .001$) and higher depression ($p < .001$), showing that in comparison to the low rejection sensitivity group, those in the high rejection sensitivity group were more dissatisfied with their relationships, and more likely to report depressive symptoms. Contrary to hypotheses, there was no relationship between rejection sensitivity and physical health or physiological stress reactivity as indexed by heart rate, blood pressure, or skin conductance. However, self-reported measures show that high rejection sensitivity dyads were significantly more likely to have rated themselves as feeling more stressed (more "anxious" and "worried", less "calm") during the conflict task than low rejection sensitivity dyads ($p < .05$), despite the fact that they had no appreciable differences from the low rejection sensitivity group in physiological reactivity, at least as indicated by the specific measures used in this investigation. The dyadic nature of this study has important implications for findings on depression and the impact of RS on relationship satisfaction. Discordance between self-reported and cardiovascular measures of stress are discussed, with methodological implications.

EFFECTS OF SOCIAL CONSTRAINTS ON DEPRESSIVE SYMPTOMS & ILLNESS INTRUSIVENESS IN CKD: THE ROLE OF AVOIDANCE & INTRUSIVE THOUGHTS

Ellen Kinner, Master of Arts¹, Anne Roche, Master of Arts², Miriam Velez-Bermudez, Master of Science², Mony Fraer, MD³, Alan Christensen, PhD²

¹University of Iowa, Iowa City, IA; ²University of Iowa, Iowa City, IA; ³University of Iowa Hospitals and Clinics, Iowa City, IA

Background: As patients with chronic kidney disease (CKD) approach end-stage renal disease (ESRD), they begin to face significant illness-related stressors including significant lifestyle disruption and reduced life expectancy. During this time, according to social cognitive processing theory, the disclosure of one's thoughts and emotions in a supportive context is critical, but social constraints (e.g. perceiving others as minimizing or uncomfortable with one's concerns), may limit this critical process from occurring. A primary aim of the current study was to examine the relationships between social constraints and depressive symptoms and illness intrusiveness in lifestyle functioning among patients with CKD who are approaching ESRD. Another aim was to examine whether disease-related avoidance and intrusive thoughts mediate these relationships.

Method: Patients approaching ESRD ($n=64$, 50% female, mean age=63.6, mean GFR=16.8) completed self-report measures of social constraints, disease-related avoidance and intrusive thoughts, depressive symptoms, and illness intrusiveness in lifestyle functioning.

Results: Initial correlations conducted found social constraints were associated with more avoidance ($r=.62$, $p < .001$) and intrusive thoughts ($r=.60$, $p < .001$) as well as greater depressive symptoms ($r=.48$, $p < .001$) and illness intrusiveness ($r=.53$, $p < .001$). Next, four mediation analyses (with bootstrapping) were conducted to examine the mediating roles of avoidance and intrusive thoughts in the relationships between social constraints and depressive symptoms and illness intrusiveness. Disease-related avoidance mediated the association between social constraints and depressive symptoms, $B=0.11$, CI [.02, .22] and illness intrusiveness, $B=0.30$, CI [.09, .57]. Disease-related intrusive thoughts similarly mediated the association between social constraints and depressive symptoms, $B=0.18$, CI [.09, .29] and illness intrusiveness, $B=0.47$, CI [.28, .50].

Conclusions: Disease-related avoidance and intrusive thoughts may play important roles in the relationships between social constraints and depressive symptoms and social constraints and illness intrusiveness manifest in patients approaching ESRD. These findings suggest that disease-related avoidance and intrusive thinking could be important targets for clinical intervention to improve outcomes in this population particularly when constraints on the open expression of disease-related thoughts and emotions exist.

PERINATAL MATERNAL STRESS AND SUSCEPTIBILITY TO INFECTIONS IN LATER CHILDHOOD: AN EARLY LIFE PROGRAMMING PERSPECTIVE

Gabriela R. Oates, PhD¹, Irena Stepanikova, PhD², Vojtech Thon, MD, PhD³

¹University of Alabama at Birmingham, Birmingham, AL; ²University of Alabama at Birmingham, Department of Sociology, Birmingham, AL; ³Masaryk University, Department of Clinical Immunology and Allergy, Brno, Jihomoravsky kraj, Czech Republic

Background: There is evidence of transmission of stress-related dysregulation from the parental organism to the offspring during early developmental stages. Research on maternal stress as a factor in immune functioning has been limited to stress exposure in utero and its effects on infants. The purpose of this study was to investigate whether perinatal maternal stress is linked to the risk of infectious diseases in children aged 7–11 years. We hypothesized that stress exposure during pregnancy and the first 6 months after delivery independently predicts common infectious diseases in mid-childhood.

Methods: Data came from the European Longitudinal Study of Pregnancy and Childhood - Czech Republic, a prospective birth cohort (N=4,811). Maternal stress, operationalized as the number of stressful life events, was examined during pregnancy and the first 6 months postpartum. Children's infectious diseases between the ages of 7–11 years, assessed by maternal report, included bronchitis/lung infection, laryngitis, strep throat, influenza/flu-like infection, cold sores, ear infection, and eye infection. General linear models were estimated to predict the number of childhood infections as a function of prenatal stress, postnatal stress, maternal health during pregnancy, delivery characteristics, and sociodemographic background. Additionally, each type of infection was modeled separately using the same predictors.

Results: Women reported on the average 3.01 prenatal and 2.24 postnatal life events and 2.24 children's infectious diseases. Consistent with our hypothesis, mothers who reported more stressful life events also reported that their children had higher number of infectious diseases between the ages of 7–11 years. In a fully controlled model, the effect was larger for postnatal ($\beta=.10$, $p<0.001$) vs. prenatal life events ($\beta=.02$, $p<0.020$). In models predicting each infectious disease as a function of prenatal life events and covariates, prenatal events were linked to an increased odds of bronchitis/lung infection (OR=1.02, $p=.014$), strep throat (OR=1.03, $p=.010$), cold sores (OR=1.02, $p=.004$), and eye infection (OR=1.02, $p=.022$). After including postnatal life events, prenatal life events remained a significant predictor for cold sores only (OR=1.02, $p=.022$), while postnatal life events independently predicted bronchitis/lung infection (OR=1.04, $p=.033$), strep throat (OR=1.06, $p=.002$), cold sores (OR=1.03, $p=.039$), and flu-like infections (OR=1.06, $p=.021$).

Conclusions: Perinatal maternal stress is linked to an increased risk of infectious diseases in school-age children. Both prenatal and postnatal stress predict infectious diseases in mid-childhood, but the postnatal life events have stronger and more consistent effects. Interventions to address stress in postpartum women may have long-term benefits for child health.

PERSONALITY DIMENSIONS PREDICT PERCEIVED STRESS LEVELS, MINDFULNESS SCORES, AND COPING STYLES IN COLLEGE STUDENTS

Rachel I. Blair, BS, CHES¹, Elizabeth Orsega-Smith, PhD², Michael Mackenzie, PhD³

¹University of Delaware, Wilmington, DE; ²University of Delaware, Newark, DE; ³Department of Behavioral Health & Nutrition, University of Delaware, Newark, DE

Background: Over half of college students report high stress levels and ineffective coping behaviors for stressors they encounter in pursuit of their academic career. Personality can modulate the ways individuals appraise and cope with stress. This study aimed to examine how Openness (O), Conscientiousness (C), Extroversion (E), Agreeableness (A) and Neuroticism (N) are associated with perceived stress, mindfulness, and coping styles in college students.

Methods: 384 participants (18–25 years), completed the Big Factor Inventory, Perceived Stress Scale (PSS), Brief COPE, The Mindful Attention Awareness Scale, and demographic questions. Bivariate correlations were used to identify variables that were significantly associated with O, C, E, A, and N.

Results: Of the 384 participants, most students were White (80.7%), Female (82%), and Juniors (30.2%) or Seniors (37.5%) in college. There was a significant inverse relationship between Conscientiousness, Extroversion, Agreeableness, and stress ($p<.01$), and a significant positive correlation ($p<.01$) between Neuroticism scores and stress. Those with high Conscientiousness, Extroversion, or Agreeableness scores were more likely to have high mindfulness scores ($p<.01$), while those who were high in Neuroticism were more likely to have low mindfulness scores ($p<.01$). Students who were high in Conscientiousness, Extroversion, and Agreeableness were more likely to practice adaptive coping techniques, such as active coping, use of emotional support, and positive reinforcement than those with high Neuroticism scores ($p<.01$). In contrast, students with high Neuroticism scores were more likely to report use of self-distraction, substance abuse, behavioral disengagement, venting, and self-blame to cope with stressful situations.

Discussion: Consistent with existing literature on adults, the results of this study suggest personality traits predict perceived stress levels, mindfulness, and coping styles in college students. If universities provide students with resources that allow them to become aware of how their personality can affect stress appraisal and coping, then they may be able to improve their perceptions and coping mechanisms for stress. Additionally, these findings may be useful to mental health professionals in helping university students cope with stressful situations.

PERSON-FOCUSED GRATITUDE BUFFERS AGAINST STRESS

Bryan Ross, B.A.¹, Michael Slepian, Ph.D.², Yanelliz Melchor Martinez³, Abraham Rutchick, Ph.D.³

¹California State University, Northridge, woodland hills, CA; ²Columbia University, New York, NY; ³California State University, Northridge, Northridge, CA

Numerous studies have shown the positive effects of experiencing gratitude. For example, gratitude appears to buffer against the effects of negative life events, and listing the things one is grateful for has been shown to reduce perceptions of daily stress. On an interpersonal level, expressing gratitude towards one's partner has been shown to increase perception of the relationship's strength, and writing letters of gratitude has been shown to increase individuals' happiness and life satisfaction, as well as reducing depressive symptoms. Given the promise of person-directed gratitude as an intervention, the present study examined the effect of prompting gratitude towards specific people on perceived stress. We hypothesized that inducing gratitude towards specific people would lower one's perceived stress. A sample of undergraduate students ($N = 92$) participated in a ten-day diary study in which (among other measures) they reported their level of gratitude and completed The Daily Inventory of Stressful Events (in which they indicated which of a series of stressors they experienced that day). Half of the participants were first asked, each day, to name someone for whom they were thankful. Multilevel model analyses showed that participants in the person-focused gratitude condition had higher daily gratitude than participants in the control condition ($b = 0.71$, 95% CI = [0.01, 1.40], $SE = 0.35$, $t(72.81) = 1.99$, $p = .05$), and these increases predicted fewer daily stressors ($b = -0.01$, 95% CI = [-0.02, -0.01], $SE = 0.004$, $t(625.02) = -3.35$, $p < .001$), and a reduction of Perceived Stress Scale (PSS) after the 10-day diary period (i.e., the reduced stress between pre-study and post-study was greater; $b = 0.82$, 95% CI = [0.38, 1.27], $SE = 0.23$, $t(72.36) = 3.64$, $p < .001$). These initial findings suggest that practicing daily gratitude, and doing so in a way targeted toward specific people, could offer a practical method to reduce the impact of stressful experiences.

STRESSFUL LIFE EVENTS PREDICT INCREASED CONSUMPTION OF SWEETS IN ADOLESCENCE: LONGITUDINAL ANALYSIS OF A PROSPECTIVE COHORT

Gabriela R. Oates, PhD¹, Elizabeth Baker, PhD², Irena Stepanikova, PhD², Julie Bienertová Vasku, PhD³

¹University of Alabama at Birmingham, Birmingham, AL; ²University of Alabama at Birmingham, Department of Sociology, Birmingham, AL; ³Masaryk University, Brno, Jihomoravsky kraj, Czech Republic

Purpose: Stressful life events (SLE) have been associated with maladaptive health behaviors, but their role in adolescent diet is not well understood. We examine longitudinally the association between SLE and consumption of sweets, snacks, and sugar-sweetened beverages among a cohort of Czech adolescents.

Methods: The study utilizes nested fixed effects models to examine dietary change between 11 and 15 years of age. Data were obtained from the European Longitudinal Study of Pregnancy and Childhood, the Czech Republic. Diet is measured as the weekly frequency of consumption of salty snacks, sweets, and sugar-sweetened beverages. SLE are measured with a scale that accounts both for the number of stressful events and their perceived impact. Additionally, we examine whether psychological, familial, and economic resources account for the relationship between SLE and diet.

Results: Cross-sectionally, we found a significant positive relationship between SLE and the diet measures. However, in the longitudinal fixed effects models only the consumption of sweets increased significantly with SLE. Psychological, familial, and economic factors were not associated with diet in the longitudinal models.

Conclusions: Adolescence is a vulnerable period of increased risk for poor dietary choices. SLE among Czech adolescents lead to an increased consumption of sweets. These findings highlight the need for interventions that help adolescents cope with stress without resorting to unhealthy diet.

GENDER COMPOSITION OF DRUG INJECTING INITIATOR-INITIATE RELATIONSHIPS IN THREE NORTH AMERICAN CITIES: A MIXED METHODS STUDY

Stephanie A. Meyers, MA¹, Sonia Jain, PhD², Ayden Scheim, PhD², M-J Milloy, PhD³, Kora DeBeck, PhD³, Kanna Hayashi, PhD³, Xiaoying Sun, MS², Richard Garfein, PhD², Steffanie Strathdee, PhD², Andrew Guise, PhD⁴, Dan Werb, PhD²

¹San Diego State University/University of California San Diego, La Jolla, CA; ²University of California, San Diego, La Jolla, CA; ³British Columbia Centre for Excellence in HIV/AIDS, Vancouver, BC, Canada; ⁴King's College London, London, England, United Kingdom

Background: Female gender is associated with heightened injection drug use (IDU)-related vulnerability, but little is known regarding the role of gender in shaping the relationship between IDU initiators and those they initiate into injection drug use. We therefore sought to explore the gender composition of injection initiator-initiate relationships and potential differences in those relationships across San Diego, Tijuana, and Vancouver.

Methods: Data from *Preventing Injecting by Modifying Existing Responses* (PRIMER), pooled and analyzed three prospective community-recruited cohorts of people who inject drugs (PWID): STAHR II, San Diego, USA; El Cuete IV, Tijuana, Mexico; and VDUS, Vancouver, Canada. Composite variables were created by combining participants' gender and the gender(s) of the person(s) to whom they reported providing injection initiation assistance in the past six months. Frequencies and chi-square analyses were created for the dependent variables of interest: initiator-initiate relationship type (i.e. male initiator-male initiate, male initiator-female initiate, male initiator-mixed gender initiates, female initiator-male initiate, female initiator-female initiate, and female initiator-mixed gender initiates) and the gender concordance (i.e. same gender relationship types) of those pairs. We also used qualitative data from PWID in San Diego and Tijuana to explore gendered pathways to injection initiation and used a thematic approach, guided by the Theory of Gender and Power, for coding and analysis.

Results: Among the 2,622 PWID included in the study, 112 (4.3%) reported providing injection initiation assistance in the past six months. We identified higher than expected gender concordance among participants and their initiates in Tijuana (83%) compared with participants and their initiates in San Diego (41%) Vancouver (35%, $\chi^2[2] = 10.3$, $p < 0.01$). Qualitative narratives ($n = 42$) revealed the importance of the gendered division of labor and power, as well as gendered social norms, in influencing injection initiation events. Women expressed both vulnerability and agency within their injection initiation events, particularly involving injection initiation by and of intimate partners.

Conclusions: This research highlights the gendered context of injection initiation events and contextual variation across settings. This can inform both site- and gender-specific interventions to reduce the risk of injection initiation and related harms.

6:15 PM-7:15 PM

A MULTI-SITE CASE STUDY EVALUATION OF MANDATED SBIRT POLICY IN MASSACHUSETTS PUBLIC SCHOOLS

Elissa Weitzman, ScD, MSc¹, Kara Magane, MS², Sharon Levy, MD, MPH¹, Julie Lunstead, MPH²¹Boston Children's Hospital/Harvard Medical School, Boston, MA; ²Boston Children's Hospital, Boston, MA

Background. A 2015 Massachusetts bill requires that all schools offer Screening Brief Intervention and Referral to Treatment (SBIRT) to middle and high school students to advance universal and indicated prevention of alcohol and other drug use and to help address access barriers for youth needing/seeking healthcare. Understanding acceptability of school SBIRT and markers of success is vital for state-scaled implementation and outcomes evaluation.

Methods. A mixed-methods evaluation using data collected and analyzed from staff focus groups (FGs) and student surveys to ascertain factors associated with acceptability in 2 districts with 5 schools & 1,326 youth. FGs (n=4) with n=46 nurses and guidance counselors, were facilitated by research staff, audio recorded and analyzed thematically. Youth in grades 7, 9, & 10 who participated in SBIRT in 2016–17 were anonymously surveyed (under passive parental consent); data were analyzed using descriptive statistics. FG and survey data were triangulated to understand staff and student perspectives together.

Results. In FGs, strong leadership, logistical support, interprofessional focus on education and relationship-building with students were associated with successful implementation. Challenges included perceptions of low parental support and student disclosure, concern for privacy, and staff burden. Among 805 student survey participants (participation 78.3%): 9.6% and 36.8% of middle and high schoolers reported past year alcohol use, with 42% and 59% of users reporting a past year binge, respectively ($p < 0.0001$). Overall, 67% agreed/strongly agreed that staff should screen students; a minority agreed/strongly agreed that “screening is an invasion of privacy” (37.9%) and “a waste of time” (30.8%). Receptiveness towards screening was higher among those who did not report past year use ($p < 0.0001$). Among students who reported being screened (n=432), 97.2% reported answering all/some questions honestly, and most agreed/strongly agreed that they felt comfortable (71.3%), their privacy was respected (84.5%), the information was useful (73.6%). Two-thirds (62.3%) agreed/strongly agreed they would return to the staff member who screened them for questions about AODs, with more agreement among past year users ($p < .034$).

Conclusion. For staff, program acceptability was high despite challenges, with success reframed as relationship building not youth disclosure. Students reported high acceptability and candid disclosure; their stated openness to returning to staff to discuss AOD use was a key indicator of success and bodes well for case finding and clinical response to at-risk youth. Results are promising for a strategy that extends SBIRT to schools in advance of diffusion and evaluation at state scale.

ADDRESSING VIRGINIA'S SUBSTANCE USE EPIDEMIC: EVALUATING A NEW STATEWIDE TREATMENT AND REIMBURSEMENT PROGRAM

Rebecca Aycock, PhD

Virginia Commonwealth University, Richmond, VA

Background: Communities across the Commonwealth of Virginia are suffering from an unprecedented substance use disorder (SUD) epidemic. Over 1,420 people died of drug overdose in Virginia in 2016, 38% more than 2015. Nationally, Medicaid members are more than three times as likely as people with private insurance to have misused prescription opioids or heroin, or suffered an overdose. Recognizing the need to mount a comprehensive response to the addiction crisis and repair Virginia's historically fragmented behavioral health system, the Virginia Department of Medical Assistance Services (DMAS), which is responsible for the state's Medicaid program, implemented the Addiction and Recovery Treatment Services (ARTS) in April, 2017. The ARTS program aims to increase access to treatment for Medicaid members with opioid or other substance use disorders by expanding benefits to include the following: inpatient detox, residential treatment, partial hospitalization, intensive outpatient programs, opioid treatment, case management, peer recovery supports, and crisis intervention.

Methods: Researchers used Medicaid claims data from April through June 2017 and the same time period in 2016. They calculated the number of unique providers, including medical and behavioral health providers providing ASAM level 1 services. They also calculated receipt of treatment using diagnosis and inpatient, outpatient, residential treatment, or prescription drug use for SUD that was paid for by Medicaid. Treatment delivery was also mapped based on health district regions.

Results: In the first 3 months on the program, the number of providers treating SUD increased from 667 prior to ARTS to 1,603. During the same time period, treatment rates among Medicaid members with SUD increased to 39% compared to 26% during a similar time period in 2016. The number of Medicaid members receiving prescriptions for opioid use disorders increased by 29%. Regional increases in SUD treatment delivery ranged from 17–77%.

Conclusions: During the first three months, ARTS has substantially increased access to SUD treatment for Medicaid members by reducing the “treatment gap” and expanding the number of health care practitioners treating Medicaid members for SUD.

CHILDHOOD ABUSE, PTSD, AND LIFETIME SUBSTANCE USE DISORDER IN LATINO AMERICANS: WHOLE-GROUP, US-BORN, AND FOREIGN-BORN MODELS

Amy L. Ai, Ph.D.¹, Catherine M. Lemieux, Ph.D.², Jungup Lee, Ph.D.³¹Florida State University, Tallahassee, FL; ²Louisiana State University, Baton Rouge, LA; ³National University of Singapore, Singapore, N/A, Singapore

Introduction: Childhood abuse (CA), posttraumatic stress disorder (PTSD) and lifetime substance use disorder (LT-SUD) are major behavioral health concerns, particularly among underrepresented populations; yet there is limited knowledge regarding their associations for Latino Americans. This study investigated the relationship of childhood physical abuse (CPA) and childhood sexual abuse (CSA) to PTSD and LA-SUD among Latino Americans ($N=2,554$) using the National Latino and Asian American Study, including analyses of nativity differences (US-born and foreign-born Latinos).

Methods: We used all Latino American ($N=2,554$) with a mean age at 38.02 years ($SD=15.03$; range, 18–97). The weighted Latino sample was roughly proportional in terms of gender (48.5% female) and nativity (43% US-born Latinos). Three path models for the whole-group, US-born, and foreign-born Latinos were conducted to examine the direct and indirect effects of CPA and CSA on LT-SUD, mediated by PTSD.

Results: Results showed higher prevalence rates of CPA (35.3% vs. 24.4%), CSA (17.4% vs. 9.3%), PTSD (6.5% vs. 4.6%), and LT-SUD (17.1% vs. 5.3%) for US-born Latinos than for foreign-born Latinos. The findings of the three final models (whole-group, US-born, and foreign-born models) fit the data adequately, with CFI (987-.980), TLI (.936-.984), RMSEA (.015-.063), and SRMR (.006-.015). Path models indicated a direct link between CPA (but not CSA) and LT-SUD and an indirect link between CA and LT-SUD through PTSD.

Conclusion: The current study is important because it expands the knowledge base regarding the behavioral health impact of inadequate or harmful child-rearing practices in Latino families. Findings underscore the need for prospective studies that evaluates culturally-relevant behavioral health screening and assessment practices with Latinos with histories of childhood trauma.

CONTEMPORARY PATTERNS OF MARIJUANA USE AND ATTITUDES AMONG HIGH SCHOOL SENIORS: 2010–2014

Jessica Braymiller, MS¹, Loren D. Masters, MPH¹, Ashley Linden-Carmichael, Ph.D.², Stephanie T. Lanza, Ph.D.²¹Penn State University, University Park, PA; ²The Pennsylvania State University, University Park, PA

Introduction. Marijuana use behavior among adolescents is of great concern as early use has been linked with numerous negative consequences including lower academic achievement, other substance use behavior, and substance use disorders later in adulthood. Although trends in behaviors and attitudes are well-established in large, national samples, information derived from these data tend to be reported as population-averages for single constructs, such as the overall rate of past 30 day marijuana use or attitudes about occasionally using marijuana on average. Examining these trends individually limits our ability to identify subgroups of individuals characterized by varying levels of use behaviors and attitudes. Given recent changes in state-level marijuana legislation, the goal of this study was to examine changes in contemporary patterns of marijuana use and attitudes over time using person-centered methods.

Methods. Data are from high school seniors in the 2010–2014 waves of Monitoring the Future, a nationally representative, cross-sectional survey in the United States. Latent class analysis was used to identify underlying patterns of marijuana use behaviors and attitudes across all years. Differences in latent class structure and membership were examined across years, and with respect to gender and race/ethnicity.

Results. Five latent classes were identified: Intolerant Non-users (50.4% of the sample), Tolerant Non-Users (10.7%), Disapproving Users (7.8%), Experimenters (5.7%), and Marijuana Enthusiasts (25.4%). After survey year was added as a grouping variable, prevalence rates for each class remained relatively stable from 2010 to 2014. Membership in the Marijuana Enthusiasts class was consistently more likely for males across all years; membership in the Tolerant Non-Users class relative to the Intolerant Non-Users class was also more likely for males, but only until 2013. Hispanic and Black individuals tended to be more likely than Whites to be Disapproving Users relative to Intolerant Non-Users.

Conclusions. Despite the changes in marijuana legalization that began to occur in 2012, contemporary patterns of marijuana use and attitudes have remained relatively stable over time. The Marijuana Enthusiasts class, characterized by recent use and approval of use at any frequency, suggests that a substantial subgroup of adolescents would benefit from prevention and intervention efforts targeting marijuana use behaviors and perceptions.

COVARIATES OF HAZARDOUS ALCOHOL USE AMONG SEXUAL AND GENDER MINORITIES IN TEXAS

J. Michael Wilkerson, PhD¹, Angela Di Paola, MS¹, Laura Witte, MPH¹, Vanessa Schick, PhD²¹UTHealth School of Public Health, Houston, TX; ²University of Texas School of Public Health, Houston, TX

Introduction. While U.S. data suggests sexual and gender minority (SGM) persons tend to consume alcohol more frequently than their heterosexual cisgender peers, data are limited on the prevalence of hazardous drinking and associated covariates of SGM persons in Texas. The purpose of these analyses was to estimate differences in the prevalence of hazardous drinking by sexual and gender identity and to identify associated covariates for intervention development.

Methods. A total of 1298 participants completed an online health needs assessment survey between March 2016 and January 2017. Survey items included alcohol consumption (AUDIT-C), illicit substance use, life experiences, and health diagnoses. Variables found significantly associated with hazardous drinking at the bivariate-level (p

Results. Participants were 38.1% male, 46.3% female, and 15.5% transgender-identified. Over a third (39.1%) of participants had a hazardous drinking score. Compared to non-hazardous drinkers, persons engaging in hazardous drinking were younger ($=20.7$ [SD=0.4] vs. $=26.5$ [SD=0.5]) and more likely to be Hispanic (41.4% vs. 26.3%). They were more likely to report using illicit drugs in past 12 months, including opioids (15.3% vs. 6.7%), stimulants (26.3% vs. 12.7%), and marijuana (37.6% vs. 21.2%); if injecting, there were more likely to share syringes (12.3% vs. 5.8%). Hazardous drinkers were also more likely to report discrimination based on sexuality (12.8% vs. 8.9%), high levels of stress (67.9% vs. 61.8%), incarceration (14.1% vs. 7.3%), and intimate partner violence (39.6% vs. 35.0%). When entered into a multivariate logistic regression model, covariates most associated with hazardous drinking were younger age (OR=0.97 [0.95–0.98]), being Hispanic (OR=1.6 [1.2–2.2]), using opioids (OR=1.7 [1.1–2.1]), stimulants (OR=1.4 [1.0–2.0]), and/or marijuana (OR=1.5 [1.1–2.1]), and incarceration (2.1 [1.4–3.3]).

Conclusions. Hazardous drinking is prevalent among SGM Texans, especially Hispanics. Co-occurring opioid and stimulant use, the sharing of syringes if injecting, and intimate partner violence are concerning. Because incarceration was more common among hazardous drinkers, opportunities exist to strengthen re-entry programs ability to screen and link persons with a history of alcohol use to agencies able to provide treatment, including medication-assisted therapies.

MAPPING ACCESS TO CARE IN HAWAII: EXPLORING THE ROLE OF GEOGRAPHIC ISOLATION ON YOUTH SUBSTANCE USE TREATMENT DISPARITIES

Emilee H. Turner, BA¹, Michelle H. Tong, BA², Daniel Galanis, Ph.D.³, Claudio Nigg, Ph.D.⁴¹University of Hawai'i at Mānoa, Honolulu, HI; ²University of Hawaii at Manoa, Honolulu, HI; ³Hawaii Department of Health, Honolulu, HI; ⁴University of Hawaii, Honolulu, HI

The 2014 U.S. Census Bureau indicates rural residents experience higher rates of poverty than their urban counterparts across age groups and race/ethnicity categories. Rural community members also experience a greater impact from mental health concerns due to accessibility, availability, and acceptability of mental health care challenges. Central to the issue of accessibility is the availability of specialty services such as substance use prevention and treatment. The 2004 National Survey of Substance Abuse Treatment Services, found that only 8.9% of treatment facilities were located in rural counties. Consistent with patterns observed nationwide, rural counties in Hawaii experience more barriers accessing services, as the majority of health resources are located in the state's urban center. Given the unique features of Hawaii, it is important to explore the role of geographic isolation (i.e., physical separation by water from the state's urban core) on prevention and treatment access. Geographic isolation is defined by county, with all non-Oahu counties identified as geographically isolated. This study aims to identify and use existing epidemiological data and utilize geocoding (i.e., converting addresses into geographic coordinates) to visually display substance use rates in relation to prevention and treatment facilities on a map. This mapping analyzes the accessibility (e.g., distance, transportation options, etc.) and availability (e.g., number of facilities, number of health professionals per capita, etc.) of substance use prevention and treatment services in Hawaii. In 2015, youth ages 12–17 residing in non-Oahu counties reported higher rates of illicit drug (35.8%), marijuana (22%), alcohol (37.5%), and tobacco use (27.2%), and nonmedical use of prescription pain relievers (14.4%) than Oahu youth. Thus, youth in geographically isolated areas do trend towards higher substance use rates compared to urban counties in Hawaii and indicates a need for analyzing treatment accessibility in rural areas. Data on adult populations is not available at the county-level. The findings from this study can be used to inform state- and county-level planning related to drug prevention and treatment initiatives.

PREDICTING DRINKING PROBLEMS IN YOUNG ADULTS: THE ROLE OF DEPRESSION AND EXECUTIVE FUNCTION IMPAIRMENT

Elisabeth O'Rourke, MA, Atara Siegel, BA, Joseph Bettcher, MA, Leslie Halpern, PhD

University at Albany, Albany, NY

Introduction. Young adulthood is often characterized by rapid executive function (working memory, planning) and social development. However, young adults are at increased risk for developing depression and increased use of illicit drugs and alcohol. Why social drinking evolves into problem drinking for some young adults is unclear. The research shows that poor executive function (EF) skills are a contributing factor to poor decision-making, and more specifically associated with increased alcohol intake. Furthermore depressive symptoms have been associated with alcohol use. This study tested a model to determine whether the relation between depression and problematic alcohol use would be mediated by EF deficits.

Method. The participants were 344 undergraduate students at a medium-sized university, [$M(\text{age}) = 19.09$, $N(\text{males}) = 202$]. The majority of participants were White (46.2%). Participants completed the following self-report measures: a demographics survey, the Center for Epidemiological Studies Depression Scale-Revised, the Behavior Rating Inventory of Executive Function Adult version, and a brief self-report of negative drinking behaviors established from previous measures of alcohol use outcomes.

Results. Females reported more depressive symptoms than males ($M=14.92$, $SD=12.97$; $M=12.02$, $SD=11.09$; $t(342)=-2.22$, $p<.05$) and males reported more drinking problems than females ($M=6.14$, $SD=5.06$; $M=4.92$, $SD=4.73$; $t(338)=2.24$, $p<.05$). Depressive symptoms were significantly positively correlated with drinking problems ($r(342)=.13$, $p<.05$) and with EF impairment ($r(342)=.49$, $p<.001$). Additionally, drinking problems was associated with EF impairment ($r(342)=.21$, $p<.001$). The regression of depression symptoms on drinking problems, ignoring the mediator, was significant, $b=.05$, $t(342)=2.41$, $p<.05$. The regression of symptoms of depression on the mediator, EF, was also significant, $b=.04$, $p<.001$. The mediator (EF), controlling for symptoms of depression, was significant, $b=.96$, $t(342)=3.20$, $p<.01$. Controlling for the mediator (EF), symptoms of depression was not a significant predictor of drinking problems, $b=.02$, $t(342)=.61$, $p=.54$. A Sobel test found full mediation in the model ($z=3.04$, $p=.002$). It was found that EF fully mediated the relationship between symptoms of depression and drinking problems.

Discussion. These findings provide support for the assertion that symptoms of depression increase the likelihood of engaging in problematic drinking behavior (drinking and driving, engaging in risky sexual behavior while drinking), which is further influenced by EF impairment. Therefore, individuals with depression and EF impairment are at much greater risk for problematic drinking behavior. Future research should examine how gender plays a role in this model and how problematic drinking behavior may further influence symptoms of depression.

STRATEGIES TO PREVENT (STOP) SUBSTANCE ABUSE: A WEBSITE FOR ADOLESCENTS IN HAWAII

Claudio Nigg, Ph.D.¹, Tatiana Phu, BA²¹University of Hawaii, Honolulu, HI; ²University of Hawaii, Honolulu, HI

BACKGROUND: Substance abuse is a global problem, and unfortunately, the state of Hawaii is home to a substantial number of substance abusers. Substance abuse is related to negative mental health and physical health outcomes. Adolescent years involve the seeking of social acceptance and “experimenting” which increases the likeliness for adolescents to experiment with drug use. In addition to health risks, adolescent drug use poses risk for addiction than may lead to drug abuse in adult years. Therefore, the first goal of this study was to investigate drugs commonly found in Hawaii and what physical, social, and health effects are related. The second goal was to address the problem of substance abuse by creating prevention methods targeted to Hawaii adolescents. Specifically, the purpose of this study was to explore the effect of substance abuse prevention education with the creation of a website targeted to adolescents in Hawaii.

METHODS: A website (<http://substanceabusehawaii.weebly.com>) was developed including drug overviews, health effects, how to stay away, external resources for prevention and treatment, and an evaluation survey. A baseline (T1) survey based on content found on website (12 items) was given to 3 grade 11 classes. Following the interaction time with the website (~15 minutes), the students completed a follow-up (T2) assessment. Additionally, a 2-inch foam ball (a choice of basketball, baseball, football, or soccer ball) advocating for a healthier method of relieving stress (a substitute activity of substance use) was provided to each participant.

RESULTS: At T1, 63/72 [participation rate=87.5%] and at T2, 62 [retention rate=98.4%] students participated (92% female; 16–17 years old; 87.2% Filipino; 6.4% other Pacific Islander; 6.4% Asian; 3.2% Hawaiian; 3.2% Caucasian; and 0.6% Hispanic/Latino [multiple responses allowed]). The number correct increased from 48.0% (SD=14.5) at T1 to 82.0% (SD=15.3) at T2 ($t(59)=13.5$, $p<.001$). There were improvements in 11/12 questions ($p<.05$). Topics that improved addressed mental disorder drug abuse, workplace meth-use in Hawaii, Americans in need of drug/alcohol treatment, stimulant drugs, side effects of drugs, drug related domestic/child abuse, short-term drug effects, Hawaii and national meth-use, chemicals in drugs, how to stay away, and ways of treatment.

DISCUSSION: Findings showed adolescents’ improved understanding on the topic of substance abuse prevention. This is promising considering the brief, inexpensive intervention which is feasibly implemented within a high school curriculum.

THE DEVELOPMENT OF A COMPUTERISED SCHOOL-BASED PREVENTION PROGRAM TO EMPOWER INDIGENOUS YOUTH: BUILDING ON STRENGTHS

Mieke Snijder, MSc, PhD¹, Lexine A. Stapinski, PhD, M.ClinPsych, BPsych(Hons)², Briana Lees, Bs(Psych)¹, Nicola C. Newton, PhD³, Katrina Champion, PhD³, Cath Chapman, PhD³, Maree Teesson, BSc Psych(Hons), PhD³

¹National Drug and Alcohol Research Centre, University of New South Wales, Randwick, New South Wales, Australia; ²University of New South Wales, Sydney, Australia, Sydney, New South Wales, Australia; ³UNSW Sydney, Sydney, New South Wales, Australia

Objectives: This project aims to develop a culturally appropriate school-based alcohol and other drugs (AOD) prevention program and an online AOD prevention portal for Indigenous youth. This presentation will discuss the innovative approaches used in the development of these resources.

Materials and methods: Two literature reviews were undertaken to 1) identify effective elements of previous AOD prevention programs with Indigenous Populations and 2) investigate risk and protective factors of AOD use for Indigenous Australians. Researchers partnered with four schools at which focus groups and interviews were conducted with teachers and parents, using an appreciative inquiry approach. Students participated in a Photovoice project where they took and shared photographs of positive social interactions in their community, and their role models. Group sharing of the photographs included a creative story telling session. Students completed a brief empowerment questionnaire before and after the consultation process.

Results: Culturally adapted mainstreet programs were most effective in prevention AOD for Indigenous youth. Effective elements of AOD programs included cultural knowledge integration, AOD skills and diversionary activities. Individual, community and societal risk and protective factors were identified for AOD use for Indigenous Australians.

Consultations indicated a need for culturally appropriate AOD prevention materials that are empowering and suitable for delivery in a mixed classroom setting. Interactive programs using technology and include storylines in line with students’ experiences are likely to be most effective. Students provided pictures of their role models (e.g. parents, sports players, cousins) and identified positive interactions in their community, from which they developed story lines to be integrated into the school-based program.

The information gathered in the literature reviews and the consultations (including photographs produced by the participating students), informed initial storylines and designs for a school-based AOD prevention program that is culturally appropriate for Indigenous students.

THE IMPACT OF NONMEDICAL PRESCRIPTION STIMULANT PROTOTYPES AND ACADEMIC CONSEQUENCES ON RISK COGNITIONS

Brianne K. Molloy, MPhil¹, Michelle L. Stock, PhD², Laura Wolter, Undergraduate Student¹, Charlotte Hagerman, B.S.¹

¹The George Washington University, Washington, DC; ²George Washington University, Washington DC, DC

Nonmedical prescription stimulant (NPS) use, or taking a stimulant (e.g., Adderall) without a prescription, is a growing health issue among college students (Weyandt et al., 2016). Despite numerous health risks (e.g., irregular heart-beat and stroke; NIDA, 2017), using NPS to study is common on campuses with rates up to 38% (Arria et al., 2013). The rising prevalence signals a need for interventions to prevent and reduce use. The Prototype-Willingness Model of health behavior suggests that altering prototypes, or perceptions of the typical person who does (or does not) engage in the health behavior, can affect willingness to engage in that behavior (Gibbons et al., 2015). However, studies have not examined this with regards to NPS use and linked academic consequences. The current study manipulated prototypes of a NPS user and non-user, and stories of academic success or failure, to examine how this information impacts perceptions of NPS use and risk cognitions.

Using a 2x2 experimental design, 174 undergraduates without an ADHD diagnosis or stimulant prescription were randomly assigned to read about: 1) a student of the same gender who either used or abstained from NPS (prototype manipulation), and 2) a resulting academic outcome (i.e., performed well or poorly on exams). Afterwards, participants reported their perceptions of the student, beliefs about NPS, and willingness to use.

ANCOVAs controlled for gender, ever use, year in school, and GPA. Results indicated main effects of prototype and academic outcome on student perceptions, such that abstainers (vs. users) and those who performed well (vs. poorly) were rated more favorably, $p \leq .001$. Pairwise comparisons revealed that abstainers (vs. users) were viewed more favorably regardless of their academic outcome, $p \leq .001$. A main effect of prototype on NPS beliefs also showed that participants in the user (vs. abstainer) group rated NPS as more effective, $p = .025$. A significant prototype X outcome interaction on NPS beliefs revealed that participants in the user-performed well group rated NPS use as the most effective, $p \leq .01$. Finally, there was a significant interaction on willingness ($p = .019$). Participants who read about a user had greater willingness to use than those who read about an abstainer when the target was said to have performed well (vs. poorly) on exams. Findings suggest that interventions should highlight academic drawbacks of use and incorporate abstainer prototypes in prevention messaging.

THE OUTCOMES OF A COMMUNITY-BASED PARTICIPATORY RESEARCH PROJECT WITH ABORIGINAL AUSTRALIANS REDUCING ALCOHOL-RELATED HARMS

Mieke Snijder, MSc, PhD

National Drug and Alcohol Research Centre, University of New South Wales, Randwick, New South Wales, Australia

Background: Solutions designed and led by Aboriginal Australians are most effective and sustainable in improving the health of Aboriginal Australians. The challenge is to bring together the leadership, skills and knowledge of Aboriginal communities with the highly specialised, real-world evaluation skills of senior researchers.

Objectives: This presentation will showcase how a community-based project aiming to reduce alcohol-related harms among Aboriginal people combined Aboriginal expertise with evaluation expertise of academics at UNSW.

Method: Using a community-based participatory research approach, researchers collaborated closely with three Aboriginal communities to identify target population and times using routinely collected data to inform the development of a community-based program. The program was designed to allow it to be standardised across communities but also tailored to the individual preferences and resources in each community. Outcomes measured were community perceptions of alcohol harms measured using a community survey and the impact on routinely collected alcohol-related crimes and ED presentations.

Results: Findings indicated a statistically significant reduction in the number of Aboriginal persons of Interest and victims of alcohol-related crimes in one community and statistically significant reductions in the number of Aboriginal people presenting to local EDs with alcohol-related injuries in two communities. There were statistically significant improvements in community members' perceptions that their community was able to make positive changes and a safe place to be during the day and at night. Finally, there were statistically significant reductions in community members' perceived frequency of alcohol-related verbal abuse and frequency of alcohol-related injuries.

BARRIERS AND FACILITATORS TO TOBACCO COUNSELING IN WIC CLINICS

Taneisha Scheuermann, PhD¹, Michelle L. Redmond, PhD², Edward F. Ellerbeck, MD, MPH³, Kimber P. Richter, PhD¹¹Department of Preventive Medicine and Public Health, University of Kansas School of Medicine, Kansas City, KS; ²Department of Preventive Medicine and Public Health, University of Kansas School of Medicine-Wichita, Wichita, KS; ³Department of Preventive Medicine and Public Health, University of Kansas School of Medicine, Kansas City, KS

Most pregnant smokers do not receive smoking cessation assistance and most women who quit during their pregnancy return to smoking within the first year postpartum. Smoking rates are higher among pregnant women enrolled in the Special Supplemental Nutrition Program for *Women, Infants, and Children (WIC)* (12.6%) compared to pregnant women overall (8.4%). WIC clinics routinely identify tobacco users and prior studies have shown that tobacco interventions in WIC clinics are feasible and potentially effective. The aim of this study was to describe barriers and facilitators to implementing evidence-based tobacco treatment in WIC clinics.

Methods: We conducted site visits with 12 urban and rural WIC clinics in Kansas. Semi-structured interviews were completed with 23 WIC coordinators, nurses, and dietitians. Interviews were audio-recorded, professionally transcribed, and imported into NVivo 11. Thematic analyses of the transcripts were guided by the COM-B (Capability, Opportunity, and Motivation – Behavior) system that summarizes the necessary conditions for behavior change and maintenance.

Results: In the *behavior* domain, coordinators at all WIC clinics reported that staff referred smokers to the quitline and almost half of the clinics had a smoking cessation program within the county health department. In the *capability* domain, many staff reported receiving training in brief tobacco treatment (e.g., ask, advise, refer) and that they had resources to refer smokers. However, barriers included low self-efficacy for providing counseling and a need for additional tobacco counseling training. In the *opportunity* domain, perceptions of opportunities to discuss tobacco use were mixed, some participants reported ample time to include tobacco counseling whereas others reported that time pressure was a barrier due to conflicting priorities. Uniformly, tobacco-related follow-up was challenging due to limited visits and lack of feedback from referral programs. In the *motivation* domain, staff reported WIC and clinic leadership support for tobacco treatment and many identified smoking cessation and reducing second hand smoke exposure as important priorities.

Conclusions: WIC clinics are currently implementing models of brief tobacco treatment and referral. Additional efforts are needed to increase WIC staff's confidence in providing tobacco counseling and to create interconnected systems for tobacco treatment that include WIC clinics and other community-level resources.

6:15 PM-7:15 PM

DISTRIBUTION OF TOBACCO RETAIL OUTLETS AND SMOKING CESSATION AMONG AFRICAN AMERICAN AND WHITE SMOKERS

Taneisha Scheuermann, PhD¹, Jarron M. Saint Onge, PhD², Nandi Taylor, MPH³, Lisa S. Cox, PhD³, Jasjit S. Ahluwalia, MD, MPH⁴, Edward F. Ellerbeck, MD, MPH⁵, Nicole L. Nollen, PhD³¹Department of Preventive Medicine and Public Health, University of Kansas School of Medicine, Kansas City, KS; ²Department of Sociology and Health Policy and Management, University of Kansas, Lawrence, KS; ³Department of Preventive Medicine and Public Health, University of Kansas School of Medicine, Kansas City, KS; ⁴Department of Behavioral and Social Sciences, Brown University School of Public Health, Providence, RI; ⁵Department of Preventive Medicine and Public Health, University of Kansas School of Medicine, Kansas City, KS

The presence of tobacco retail outlets increases exposure to tobacco advertising and provides cues to purchase tobacco. Previous studies have found greater tobacco outlet density in disadvantaged areas and in communities with higher proportions of African Americans. The aim of this study was to determine whether tobacco outlet density and proximity were negatively associated with successful quitting among lower income African American and White smokers.

METHODS: Participants were 221 African American and 219 White smokers enrolled in a smoking cessation cohort intervention who received both counseling and varenicline. Eligibility criteria included income < 400% federal poverty level (FPL). Tobacco retail outlet addresses were obtained from state agencies in Kansas and Missouri. Addresses were geocoded using ArcGIS. Residential proximity to the nearest outlet and outlet density (number of outlets within 500m [0.31 miles] and 1km [0.62 miles]) were calculated. Analyses included mixed-effects logistic regression models, adjusting for study stratification factors (gender, age) and baseline cigarettes per day because they are known predictors of cessation.

RESULTS: The majority of participants (71%) had incomes \leq 200 FPL. Whites were more likely to be cotinine-verified abstinent at 6 month follow-up (OR = 2.66, 95% CI 1.41, 5.02, $p = 0.004$). Median proximity was 655m (0.41 miles) for African Americans and 974 m (0.61 miles) for Whites. Few outlets were located within 500m of residences (median of 1 for African Americans and 0 for Whites). Neither proximity nor density within 500m was associated with smoking cessation. African American participants had a median of 31 outlets within 1km and the median for Whites was 20. Each additional outlet within 1km lowered odds of quitting by 2% (OR = 0.98, CI % 0.96, 0.99, $p = 0.01$). Race and abstinence had statistically significant associations in each model. We found an interaction between race and outlet density within 1km ($p = 0.04$). Separate adjusted models by race showed that greater outlet density within 1km decreased African Americans odds of quitting (OR = 0.97, 95% CI 0.96, 0.999, $p = 0.04$), but there was no association for Whites.

CONCLUSIONS: Distribution of tobacco outlets may be a contributing factor to tobacco-related racial health disparities, even among smokers who are willing to quit and are receiving smoking cessation assistance. Future studies are needed to inform policy on the tobacco retail environment in order to further reduce smoking prevalence and health disparities.

DOCUMENTATION OF ASSISTANCE PROVIDED BY PRIMARY CARE PROVIDERS TO SUPPORT SMOKING CESSATION AMONG ASIAN AMERICAN PATIENTS

Isabel Nguyen, BS¹, Khanh Hoa T. Nguyen, BA², Tung Nguyen, MD¹, George Lee, MD², Thu Quach, PhD², Janice Y. Tsoh, PhD³

¹University of California - San Francisco, San Francisco, CA; ²Asian Health Services, Oakland, CA; ³University of California San Francisco, San Francisco, CA

Background: Clinical practice guidelines recommend addressing tobacco use by the 5 As (Ask, Advise, Assess, Assist, and Arrange). Asian American male immigrants have high rates of smoking. This study examined the documentation of “Assist” among Chinese, Korean, and Vietnamese-speaking patients.

Methods: We conducted content analyses of progress notes abstracted from electronic health record (EHR) of 106 male smokers who enrolled in one of the two smoking cessation intervention trials. De-identified progress notes, limited to one primary care visit immediately prior to trial enrollment, were coded for presence or absence of “Assist” and the types of assistance documented (medication types, education or counselling, or quitline referrals). We used generalized estimating equations (GEE) to adjust for provider clusters and examined the associations between patient characteristics (demographics, health conditions, patient’s readiness as assessed by providers) and EHR-documented “Assist.”

Results: The participants’ mean age was 56 (range: 28–73), with 62% Vietnamese, 24% Korean, and 14% Chinese. The mean cigarettes smoked daily was 9.4. Most patients (90%) had at least one chronic conditions such as diabetes (30%), hypertension (59%), or hyperlipidemia (68%). The overall documentation rate of “Assist” was 14%; among patients who were ready for quitting, 80% had “Assist” documented. Most received a single type of assistance (67%). Medications (53%) and education or counselling (47%) were most frequently documented; 20% were referred to quitline. Nicotine patches were most frequently prescribed (63% of those offered medications). A substantial portion (27%) of the patients declined provider’s assistance. GEE model found that patients who were documented as “contemplative or ready” were most likely to be provided with assistance when compared to patients documented as “precontemplative or not motivated” (OR: 9.1; $p = 0.02$) or to those without documentation of readiness for quitting (OR: 28.1; $p < 0.001$). No other patient characteristics examined were associated with the documentation of “Assist.”

Conclusion: Documentation of “Assist” was associated with providers’ assessment of patients’ readiness for quitting. One in four patients declined assistance when offered. Future investigation is warranted to determine barriers for providing assistance to smoking patients, particularly in addressing patients’ low motivation for quitting.

EVALUATING A UNIVERSITY TOBACCO-FREE CAMPUS POLICY USING GEOSPATIAL TECHNOLOGY

Sarah E. Powell, Bachelor of Science Public Health, Master of Science Epidemiology (May 2018)¹, Amy Gatto, MPH², Rita DeBate, PhD, MPH, FAED, FAAHB²

¹College of Public Health, University of South Florida, Orlando, FL; ²University of South Florida, Tampa, FL

Problem and Significance: A college campus implemented a tobacco-free policy in 2016 that banned the use of tobacco products, such as cigarettes, e-cigarettes, smokeless tobacco, and hookah. However, tobacco use continued to be observed on campus. To analyze this newly implemented tobacco-free policy a cross-sectional study using a campus wide survey and observational geospatial data of tobacco policy violations was implemented. Together the two evaluation methods were used to determine next steps for implementation and increased enforcement of the tobacco-free policy.

Description: The survey collected information regarding knowledge of the tobacco-free policy, intention to intervene if observed tobacco-free policy violations occur, and opinion of the tobacco-free policies overall effect. The geospatial data was collected using ArcGIS Collector, which is a mobile application. With the ArcGIS Collector application, points of observed tobacco-free policy violations are saved on volunteers’ mobile devices. These violation coordinate points are all uploaded to ArcGIS online to create a map that can be further analyzed to determine where on campus violations are occurring.

Results: The survey indicated a lack of knowledge of the tobacco-free policy at the University. A total of 72.4 hours were spent collecting observational data that reveals where tobacco use continues on campus. The final map created on ArcMap had a centralized mean and median along with no apparent directional distribution. Therefore, no hotspots could be identified since tobacco policy violations were occurring all across campus.

Conclusions: The created map allows campus policy makers to visualize where tobacco policy enforcement needs strengthening. As more people contribute to the policy violation data the hotspots and clusters may become more apparent. However, even with no identified hotspots the map indicates that the policy needs to be re-implemented campus wide. Since violations were occurring all across campus there needs to be focus of policy education and enforcement all over campus. This evaluation technique can be used to continuously collect data and determine areas of campus that need focus. In this study the recommended steps were re-implementing the tobacco-free policy. With the growing number of colleges and universities creating tobacco-free policies, new and innovative evaluation techniques are needed to ensure the policies are resulting their desired effect: reduced smoking on campuses.

EXECUTIVE FUNCTION IN RURAL OLDER ADULT SMOKERS: INFLUENCE OF DEPRESSION AND NICOTINE DEPENDENCE

Nik Silva¹, Cherie Conley, RN, BSN, MHS², Shawn McClintock, PhD³, Devon Noonan, PhD, MPH, FNP-BC⁴¹Wake Forest University, Wake Forest, NC; ²Duke University School of Nursing, Raleigh, NC; ³UT Southwestern Medical Center, Dallas, TX; ⁴Duke University, Durham, NC

Introduction. Rural older adults are an underserved population with disproportionately high rates of smoking and smoking-related morbidity and mortality. Cessation efforts might be difficult among older adults given the role of executive function, top down mental processes that are necessary for control of behavior. Approximately one-third of older adults have deficits in executive function, which may affect behavior change. This pilot project aimed to determine baseline executive function levels in older adult smokers and addressed whether depression and nicotine dependence are related to executive dysfunction to inform the development of a future cessation trial.

Methods: The sample included 40 adults recruited from two primary care clinics in North Carolina. Inclusion criteria were over 60 years of age, smoked 100 cigarettes in lifetime, currently smoked an average of five cigarettes/day, and residential address in a rural census tract. Global Executive Composite (GEC) and Behavioral Regulation Index (BRI) were measured using the Behavior Rating Inventory of Executive Function-Adult (BREIF-A). Nicotine dependence (ND) and screening for clinical depression (CD) were assessed using the Fagerstrom Test and Center for Epidemiologic Depression Scale-10, respectively. Analysis of covariance methods were used to determine whether executive function was related to CD and ND, adjusting for age. Non-directional tests were performed with significance set at 0.10 for this exploratory analysis.

Results: Among the 40 smokers, 33% had executive function difficulties, 43% reported moderate/high ND and 36% screened positive for CD. Smokers with CD had significantly greater executive function difficulties than those without CD (GEC $p=0.0003$, BRI $p<.0001$), and moderate/high ND was associated with greater executive function difficulties compared to those with milder ND (BRI $p=0.0942$). Together CD and ND explained 50% of the variability of GEC scores.

Conclusions: Executive function difficulties, which may impact smoking cessation success, are common in rural older adult smokers and associated with depression and nicotine dependence severity. Smoking cessation interventions for older smokers should account for baseline executive function, a common age-related barrier to behavior change. Interventions aimed at improving executive function paired with smoking cessation interventions may be warranted in this population.

PSYCHIATRIC AND SUBSTANCE USE SYMPTOMS: RELATION TO MOTIVATION AND SELF-EFFICACY TO QUIT SMOKING AMONG PSYCHIATRIC INPATIENTS

Richard A. Brown, Ph.D.¹, Haruka Minami, Ph.D.², Jacklyn Hecht, R.N., M.S.N.³, Kimberly L. Kjome, M.D.⁴, Ashleigh J. Smith, M.S.W.⁵, Liana A. Reves, B.A.⁶, Christopher W. Kahler, Ph.D.⁷, Erika L. Bloom, Ph.D.⁸, Douglas E. Levy, Ph.D.⁹, Lawrence H. Price, M.D.¹⁰, Nancy A. Rigotti, M.D.¹¹¹University of Texas at Austin, Austin, TX; ²Fordham University, Bronx, NY; ³UT Austin School of Nursing, Austin, TX; ⁴Dell Medical School/Seton Healthcare Family, Austin, TX; ⁵Seton Healthcare Family, Austin, TX; ⁶Seton Shoal Creek Hospital, Austin, TX; ⁷Brown University School of Public Health, Providence, RI; ⁸Alpert Medical School of Brown University/Rhode Island Hospital, Providence, RI; ⁹Harvard University/Massachusetts General Hospital, Boston, MA, MA; ¹⁰Alpert Medical School of Brown University/Butler Hospital, Providence, RI; ¹¹Harvard Medical School/Massachusetts General Hospital, Boston, MA

The current study examined the relationships between readiness/motivation to quit, past quit attempts and psychiatric symptoms as well as substance use among 216 adult smokers with serious mental illness (SMI) receiving psychiatric inpatient care and enrolled in a smoking cessation study. Of 216 participants, 55 (44.4%) reported that their current goal is “to quit completely,” 22 (17.7%) “to quit smoking, but realize a slip is possible,” 18 (14.5%) “to smoke occasionally, when the urge is strong,” 1 (0.8%) “to quit smoking for a limited time,” 19 (15.3%) “to be able to control how much I smoke,” and 9 (7.3%) having “no goal.” Regression analyses showed that greater depressive symptoms significantly predicted reduced confidence in quitting (likelihood of success) and greater anticipated difficulty of quitting smoking, controlling for gender and nicotine dependence. Readiness to quit, desire to quit, or willingness to work hard at quitting did not differ as a function of depressive symptoms. Severity of anxiety, psychotic, or emotional liability symptoms did not predict any of these motivation variables. On the other hand, those with more frequent emotional/psychological problems caused by alcohol use reported significantly greater willingness to work hard at quitting, greater number of past serious quit attempts and quit attempts that lasted over 24 hours, controlling for gender and nicotine dependence. However, frequency of emotional problems due to alcohol did not significantly predict the longest duration of abstinence in the past quit attempts. None of the psychiatric symptoms predicted the number of or the longest duration of past quit attempts. These findings indicate that over 60% of individuals receiving psychiatric hospitalization have quitting smoking as a goal, suggesting their receptivity to smoking cessation treatment and highlighting the importance of developing efficacious tobacco cessation intervention approaches for this SMI population. Findings also suggest the importance of approaches to engender greater self-efficacy and resilience during quitting for smokers with higher levels of depressive symptoms.

YOUNG ADULT OUTCOME EXPECTANCIES FOR ELECTRONIC NICOTINE DELIVERY SYSTEM USE

Marie Chesaniuk, MA¹, Alexander Sokolovsky, PhD²¹University of Illinois at Chicago, Chicago, IL; ²Brown University, Providence, RI

This study examined the associations between outcome expectancies, ENDS use, and cessation outcomes among a sample of young adults (N=304; mean age: 22.4; 38.2% female; 62.8% white). We hypothesized that more positive outcome expectancies would be associated with more use days, higher daily use frequency, fewer reports of cessation, and shorter cessation duration. Participants who self-identified as regular ENDS users and self-reported using within a week of data collection completed a survey on the Amazon MTurk platform. Measures included demographics, ENDS use and cessation behaviors, and an adapted version of the Smoking Consequences Questionnaire. Mean number of days smoked in the past 30 days was 21.6 with 40.5% of participants reporting daily use. 37.5% of participants reported at least one prior quit attempt with an average length of 26.55 days. Average length of non-use excluding quit attempts was 15.55 days. More men than women attempted quitting ENDS. T-tests revealed gender differences across outcome expectancies. We fit Poisson regression models regressing the three outcome variables onto covariates of sex, past year combustible cigarette use, and frequency of ENDS use 12 months prior. We then partially adjusted for each outcome expectancy in a subsequent model. Males were more likely to report a quit attempt and report a longer quit duration than females. Frequency of ENDS use 12 months prior was associated with more past month use days and higher frequency of use. Past year combustible cigarette use was associated with lower likelihood of reporting a quit attempt and shorter quit duration. Weight control, negative affect relief, and boredom relief expectancies were associated with greater frequency of use, lower likelihood of reporting a quit attempt, and shorter quit duration. ENDS outcome expectancies are potent predictors of ENDS use and cessation outcomes. Interventions aiming to achieve cessation, particularly among ENDS and combustible tobacco co-users, should target these expectancies.

This work was supported by a Georgia State University Tobacco Center of Regulatory Science dissertation award, T32 DA016184 (PI: Rohsenow); and T32 AA007459 (PI: Monti).

A MIXED METHODS APPROACH TO UNDERSTANDING GROUP COHESION IN THE BREATHEASY SMOKING CESSATION STUDY

Rochelle Rosen, PhD¹, Joseph Fava, PhD², Ernestine Jennings, PhD¹, Shira Dunsiger, PhD³, Ryan Lantini, MA², Santina Horowitz, BA², Beth Bock, PhD⁴¹The Miriam Hospital & Brown University, Providence, RI; ²The Miriam Hospital, Providence, RI; ³The Miriam Hospital/Brown University, Portsmouth, RI; ⁴Brown Medical School, Webster, MA

Background: *BreatheEasy* is a NCCIH-funded randomized clinical trial examining the efficacy of yoga as a complementary therapy for smoking cessation. From 9/2012 – 6/2016 12 cohorts of smokers received cognitive behavioral therapy for smoking cessation and either Iyengar yoga (n=113) or a wellness control class (n=114). Smoking cessation met once weekly; yoga or wellness met twice weekly for 8 weeks. Qualitative focus groups were conducted with 121 participants (5–13 per group) in both the yoga (n=61) and wellness (n=60) cohorts.

Methods: Quantitative measures included a 22-item Group Cohesion Scale (GCS); parallel analysis and the scree test were used to identify subscales. Focus group participants were asked about their study and quitting experiences; transcripts were coded by two qualitative analysts for Applied Thematic Analysis.

Results: At 8 weeks, 28.1% of yoga and 23.5% of wellness participants reported 7-day point prevalence abstinence (PPA). Dose of yoga received was significantly associated with greater odds of 7 day PPA at 8 weeks (p<.05). Quantitative analysis of the GCS resulted in a 2-component solution: 12 items on Positive Cohesion and 7 items on Negative Cohesion scales. Coefficient Alpha (internal consistency reliability) was very good (.90) for Positive Cohesion and adequate (.73) for Negative Cohesion. The correlation between the 2 subscale scores was -.41. Both positive and negative cohesion are significantly associated with self-reported quit at 6 months (OR 2.21 and 1.99 respectively) among wellness participants, but not yoga participants. Qualitative data indicates that the group was an essential part of the study experience; this was true of both cohort-specific classes (i.e. yoga or wellness) and smoking cessation classes. Regardless of success in quitting, most participants found the group experience to be important: groups provided accountability, strategies for quitting and social support. Qualitative data analysis of comments about the group by cohort and by quantitative GCS are presented to further understand the impact of the group-based delivery of this intervention.

Conclusions: This is the first large scale trial of yoga for smoking cessation with men and women. Qualitative and quantitative data together provide understanding of the importance of group cohesion and a group-based intervention experience for trial participants.

“ORGANIC,” “NATURAL,” AND “ADDITIVE-FREE” CIGARETTES: DO DISCLAIMERS OFFSET ADVERTISING CLAIMS’ EFFECTS ON RISK PERCEPTION?

Sabeeh A. Baig, MS¹, M. Justin Byron, PhD, MHS², Allison J. Lazard, PhD², Noel T. Brewer, PhD¹¹University of North Carolina, Chapel Hill, NC; ²University of North Carolina at Chapel Hill, Chapel Hill, NC

Introduction. The U.S. Tobacco Control Act restricts advertising or labeling that suggests that a tobacco product is less harmful than another commercially marketed product. Natural American Spirit, a cigarette brand with rapidly increasing market share, frequently uses “organic,” “natural,” or “additive-free” claims in advertising. Historically, brands such as Winston and Nat Sherman have also used similar claims in their advertising. We examined how “organic,” “natural,” and “additive-free” advertising claims and corresponding disclaimers affect perceptions of cigarettes’ harm.

Methods. Participants were a national probability sample of adults in the US ($n = 1,114$). We conducted a between-subjects experiment in which participants viewed a Natural American Spirit cigarettes ad claiming they were “organic,” “natural,” “additive-free,” “light,” or “regular,” and with or without a matching disclaimer (e.g., “Organic does not mean a safer cigarette.”). The outcome was perceived harm of the advertised cigarettes. Among smokers ($n = 344$), we also assessed interest in switching within their current brand to cigarettes with this characteristic (e.g., “additive-free”).

Results. Advertising claims in the ad had a large effect on perceived harm (Cohen’s $d = 0.87$, 95% CI: 0.47–1.29). Claims of cigarettes being “organic,” “natural,” or “additive-free” reduced perceived harm from the advertised cigarettes, as compared to “regular” and “light” claims. Disclaimers had a small effect, increasing perceived harm ($d = 0.25$, 95% CI: 0.08–0.41). The problematic claims also increased smokers’ interest in switching while disclaimers had no effect on smokers’ interest in switching.

Conclusions. “Organic,” “natural,” and “additive-free” claims may mislead people into thinking that the advertised cigarettes are less harmful than other cigarettes. Disclaimers did not offset these misperceptions of harm. The U.S. Food and Drug Administration should restrict the use of these misleading claims in tobacco advertising. Our findings may also support the regulatory efforts of the 180 countries that have committed to banning misleading claims under the WHO Framework Convention on Tobacco Control.

ASSOCIATIONS OF RESPONSES TO PICTORIAL CIGARETTE WARNING LABELS WITH CHANGES IN QUITTING ATTITUDES, BELIEFS, AND INTENTIONS

Melissa Mercincavage, PhD¹, Kirsten Lochbuehler, PhD¹, Alexandra A. McCullough, B.S.², Valentina Souproutchouk, BA³, Andrew Strasser, PhD⁴¹University of Pennsylvania, Philadelphia, PA; ²Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; ³University of Pennsylvania, PHILADELPHIA, PA; ⁴Tobacco Center of Regulatory Science, Philadelphia, PA

Background: The tobacco industry contested the US FDA’s efforts to strengthen warning labels on cigarette packaging based on claims that pictorial warning labels (PWLs) evoke emotion rather than inform consumers. The industry further argued that there is no evidence that PWLs promote smoking cessation. To experimentally test these claims, we examined smokers’ responses to the nine court-defeated FDA-proposed PWLs following a 10-day exposure period, and their associations with changes in quitting attitudes, beliefs, and intentions over this period.

Methods: Non-treatment-seeking, daily smokers ($N = 321$; mean age = 43.3; 58.9% male; 54.2% Black; mean cigarettes per day = 15.2) completed a randomized, parallel design laboratory-based trial during which they received their preferred brand cigarettes affixed with one of nine PWLs for 10 days. We assessed quitting attitudes, intentions, and beliefs at the onset and end of the study. At study end, after completing all measures, smokers rated their PWL on a 5-point scale (1 = not at all, 5 = extremely) comprising 8 cognitive attributes: memorable, understandable, shocking, informative, offensive, boring, relevant, and interesting.

Results: Collectively, mean ratings of the PWLs were high for memorable, understandable, informative, relevant, and interesting attributes (range = 3.4 to 4.0), and low for shocking, offensive, and boring attributes (mean scores = 2.9, 1.7, and 1.5, respectively). Individual PWLs differed on the shocking, offensive, and boring attributes (p ’s $\leq .001$); e.g., quitter PWL was rated as more boring than all but one other PWL. Quitting attitudes, beliefs, and intentions increased over the study (p ’s $< .001$); these changes did not differ by PWL (p ’s $> .2$). Changes in quitting attitudes and intentions were positively associated with all attributes except offensive and boring (p ’s $< .05$); beliefs were not associated with any cognitive attributes (p ’s $> .2$).

Conclusions: Contrary to industry claims, smokers’ ratings of PWLs were generally high for desirable attributes (e.g., informative, interesting) and low for negative attributes (e.g., offensive, boring). Further, responses to desirable—but not negative—attributes were associated with increases in quitting attitudes and intentions. Results suggest that repeated exposure to PWLs is unlikely to adversely emotionally impact non-treatment-seeking smokers, and instead, may likely increase attitudes and intentions, which may lead to cessation.

CORRELATES ASSOCIATED WITH PAST 30 DAY SMOKING IN A PRE-DOMINANTLY MEXICAN AMERICAN YOUNG ADULT SAMPLE

Perla Perez, N/A, Roman Fregoso, B.S., N/A, Lizette Salcido, N/A, Viridiana Martinez, N/A, Jose Alonso Cabriaes, Ph.D., Theodore Cooper, Ph.D.

University of Texas at El Paso, El Paso, TX

Although literature on tobacco use is extensive, there is an insufficient amount of research that focuses on Hispanic young adults and smoking. The aim of the study is to identify correlates associated with past 30 day smoking in Hispanic young adults.

Participants on the U.S./Mexican border ($n=725$; ages 18–30; $M_{age}=21.4$, $SD=2.96$; 71.9% female; 60% Mexican American) were recruited through digital media and radio. Consent was completed prior to proceeding with the online assessment (tobacco use, sociodemographic factors, daily stressors, social activities, acculturation, and past 30 day binge drinking).

Fifteen percent reported past 30 day smoking, 44.1% reported lifetime binge drinking, and 25% reported past 30 day binge drinking. A logistic regression (0 = no, 1 = yes; Nagelkerke $R^2=20\%$) assessed sociodemographic and psychosocial/health correlates of smoking (≥ 1 cigarette in past 30 days). Correlates associated with higher odds of past 30 day smoking were: education (High School/GED diploma compared with graduate coursework, marginally; OR = 4.24, CI [0.97, 18.55]), income (less than \$15,000 compared with $> \$50,000$; OR = 2.73, CI [1.16, 6.39]), and past 30 day binge drinking OR = 4.19, CI [2.40, 7.31].

That lower income was again associated with increased smoking suggests the continued assessment of income and other related factors such as access to education about the consequences of smoking and opportunities to quit smoking. That lower education was associated with greater smoking suggests that education may be a protective factor against smoking, and that the university environment, for example, may provide fewer social opportunities to smoke and greater access to prevention and cessation programs. Finally, the strong association observed here between smoking and drinking suggests that factors associated with smoking and drinking such as mood, peer group, perceived discrimination, and perceived consequences associated with use are also assessed. Future studies should continue to assess these relationships in Hispanic young adults, keeping in mind while doing so that more nuanced characteristics relative to other ethnocultural groups are included such as education about smoking consequences, access to prevention and cessation programs, and factors related to polysubstance use.

FACTORS PREDICTING CLIENT RE-ENROLLMENT INTO A TOBACCO CESSATION QUITLINE

Uma Nair, PhD¹, Patrick O'Connor, PhD¹, Melanie Bell, PhD², Cynthia Thomson, PhD, RD¹, Benjamin R. Brady, MS, MPH³

¹University of Arizona, Tucson, AZ; ²The University of Arizona, Tucson, AZ; ³University of Arizona, Sahuarita, AZ

Smoking is a chronic relapsing disorder and a large proportion of smokers who attempt to quit relapse within the first six months. Tobacco cessation quitlines are effective strategies to disseminate evidence-based cessation services and may have potential to re-engage former clients. However, little is known of factors that influence relapsed clients to re-enroll in cessation services. The purpose of this study was to examine factors that may predict reenrollment in the Arizona Smokers' Helpline (ASHLine) - Arizona's state quitline. Data collected from January 2011-June 2016 ($N=49,284$) was analyzed; demographics, smoking history, and nicotine dependence were assessed at baseline. Descriptive statistics were used to identify differences in baseline, in-program, and program follow-up outcomes between clients who enrolled only once and more than once (re-enrollees). Logistic regression was used to predict the odds of re-enrollment. Mean client age was 49.0, 84.1% had at least a high-school education, and 79.9% reported being White/non-Hispanic. Almost 10% of the sample had enrolled more than once. Likelihood of reenrollment was significantly associated with being male (OR = 0.78; CI: 0.70, 0.87) and reporting a mental health condition (OR = 1.23; CI: 1.10, 1.37) at the time of enrollment. Finally, clients who reported not being 30-day abstinent at 7-month follow-up had an odds ratio of re-enrolling 2.77 times that of someone who was 30-day abstinent at 7-month follow-up (95% CI: 2.40, 3.20). Identifying factors that predict client re-enrollment can assist quitlines in developing recruitment messages and service offerings tailored to those most likely to re-enroll. Eight-two percent of clients who were still smoking seven months after their first enrollment did not re-enroll into services; this indicates a missed opportunity by quitlines to re-engage smokers. Quitline efforts in this area should be bolstered through strategies to re-engage exiting clients into cessation services and by offering specialized clinical protocols to aid successful long-term smoking behavior change.

FEASIBILITY AND PRELIMINARY EFFECTS OF INCORPORATING SMOKING-RELATED CONTEXTS INTO AN EXTINCTION-BASED CESSATION THERAPY

Maggie M. Sweitzer, Ph.D.¹, Jennifer G. Stevenson, Ph.D.¹, Jason A. Oliver, Ph.D.¹, Cynthia A. Conklin, Ph.D.², Zach Rosenthal, Ph.D.¹, Joseph McClellan, Ph.D.¹

¹Duke University Medical Center, Durham, NC; ²University of Pittsburgh Medical Center, Pittsburgh, PA

Combining very low nicotine content (VLNC) cigarettes with nicotine patch prior to quitting smoking reduces dependence and withdrawal symptoms, and improves cessation outcomes. These beneficial effects are thought to operate via a process of extinction, wherein the reinforcing effects of nicotine are uncoupled from the behavior of smoking. Increasing the variety of contexts in which this extinction process occurs may help to improve the efficacy of this treatment. In this pilot feasibility trial, we examined the incremental benefit of adding laboratory cue exposure sessions (multiple context extinction; MCE) to VLNC/patch smoking cessation treatment. Adult daily smokers participated in a cessation trial in which they smoked VLNCs while wearing nicotine patch for 3 weeks prior to making a quit attempt. During the pre-quit period, participants attended six, 60-min laboratory sessions, in which they smoked 4 VLNCs while viewing a series of images. Participants (n=34) were randomized to one of two conditions, which differed only in the content of the images presented: personal and unfamiliar smoking-related contexts (MCE+) or nature contexts (MCE-). Cue-elicited craving was assessed at baseline (prior to randomization) and following 24 hrs abstinence (post-quit). At each MCE visit adherence to VLNCs was assessed via timeline follow-back, and dependence was measured with the Fagerstrom Test of Nicotine Dependence. Participants were provided with nicotine patches during the quit attempt and returned to the lab 1, 3, 6, and 10 weeks post-quit to assess smoking outcomes. Randomized participants completed an average of 5.6 (+/- 1.1) MCE+ sessions and 5.6 (+/- 1.2) MCE- sessions. Self-reported adherence with patches and VLNCs during the pretreatment period was excellent, with patch use reported on >99% of days and VLNCs comprising 97.5% of all cigarettes smoked. Adherence did not differ by group on any measure. For both groups (MCE+ and MCE-) dependence and cue-elicited craving decreased from baseline to post-quit (both p's < .05). During the quit attempt, 35.3% of smokers in the MCE+ group maintained continuous abstinence through week 10, compared with 17.6% in the MCE- group (ns). These preliminary results support the feasibility of multiple context extinction and suggest that this may be a promising intervention to improve cessation outcomes. Future research in a larger sample is warranted.

LIVE COUNSELOR CONTACT IN A FACEBOOK INTERVENTION PREDICTS SMOKING CESSATION OUTCOMES

Johannes Thrul, PhD¹, Oona Kelly, BA², Danielle Ramo, PhD²

¹Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; ²University of California San Francisco, San Francisco, CA

Background: Digital smoking cessation interventions frequently use automated delivery of content and it is unclear if live counseling provides added benefits. We investigated how well participants engaged with live counseling sessions compared to automated content in a Facebook intervention and if attending these sessions predicted smoking abstinence.

Methods: The Tobacco Status Project (TSP) is a 90-day Facebook intervention for young adults (18–25) utilizing automated posts and weekly sessions with a smoking cessation counselor in private Facebook groups tailored to readiness to quit smoking (precontemplation, contemplation, preparation). Data came from the treatment group of a randomized controlled trial (N=251). The analytical sample consisted of 2,943 posts, 331 (11%) of which were live-counselor initiated, the rest were automated. Logistic regression analyses examined whether extent of counselor contact predicted saliva cotinine verified abstinence at 3 months controlling for gender, readiness to quit, and extent of engagement with automated content. Poisson regressions were used to predict participant engagement (number of comments) based on post content area, stratified by readiness to quit smoking and controlling for Facebook group and post timing.

Results: Participation in live counseling predicted 3-month biochemically verified abstinence, (adjusted Odds Ratio=1.087 [95% CI 1.002, 1.181]). All posts generated 8,403 participant comments (M=2.8 comments per post). Participants in precontemplation engaged as much with the smoking cessation counselor as they did with the most engaging automated content (motivational content). Participants in contemplation engaged significantly less with the counselor than with the most engaging automated content (motivational content). Participants ready to quit within the next 30 days engaged significantly more with the counselor than with the most engaging automated content (cessation advice).

Discussion: In digital interventions, counselor contact may be beneficial in addition to automated posts at yielding engagement and abstinence; however, participants engage differently with live counseling according to their readiness to quit smoking.

PATTERNS OF POLYTOBACCO USE AMONG A COMMUNITY SAMPLE OF SOUTHERN AFRICAN-AMERICAN AND WHITE CIGARETTE SMOKERS

Jukelia Bess, BA, Hope Landrine, PhD, Irma Corral, PhD, MPH

Brody School of Medicine, East Carolina University, Greenville, NC

Many cigarette smokers concurrently use other tobacco products such as cigars or cigarillos (i.e., polytobacco use). Studies have found that African Americans (AAs) are more likely than Whites to be polytobacco users insofar as they simultaneously use cigarettes and cigarillos. Such studies generally have excluded use of smokeless (chew) tobacco. Chew tobacco use however is common among Whites in rural areas and among Whites in the southeastern US. Including chew may reveal new patterns of polytobacco use and also might decrease racial disparities in that use. This preliminary study is the first to examine polytobacco and chew use among southern AA and White adults. Participants were a random household sample of 1,670 AA and White adults who ranged in age from 19 to 97 years (Mean = 42.6, sd = 15.6). They completed a brief, anonymous survey on their demographics (age, gender, income, education); ever and current cigarette smoking; number of cigarettes smoked per day; use of cigarillos, cigars or pipes; and use of chew. The sample included 512 current cigarette smokers upon whom analyses are based. Univariate analyses revealed no racial difference in cigarette smoking prevalence (Whites = 32.7%, AAs = 31.7%), and two unique patterns of polytobacco use: Significantly more Black than White men used cigarettes in combination with cigarillos, cigars, or pipes (Polytobacco Pattern 1) but there were no racial differences in this pattern among women. Significantly more Whites than Blacks (both genders) used chew concurrently with cigarettes, chew concurrently with cigarillos, and chew concurrently with both (Polytobacco Pattern 2). In the logistic regression using demographic variables to predict concurrent use of cigarettes and cigarillos, cigars, or pipe (Pattern 1), race was not significant, but age (lower use by older people), education (lower use with higher education), and gender (lower use among women) were significant. In the logistic regression predicting concurrent use of chew and any other tobacco product, race was significant with Whites 3.8 times more likely than Blacks to exhibit Pattern 2. Age and gender were not significant, but education (higher) was associated with lower use. AA disparities in polytobacco use were not found when chew was included in analyses, and unique racial patterns of polytobacco use were revealed, with potentially dangerous use patterns and racial disparities among Whites.

SIRI, HOW DO I QUIT SMOKING? ONLINE CESSATION INFORMATION SEEKING BY U.S. SMOKERS, 2005–2015

Michael S. Amato, PhD, Amanda L. Graham, PhD

Truth Initiative, Washington, DC

Background: Many services exist online to help smokers who want to quit, but recent estimates of the number of smokers seeking those services are not readily available. The most recent available estimates indicate 9% of all US adults sought cessation information online in 2006 (Fox S. Health Topics. Pew Research Center; 2011). This study aimed to determine consumer demand for online cessation information.

Methods: We analyzed longitudinal data from the Health Information National Trends Survey (HINTS), a nationally representative, population based survey conducted by the National Cancer Institute. In 2005, 2011, 2013, and 2015, the survey asked US adults whether they (1) ever go online to use the internet, WWW, or email; and (2) had used the internet to look for information about quitting smoking within the past 12 months. We estimated the proportion and number of U.S. adult cigarette smokers who went online and searched for cessation information in each of those years. Current smokers were defined as “everyday/someday” smokers, with ≥ 100 lifetime cigarettes. Cross-year comparisons were assessed with logistic regression.

Results: The proportion of US adult smokers who went online increased from 55.8% in 2005 (95% CI = [51.3, 60.0]) to 73.0% in 2015 [66.1, 79.0]. The proportion of U.S. adult smokers who searched online for cessation information rose over the past decade: 17.3% in 2005 [13.7, 22.0]; 20.9% in 2011 [15.5, 28.0]; 25.6% in 2013 [19.7, 33.0]; and 23.4% in 2015 [16.9, 31.0], $p=0.04$. An alternate analysis, in which the denominator included only smokers who reported using the internet, revealed that approximately 1/3 of internet-using smokers searched for cessation information in each year (range: 29.4% to 32.7%). In 2015, the most recent year, an estimated total of 8,494,524 smokers searched online for cessation help.

Conclusions: Each year, over 8 million American smokers look for cessation assistance online. Among internet users, demand for online cessation information has remained stable over the past decade. However, increases in the proportion of smokers who use the internet has translated to increases in the proportion of smokers actively searching for cessation information online. Improvements to the effectiveness of online cessation interventions, as well as strategies that increase access to the internet among populations with high smoking rates, both have potential to reduce the population prevalence of cigarette smoking.

SMOKERS' PERCEPTIONS AND LIKELIHOOD OF FUTURE USE OF THE ELECTRONIC WATERPIPE

Andrea Stroup, M.P.H., M.S., Steven Branstetter, Ph.D.

Pennsylvania State University, University Park, PA

Introduction: The reduction of young adult waterpipe smoking remains a national public health priority. Although there has been expanding efforts to decrease traditional waterpipe (TW) use, there is a new waterpipe product on the market that has yet to be investigated. To date, there are no known studies investigating electronic waterpipe (e-waterpipe) smoking. As such, the proposed research will aid in the development of efforts to identify and evaluate the novel e-waterpipe.

Methods: Regular electronic cigarette users (n=26) aged 18–34 were given twenty minutes to smoke an e-waterpipe in a laboratory setting where smoking behaviors were recorded. Subjective and objective measures were collected pre- and post-smoking. Measures included spirometry parameters and questionnaires on perceptions of use and likelihood of future use.

Results: Approximately 76.9% felt positive about smoking an e-waterpipe and 80.8% intended to speak positively about their smoking experience. Overall, 73.1% reported that e-waterpipe use was satisfying. When comparing the e-waterpipe to their personal electronic smoking devices, 42.3% believed that smoking e-waterpipe was safer and 30.8% thought e-waterpipe use was healthier. More than half of the participants reported more positive health effects from smoking the e-waterpipe compared to their own smoking device.

Conclusion: Findings suggest that e-waterpipe use has the potential to become popular within the emerging adult population. This pilot study demonstrated that users had positive perceptions toward willingness and likelihood of future use, attitudes, sensory beliefs and expected health outcomes. Further research is necessary to understand prevalence of use and the associated health risks and to compare the risks of e-waterpipe and traditional waterpipe smoking.

SMOKING HABITS AND AWARENESS ABOUT ANTI-SMOKING ACTS AMONG GENERAL PUBLIC IN GURGAON, HARYANA, INDIA

clement Joy Kingsly Francis, MBA

Nestle India Limited, Gurgaon, Haryana, India

Background: India is the world's third largest tobacco-growing country. The Indian scenario as far as tobacco consumption is concerned is far worse because of the prevalence of the tobacco chewing habit which covers a wide spectrum of socioeconomic and ethnic groups and is spread over urbanized area as well as remote village. Tobacco use is alarming in terms of its current and projected future impact on global mortality. Recent shift in global tobacco consumption to developing countries indicate that an estimated 930 million of the world's 1.1 billion in India alone. Despite the facts, that the harmful effects of tobacco chewing and smoking are widely known, many young people start smoking during adolescence, largely because they believe that smoking will boost their social acceptability and image. This study was contemplated with an aim to assess tobacco / smoking habits and awareness about anti-smoking act among general public in Gurgaon, Haryana, India.

Method: A structured questionnaire consisting of 14 questions related to tobacco/ smoking habits and awareness about anti-smoking act were asked to general public and their response was recorded. Random sampling method was used and data was collected from a cross-sectional survey. Anti-tobacco counselling was given on the spot and followed.

Results: The study population consisted of total 430 individuals, male 364 (84.65%) and females 66(15.34%). Then the questionnaires were asked and statistically analyzed. Around 286 (78.57%) from 364 male were indulged in some form of tobacco usage (smoker =32.86%, tobacco chewer = 16.78%, both =11.18 %, alcohol +tobacco user =21.67%). In the present study, most common cause of tobacco use was pleasure 40.5%, inducing factor were friends 53.1% followed by parents and siblings. 36.20% patients used tobacco as second hand exposure in job places. 54.8% were aware about the anti-smoking act in public places, so only 8.6% people from all males enrolled, were smoking in public places.

Key words:Tobacco chewing, smoking, anti-smoking act, prevalence.

TOBACCO USE, AWARENESS AND CESSATION AMONG MALAYALI TRIBES, YELAGIRI HILLS, TAMIL NADU, INDIA

Delfin Lovelina Francis, MDS

Dr MGR Medical University, Chennai, Tamil Nadu, India

BACKGROUND: Health is a state of complete wellbeing free from any discomfort and pain. Despite remarkable world-wide progress in the field of diagnostic, curative and preventive medicine, still there are large populations of people living in isolation in natural and unpolluted surroundings far away from civilisation, maintaining their traditional values, customs, beliefs and myths. India has the second largest tribal population of the world next to the African countries. About half of the world's autochthonous people live in India, thus making India home to many tribes which have an interesting and varied history of origins, customs and social practices. The present study was conducted to assess the tobacco use, awareness and its effect on health among Malayali tribes, Yelagiri Hills, Tamil nadu, India.

METHODOLOGY: The inhabitants of the 14 villages of the Yelagiri hills, who have completed 18years and residing for more than 15years present on the day of examination and who were willing to participate in the study were included.

Data was collected from a cross-sectional survey, using a Survey Proforma, clinical examination and a pre-tested questionnaire which included Demographic data, tobacco habits. An intra-oral examination was carried out by a single examiner to assess the Oral Health Status using WHO Oral Health Surveys – Basic Methods Proforma (1997).SPSS version15 was used for statistical analysis.

RESULTS: Results showed that among 660 study population, 381(57.7%) had no formal education. Among the study population 75% had the habit of alcohol consumption. Of those who had the habit of smoking, 26% smoked beedi, 10.9% smoked cigarette, 65% chewed raw tobacco, 18% chewed Hans and 28% had a combination of smoking and smokeless tobacco usage. The reason for practicing these habits were as a measure to combat the cold, relieving stress and body pain after work, and the lack of awareness of the hazards of the materials used. Prevalence of oral mucosal lesions in the study population was due to tobacco usage and alcohol consumption and lack of awareness regarding the deleterious effects of the products used.

CONCLUSION: From the results of this study it may be concluded that the Malayali tribes were characterized by a lack of awareness about oral health, deep rooted dental beliefs, high prevalence of tobacco use and limited access to health services.

KEY WORDS: Malayali tribes, Tobacco usage, oral health status, WHO oral health proforma, Beliefs.

TREATMENT NEEDS, SMOKING CHARACTERISTICS, AND MENTAL HEALTH FUNCTIONING AMONG COPD HELPLINE CALLERS

Amanda R. Mathew, PhD¹, Cherylee Bridges, RN², Miriam Guzman, MHA¹, Susan Yount, PhD¹, Ravi Kalhan, MD, MS¹, Brian Hitsman, PhD¹¹Northwestern University Feinberg School of Medicine, Chicago, IL; ²American Lung Association, Springfield, IL

Background: Telephone quitlines are an effective population-based strategy for smoking cessation, particularly among individuals with tobacco-related diseases such as Chronic Obstructive Pulmonary Disease (COPD). Expanding quitline services to provide patient education and address other clinical issues among COPD patients is potentially beneficial; however, data are needed to identify specific treatment needs in this population.

Methods: We examined treatment needs, smoking status, and mental health symptoms among individuals with COPD who received services from the American Lung Association (ALA) Lung Helpline and Tobacco Quitline. Data were drawn from a nationwide, phone-based needs assessment survey of 6194 participants conducted between 2011 and 2017.

Results: Participants were older adults (57.6 ± 9.5 years), 83.8% were Non-Hispanic Caucasian, and 66.9% were women. Nearly all participants (94.8%) saw a doctor or medical professional regularly, but more than half (53.6%) were not receiving treatment from a lung specialist. Most participants (73.6%) were interested in receiving additional information on lung health topics. The majority of participants reported no prior instruction on breathing exercises (66.8%), energy conservation (74.8%), or clearing their airway (68.5%). Participants reported significant disease burden: 78.1% reported disease-related interference in daily activities, 29.6% had been hospitalized within the past 6 months for their breathing, and 16.3% were not confident in managing their COPD. Current smokers (80.2%) were highly nicotine dependent, with 82.9% smoking more than 10 cigarettes per day and 91.5% smoking within 30 minutes of waking. Lastly, nearly half of participants (44.9%) reported experiencing current symptoms of anxiety or depression. Those with vs. without anxiety/depression had higher rates of disease-related interference (83.9% vs. 73.5%, $p < .001$) and past-6 month hospitalization (33.4% vs. 28.3%, $p < .001$).

Conclusion: This population-based needs assessment survey identified strong interest in lung health education among individuals with COPD. Specific areas of need included self-management strategies for breathing and energy conservation, information on disease management, and nicotine dependence treatment. Further, anxiety and depression were commonly reported comorbidities that were associated with more severe disease impairment and higher hospitalization risk, highlighting the importance of addressing mental health issues. Phone-based outreach services that target multiple behavioral needs of COPD patients are a promising strategy to improve outcomes in this population.

8:00 AM-9:15 AM

PHYSICAL ACTIVITY RESEARCH IN THE 21ST CENTURY: HARNESSING KEY PATHWAYS FOR ACHIEVING GLOBAL IMPACT

Abby C. King, PhD¹, James F. Sallis, PhD², Sandra J. Winter, PhD, MHA³, Abby C. King, PhD¹, Tracy Orleans, PhD⁴¹Stanford Prevention Research Center, Palo Alto, CA; ²UC, San Diego, La Jolla, CA; ³Stanford University School of Medicine, Palo Alto, CA; ⁴Robert Wood Johnson Foundation, Princeton, NJ

Modest and uneven progress in reducing the physical inactivity epidemic in the U.S. and worldwide is not sufficient to improve population health. This symposium highlights three potentially transformative pathways for creating the conditions for more active populations: improving built environments, expanding citizen science, and leveraging information and sensing technologies. Dr. James Sallis will describe how evidence from the International Physical Activity and Environment Network (IPEN) is being translated into actionable strategies for promoting “active cities” worldwide. Dr. Sandra Winter will present findings from the *Our Voice* Citizen Science Global Network, in which residents from ethnically diverse communities have successfully changed community environments and policies to promote active living. Dr. Abby King will highlight some of the latest trends in physical activity data capture using cutting-edge technologies that can set the stage for transformative shifts in physical activity surveillance and intervention. Finally, Dr. Tracy Orleans will recommend ways to improve research, combine these strategies and accelerate their application for bigger impact both in the US and globally.

Symposium 32A

EVIDENCE TO GUIDE POLICIES FOR MORE ACTIVITY-FRIENDLY CITIES WORLDWIDE: CONTRIBUTIONS OF IPEN

Dr. James F. Sallis, PhD

A notable trend in the physical activity field in the 21st Century has been an increasing focus on environment and policy factors in shaping physical activity. The basic concept is that 20th Century trends in urban design, automobile-dominated transportation, and technologies transforming work and leisure are root causes of the global epidemics of inactive lifestyles and related chronic diseases. Not only has the evidence in this area grown dramatically, but national and international recommendations and government policies are becoming more consistent with the evidence. Based on studies begun in the US, IPEN (International Physical activity and Environment Network) was launched in 2004 to encourage, support, and coordinate studies of environmental correlates of physical activity, sedentary behavior, and obesity worldwide. The rationale for IPEN was that including worldwide variation in environments would produce more accurate effect sizes, and country-specific data are particularly influential for stimulating local policy change. Twelve countries on 5 continents participated in the NIH-funded IPEN Adult study. Publications to date have documented moderate-to-strong associations of various environmental features with total physical activity, active transport, active recreation, and obesity. A commentary accompanying one paper estimated that 2 million deaths per year worldwide could be averted if everyone lived in activity-supportive communities. An IPEN Adolescent study has been completed, and several countries have collected comparable data on older adults. IPEN investigators are actively engaged in translating research findings to policy and practice through such efforts as disseminating lay summaries of papers, media outreach, presentations at policy-oriented conferences, consulting with local and national governments, and consulting with international groups such as the World Health Organization, World Bank, and multiple advocacy and professional organizations. Concepts such as “walkability” were unknown in public health at the beginning of the 21st century, but in a relatively short time environmental change has become central to public health goals and activities, and city planning, transportation, parks departments, as well as elected leaders of cities, increasingly consider the health consequences of their decisions.

Symposium 32B

ACTING LOCALLY TO IMPROVE HEALTH GLOBALLY: ENGAGING CITIZEN SCIENTISTS TO CHANGE ENVIRONMENTS AND POLICIES FOR ACTIVE LIVING

Dr. Sandra J. Winter, PhD, MHA

Technological advancements in the 21st century have enabled residents to contribute to science by gathering local data to inform a range of environmental endeavors such as monitoring solar eclipses and documenting trends in bird migration. The evidence-based *Our Voice (OV)* approach to advancing health equity engages citizen scientists in new ways, both expanding the reach of community-engaged research and optimizing its impact. *OV* citizen scientists participate in a 4-step process in which they use a simple mobile app (the Discovery Tool) to document aspects of their community that impact healthy living; meet with other citizen scientists to discuss findings and agree on priorities for action; present their data to local decision-makers; and advocate for lasting positive changes in their local environments. This presentation will highlight research projects that have engaged citizen scientists across cultures and age groups to address a wide variety of community health challenges. Projects in the US have included older adults working to increase food access and walkability in low-income neighborhoods; multi-generational efforts to document and improve safe routes to school; LGBT adults identifying features that promote neighborhood safety and inclusion; and African-American women conducting walkability assessments across multiple cities to inform community improvement plans. At a global level, the Discovery Tool has been translated into 7 languages and the *OV* model has been adapted for use in diverse communities in Chile, Colombia, Israel, South Africa, Taiwan, Mexico and Canada. Social, environmental and policy changes stemming from *OV* include creation of senior-friendly walking maps; planting of a new community garden; formation of an older adult advocacy group at an affordable housing site; installation of street and curb signage to improve pedestrian safety; regeneration of a public art project; outreach to corner store owners to improve healthy food access; allocation of new city funds for sidewalk improvements; and adoption of new community-driven Safe Routes to School campaigns. To build on the successes of this global research platform, an *Our Voice* Global Network was formed in 2016. The Network is committed to building a scientific road map, identifying and sharing measurement tools to track impact, coordinating cross-site comparisons, and generating, refining, and disseminating best practices. Network processes and outcomes will be reviewed.

Symposium 32C

LEVERAGING THE POWER OF THE MOBILE HEALTH REVOLUTION TO PROMOTE POPULATION-WIDE PHYSICAL ACTIVITY & REDUCE SEDENTARY BEHAVIOR

Dr. Abby C. King, PhD

With the arrival of the smartphone and other mobile and wearable devices, the behavioral health science field is on the cusp of a paradigm shift. The passive sensing capabilities of such devices open the door to near-continuous, often lower-burden assessment of physical activity (PA). In addition, the self-reporting capacities of mobile devices and direct linkages with social and environmental online platforms and datasets (e.g., online social networks; geographical information systems [GIS]) provide access to heretofore unattainable contextual factors influencing PA and sedentary behaviors across different life stages, circumstances, and geographic locations. Of particular note, US subgroups who rely on smartphones for online access at elevated levels include several racial/ethnic minority groups and those with low household incomes and educational attainment. As such, smartphones have the potential to mitigate health disparities and other inequalities. In contrast to traditional epidemiological approaches, mobile health platforms allow for dynamic daily measurement and more nuanced investigation of multiple health behaviors and their surrounding contexts. Academic-technology industry partnerships can liberate such datasets and usher in new insights about longitudinal health behaviors and their dynamic patterns of change. The purpose of this presentation is to highlight some of the latest trends and opportunities in the “big data” field of direct relevance to the promotion of regular PA and reduced sedentary behavior. Among the types of innovative investigations that will be highlighted are results from a global commercial smartphone health behavior app that has captured worldwide patterns and differences in PA “inequality” (the amount of variability in PA levels within a nation), which was shown to be a strong predictor of obesity incidence and linked in the US with city-based walkability levels; leveraging of social interactions in online social networks to influence “off-line” PA levels; harnessing online challenges and similar “gamification” activities to shape increased PA in diverse subpopulations, including those with low general levels of PA; and use of public webcams to crowdsource pedestrian and cyclist behaviors in different locales. Finally, current challenges and future directions in the field will be discussed, along with ways that behavioral medicine scientists can take advantage of these trends in augmenting their research.

ETHICS, VALUES, AND DIGITAL HEALTH RESEARCH: THE CASE OF FITBIT

Sherri Sheinfeld Gorin, PHD¹, Matthew P. Buman, PhD², Ernesto R. Ramirez, PhD, MS³, Michelle De Mooy, BA, Government; MA, Strategic Communications⁴, Camille Nebeker, Ed.D, M.S.,⁵

¹Columbia University, New York, NY; ²Arizona State University, Phoenix, AZ; ³Fitabase, San Diego, CA; ⁴Center for Democracy & Technology, Washington, DC; ⁵UC San Diego, La Jolla, CA

By using digital tools and computational methods, including mobile apps, wearable sensors and social network platforms, we are now able to observe individuals in real time and deploy personalized and just-in-time, adaptive health interventions. Not only are the tools and methods changing, but the research ecosystem is much more diverse. In addition to the traditional academic researchers, the technology industry now collects massive amounts of consumer data which present opportunities to learn about factors influencing human health. Moreover, the tech industry is now a major player in the biomedical and behavioral research arenas. Developing and navigating collaborative relationships between academic and industry partners are challenging due to their different core objectives, yet are critical to the future of ethical and responsible digital health research. Regardless of what entities are involved, the vast quantities of personal—often identifiable—health information created via pervasive sensing and computational techniques are raising new ethical and regulatory challenges. In this symposium, we identify many of these issues with a detailed example of a commercial product - Fitbit, that is used by a growing number of physical activity researchers. Our speakers will present: 1- how a wearable, passive sensor is used in academic research to capture personal health data; 2- the role of an intermediary that facilitates access to data captured by a commercial product; and 3- consumer privacy rights and data use expectations. In closing, our discussant will address the overarching and complex ecosystem for these products, the regulatory challenges to their use, and offer recommendations for advancing ethical and responsible digital health research.

Symposium 33A

WEARABLE TECHNOLOGIES: EVIDENCE FOR EFFECTIVENESS AND ETHICAL QUESTIONS

Dr. Matthew P. Buman, PhD

Wearable technologies offer unprecedented opportunities to advance research and improve health outcomes across a range of disciplines from epidemiology, to behavioral science, to healthcare delivery. The pace at which industry can develop, refine, and bring to market new technologies far outpaces that of traditional academic bioengineering groups which historically have driven the tools used by the research community. Leveraging consumer-focused wearable technologies (e.g., Fitbit) in biomedical and behavioral research offers important advantages and opportunities to more rapidly advance scientific discovery and improve population health. However, it also presents unique technical, scientific, and ethical challenges that must be navigated by the researcher throughout the research process. The purpose of this presentation is to describe the scope of research led by academic researchers and behavioral scientists leveraging Fitbit and related technologies with a specific focus on validation studies, observational and longitudinal studies, and population- and clinical-based intervention studies. The presenter will highlight ongoing NIH-funded clinical trials that seek to leverage Fitbit technologies to support behavior change interventions in two distinct populations: prediabetic US Veterans recruited from a primary care unit in the VA health care system and individuals with obstructive sleep apnea recruited from a sleep disorders clinic in a large hospital system. Lastly, we will discuss implications for using wearable technologies in research as it relates to critical research design decisions, need for interdisciplinary teams to address technical challenges, and ethical considerations that have unique implications for researchers, health care systems, and patients.

Symposium 33B

FITABASE AND TRACKING CONSUMER HEALTH BEHAVIORS: ONE USE CASE WITH ETHICAL CAVEATS

Dr. Ernesto R. Ramirez, PhD, MS

Fitabase is a five-year old software development company that has supported over 450 research studies and digital health projects that make use of Fitbit wearable devices. Fitabase was founded in 2012 in order to meet the growing need from the academic and clinical research and health services community to easily use newer consumer devices for tracking health behaviors without investing in costly and time-intensive technical development and support. Our Fitabase platform is routinely used to remotely monitor participants, access near real-time data, and provide robust data export capabilities for researchers who are conducting independent data analysis. Our experience, through creating a lasting partnership with Fitbit Inc. and developing software tools that support behavioral health research community, has provided us with numerous insights into the methodological, technical, and ethical issues that arise when working with consumer digital health tools and their data.

A brief overview of the Fitabase platform will be given, paying particular attention to the authorization protocols that allow for the sharing of data across technical infrastructures. We will also discuss our terms of service and privacy policies as they pertain to data sharing and the storage and access rights of data we collect on behalf of our research customers, and how they were developed. Over the last five years we have numerous experiences working with a variety of academic and for-profit entities and will present examples of issues we have encountered that deal with protecting participant privacy, and how our data access and storage features are designed to reflect ethical and privacy principles. Specific emphasis will be placed on how our research customers make use of de-identification methods across the device, account, and data collection processes, and how these features and processes can be reflected in communication with institutional review boards. Lastly, we will provide examples, based on our experience, as to how commercial entities can work hand-in-hand with the research community to support innovative study designs and data gathering at scale.

Symposium 33C

PRIVACY, TERMS, AND CONDITIONS: ETHICS AND DIGITAL HEALTH

Michelle De Mooy, BA, Government; MA, Strategic Communications

The Center for Democracy & Technology (CDT) is a nonprofit technology advocacy organization that champions global civil liberties and human rights online. The work of the Privacy and Data Project focuses on advancing individual dignity and autonomy in digital systems, through technical and policy levers.

In 2016, CDT released a report that detailed its collaboration with Fitbit to develop privacy-protective and ethical internal research procedures for wearable technology companies. Wearable sensor technology, in particular, has the potential to transform health care and our understanding of our own bodies and habits. The investigation and testing of these sensors in the commercial sector offer an unprecedented opportunity to leverage biometric data, both to improve individual health through the development of better products and to advance the public good through research. However, research with wearable sensor data must be done in a manner that is respectful of ethical considerations and consumer privacy. Not only will the processes that govern this research define the potential public good derived from wearables, they will encourage user trust in wearables and promote participation. Therefore, the research and development (R&D) teams at these companies are not just engines of innovation, but also have the potential to be an important part of our social infrastructure. R&D teams in wearable technology can and should also be laboratories of privacy and ethical research best practices. Some companies, such as Fitbit, leverage the talent and expertise on their teams to embed privacy into their technology.

In this session, will discuss the specific policies and procedures used by Fitbit's R&D team and the frameworks used by CDT to create recommendations on data security, privacy, and ethics for commercial health researchers. We'll also touch on how ethical frameworks can approach issues facing academic and commercial researchers today, such as data scraping and the mitigation of unintended bias in the creation of algorithms that deliver health-related content to users.

INNOVATIVE TECHNIQUES TO ENHANCE ENGAGEMENT AND RETENTION IN RCTS: MOVING TOWARDS EVIDENCE-BASED PROCEDURES

Danielle E. Jake-Schoffman, PhD¹, Roxana Farias, MPH², Tricia Leahey, PhD³, Susan D. Brown, PhD⁴, Monica L. Baskin, PhD⁵¹University of Massachusetts Medical School, Worcester, MA; ²Stanford University School of Medicine, Stanford, CA; ³University of Connecticut, Storrs, CT; ⁴Kaiser Permanente Northern California, Oakland, CA; ⁵University of Alabama at Birmingham, Birmingham, AL

Among the most challenging aspects of successfully administering a randomized behavioral trial are maintaining participant engagement in the intervention and retaining participants through follow-up assessment visits. A number of procedures are routinely used during trial enrollment in an effort to boost engagement and retention, such as in-depth screening visits, orientation sessions, behavioral contracts, and run-in periods. However, these procedures typically require large investments of staff time and trial resources, there is little data to describe the impact of the procedures on participant engagement and retention, and there is even less known about the mechanisms of impact by which the procedures improve trial quality. Additionally, concerns exist about whether adding new or complicated enrollment procedures to a trial protocol could limit the generalizability its results or compromise the diversity of the sample. Here, we present early data to demonstrate the impact of orientation sessions and run-in periods on a range of behavioral weight loss interventions. The first presenter will discuss an innovative approach to orientation sessions, the Methods-Motivational Interviewing (MMI) approach, originally designed as an in-person group-based orientation session, which has since been adapted to a variety of trial settings, participant populations, and delivery modes. The presenter will share data from an on-going trial where the MMI approach is implemented as an interactive webinar, in response to early differential engagement in the intervention. The second presenter will discuss another example of the implementation of the MMI approach, in a study of gestational weight gain among low income women. In this trial, the MMI approach is implemented as a conference phone call to accommodate the technology ownership of the target participants. Data from the on-going trial will be shared to describe the changes in trial enrollment, attendance, and retention before and after implementing the sessions. The third presenter will discuss the results of a preliminary test of the impact of the MMI approach on participants' research literacy about trial retention and trust in the research team before and after attending an in-person group-based orientation session. The fourth presenter will discuss data from a behavioral run-in period before a weight loss trial, to investigating if the run-in predicted participant treatment adherence during the trial. Finally, the discussant will provide a summary of the study findings and lead a conversation about the considerations for implementing these trial procedures, the potential implications for generalizability, and the next steps for generating evidence to support efficient and effective trial pre-enrollment procedures.

Symposium 34A

INCREASING RETENTION IN RCTS: THE METHODS-MOTIVATIONAL INTERVIEWING APPROACH TO ORIENTATION SESSIONS

Danielle E. Jake-Schoffman, PhD

Orientation sessions in randomized clinical trials serve primarily to communicate trial procedures to potential participants, while they could be used to involve participants in the research experience on a deeper level by engaging them in the scientific rationale of the trial design, research questions, and methods. This may also provide participants with a more comprehensive understanding of the commitment entailed in trial enrollment, thus enhancing retention, regardless of participants' own trial experience or degree of individual success. Our Methods-Motivational Interviewing (MMI) approach leverages interactive orientation sessions, held pre-randomization, to set clear expectations for participants (e.g., transparency about lengthy assessments), explain the scientific rationale for methodological procedures (e.g., randomization and impact of dropouts on scientific conclusions), diffuse ambivalence about research participation using motivational interviewing techniques (e.g., remaining neutral regarding participation), and make explicit two commitments (i.e., to self and trial methods). Originally delivered as in-person group-based sessions, the MMI approach has been adapted to a range of trial designs, settings, and participants. Here we describe innovative modifications to the approach to enhance the fit with trial needs, through pre-randomization webinars. These orientation session webinars were implemented in the Get Social weight loss trial, after early data showed differential participation. In a set of webinar slides, a research team member presents the orientation session, including a detailed description of trial expectations. Then, using motivational interviewing techniques, an interactive discussion is facilitated through the webinar chat function to elicit potential participants' views on the pros and cons of participating in both of the study conditions. The trial and data collection are ongoing. To date, and correcting a trend toward differential participation, the MMI approach is associated with a significant increase in participation (measured by % participation in 0 intervention sessions) in the control group (pre-implementation 28% vs. post-implementation 6%, difference: -22%, 95% CI: -39, -5; no difference in intervention group: pre-implementation 3% vs. post-implementation 3%, difference: 1%, 95% CI: -7.3, 8.6), thus. Further, retention significantly increased at the 6-month follow-up visit (pre-implementation 81% vs. post-implementation 97%, difference 16%, 95% CI: 5, 26). Practical tips for adapting and implementing the MMI approach in a variety of trial settings will be provided, such as considerations of differences between study conditions and potential session delivery methods. Future research directions such as the design of randomized experiments to test the MMI approach will be discussed.

Symposium 34B

PARTICIPANTS' RESEARCH LITERACY ABOUT RETENTION AND TRUST IMPROVE AFTER ATTENDING INTERACTIVE ORIENTATION SESSIONS

Roxana Farias, MPH

Background: Participant research literacy is essential for informed participation in clinical trials. In prior work, we described a novel practical approach for improving participants' research literacy—interactive in-person group-based orientation sessions held prior to randomization. We designed these sessions in part to clearly explain the methodological rationale for trial procedures, such as completing all follow-up assessments, and speculated that transparency about methodology could increase participant trust of the research team even though trust is (purposely) not mentioned during the orientation sessions.

Objective: Here, we examined whether individuals increased their research literacy about the importance of trial retention and their trust in the research team after attending an in-person group-based orientation session.

Methods: The sample consisted of overweight/obese adults with elevated blood pressure potentially interested in participating in a 3-year behavioral weight-management intervention trial (n=233, 43.4% men, 41.2% Asian, 5.6% Black, 6.0% Latino, 0.9% Native Hawaiian, 40.8% White, and 5.6% Multi-Racial/Ethnic). Knowledge was assessed with a categorical question that asked about the effect of dropouts on the conclusions that an evaluation team could draw from a hypothetical program, i.e., if participants who were not successful did not come back to be measured, the evaluation team would (erroneously) conclude the program was more successful than it really was. Trust was assessed with a 5-point scale with response options (not at all, a little bit, moderately, quite a bit, extremely) from 1–5.

Results: Before the orientation session, only 61.8% of potential participants correctly answered the knowledge question. After the orientation session, 84.5% correctly answered, an absolute percentage increase of 22.7% [CI 16.4% to 29.1%], $t(232) = 7.0$, $p < .0001$, or 1 in 5 more individuals. Potential participants also trusted the research team more after the orientation session, a mean increase of 0.5 [CI 0.4 to 0.6 units] from 3.9 ± 0.8 to 4.4 ± 0.7 , $t(232) = 9.9$, $p < .0001$.

Conclusions: Promisingly, the orientation session improved participant research literacy and participant trust. Future trials could experimentally test whether similar sessions improve not only research literacy and trust, but also trial retention, especially among populations with less initial trust about research.

Symposium 34C

CLINICAL TRIAL METHODOLOGY: ARE BEHAVIORAL RUN-INS EFFECTIVE?

Tricia Leahey, PhD

Background. Large-scale efficacy trials such as the Diabetes Prevention Program (DPP) have relied on behavioral run-ins to identify and enroll participants likely to adhere to study protocols. Behavioral run-ins involve the completion of an important and difficult task that will be required during treatment. In weight loss trials, run-ins typically involve self-monitoring diet and activity for up to 3 weeks. Oftentimes, a staff interview follows the behavioral task. During the interview, the staff member ascertains the participant's reaction to self-monitoring and explores any anticipated concerns regarding study involvement (e.g., time commitment, possible schedule change). Despite the use of behavioral run-ins in major efficacy trials (e.g., DPP, Look AHEAD), and that such procedures are resource intensive (staff time), to our knowledge, this is the first study to examine whether a behavioral run-in is indeed effective at predicting adherence in a health behavior change intervention.

Methods. Individuals interested in enrolling in a weight loss trial completed a behavioral run-in (1 week of monitoring diet and activity plus staff interview). Based on run-in data (number of monitoring days, qualitative interview data), research staff identified each participant as likely to be either a high, moderate, or low adherer. Those predicted to be high and moderate adherers were enrolled in the 12 month trial. Adherence was compared between the two groups.

Results. Among those enrolled (N=273, 75% female, 27% minority, 52 ± 6 years, $35 \pm 3 \text{ kg/m}^2$), N=223 were predicted to be high adherers and N=50 moderate adherers. High vs. moderate adherers did not differ on age, race, ethnicity, or socioeconomic status. However, they did differ on sex; men were more likely to be identified as likely high adherers than women ($p=.01$). Analyses examining whether behavioral run-in classifications predicted treatment adherence revealed significant effects. Participants expected to be high adherers based on their behavioral run-in did in fact attend more intervention sessions ($p<.001$) and complete more self-monitoring records during treatment ($p=.005$). They also lost more weight ($p=.03$). Adherence to the assessment protocol did not differ by group ($p=.70$).

Conclusion. This study is the first to provide evidence that behavioral run-ins, while resource intensive, are effective at identifying individuals likely to adhere to treatment protocols in randomized trials involving behavioral interventions.

Symposium 34D

REMOTELY-DELIVERED ORIENTATION SESSIONS TO RETAIN PARTICIPANTS IN A PREGNANCY LIFESTYLE INTERVENTION: THE GLOW TRIAL

Dr. Susan D. Brown, PhD

Low retention in clinical trials undermines validity, wastes resources, disheartens staff, and may signal unmet participant expectations. Orientation sessions conducted before randomization, using motivational interviewing techniques, are one approach to clarify trial requirements, resolve ambivalence about participating, and build participants' commitment to the scientific premise. Remotely-delivered sessions could support broad dissemination of this approach in "hard to reach" populations, especially for telehealth intervention trials. We describe an orientation session (OS) protocol implemented mid-way through the "Gestational Weight Gain and Optimal Wellness" (GLOW) study, an ongoing weight management trial in an integrated healthcare delivery system. The trial compares usual care to a mainly telephone-based, 13-session lifestyle intervention among overweight and obese pregnant women (64% racial/ethnic minorities). Originally, potentially eligible women identified in electronic health records in early pregnancy received a recruitment letter and call, and completed a baseline clinic visit before randomization. Mid-way through the trial, we implemented an OS protocol between the recruitment call and baseline visit to better calibrate expectations and improve retention in the pregnancy intervention. Women participated in an OS via conference call, in small groups or individually, with written materials emailed in advance. A trial co-investigator or project manager facilitated discussion, e.g., eliciting pros and cons of random assignment, discussing commitments to clinic visits and intervention activities, and whether women could make time to participate. We compared retention in the intervention among 151 participants randomized before vs. after implementation of the OS protocol (pre-OS, $N = 78$ vs. post-OS, $N = 73$). We report descriptive results, pre- vs. post-OS, in the proportions completing zero sessions (2.6% vs. 0%), < 4 sessions (15.4% vs. 8.2%), < 8 sessions (16.7% vs. 11.0%), and all 13 sessions (80.8% vs. 82.2%; all p -values $\geq .16$). Interim findings suggest that remotely-delivered orientation sessions are feasible among pregnant women. We observed small absolute improvements in retention, especially in the beginning of a multi-session intervention. Improvements achieved with orientation sessions may be incremental, depending on the base rate in a given trial. Practical lessons learned and directions for future research will be discussed.

USER-CENTERED DESIGN IN BEHAVIORAL MEDICINE- METHODS FOR PRAGMATIC INTERVENTIONS

Sarah L. Mullane, PhD¹, Michelle L Takemoto, PhD², Sarah L. Mullane, PhD¹, Rebecca J Bartlett Ellis, PhD, MSN, BSN, BSBM³, Devin Mann, MD, MS⁴

¹Arizona State University, Phoenix, AZ; ²University of California, San Diego, La Jolla, CA; ³Indiana University, Indianapolis, IN; ⁴NYU School of Medicine, New York, NY

Transitioning from efficacy to effectiveness trials remains to be a significant challenge in the behavioral field. Emerging theories suggest that critical intervention design flaws may be identified prior to implementation by applying user-centered design principles often employed in the engineering field. This is an emerging area of interest, particularly given the interest in digital behavior change interventions (DBCI's). In this symposium, we present how user-centered design principles may be applied using qualitative, mixed method, co-design, and agile processes. More specifically, we describe how these principles can be applied in both non-clinical and clinical settings, from early pilot studies to large scale digital healthcare delivery systems. Dr. Michelle Takemoto will first present the importance of user-centered qualitative research when using wearable devices and how perceived usefulness may influence intervention design, participant recruitment and compliance in non-clinical settings. Dr. Sarah Mullane will propose how to transform this qualitative input into quantitative output using a user-centered correlational matrix tool to accommodate different user personas, prioritize requirements and identify design flaws. The transition to larger scale user-centered practices in clinical settings will be provided by Dr. Rebecca Ellis, who will present the value of Co-design practice and iterative design to target the end-user that led to the development of a smart pillbox and smartphone app that together work to support medication management. Finally, Dr. Devin Mann will highlight the emerging success of the Ambulatory Product Research and Innovation Lab (APRIL); a joint research-operational IT-led initiative created to infuse user-centered design and agile development principles and practices into the building of innovative digital tools across the health system. The role of Chair will be fulfilled by Dr. Sarah Mullane to introduce the concept of user-centered design, the symposia content and each presenter. Questions and points of discussion will be encouraged by all members of the symposia panel.

Symposium 35A

EXPLORING USER PERSPECTIVES TOWARD WEARABLE DEVICES THROUGH FOCUS GROUPS TO DESIGN USER-CENTERED BEHAVIORAL INTERVENTIONS

Dr. Michelle L Takemoto, PhD

Background: Recent epidemiological evidence estimates people spend 7.7 hours per day sedentary. Wearable devices represent a novel strategy to target sedentary behavior (SB), but additional user research is needed to understand how devices can be used to change the behavior. Researchers must design digital health interventions grounded in an in-depth qualitative understanding of target end-users. Extracting and incorporating user perspectives can be facilitated by conducting focus groups.

Purpose: The purpose of the current study was to explore the perceived acceptability, usability and usefulness of wearable devices in changing SB through focus groups.

Methods: We conducted 4 focus groups with a total of 15 participants to discuss 7 different wearable devices with SB capabilities. Focus groups have often been used in both marketing and advertising to gather end-user feedback on products. During our focus groups, participants commented on the wearability, functionality, and feedback mechanism of each device. Participants were asked to vote on their 'least' and 'most' favorite devices as well as design and describe their ideal or "dream" wearable device.

Results: Analysis resulted in 14 codes that were grouped into themes. Three themes emerged from our data: 1) Features of the device; 2) Data the device collected; and 3) How data are displayed. Users concluded that current devices on the market lacked a specific focus on SB in terms of features, data and display, which limited the perceived usefulness of the devices in reducing SB.

Conclusions: Overall, users perceived wearable devices to be usable and acceptable; however, specificity of design and feedback (e.g., encouraging SB behavior change with SB specific feedback) is required to increase perceived usefulness and ultimately influence behavior. Given the high variability in desired features, feedback, and wear location associated with wearable devices, failure to consider the end-user perspective and perceived usefulness may impact intervention recruitment and compliance within behavioral research.

Symposium 35B

THE ‘HOUSE OF QUALITY FOR BEHAVIORAL SCIENCE’—A USER-CENTERED TOOL TO DESIGN PRAGMATIC, BEHAVIORAL INTERVENTIONS

Miss Sarah L. Mullane, PhD

Purpose: Emerging theories suggest that critical intervention design flaws may be identified prior to implementation by applying user-centered design principles often employed in the engineering field. However, tools within behavioral science to facilitate this practice are limited.

Methods: We propose an adaptation of the Quality Function Deployment “House of Quality” (HOQ) correlation matrix tool currently used for user-centered design in the engineering field. We present a detailed description of the adapted tool - “House of Quality for Behavioral Science” which aims to balance researcher and participant needs. A use-case scenario within the trucking industry is provided to demonstrate the translation of qualitative inputs into quantitative outputs and initial design influences for user-centered health solutions.

Results: Completion of the relationship correlation matrix increased requirement ranking variance for the researcher ($\sigma^2 = 0.47$ to 7.19) and participant ($\sigma^2 = 0.56$ to 3.89) perspective. Four intervention design flaws were identified via the preliminary tool application; 1) light-intensity physical activity limit (≤ 30 min); 2) improvement of rest areas and parking; 3) additional outcomes needed (sleep and alertness) and; 4) negative response to an app based intervention.

Conclusions: Requirements elicitation and application of the adapted HOQ increased requirement variance and facilitated requirement prioritization (ranking). A correlational matrix tool such as the “House of Quality for Behavioral Science” may provide a structured user-centered design approach (complementary to existing frameworks) that translates qualitative input into quantitative outputs, balances researcher and participant needs and identifies design flaws for pragmatic behavioral intervention design.

Symposium 35C

CO-DESIGNING MOBILE HEALTH TECHNOLOGY FOR MEDICATION MANAGEMENT: INVOLVING TARGET USERS IN THE DESIGN PROCESS

Rebecca J Bartlett Ellis, PhD, MSN, BSN, BSBM

Background: Adherence to antihypertensive medication treatment regimens can significantly reduce risks for morbidity and premature mortality in people with chronic disease. However, nonadherence remains a significant barrier. Mobile technologies offer potential solutions to support behaviors associated with non-adherence, given these technological solutions are adaptable to people’s lives. In this presentation, we describe use of co-design as a way to design adaptable solutions that are not only user-centered, but user-designed.

Methods: Co-design is a form of participatory design that engages people who are representative of the target end-user in the iterative design of a solution. To develop our intervention, InterACT™, our interdisciplinary research team worked with a 5-person co-design team over a 3-month period. Co-design activities were systematically employed and included 1.) describing existing states and 2.) designing ideal states and solutions, and then we field-tested solutions. Usability and concept acceptability testing were simultaneously conducted with end-users ($n=19$) in the clinic setting and feedback was shared with the team to co-design the next iteration of InterACT™.

Results: Design activities conducted with the co-design team helped to identify important design attributes for InterACT™. Design attributes were subsequently integrated into a final solution consisting of a smart pillbox and smartphone app that together work to support medication management.

Conclusion: Co-design is a user-guided approach to user-centered design. Co-design activities can be useful to identify workable solutions that are acceptable and adaptable for the target user and identify attributes for which expert researchers may be unaware – creating opportunity and challenge in this iterative process.

Symposium 35D

INFUSING DESIGN THINKING INTO A HEALTH SYSTEM ONE DIGITAL INTERVENTION AT A TIME: THE AMBULATORY PRODUCT RESEARCH AND INNOVATION LAB (APRIL) AT NYU LANGONE HEALTH

Dr. Devin Mann, MD, MS

Purpose: To develop in-house capacity to support clinicians and researchers across the health system in developing digital technologies necessary to realize innovative ideas designed for scalable clinical implementation.

Methods: The Ambulatory Product Research and Innovation Lab (APRIL) at NYU Langone Health is a joint research-operational IT-led initiative created to infuse user-centered design (UCD) and agile development principles and practices into the building of innovative digital tools across the health system. APRIL leverages a cross functional team with expertise in design thinking, agile product development, user interaction design, rapid pilot testing and iteration, to shepherd research/clinical teams through all phases of digital development from discovery and ideation to prototyping and pilot testing. The team collaborates closely with the sponsoring healthcare delivery research team to generate digital tools that leverage the latest science and design principles to facilitate broad healthcare implementation.

Results: APRIL has two digital intervention development projects in its current portfolio. These digital development projects exemplify our effort to apply current “best practice” with regard to UCD and agile methodologies into digital innovation and user-centered design; developing capacity for building effective digital interventions hospital system-wide. To facilitate acculturation of agile, UCD approaches, substantial effort has been made to educate the collaborative teams on the process. Multiple design thinking workshops have been held to foster vision and strategy alignment as well as harmony in feature requirements and minimal viable products. Early wireframing, collaborative design sprints and other customizations to the agile UCD approach have been used to bridge the gap between team cultures in digital development and healthcare delivery research. This iterative approach to refining the agile UCD process to the local environment has fostered a pragmatic approach and swift progress towards pilot digital tool launches. Each project presents unique opportunities and challenges with respect to balancing APRIL’s adherence to agile development, high quality research and alignment with organizational, enterprise wide goals.

Conclusion: APRIL’s integration of agile, user-centered approaches with healthcare delivery research expertise represents an exciting laboratory environment for producing new digital products inherently positioned to disrupt healthcare delivery.

'ALL THE FEELS': COMPLEX QUESTIONS REGARDING THE LIMITS AND CONSTRUCT VALIDITY OF AFFECTIVE DETERMINANTS OF EXERCISE BEHAVIOR

Courtney J. Stevens, PhD¹, Arielle S. Gillman, MA², Austin S. Baldwin, PhD³, Jessica A. Emerson, MS⁴, David Williams, Ph.D.⁵¹Geisel School of Medicine at Dartmouth, Lebanon, NH; ²University of Colorado Boulder, Boulder, CO; ³Southern Methodist University, Dallas, TX; ⁴Brown University, East Providence, RI; ⁵Brown University School of Public Health, Providence, RI

The relationship between cardiorespiratory exercise engagement and improved health outcomes is well established, but only 49% of American adults meet the *minimum* recommendations for weekly exercise, and 25% of the US adult population is completely sedentary. Data collected from objective sources (e.g., pedometers, accelerometers) suggest rates of exercise participation are likely far lower still. In recent years, the extent to which affective factors may help to explain the uptake and maintenance of exercise behavior has garnered increased attention. Our symposium seeks to highlight recent findings that conflict with the established literature, define affect in different ways, and explore the validity of various definitions of affect used in exercise research. First, Gillman examines the relationship between *affective response* to exercise and future exercise behavior as a function of exercise training volume (intensity and duration). Contrary to preliminary findings in this area, she does not find differences in affective response to exercise across training volume conditions, and average affective response to exercise during a 16-week training period is not associated with exercise behavior at 6-months follow up. Gillman does, however, find significant positive associations between affective response to exercise and other theory-based psychosocial constructs (e.g., self-efficacy, attitudes, intentions). Next, Emerson explores the associations between *incidental affect*, assessed via ecological momentary assessment (EMA), and exercise behavior. She finds evidence supporting bidirectional, reciprocal relationships between incidental affect and exercise behavior such that greater positive incidental affect predicts more exercise engagement, and greater exercise engagement predicts more positive incidental affect. Baldwin presents data collected from two investigations, each assessing common variance in *affective processing* constructs and their influence on exercise behavior. His results show that there is considerable empirical overlap among conceptually similar affective processing variables, which raises important considerations about construct validity with respect to advancing theory and exercise behavior intervention development. Finally, Williams synthesizes the lessons learned from the studies presented in this symposium and posits directions for future research.

Symposium 36A

RESPONSES TO EXERCISE OF VARIED INTENSITY AND DURATION: RELATIONSHIPS AMONG AFFECT AND PREDICTORS OF FUTURE EXERCISE BEHAVIOR

Arielle S. Gillman, MA

In recent years, there has been increasing attention paid to the role that affective factors (feelings of pleasure and displeasure) may play in driving the uptake and maintenance of health behaviors, including exercise. Previous work has demonstrated that exercise-related affect is associated both with future physical activity engagement (Kwan & Bryan, 2010; Williams, Dunsiger, Jennings, & Marcus, 2012) and with individuals' overall attitudes, self-efficacy, and intentions about exercise behavior (Kwan & Bryan, 2010b), which inform future decisions to exercise. However, this previous work has only examined relationships between affect during a *single* bout of exercise and future exercise behavior and its correlates; thus, we do not know whether whether *changes* (i.e., improvements) in affect over time may predict these outcomes. In the current study, 271 women were recruited to participate in a 16-week supervised exercise intervention and were randomly assigned to both *intensity* of exercise (high versus low) and *duration* of the exercise bout (20 versus 40 minutes). Affective response was measured every ten minutes during a selected exercise bout at the 0-, 4-, 8-, and 16-week time points during the intervention. Six months after the intervention, participants reported on their post-intervention minutes of exercise behavior and psychosocial predictors of exercise behavior including intentions, attitudes, self-efficacy, and exercise identity. We used multilevel modeling to examine changes in affect over the course of the intervention as a function of training condition, and test relationships between exercise-related affect, psychosocial predictors of exercise behavior, and follow-up exercise behavior. We found that an individual's average affective response throughout the intervention was associated with intentions ($p = .04$), attitudes ($p = .007$), exercise identity ($p = .006$), and self-efficacy ($p = .04$) at the six-month follow-up, but not self-reported minutes of exercise. These relationships held when controlling for intervention condition. Across participants, affect did not change over the course of the intervention ($p = .49$), and individual changes in affect were not significantly associated with any of the follow-up outcomes. These findings suggest that future intervention work might benefit from examining strategies individuals can use to improve exercise-related affect.

Symposium 36B

AFFECTIVE PROCESSING FACTORS IN EXERCISE: EXAMINING THE EMPIRICAL OVERLAP AMONG CONCEPTUALLY SIMILAR CONSTRUCTS

Austin S. Baldwin, PhD

Background: Evidence to date is clear that affective processing factors (e.g., affective attitudes, enjoyment, affective associations) are robust predictors of exercise (Rhodes et al., 2009). An important issue needing to be addressed is the extent to which these conceptually similar factors overlap empirically and are distinct from other constructs. In two recent studies, we addressed this issue using two different approaches.

Methods: In the first study, healthy young adults ($N = 69$) completed measures of affective processing variables (affective attitudes, affective associations) and then a moderate-intensity exercise bout during which we measured their affective response. We tested whether the variables predicted unique variance in affective response, a key determinant of exercise behavior. In the second study, we examined the construct validity of affective processing scales (enjoyment, affective attitudes, affective associations) using data from two large samples of adult participants ($N = 1,044$ and $N = 359$). We examined the scales' convergent validity to each other and their discriminant validity from exercise self-efficacy.

Results: In the first study, affective attitudes and affective associations both predicted affective response in univariate models ($Bs > .34$, $ps < .003$, but neither significantly predicted when paired in the same model ($Bs < .26$, $ps > .09$), suggesting they predict overlapping variance in affective response. In the second study, the strength of the convergent correlations suggested that scales of affective attitudes, affective associations, and enjoyment may be measuring the same construct ($rs = .65$ to $.85$). However, all the scales also had considerable construct validity limitations, including poor discriminant validity from exercise self-efficacy ($rs = .54$ to $.62$).

Conclusions: Findings from both studies indicate that there is substantial empirical overlap among conceptually similar affective processing variables in exercise behavior (affective attitudes, affective associations, enjoyment). Moreover, current measures of these constructs have significant construct validity limitations. Both sets of findings illustrate important limitations on future advances in theory and intervention on affective processes in exercise. Developing clearer understanding of the conceptual boundaries of the constructs and how best to measure them and intervene on them will be discussed.

Symposium 36C

RECIPROCAL ASSOCIATIONS BETWEEN AFFECT AND EXERCISE USING ECOLOGICAL MOMENTARY ASSESSMENT

Ms. Jessica A. Emerson, MS

Prior research suggests that exercise can influence how people feel later on in the same day (i.e. incidental affect). A different question asks whether there are effects of how people feel throughout the day on whether or not they engage in exercise. The focus of the present study is to examine the likely reciprocal relationship between incidental affect and exercise behavior within the same day. Fifty-nine previously low-active (< 60 min/week), overweight (BMI: 25 – 39.9) adults (ages 18–65) participated in a six-month exercise promotion study. Using ecological momentary assessment, participants reported their exercise sessions, and incidental affective valence (feeling good/bad) was assessed using the 11-point Feeling Scale at random times throughout the day. We expected to find support for both directions of effects, with exercise predictive of greater positive incidental affect later in the day, and greater positive incidental affect predictive of subsequent exercise behavior later that day. We also tested the relative strength of each direction of effects. A cross-lagged autoregressive model showed that when participants felt more positive incidental affect earlier in the day they were more likely to exercise later on ($b = .58$, $p < .01$). Additionally, on days when participants exercised they reported greater positive incidental affect later on ($b = .26$, $p < .01$). The effects of incidental affect on exercise behavior were stronger than those of exercise on subsequent incidental affect ($t = 23.54$, $p < .01$). The findings support the reciprocal effects in both directions for incidental affect and exercise, and suggest that positive shifts in incidental affect may precede positive changes in exercise behavior.

FEASIBILITY BEFORE EFFICACY: DESIGNING AND CONDUCTING INFORMATIVE, FUNDABLE FEASIBILITY STUDIES

Lanay Mudd, PhD¹, Jennifer Huberty, PhD², Elena Salmoirago-Blotcher, MD, PhD³, Wendy Weber, ND, PhD, MPH⁴

¹National Institutes of Health, Bethesda, MD; ²Arizona State University, Phoenix, AZ; ³The Miriam Hospital, Alpert Medical School of Brown University, Providence, RI; ⁴NCCIH/NIH, Bethesda, MD

Novel behavioral interventions are increasingly being developed and tested for efficacy on a range of health outcomes in various populations. However, researchers often overlook the need for feasibility pilot work prior to proposing and enacting full-scale efficacy trials. When results from such trials show a certain intervention to be ineffective, it is often impossible to determine whether the intervention actually had a null effect, or whether the study failed due to inadequate methodology. This session will describe the process of intervention development and the uses/misuses of feasibility work. We will discuss ongoing and completed feasibility trials as practical examples, and describe NIH funding mechanisms that support feasibility pilot work. Dr. Mudd will set the stage with an overview of NIH policies related to clinical trial research, as well as specific funding opportunities meant to support feasibility work to help investigators collect much needed building blocks in preparation for the next step - the design of an efficacy trial. Dr. Huberty will provide an overview of her currently funded feasibility study that is developing an online yoga intervention for women after stillbirth. She will review results from her phase 1 qualitative work which helped to further refine her intervention for feasibility testing in phase 2. Dr. Salmoirago-Blotcher will review results from her recently completed feasibility trial of a tai chi intervention to overcome barriers to cardiac rehabilitation, and how these findings are informing the design of the next stage of her research. The session will conclude with a discussion of uses and misuses of feasibility pilot studies moderated by Dr. Weber, and time for Q&A with the attendees.

Symposium 37A

STUDY PROTOCOL AND PHASE ONE FINDINGS FOR A FEASIBILITY TRIAL OF AN ONLINE YOGA INTERVENTION FOR MOTHERS AFTER STILLBIRTH

Jennifer Huberty, PhD

Background: Stillbirth (in-utero fetal death ≥ 20 weeks gestation) is a major public health issue ($\approx 26,000$ pregnancies in the U.S.). Women who experience stillbirth, compared to women with live birth, have a nearly 7-fold increased risk of a positive screen for Post-Traumatic Stress Disorder (PTSD). Novel approaches targeting mental health are critical. Yoga is efficacious, safe, acceptable, and cost-effective for improving mental health in a variety of populations but has yet to be tested among mothers with PTSD symptoms after stillbirth.

Methods: We present Phase one of a three-year online yoga feasibility trial that entailed the development of an online-yoga prescription and interviews to identify cultural barriers to recruitment in non-Caucasian women (i.e., predominantly Hispanic and/or African American) who have experienced stillbirth ($N=5$); both informing Phase two. For the yoga prescription, 30 videos from the Udaya library (online yoga) were randomized to 10 women so that each video was completed three times (nine videos per woman). A two-item investigator developed Likert-scale was used to assess emotional regulation (ER) and self-compassion (SC) pre-post completion of each video. Beliefs and barriers were determined using phone interviews.

Results: The mean difference between pre-post ER and SC scores established the final online yoga prescription. Videos were not used if they had a negative mean difference or $\leq 10\%$ improvement on ER and SC assessments. In partnership with Udaya, the research team filmed eight 30-minute control videos and 12 30-minute intervention videos (for phase two). The final prescription had 37 (25 tested, 12 filmed) videos. Beliefs about yoga included stress relief, relaxation, feel good about body, calming, flexibility and many women felt that online would be more convenient. Perceived barriers to yoga included cost, no friends/family to do yoga with, lack of childcare, determination, location, and time. Recommendations for recruitment included send post cards, use social media, run newspaper ads, no flyers with pictures of children or pregnant women, flyers with pictures of minority women, grocery store or retail gift cards, epublications (essence.com, madamnoire.com), offer incentives that acknowledge/honor the child (pendant, donation in the name of).

Discussion: Findings from this study informed Phase two, the three-group randomized feasibility trial to determine the effectiveness of online yoga to improve PTSD symptoms.

Symposium 37B

THE GENTLE REHAB STUDY: TAILORING TAI CHI TO THE NEEDS OF ACUTE CORONARY EVENTS SURVIVORS WHO DO NOT ATTEND CARDIAC REHABILITATION

Elena Salmoirago-Blotcher, MD, PhD

Background. Cardiac rehabilitation programs (CRP) reduce cardiovascular mortality in survivors of acute coronary events (ACE), but more than 70% of patients—in particular older, female, and physically deconditioned patients—decline participation in CRPs. Tai chi—a practice based on light/moderate aerobic exercise accompanied by meditative components—could overcome some of the existing barriers to CRP attendance in this population.

Methods. In preparation for a large efficacy trial, this study was designed to:

1) Develop a tai chi intervention tailored to the needs of ACE survivors declining CRP. This was accomplished by assembling a team of experts in CRP, exercise physiology, and tai chi and using a modified Delphi approach to adapt an existing tai chi intervention to the specific needs of this population;

2) Determine the feasibility, safety, acceptability, and adequate dose of the tailored tai chi intervention. ACE survivors declining CRP enrollment were randomized to a “LITE” (2 sessions/week for 12 weeks) or to a “PLUS” dose condition (3 sessions/week for 12 weeks, then maintenance classes for 12 additional weeks). Feasibility (retention and attendance rates), acceptability (quantitative and qualitative assessments), moderate-to-vigorous physical activity (MVPA, assessed via accelerometry), weight, and QOL (SF-8) were measured at baseline, 3-, 6-, and 9 months since baseline. Aerobic fitness (stress test) was assessed at baseline and after 3 months.

Results. Twenty-nine participants—13 PLUS, 16 LITE; average age 67.9 years (SD=10.3), 27% female, and 93% white—were enrolled in the study. Fifty percent of the study participants were diabetic, 75% had high cholesterol levels, more than 50% were obese, and 30% were smoking at the time of enrollment. Both tai chi doses were safe, feasible, and enjoyable. Compared to the LITE dose, the PLUS dose improved MVPA, weight, and QOL. No changes in aerobic fitness were observed in either condition. This presentation will discuss these results in detail, focusing in particular on ways in which these findings will guide next steps in this line of research and on challenges encountered during the study.

Conclusions. Tai chi is a feasible, enjoyable, and safe exercise option for ACE survivors who are unable or unwilling to attend traditional CRPs. If proven effective in larger studies, tai chi could be offered as an alternative exercise option within existing CRPs or within the context of community-based rehabilitation programs.

Symposium 38

8:00 AM-9:15 AM

STOP (SUMMER TIME OBESITY PREVENTION) ACCELERATED WEIGHT GAIN AND FITNESS LOSS AMONG YOUTH

Michael W. Beets, M.Ed., M.P.H., Ph.D.¹, Keith Brazendale, PhD¹, Jennette P. Moreno, PhD², Paul von Hippel, MStat, PhD³, Amy Bohnert, Ph.D.⁴

¹University of South Carolina, Columbia, SC; ²Baylor College of Medicine, Houston, TX; ³University of Texas, Austin, TX; ⁴Loyola University of Chicago, Chicago, IL

Over the past three decades, mounting evidence shows that summer vacation, for many youth in the US, is a time of excessive weight gain and loss of fitness, contributing to increased prevalence of obesity among school age children. The first documented evidence of the accelerated weight gain phenomenon comes from a national cohort of kindergarteners that began in 1998. For fitness loss, the first evidence dates back to the early 1990s from a physical education intervention in elementary schools. Since then, a large and robust literature base comprised of multiple, independent, large-scale observational and intervention studies have demonstrated support for these initial findings. The prevention of accelerated summer weight gain represents an important opportunity to address the obesity epidemic among US children. However, the reasons why children and youth gain unhealthy amounts of weight and lose fitness during summer vacation remain unknown. This symposium will provide three perspectives on the negative health impact of summer vacation. The presentations will cover theoretical or conceptual frameworks for understanding this phenomenon and possible solutions for mitigating the unhealthy effects of summer. The first presentation will discuss the health inequity of summer vacation and propose the Health Gap Hypothesis which attempts to understand the disparities in summer weight gain/fitness loss among racial/ethnic minority groups and income status. The second presentation will discuss the role year round school calendars may play in the mitigation of the negative health impact of summer on both weight gain and fitness loss. From a circadian rhythms perspective, the final presentation will report tests of the disrupted behavioral rhythms hypothesis, assessing differences in children's behavioral rhythms during the school year and summer and their association with seasonal changes in BMI. The discussant will synthesize these presentations and provide their perspective on future steps towards understanding and ameliorating the negative health impact of summer.

Symposium 38A

SUMMER TIME OBESITY PREVENTION (STOP): THE HEALTH GAP HYPOTHESIS

Keith Brazendale, PhD

Education has a long and robust history of studies showing that the achievement gap in academic performance widens over summer vacation between children from low-income and middle-to-upper-income households, and between children from ethnic/minority backgrounds compared to their white non-Hispanic peers. Likewise, during the summer, children gain 3 to 5 times more weight than they do over the entire 9 month school year, and this accelerated weight gain is more pronounced in children from low-income ethnic/minority households. The author's hypothesize that disparities in overweight and obesity among low-income minority households is largely driven by a greater acceleration in weight gain occurring over the summer months. Referred to as the “Health Gap Hypothesis”, the author's will present data that shows support towards the notion that this “health gap” exists largely due to a lack of access to structured summer programming that regulates children's obesogenic behaviors (e.g., activity, sedentary time, diet, sleep). Several studies show a minimal increase or a decrease in body mass index during the school year. The authors speculate that this is largely due to the structure and presence of the school day itself. Over summer, children from high-income households continue to maintain a routine and/or structure to their day with greater access to structured summer programming. A recent report from the American Camping Association showed 80% of children attending traditional summer camps were from middle to upper income families. We believe this unequal access accounts for a widening of the “health gap” over the summer and across time, and that this widening is one of the primary reasons why rates of childhood overweight and obesity are significantly higher in children from low-income households and ethnic/minority backgrounds compared to their higher-income peers. The “Health Gap Hypothesis” can be used to help explain health disparities in weight status between children from high and low-income households. As a whole, summer represents a form of double jeopardy for children from low-income households where they are losing academic ability and exasperating health disparities.

Symposium 38B

TESTS OF THE DISRUPTED BEHAVIORAL RHYTHMS HYPOTHESIS FOR ACCELERATED SUMMER WEIGHT GAIN

Dr. Jennette P. Moreno, PhD

Background: The school-summer paradigm offers an opportunity to explore school-summer differences in children's behavioral rhythms and their association with seasonal changes in BMI. In the absence of the environmental demands and cues associated with the school year, children's behavioral rhythms (e.g., sleep/wake patterns) may be less stable contributing to misalignment of endogenous circadian rhythms and weight gain. Specifically, during summer children may go to bed later, leading to later bedtime and altered sleep midpoint (a proxy for circadian timing). Later bedtimes may result in shortened total sleep duration due to failure to compensate with a wake time late enough to make up for the later bedtime.

Methods: A longitudinal observational study involving 119, 5–8 year olds was conducted during the 2016–2017 school year and summer. Sleep timing (phase delay and sleep midpoint) and sleep duration were assessed using Actigraph GT3x-BT monitors worn on the wrist of their non-dominant hand for 8 days during the fall semester and again during the summer when children were not in school. Actilife software, using the Sadeh algorithm, was used to identify sleep epochs. Differences in children's average bedtime, wake time, sleep midpoint, and sleep duration during the school year and summer were compared using repeated measures ANCOVAs, using BMI percentile as covariate. The effect size (ES) was assessed by Cohen's *d* and was interpreted as large, medium, or small, if *d* was greater than 0.8, between 0.5 and 0.8, or less than 0.2, respectively. Significance level was set at $p < 0.05$.

Results: Ninety-nine participants completed both the school year and summer actigraphy assessment (6.9 ± 85 years, 52% female, 34% overweight). During summer children on average went to bed later (1.8 times = 88min; 95%CI 74.23–102.63, $pd=1.27$) and demonstrated later mean sleep midpoint (29%=82 min, 95%CI 67.68–95.48, $pd=1.20$) compared to the school year. While children exhibited later wake times during summer (14%=75 min, 95%CI 60.13–89.33, $pd=1.05$), they failed to adequately compensate for their later bedtimes, resulting in shortened average sleep duration during summer (3%=15 min, 95%CI 6.20–21.20, $pd=0.39$).

Conclusions: During summer, children demonstrated significant changes in their sleep/wake patterns compared to the school year. Our findings provide preliminary support for the disrupted behavioral rhythms hypothesis for accelerated summer weight gain during early elementary school. Future analyses should examine associations between changes in children's behavioral rhythms and seasonal changes in BMI.

Symposium 38C

DO YEAR-ROUND SCHOOL CALENDARS REDUCE OBESITY?

Paul von Hippel, MStat, PhD

BACKGROUND. Children gain body mass index (BMI) more quickly during summer vacation than during the school year. Year-round school calendars, which shorten the summer vacation while adding breaks to the rest of the year, are hypothesized to reduce BMI gain during summer, but may increase BMI gain during the rest of the year.

DATA. We use data from the Early Childhood Longitudinal Study, Kindergarten Class of 1998–99, a nationally representative sample of US school children. Children's BMI was measured in the fall and spring of kindergarten and first grade. The data include 606 children in 30 year-round schools, who we compare to 2,107 children in 105 traditional nine-month schools that are in the same geographic areas, primarily in the western US. Our models control for child demographics.

METHOD. Using multilevel growth models, we compare the BMI growth of children in year-round schools and nine-month schools, during the summer and during the months of the traditional kindergarten and first grade school years.

RESULTS. During the summer, children in year-round schools lose BMI while demographically similar children in other schools gain BMI. But during the rest of the year, children in year-round schools gain BMI faster than other children. In total, over a 12-month period, children in year-round schools gain at least as much BMI as other children.

CONCLUSION. The results do not suggest that year-round schools reduce obesity.

Symposium 39

8:00 AM-9:15 AM

TRUST AND (MIS)INFORMATION IN THE ERA OF SOCIAL MEDIA: FROM THEORY TO PRACTICE

Anna Gaysynsky, MPH¹, Emily B. Peterson, PhD¹, Jeanine Guidry, Ph.D.², Emily Vraga, Ph.D.³, Wen-ying Sylvia Chou, PhD, MPH⁴

¹National Cancer Institute, Rockville, MD; ²Virginia Commonwealth University, Richmond, VA; ³George Mason University, Fairfax, VA; ⁴National Cancer Institute, Rockville, MD 20892, MD

Approximately two-thirds of American adults get at least some of their news from social media platforms, including Facebook, YouTube, and Twitter. At the same time, confidence in mass media has dropped to its lowest level in history, with less than half of Americans reporting that they trust mass media sources. Trust in other public institutions (such as the federal government) has also fallen below historical averages in recent years. These developments present a serious challenge to public health. As more people turn to social media for health information, and fewer rely on public institutions or mainstream media outlets for news, communicating evidence-based health information to the public and combatting the spread of misinformation is becoming increasingly difficult.

While it is widely recognized that social media has transformed the way individuals obtain information, the role of trust and source credibility in social media communication has received relatively little attention even though these factors may be important predictors, mediators, or outcomes of changing communication patterns. This symposium will explore trust and credibility in the context of information-sharing on social media in order to highlight the importance of these constructs, survey relevant theories and analytic approaches, and introduce opportunities to leverage this theoretical understanding to improve health communication practice.

The first presenter will provide an overview of the ways trust and credibility have been conceptualized in various theories and explore the unique characteristics of social media that increase the saliency of these constructs. The second presenter will describe several examples of health misinformation on social media, with a focus on misinformation sources, conspiracy theories, and distrust. The third presenter will discuss a number of studies that suggest potentially effective strategies for correcting misinformation shared on social media. The discussant will summarize the presentations and suggest implications for practice and future research.

Symposium 39A

‘TRUST’ IN COMMUNICATION THEORY: CURRENT APPLICATIONS AND THE ROLE OF SOCIAL MEDIA

Dr. Emily B. Peterson, PhD

In the era of social media, health-promoting messages are increasingly being challenged by myths, misinformation, and opinions. When faced with health (mis)information, perceptions of trust and source credibility greatly affect whether and how individuals evaluate, process, and act on these messages. There is growing evidence that levels of trust in traditional and expert sources of information – such as doctors, government agencies, large news organizations, and scientific bodies – are eroding among some segments of the American population. These changes may have implications for health communication efforts, including appropriate strategies for message dissemination and the correction of misinformation. Therefore, a critical review examining how trust is currently being conceptualized in behavioral and communication theories is urgently needed. In doing so, it is vital to explore both how trust is theorized (e.g., as an outcome or predictor variable) and the underlying mechanisms by which trust is thought to influence and be influenced by other constructs.

This presentation will first provide an overview of the ways trust has been defined, operationalized, and applied in leading health communication and behavior theories and highlight relevant research from other disciplines, such as political science and marketing. Trust and related concepts will be explored from a variety of perspectives, such as information processing (e.g., elaboration likelihood model), message effects (e.g., extended parallel process model), and behavioral prediction (e.g., theory of planned behavior). The presentation will synthesize the complex relationship between trust and health-related knowledge, attitudes, and behaviors, with trust inconsistently theorized as a predictor, mediator, moderator, and/or outcome variable.

The presentation will conclude by highlighting the importance of studying the influence of trust in the context of social media and discussing how the key characteristics of social media – such as source anonymity, rapid diffusion of information, Web site algorithms, and information silos— may require researchers to rethink how trust is understood in existing theories or to develop new theories to better explain the role of trust in the context of peer-to-peer information exchange. Throughout the presentation, gaps and areas for future research will be identified.

Symposium 39B

HEALTH MISINFORMATION ON SOCIAL MEDIA PLATFORMS: CONSPIRACIES, UNTRUSTWORTHY SOURCES, AND PANIC

Jeanine Guidry, Ph.D.

The volume of health information available on social media platforms has increased dramatically over the past decade. People increasingly search for health information online, the information they find is often incorrect, and they will frequently act on this erroneous information. In addition, it is often difficult to determine the level to which online sources can be trusted. Finally, expressed trust in public health institutions has eroded on social media. In this context, it is becoming increasingly important for practitioners to be aware of health-related conversations occurring on social media.

This presentation will provide an overview of several quantitative content analyses focused on health misinformation appearing on social media platforms such as Twitter, Instagram, and Pinterest. Mentions of perceived untrustworthy entities, conspiracy theories, and civil liberties in these posts and conversations will be specifically highlighted. The presentation will first explore the representation of tobacco alternatives such as e-cigarettes and hookah on Instagram and Pinterest. Recent studies show that commercial entities have taken over much of the conversation on these platforms, with the majority of posts originating with some sort of business, and nearly all posts presenting tobacco alternatives as healthy and safe, without mentioning possible negative effects.

Next, studies focused on the recent Ebola and Zika outbreaks will be discussed. These analyses showed the presence of conspiracy theories in the public discourse (e.g. those suggesting that governments are responsible for creating either of these diseases and/or for their entry into certain countries). Social media misinformation also played a significant role in promoting the panic surrounding the outbreaks, particularly in the case of Ebola.

Finally, while misinformation about vaccines has long been a public health concern, it has taken flight on social media. For example, studies have shown that on Pinterest, which has a largely female usership and is mostly thought of as a place to share recipes and decorating ideas, close to 75% of vaccine-focused posts have an anti-vaccine message. A recent study on the sources of vaccine misinformation on Pinterest also showed that two of the accounts that elicit the highest engagement are attributed to physicians.

The presentation will conclude by highlighting a common thread running through all these cases: the limited engagement of public health entities in these social media conversations.

Symposium 39C

EMPOWERING CITIZENS AND ORGANIZATIONS TO CORRECT HEALTH MISINFORMATION ON SOCIAL MEDIA USING EXPERT SOURCES

Dr. Emily Vraga, Ph.D.

While the prevalence and spread of misinformation on social media is a pressing challenge in public health, social media platforms also offer unique opportunities to immediately correct misinformation when it is shared. This presentation will discuss a series of experimental studies that explore the potential for *observational correction* of health misinformation on social media, which occurs when people see misinformation shared on social media being corrected and, as a result, update their own attitudes to reflect a position supported by the best available evidence.

In all the studies presented, participants saw a social media user post an incorrect health claim about a controversial health issue, with a link to a news story supporting their incorrect claim, and then observed that misinformation being corrected. The results suggest that while observational correction can be effective, its success depends on the health topic and the source of the corrective information. Specifically, corrective efforts failed for a well-known and polarized issue (whether vaccines cause autism) but were effective for both an established health issue (whether GMO foods cause illness) and an emerging one (whether GMO mosquitos caused the Zika virus to spread). Both algorithmic corrections (e.g., the Facebook related stories function) and corrections provided by other users mitigated misperceptions among participants seeing the corrections, so long as users provided links to credible information to support their correction. In addition, a single response from the CDC to misinformation about the Zika virus on Twitter was effective in mitigating misperceptions about the causes of the pandemic, without harming the perceived credibility of the CDC. Across studies, the effects of the corrective information were stronger among subjects who were originally misinformed about the health topic, suggesting this approach may reach those individuals in greatest need of correct information.

This research suggests that personal connections are not necessary for correction to occur on social media when expert sources can be referenced. Government agencies, fact-checking websites, and news articles appear to be trusted sources for corrections. Public health agencies and officials should create credible and easily shared corrective information on controversial health topics, and may also consider monitoring social media feeds for misinformation to offer corrections in real time.

Symposium 40

8:00 AM-9:15 AM

EXTENDING THE REACH OF LONGITUDINAL STIGMA RESEARCH TO ADVANCE HIV TREATMENT AND CARE

Valerie A. Earnshaw, PhD¹, Gregory Greenwood, Maryland², Lisa A. Eaton, PhD³, Christopher G. Kemp, MPH PhD⁴

¹University of Delaware, Newark, DE; ²NIMH/ Division of AIDS Research, Bethesda, MD; ³University of Connecticut, Storrs, CT; ⁴University of Washington, Seattle, WA

Despite biomedical advances, stigma continues to be a critical barrier to HIV treatment and care. Research evidence suggests that stigma undermines engagement in HIV care, uptake of evidence-based HIV treatment including Antiretroviral Therapy (ART), and physical health outcomes including CD4 count and viral load among people living with HIV (PLWH). Longitudinal research that investigates which stigma mechanisms (e.g., internalized, experienced, and/or anticipated) relate to HIV treatment and care outcomes, as well as the pathways whereby stigma relates to these outcomes, is needed to inform targeted interventions to improve the wellbeing of PLWH. Additionally, strategies to extend the reach of this research to policymakers, government agencies, community organizations, healthcare practitioners, and other sectors are needed to develop, implement, and sustain these interventions. This symposium showcases three cutting-edge research studies to foster greater understanding of associations between stigma and HIV treatment and care, and identify strategies to extend the reach of this research to key audiences. Studies focus on diverse populations from the United States (US) and South Africa, including newly-diagnosed Black men who have sex with men in the Southern US, African American women living with HIV in the Southern and Mid-Western US, and people who have been diagnosed with HIV but have not initiated ART in South Africa. They examine associations between different HIV stigma mechanisms and key outcomes, including engagement in healthcare services, ART utilization, and viral load. Moreover, they explore the roles of several mediating mechanisms in these associations, such as social support and various forms of coping. All studies draw on longitudinal data and examine stigma during critical time periods for HIV treatment and care, such as pre- to post-HIV diagnosis. Discussion will be led by a Program Officer in the HIV Prevention and Care Continuum, Co-Morbidities, and Translational Research Branch at NIMH, and focus on strategies to extend the reach of research on stigma and HIV treatment and care to policymakers, government agencies, community organizations, healthcare practitioners, and other sectors to improve efforts to treat HIV.

Symposium 40A

INTERNALIZED STIGMA AND VIRAL LOAD: A LONGITUDINAL EXPLORATION OF MEDIATING MECHANISMS IN SOUTH AFRICA

Dr. Valerie A. Earnshaw, PhD

Research suggests that internalized HIV stigma is associated with less engagement in HIV-related health behaviors, including non-utilization of antiretroviral therapy (ART), among people living with HIV (PLWH). ART non-utilization can lead viral load to be unsuppressed, which undermines the health of PLWH and increases risk of HIV transmission to others. It has been hypothesized that coping may play a role in associations between internalized stigma and health behaviors and outcomes. Yet, these processes remain understudied, including the specific forms of coping that may mediate these associations. Research that uses longitudinal data and differentiates between forms of coping may inform efforts to address stigma, improve coping, and ultimately enhance HIV treatment and prevention efforts. The current study draws on data collected from 414 PLWH in South Africa between July 2014 and July 2015. Adult PLWH were eligible to participate if they were eligible for ART, but had not yet initiated ART, and were not pregnant. Self-report data, including internalized stigma, avoidant coping (denying and distracting oneself from stressors), and substance use coping (using drugs and alcohol in response to stressors), were collected from participants at baseline and three months. Medical data, including ART initiation and viral load, were collected from the National Health Laboratory Service database at six and nine months. Path analyses were conducted using Mplus to test for longitudinal mediation. The final model was a good fit for the data [$\chi^2(66)=77.06$, $p=0.17$; RMSEA=0.02]. Results suggest that internalized stigma at baseline was associated with avoidant coping at three months. Avoidant coping at three months was associated with lack of ART initiation at six months which was in turn associated with viral load non-suppression at nine months. Significant indirect effects were observed between internalized stigma with lack of ART initiation and unsuppressed viral load via the mediator of avoidant coping. Substance use coping was associated with unsuppressed viral load, but did not mediate associations between internalized stigma and viral load. Analyses highlight the role of avoidant coping in associations between internalized HIV stigma and behavioral and physical health outcomes among PLWH. Intervention strategies are needed to address internalized stigma and avoidant coping to enhance HIV treatment and prevention efforts.

Symposium 40B

A LONGITUDINAL STUDY OF HEALTH RELATED STIGMA AMONG BLACK MEN WHO HAVE SEX WITH MEN NEWLY DIAGNOSED WITH HIV/STI

Dr. Lisa A. Eaton, PhD

Since the beginning of the HIV epidemic in the US, stigma has stymied prevention and treatment efforts. In this time, considerable attention has been focused on the need to address stigma, but limited work has been conducted on understanding the intricacies of stigma or in stigma intervention development. For example, it is known that stigma acts as a barrier to health care engagement, but it is unclear how the type, source, or strength of stigma affects this relationship. The US HIV epidemic is elevated among marginalized populations, in particular, among Black men who have sex with men (BMSM). It is estimated that by age 40, with current transmission rates, 60% of BMSM could test HIV positive (Matthews, 2016). Linkage and engagement in health care provides BMSM with effective options for HIV prevention (e.g., STI testing/treatment, HIV pre-exposure prophylaxis, sexual risk reduction programs), but our model of health care does not adequately address stigma, and therefore, many BMSM remain without care. For the current study, in order to understand how experiences of stigma are related to health care engagement, we assessed multiple forms of stigma, both pre and post HIV/STI diagnosis, in a year-long, longitudinal study among BMSM (N=151) residing in and around the Atlanta metro area (data collected 2014–2016). Earnshaw and Chaudoir's (2009) HIV Stigma Framework guided the assessment approach and included investigating pre diagnosis levels of HIV/STI prejudice, stereotypes, and discrimination, and post-diagnosis levels of enacted, anticipated and internalized stigmas. Fifty participants were newly diagnosed with HIV, and 101 were newly diagnosed with STI. Higher levels of both enacted ($M=2.16$, $SD=2.28/M=1.78$, $SD=2.10$, $t(1451)=3.25$, $p<.001$) and anticipated ($M=2.24$, $SD=2.50/M=1.78$, $SD=2.34$, $t(1451)=3.57$, $p<.001$) stigmas were associated with a greater likelihood of not linking and engaging in health care during the year post diagnosis. Internalized stigma, however, was unrelated to linkage and engagement in care ($M=2.22$, $SD=.83/M=2.17$, $SD=.79$, $t(1451)=1.14$, $p>.05$). Further, pre-diagnosis levels of prejudice towards people with HIV/STI predicted higher levels of post-diagnosis enacted stigma ($b=0.37$, $SE=0.14$, $p<.05$), anticipated stigma ($b=0.30$, $SE=0.13$, $p<.01$), and internalized stigma ($b=0.17$, $SE=0.06$, $p<.01$). Findings from this study are the first of their kind and provide a clearer understanding of how stigma unfolds during a critical time for HIV/STI testing and treatment. Outcomes can be used to improve the tailoring of stigma intervention work, and therefore, health care access and HIV/STI prevention among BMSM.

Symposium 40C

STIGMA, SOCIAL SUPPORT, AND SUBSEQUENT VIRAL LOAD AMONG AFRICAN AMERICAN WOMEN LIVING WITH HIV: AN EXPLORATORY LONGITUDINAL MEDIATION ANALYSIS

Mr. Christopher G. Kemp, MPH PhDc

STUDY OBJECTIVES: African American women are over-represented among women living with HIV in the United States. They are also less likely than other women to engage in and be adherent to antiretroviral therapy and may experience relatively poor HIV-related health outcomes. HIV stigma can be a barrier to treatment adherence, and social support may reduce the burden of HIV stigma. We explored longitudinal mediation of associations between HIV stigma and HIV RNA levels (viral load [VL]) by social support, among African American women receiving treatment for HIV.

METHODS: We used longitudinal data from a randomized controlled trial of an intervention to reduce HIV stigma among African American women in HIV care. We collected self-reported data at baseline, post-intervention, and 6, 8, 10, and 14 months, from May 2013 to December 2016. We extracted VL data from medical records. Primary outcomes were the log of mean VLs for each participant over the period following each timepoint until the next timepoint and whether participants were virally suppressed (VS, all VLs under 200 copies/ml) during the same period. We longitudinal mixed-effect models to explore whether HIV stigma and social support were associated with subsequent log mean VLs, probability of VS, or probability of transition from non-VS to VS. We used longitudinal causal mediation analysis to explore whether associations between stigma and VL were mediated by social support. We adjusted for trial arm, time, and their interaction, alongside confounders.

RESULTS: We analyzed data from 224 participants. At baseline, mean HIV stigma was 32.0 (standard deviation [SD]: 12.0, range: 14–70), mean internal stigma was 13.3 (SD: 6.2, range: 6–30), mean external stigma was 11.2 (SD: 5.7, range: 6–30), and mean social support was 30.9 (SD: 12.2, range: 0–44). Mean of log mean VLs was 4.4 (SD: 2.4), and 79.0% had VS. Higher HIV stigma levels ($p=0.041$) and lower social support levels ($p=0.028$) were associated with higher subsequent log mean VL levels. Higher external stigma levels ($p=0.048$) were associated with reduced probability of subsequent VS. Increased external stigma ($p=0.022$) and decreased social support ($p=0.025$) over time were associated with subsequent increases in log mean VL levels. Increased external stigma was associated with reduced probability of subsequent transition from non-VS to VS ($p=0.027$). Social support mediated 26.3% of the association between stigma and log mean VL (average causal mediation effect [ACME]=0.12, $p=0.028$).

DISCUSSION: This exploratory longitudinal analysis suggests that HIV stigma and social support may predict VL outcomes among African American women in primary HIV care. Ongoing external stigma may hinder the transition from non-VS to VS. Stigma appears to operate through social support and other pathways. To improve HIV outcomes in this population, interventions should leverage social support and mitigate stigma.

8:00 AM-9:15 AM

OPTIMIZING PATIENT-CENTERED PSYCHOSOCIAL ONCOLOGY IN DIVERSE PATIENTS: MOVING FROM IDENTIFICATION TO INTERVENTION

Betina Yanez, Ph.D.¹, Patricia I. Moreno, Ph.D.¹, Laura C. Bouchard, Ph.D.², Elizabeth L. Addington, PhD¹, Rina S. Fox, Ph.D., M.P.H.¹, Frank Penedo, PhD²

¹Northwestern University Feinberg School of Medicine, Chicago, IL; ²Northwestern University, Chicago, IL

Patient-centered approaches in oncology are increasingly important to both identifying unmet needs and concerns of diverse oncology patients and survivors as well as the health-related quality of life (HRQoL) of diverse patients. Furthermore, engaging a range of key stakeholders to identify the unmet needs among patients is crucial to the development of tailored and efficacious interventions. For example, the recent movement toward precision medicine presents a unique opportunity to guide treatment selection and delivery based on the patients' individual genomic profiles, yet little research has investigated patients' needs, expectations, and concerns throughout this process. As another example, given the well-documented HRQoL disparities among African Americans and Hispanics/Latinos following a cancer diagnosis, more research is needed to elucidate the specific needs of underserved patient populations and inform the development of culturally-sensitive interventions and community-based approaches that improve HRQoL among individuals diagnosed with cancer. However, few studies have specifically focused on patient-centered approaches to optimizing outcomes among diverse, underrepresented cancer patients. In this symposium, speakers will present findings from two observational studies that identify unmet needs in understudied cancer populations and two interventions aimed at improving the HRQoL in racially/ethnically diverse cancer patients. The first speaker will present data on the prevalence and severity of unmet supportive care needs among Hispanic/Latino cancer survivors (N = 288) and examine the association between unmet supportive care needs on both symptom burden and satisfaction with cancer care. The second speaker will present findings from a qualitative study (N= 28) aimed at identifying the educational needs, concerns, and expectations of patients and other stakeholders (e.g., oncologists, nurses) involved in the delivery and receipt of genomic tumor sequencing to inform treatment-related decision making among patients with advanced cancers. The third speaker will share findings from a randomized web-based cognitive behavioral stress management trial to improve HRQoL among a diverse sample of men (N= 191) with advanced prostate cancer. The fourth speaker will present data on a longitudinal community-based trial of yoga for Hispanics/Latinas (N = 39) diagnosed with breast cancer. Finally, the discussant will reflect on some of the strengths of patient-centered research in oncology, as well as lessons learned from these studies and future directions.

Symposium 41A

UNMET SUPPORTIVE CARE NEEDS IN LATINO CANCER SURVIVORS: PREVALENCE, SEVERITY, AND ASSOCIATIONS WITH SYMPTOM BURDEN AND SATISFACTION WITH CANCER CARE

Dr. Patricia I. Moreno, Ph.D.

Quality of life disparities among Latino cancer survivors are well-documented, however no previous research has characterized unmet supportive care needs in this population. The aim of this study was to elucidate the prevalence and severity of unmet supportive care needs in Latino cancer survivors and examine the association between unmet supportive care needs and both symptom burden and satisfaction with cancer care. Latinos who had completed primary treatment for breast, prostate, or colorectal cancer (N = 288) completed questionnaires as part of an NCI-funded project. Supportive care needs were assessed in five domains: psychological needs (PSY), health system & information needs (HSI), patient care & support needs (PCS), physical & daily living needs (PDL), and sexuality needs (SXN). Our unique sample was primarily foreign-born, Spanish-speaking, had a high school education or less and an annual household income below \$50,000, and reported greater unmet supportive needs compared to previously published norms in non-Hispanic white samples. Across the three cancer types, the two most common unmet needs were in the PSY domain: fears of recurrence (32.6%) and concern for close others (31.3%). However, there was significant variability in unmet supportive care needs by cancer type. The three most prevalent unmet needs among prostate cancer survivors were in the SXN domain, whereas the three most common unmet needs among breast and colorectal survivors were in the PSY and PDL domains. Factors associated with greater unmet needs included more recent cancer diagnosis (OR .98 [.96-.99]), younger age (OR .96-.97 [.93-.99]), female gender (OR 2.53-3.75 [1.53-7.36]), and being single (OR 1.82 [1.11-2.97]). Breast cancer survivors reported greater unmet needs than both prostate and colorectal cancer survivors (OR 2.33-5.86 [1.27-14.01]). Unmet needs were significantly associated with lower satisfaction with cancer care (HSI: B=-3.81, SE=1.18; PCS: B=-3.57, SE=1.47; PDL: B=-3.65, SE=1.46; SXN: B=-2.05, SE=1.24) and greater cancer-specific symptom burden in both breast (PSY: B=-8.30, SE=1.33; HSI: B=-6.36, SE=1.39; PCS: B=-4.20, SE=1.45; PDL: B=-4.18, SE=1.44; SXN: B=-6.24, SE=1.54) and prostate (PSY: B=-6.01, SE=2.02; HSI: B=-6.75, SE=2.12; SXN: B=-8.13, SE=1.67) cancer survivors. Findings document elevations in unmet supportive care needs in Latino cancer survivors and can inform targets of intervention in efforts to improve quality of life and reduce disparities among Latino cancer survivors.

Symposium 41B

ADVANCED CANCER PATIENTS' AND STAKEHOLDERS' ATTITUDES TOWARD CANCER GENOME SEQUENCING TO GUIDE TREATMENT: A QUALITATIVE STUDY

Laura C. Bouchard, Ph.D.

Objective: Precision oncology involves guiding cancer treatments based on an individual tumor's sequence of genomic targets. Using cancer genome sequencing may be more effective for treating cancer; however, results can be complex, difficult to communicate, and may not provide definitive or effective treatment options. This qualitative phenomenological study aimed to assess patients' and providers' experiences and expectations with cancer genome sequencing to identify their informational and supportive needs.

Method: Patients with advanced cancer who underwent cancer genome sequencing (n=16) and providers (n=12) in a precision oncology clinic participated in semi-structured interviews assessing their educational needs, concerns, and expectations for cancer genome sequencing. The one-hour interviews were audio-recorded and transcribed. Two independent coders identified patient and provider themes.

Results: Patients were mostly female (56%) with a mean age of 57.6 years ($SD=15.1$). Cancer diagnoses were primarily breast (38%) and most had metastatic disease (63%). Providers were oncologists (58%), oncology nurse practitioners (25%) and oncology fellows (17%). Among non-fellows, mean years of experience in oncology was 7.4 ($SD=5.6$; range 2.5–19.0 years) and mean years referring patients to cancer genome sequencing was 2.9 ($SD=1.5$; range 1.0–6.0 years). During the individual interviews, all patients and providers discussed the limited information patients have about cancer genome sequencing, as well as the associated financial challenges. All patients and most providers (75%) discussed challenges regarding patient-provider communication, and all patients and most providers (67%) discussed healthcare system challenges. Most patients (63%) and providers (67%) discussed the emotional concerns patients experience during cancer genome sequencing. Specific to providers, all discussed the goals and strategies of using cancer genome sequencing to inform cancer treatment decision-making. Finally, most providers (67%) discussed their own barriers to providing cancer genome sequencing services to their patients.

Conclusion: Patients with advanced cancer and oncology providers identified unique challenges related to cancer genome sequencing. Identifying educational and supportive needs is a critical step in developing tools to enhance patient and provider experiences and expectations in cancer genome sequencing.

Symposium 41C

RESULTS OF COMMUNITY-BASED YOGA PLUS UNSTRUCTURED VS. FACILITATOR-GUIDED GROUP DIALOGUE WITH LATINA BREAST CANCER SURVIVORS

Dr. Elizabeth L. Addington, PhD

Introduction: Although many studies demonstrate efficacy of yoga for improving adjustment and decreasing symptom burden among women with breast cancer, most have been conducted with primarily white samples in the academic setting. Research is needed to examine community-based adaptations of yoga for Latinas with cancer, who report higher distress, more social withdrawal, and poorer quality of life than other racial/ethnic groups of cancer survivors.

Methods: Overweight and obese Spanish-speaking female breast cancer survivors were enrolled in a 12-week, non-randomized, community-based yoga pilot study that included 30 minutes for a healthy snack and discussion at the end of each class. For participants in two courses (n=22), this time was devoted to unstructured, peer dialogue and social connection. During two separate courses (n=17), group discussions at sessions 3, 6, 9 and 12 were instructor-facilitated instead, focusing on participant experiences with yoga and its effects on their daily life. We conducted repeated measures ANOVAs, controlling for baseline expectancy, to test within- and between-group differences in patient-reported outcomes (PROMIS) between baseline, 12, and 24 weeks.

Results: Within the group of participants who attended Spanish language yoga classes followed by unstructured group dialogue, depression decreased significantly from baseline to week 12 and from week 12 to week 24. Participants who attended the courses with facilitator-guided group dialogue also demonstrated statistically significant within-group decreases in depression at week 12 and week 24, as well as statistically significant within-group decreases in pain interference and fatigue at week 12. When examining between-group differences, results for satisfaction with social roles and positive affect/wellbeing at week 12 favored the facilitator-guided groups.

Conclusion: This study provides preliminary evidence that both unstructured and facilitator-guided group discussion may benefit Spanish-speaking breast cancer survivors participating in community-based yoga. However, compared with peer-to-peer discussion, structured group dialogue led by the interventionist may be especially effective for improving psychosocial outcomes and decreasing symptoms. Future studies using a randomized design are needed to further explore these findings.

Symposium 41D

EFFECTS OF A TECHNOLOGY-ASSISTED CBT-BASED INTERVENTION ON THE PSYCHOSOCIAL FUNCTIONING OF MEN WITH ADVANCED PROSTATE CANCER

Rina S. Fox, Ph.D., M.P.H.

Cognitive behavioral therapy-based stress- and self-management interventions (e.g., Cognitive Behavioral Stress Management; CBSM) have been shown to mitigate the physical and psychological symptoms of localized prostate cancer. However, traditional psychosocial interventions require patients to attend in-person sessions, which can present challenges for advanced prostate cancer (APC) patients who may experience greater functional limitations and heightened symptom burden. Treatments delivered via the Internet can remove barriers associated with travel, and enable computerized adaptive testing (CAT) approaches, such as those available through the Patient-Reported Outcomes Measurement Information System (PROMIS), to repeatedly assess psychosocial functioning while minimizing response burden. This study evaluated the impact of a technological adaptation of CBSM on symptoms of depression, anxiety, fatigue, pain interference, and physical functioning among a diverse group of men with APC undergoing hormone therapy (HT). Patients were randomized to participate in a CBSM group intervention ($n=95$) or a health promotion (HP) attention-matched control condition ($n=96$). Participants attended all sessions with trained facilitators via video conferencing using tablet computers, and completed PROMIS CATs weekly from their homes during the 10-week intervention period. Multilevel modeling demonstrated no significant group-by-time interactions from week 1 to week 10 for any of the five psychosocial domains explored after controlling for sociodemographic (i.e., age, race, ethnicity, marital status, income) and medical (i.e., comorbidities, metastatic status, history of prostatectomy, chemotherapy within the prior six months, radiation within the prior six months, years since diagnosis) variables. However, despite the lack of omnibus interaction effects, simple effects demonstrated significant decreases in PROMIS Anxiety scores from week 1 to week 10 for both the CBSM (mean difference [ΔM] = -3.38; $p=.01$) and HP groups ($\Delta M = -3.09$; $p=.01$), as well as a significant decrease in PROMIS Depression scores from week 1 to week 10 for the CBSM group ($\Delta M = -2.69$; $p=.04$), but not the HP group ($\Delta M = -1.88$, $p=.11$). Results demonstrated the feasibility and benefits of utilizing PROMIS CATs to repeatedly assess psychosocial functioning from afar, and indicated that technology-administered CBSM may be an effective strategy to decrease psychosocial distress among men with APC undergoing HT.

Symposium 42

8:00 AM-9:15 AM

USING TECHNOLOGY TO INFORM AND ENHANCE CLINICAL PRACTICE TO IMPROVE BARIATRIC SURGERY OUTCOMES

Stephanie P. Goldstein, M.S.¹, J. Graham Thomas, PhD², Lauren E. Bradley, PhD³, Diana Thomas, Ph.D.⁴, Dale S. Bond, PhD⁵

¹Warren Alpert Medical School of Brown University, Providence, RI; ²Brown University School of Medicine & The Miriam Hospital, Providence, RI; ³Rush University Medical Center, Chicago, IL; ⁴United States Military Academy, Randolph, NJ; ⁵The Miriam Hospital/Brown Alpert Medical School Weight Control and Diabetes Research Center, Providence, RI

Bariatric surgery produces large, sustained weight losses that result in improved health and quality of life for many patients with severe obesity. However, substantial variability in outcomes has been observed with up to one-quarter of patients experiencing sub-optimal weight loss and many individuals experiencing weight regain as early as 18 months post-operatively (post-op). The recent rise of powerful web-based, mobile, and statistical technologies shows promise for enhancing the assessment and treatment of behavioral, psychosocial, and surgical factors related to poor post-op outcomes. The overarching goals of this symposium are to (1) identify the primary barriers to care among bariatric surgery patients, (2) describe the ways in which specific technologies can be harnessed to address identified barriers, and (3) present preliminary findings on the described technological approaches. The first speaker will present on the development and implementation of a multi-modal assessment platform that utilizes ecological momentary assessment as well as passive physical activity and eating sensors. Initial data regarding which behavioral and psychosocial risk factors contribute to outcomes will be presented. Ways in which these data can influence clinical post-op guidelines will be explored. The second speaker will present on the effectiveness of a remotely delivered, acceptance-based behavioral intervention for targeting post-op weight regain. The utility of a web-based intervention for this population, as well as the importance of addressing psychological barriers to post-op adherence will be discussed. The last speaker will discuss the development of a machine learning system that utilizes pre-operative factors (e.g., demographics, medical diagnoses, eating behaviors and physical activity) to choose the optimal type of bariatric surgery and lifestyle plan for each patient. The way in which the system individually tailors recommendations based on a variety of pre-operative factors will be demonstrated. Together, these presentations will highlight the ways in which novel applications of technology can inform clinical practice and extend the reach of effective treatment and assessment in this population. Methods described during this symposium are especially relevant as they can be generalized to enhance clinical care for other types of health behavior concerns.

Symposium 42A

WIRELESS SENSOR INTEGRATION TO IMPROVE ECOLOGICAL MOMENTARY ASSESSMENT OF BARIATRIC SURGERY PATIENTS BEHAVIORS & EXPERIENCES

Dr. J. Graham Thomas, PhD

The methods used historically to study weight-related behaviors and experiences (e.g., retrospective self-report questionnaires, clinical interviews, paper diaries) are subject to forgetting, bias introduced by heuristics used to counter forgetting, poor awareness of behaviors/experiences, reliance on patients to report on associations between behaviors and/or experiences that may fall outside of their awareness. Ecological Momentary Assessment (EMA) counters these challenges by capitalizing on mobile technology to solicit self-report of behaviors, experiences, and environmental conditions several times per day over several days. However, challenges remain related to the reliance on self-report and the difficulty of collecting information on discrete events such as eating episodes and bouts of physical activity, near to the time of their occurrence, without overburdening participants. This presentation describes the application of mobile sensor technology in an ongoing study, "Ecological Momentary Assessment of Behavioral and Psychosocial Predictors of Weight Loss Following Bariatric Surgery" (R01 DK108579) to reduce reliance on self-report of key eating and physical activity behaviors, and to use objective data to trigger self-report of behaviors as they occur. The presentation will begin with overview of study aims, which involve identifying behavioral, psychosocial, and environmental predictors of success and risk after bariatric surgery. Next, the process of developing the technology will be reviewed, with an emphasis on how the technology was designed to meet the study aims, how challenges in technical development were addressed, and the strengths and weaknesses of the resulting platform. Two methods for incentivizing adherence to the measurement protocol will be compared and contrasted (i.e., incentivizing for maintaining a level of compliance above a minimum threshold versus incentivizing per response). Examples of data and findings resulting from the study will then be reviewed, with an emphasis on appropriate analytic approaches and the unique learnings that can be obtained from such data. The presentation will conclude with a discussion of how the learnings can be applied in clinical contexts, and future directions for further improving EMA platforms involving integrated sensors for objective monitoring.

Symposium 42B

EVALUATING THE UTILITY OF REMOTELY-DELIVERED BEHAVIORAL INTERVENTIONS TARGETING POST-BARIATRIC SURGERY WEIGHT REGAIN

Lauren E. Bradley, PhD

Although bariatric surgery is the most effective treatment for severe obesity, a substantial number of patients have poor weight loss outcomes and would benefit from postoperative intervention. One significant barrier to patients receiving this intervention is the well-documented loss to follow-up, with up to 72% of patients missing post-surgical appointments within two years after surgery. Moreover, researchers have consistently documented difficulty recruiting and retaining bariatric surgery patients in trials of postoperative intervention. Significant barriers to in-person treatment include geographical and time constraints. These barriers may be mitigated by utilizing innovative technological advances, allowing for better reach and engagement in treatment for this population. We developed a remote-based behavioral treatment program targeting the causes of weight regain, including maladaptive eating behaviors, delivered via online modules and brief phone coaching. In our initial open trial pilot study (n=16), participants rated the intervention as highly acceptable and demonstrated clinically significant weight losses. We are now evaluating the effectiveness of this 10-week intervention in a larger sample of post-bariatric surgery patients who are regaining weight compared to a wait-list control. Data collection is ongoing (current n=30), and retention is high (88%). Initial data from treatment completers (n=11) indicate high levels of satisfaction with the intervention (4.7 out of 5.0). Greater improvements in eating behavior, including symptoms of binge eating and emotional eating, in the treatment condition vs. wait-list control have been observed. However, weight losses in the treatment condition thus far are minimal ($0.7\% \pm 1.9\%$ total body weight loss) and not significantly different than those assigned to the wait-list control (n=14, i.e., $0.7\% \pm 2.6\%$ weight gain). Moderation analyses will be completed once data collection is complete (anticipated total n=50) to better understand which patients most benefit from this intervention. Overall, initial data indicate good retention and positive effects on maladaptive eating behaviors, and while short-term changes in weight appear minimal, the program may reduce weight gain over the longer term. The remote delivery method used appears to be a promising strategy for reaching a population that has been consistently difficult to reach and retain.

Symposium 42C

APPLICATION OF ARTIFICIAL NEURAL NETWORKS FOR PREDICTING LONG-TERM BARIATRIC SURGERY OUTCOMES FROM PRE-OPERATIVE MARKERS

Dr. Diana Thomas, Ph.D.

Pre-operatively predicting individual success can improve patient response by identifying optimal surgical procedures and patient risk. Current models relying on regression have resulted in weak correlations. Neural networks offer a flexible method to amplify predictions in a manner that can assist in surgical decision making. To predict long-term weight loss success using artificial neural networks, we applied two separate surgical databases. The first database (N=491) consisted of surgeries performed using the sleeve method and contained data on 1-year diabetes remission and weight loss success (50% weight loss from baseline). The second database (N=216) included long-term (4 months to 1 year) results from gastric bypass, sleeve, duodenal switch, and band. Input neurons applied for the first database consisted of pre-operative age, weight, height, gender, sleep apnea, date of long-term weight measurement and hypertension status. Output neurons set as weight loss success defined by 15% weight lost from baseline. In the second database, input neurons included pre-operative age, weight, height, body mass, gender, diabetes status, and hypertension status. Output neurons were set to percent weight loss at the third follow up visit scheduled between 4 months and 1 year post surgery. Using only pre-op data as input neurons, the area under the curve (AUC) for neural network prediction for one year weight loss success was 0.73. The prediction for diabetes remission results in AUC of 0.79. With additional inputs such as surgery type and preoperative diabetes status, prediction of success was 0.86. The most important variables contributing to prediction were the data of follow-up visit, baseline weight, and patient age. The application of neural networks to predict the long-term impact of bariatric surgery from pre-operative data serves as an effective and superior method to existing models. Based on these results, we developed a user-friendly app that identifies optimal surgery type after input of baseline pre-operative data. A similar app was designed for 1 month post-surgery. This presentation will discuss the data and methods used to build our artificial neural networks, as well as provide a demonstration of the algorithm-based apps.

43 8:00 AM-9:15 AM

EXTENDING THE REACH OF EVIDENCED-BASED TREATMENTS FOR VULNERABLE, HARD TO REACH, HIV-AFFECTED POPULATIONS IN SOUTH AFRICA

Christina Psaros, PhD¹, Greer A. Raggio, PhD, MPH², Jessica Magidson, Ph.D.³, Sannisha K. Dale, PhD⁴

¹Massachusetts General Hospital/Harvard Medical School, Boston, MA; ²Massachusetts, Boston, MA; ³Massachusetts General Hospital/ Harvard Medical School; University of Maryland, College Park, Boston, MA; ⁴University of Miami, Coral Gables, FL

South Africa bears a disproportionate burden of medical (i.e., HIV/AIDS) and psychiatric illness (e.g., depression, substance use disorders). Yet, there is less than 1 physician per 1,000 people in South Africa, and even fewer psychologists/psychiatrists, making effective treatment and prevention a challenge. Improving our understanding of how to effectively deliver evidence-based treatments by paraprofessionals in this setting is imperative. Stigma around HIV and mental health further compromises the ability to deliver effective interventions. This symposium directly addresses the theme of the 2018 meeting of “extending our reach” by providing data from pilot studies aimed at increasing the reach of effective treatment and prevention interventions in vulnerable populations. Dr. Christina Psaros will present the results of a randomized pilot trial evaluating the preliminary efficacy of a problem-solving therapy based intervention to treat depression and improve adherence to the preventing mother to child transmission (PMTCT) cascade. This paraprofessional-delivered intervention focuses on pregnancy and postpartum behaviors meant to prevent vertical transmission of HIV, including postpartum continuation of antiretroviral therapy and initiation of contraception to better time subsequent pregnancies to maximize health outcomes. Dr. Greer Raggio will present findings from a study that examines the feasibility and effectiveness of a safer conception counseling intervention for HIV-positive men in South Africa that effected 100% ART uptake and enhanced safer conception practices. This study demonstrates expanding reach of services that historically have been unavailable to HIV-infected men. Dr. Jessica Magidson present findings from an implementation science study examining the feasibility and acceptability of peer-delivered substance use treatment in HIV care in South Africa. Findings have the potential to inform our future efforts to expand peer-delivered substance use treatment in under-resourced primary care settings. The discussant is Dr. Sannisha Dale, an expert in resilience, trauma, and health outcomes among individuals with HIV and those at risk for HIV, as well as psychosocial (e.g., discrimination) and structural factors (e.g., poverty) that relate to health disparities.

Symposium 43A

PROJECT INSPIRED: A PILOT TRIAL OF DEPRESSION AND ADHERENCE TREATMENT FOR HIV-INFECTED WOMEN IN SOUTH AFRICA

Dr. Christina Psaros, PhD

Introduction: South Africa has the largest number people living with HIV in the world with rates as high as 40% among pregnant women. Depression is a robust predictor of nonadherence to behaviors critical to optimizing health of HIV exposed infants and mothers, such as engagement in the prevention mother to child transmission (PMTCT) cascade; perinatal depression may affect upwards of 50% of women. Interventions that target mental health and adherence to PMTCT are urgently needed.

Method: 23 pregnant women age 18–45 (median age=24) diagnosed with HIV during the current pregnancy and receiving highly active antiretroviral therapy (HAART) were recruited from a district antenatal clinic in KwaZulu-Natal, South Africa and randomized to active treatment or wait-list control. The intervention was based on problem-solving therapy and targeted factors likely to impact depression (e.g., social support, stigma) and adherence to the PMTCT cascade, including postpartum contraceptive use. Assessments were conducted pre and post intervention with individual qualitative exit interviews. Outcomes were analyzed using independent samples t-tests; grounded theory was used to analyze qualitative data.

Results: Only 13% of pregnancies were planned and 61% of participants did not know their partner's HIV status. 83% of participants met criteria for major depression at baseline. Intervention participants had a significant decline in depressive symptoms (Edinburgh Postnatal Depression Scale) between pre and post treatment (M=19.62) relative to the control condition, ($t(21)=4.47$, $p<.001$). Intervention participants (M=98.4%) had greater self-reported HAART adherence at post treatment relative to controls (M=88.8%), though the difference was non-significant, $t(16)=-2.05$, $p=0.094$. All participants (both arms) reported initiating contraceptives. Social support from the intervention, improved self-esteem, and support for HAART pill taking emerged as prominent themes related to perceived benefits of the intervention. Participants expressed a desire for additional sessions.

Discussion: An evidenced based, combined depression and adherence treatment showed preliminary evidence of efficacy in this historically neglected and high risk population. Additional research is needed to demonstrate efficacy and identify strategies to disseminate effective interventions to HIV-infected women during the perinatal period to best optimize the health of women and children.

Symposium 43B

SAFER CONCEPTION FOR MEN LIVING WITH HIV PLANNING TO CONCEIVE WITH AT-RISK PARTNERS

Dr. Greer A. Raggio, PhD, MPH

Background: Many men living with HIV (MLWH) desire children, leading to sexual practices that may put uninfected partners at risk. In eThekweni District, South Africa (SA), where 42% of women presenting for antenatal care test positive for HIV, use of safer conception strategies (e.g., adherence to antiretroviral treatment (ART), limiting unprotected sex to peak fertility) is critical for preventing HIV transmission. However, current prevention programs in SA do not routinely offer safer conception counseling for men or women.

Methods: We are conducting an open pilot of a safer conception intervention for MLWH who want to have children with HIV-negative/unknown-serostatus partners in eThekweni District, SA. The intervention was comprised of 5 individual counseling sessions led by a lay counselor. Session material emphasized cognitive-behavioral skills and education to promote safer conception strategies, with an emphasis on ART initiation/adherence. Men were eligible to participate if they were HIV-positive, not taking ART (or recently initiated), had an HIV-negative/unknown-serostatus sexual partner, and desired to conceive ≤ 1 year. Men completed quantitative surveys at baseline and post-intervention and a qualitative exit interview, and responded to SMS queries regarding sexual practices throughout. Study outcomes included study retention, HIV disclosure to pregnancy partner, ART uptake/adherence, and HIV-RNA suppression.

Results: Of 16 participants enrolled (median age, 29; range, 24–44), only 2 men had disclosed their HIV status to pregnancy partners at baseline. Ten (63%) have completed all 5 study visits to date (3 lost to follow-up, 3 ongoing). 63% of SMS responses showed consistent condom use with pregnancy partners outside the peak fertility period. Among completers, there was 100% ART uptake and viral suppression at post-intervention. Median ART adherence over time ranged 80–100% (group mean = 90%). HIV disclosure to pregnancy partners was reported by 80% of male participants by post-intervention.

Conclusions: A brief safer conception counseling program for MLWH promoted consistent condom use, and uptake of ART and HIV-RNA suppression among 100% of male completers. Given the challenges of engaging and retaining men in care, addressing reproductive goals appears to be a feasible and effective strategy to promote health and reduce transmission to partners and offspring. Future studies should evaluate feasibility and efficacy on a larger scale.

Symposium 43C

ADAPTING EVIDENCE-BASED, PEER-DELIVERED SUBSTANCE USE TREATMENT FOR HIV CARE IN SOUTH AFRICA

Dr. Jessica Magidson, Ph.D.

Background: Substance use disorders (SUDs) are a known barrier to achieving the UNAIDS 90-90-90 treatment target in South Africa—the country with the largest HIV/AIDS burden globally. SUDs are prevalent in South Africa and interfere with HIV treatment adherence and viral suppression, yet are not routinely treated in HIV care. More research is needed to evaluate how to integrate SUD treatment into HIV care in South Africa using culturally adapted, evidence-based approaches.

Methods: This study is a hybrid-effectiveness implementation trial aiming to adapt a cognitive behavioral therapy-based intervention for substance use for integration into HIV care in Cape Town, South Africa. Phase I included semi-structured individual interviews with patients and providers at two clinic sites in Khayelitsha, a peri-urban area of Cape Town. Patients with moderate/severe substance use involvement (WHO-Assist score ≥ 4) and detectable HIV viral load, and HIV and SUD treatment providers across a range of disciplines and roles were enrolled. Patients and providers reported on preferences regarding an integrated substance use and adherence intervention and provided feedback on the proposed intervention components. Interviews were transcribed from isiXhosa into English and analyzed with thematic analysis using NVivo v. 11.

Findings: Patients ($n=19$) were 54% female, mean age=39.5 ($SD=8.2$), and 100% Black African. Prevalent substances were alcohol and marijuana. Mean WHO-Assist scores for alcohol were 15.75 ($SD=8.0$) and for marijuana 9.6 ($SD=11.89$). Providers ($n=11$) were 82% female, mean age=43.5 ($SD=7.6$), and 72.3% Black African. They included nurses, physicians, community health workers (CHWs), addiction and adherence counselors. Preferences for an integrated substance use and adherence intervention included: focusing on alternative positive activities not related to substance use, and using peers with their own personal history of addiction and HIV infection as interventionists. Treatment components were viewed to be appropriate and acceptable to patients and providers. Providers also suggested incorporating CHWs to screen for substance use during routine home visits for patients not engaged in HIV care.

Conclusions: Cognitive behavioral therapy-based interventions were seen as appropriate for treating substance use in this setting. Peers and lay health workers may be useful for integrating SUD treatment into HIV care in resource-constrained care settings in South Africa.

Symposium

44 8:00 AM-9:15 AM

GXE INTERACTION IN OBESITY AND CHRONIC DISEASES: BIOLOGIC RISK AND NEURO-BEHAVIORAL DIFFERENTIAL SUSCEPTIBILITY

Laurette Dube, PhD¹, Spencer Moore, MPH, PhD², Robert Levitan, MD, MSc³, James L. Kennedy, MD, PhD³, Paul Franks, PhD⁴, Patricia P. Silveira, MD, PhD⁵¹McGill University, McGill Centre for the Convergence of Health and Economics, Montreal, PQ, Canada; ²University of South Carolina, Columbia, SC; ³University of Toronto, Toronto, ON, Canada; ⁴Harvard T.H. Chan School of Public Health., Boston, MA; ⁵McGill University, Montreal, PQ, Canada

Recent advances in genotyping has enabled genome-wide association studies of large population samples that have discovered polygenic risk scores for obesity and other lifestyle-related health problems, with evidence accumulating of moderating effects of diverse environmental layers over the life course. In parallel, multi-loci and candidate-gene studies have examined neurobehavioral responsiveness to environment in term of early life context and socio-economic status. These have provided support for dopaminergic genetic vulnerability under adverse conditions as well as vantage sensitivity to supportive environment (the Differential Susceptibility Hypothesis (DSH)). In spite of their potential for targeted prevention and treatment, neither line of work has been sufficiently integrated into public health, clinical research and practice, nor have the single and combined pathways of actions been examined in a single research pipeline. Yet, these multi-dimensional and multi-layered influences all contribute to behavior and health conditions at any point in time in diverse environments. This symposium brings together leading scientists that have done pioneer work in both lines of research with, as discussants, public health and clinician experts (Spencer Moore, public health scientist from Univ. of South Carolina; Robert Levitan, clinician scientist from Univ. of Toronto). Prof. Paul Franks will review current state of knowledge on genome-wide diet and physical activity interaction with adiposity, BMI and diabetes, presenting meta-analysis and findings on an European prospective cohort and the USA Diabetes Prevention Program. Prof. James Kennedy will review the current state of methodology and the advances in distinguishing biological and behavioral genetic risks and examining how they interact with environmental layers that accumulate over the life course to impact obesity and chronic diseases - findings from Canadian birth and adult prospective cohorts will be presented. Prof. Patricia Silveira will report three sets of empirical results from multi-loci and candidate-gene studies on two child samples that provide partial support for the DSH of dopamine signaling on the adaptiveness of food choice and body weight consequences. Environmental contexts range from fetal conditions to maternal sensitivity to the obesogenic food environment. Discussants will address challenges and possibilities awaiting scientists and practitioners in bringing societal-scale solution to both biological risk and neurobehavioral differential susceptibility. The session will be chaired by Laurette Dube, senior author in a *JAMA: Pediatrics* article supporting the DSH with results showing that children carrying a 7-repeat allele of DRD4 gene eat more fat than the sample average of their socio-economic living conditions if they are in low SES, but less fat than average if they live in high SES.

Symposium 44A

BIOLOGICAL AND BEHAVIORAL GENETIC RISKS AND THE INTERACTION WITH ENVIRONMENTAL LAYERS OVER THE LIFE COURSE

Dr. James L. Kennedy, MD, PhD

In this presentation, Prof. James Kennedy will review the current state of methodology and the advances in distinguishing biological and behavioral genetic risks and examining how they interact with environmental layers that accumulate over the life course to impact obesity and chronic diseases. Genomic structure and phenotypic plasticity is one ubiquitous characteristic found across most, if not all, life forms. The variation in structure, physiology and behavior arises in response to the state of past and present environments and is believed to be adaptive by proving increased biological fitness – enhancing survival and reproductive success especially in unpredictable or varying environments. Phenotypic variation generally arises during development and is believed to involve epigenetic mechanisms secondary to both internal and external environments. The most studied forms of developmental plasticity are related to the response to extreme or adverse insults. However, increasing interest is being given to responses to positive experiences, which altogether has been conceptualized under neurobehavioral differential susceptibility. This presentation will review the diverse methods to examine biological and neurobehavioral genetic versus environmental heterogeneity interaction as they related to lifestyle behavior, obesity and chronic diseases, presenting data from Canadian adult and children cohorts that brings insights into the mechanisms and intervention opportunities for a new era of more precise medicine.

Symposium

44B

LIFESTYLE AND DIABETES PRECISION MEDICINE

Paul Franks, PhD

This presentation will review the most recent 15 years of research that has combined major developments in genomic technologies and their application to large, well characterised collections of samples to examine the interplay of genetic variation, pharmacotherapy and lifestyle in obesity, type 2 diabetes and cardiovascular disease. Prof. Paul Franks will report genome-wide association studies of the GLACIER prospective cohort of around 20,000 adults and the USA Diabetes Prevention Program cohorts that have discovered polygenic biological risk scores for adiposity, BMI, diabetes, and cardio-vascular diseases as well as the more recent meta-analysis of the interactions of these biological genetic risks factors with eating and physical activity behaviors. He will also report on the recent discovery of novel biomarkers for type 2 diabetes as part of the DIRECT and RHAPSODY European projects for innovative medicines and explore how these biomarkers could inform the development of a full precision lifestyle and diabetes research program that goes beyond present precision medicine. Optimizing therapy using patient-level biomarker data has stimulated enormous interest throughout society as it can potentially provide more effective, less costly and safer ways of preventing, treating, and perhaps even curing diseases. Moving beyond one-size-fits-all public health interventions, applying a similar approach to both the biological and neurobehavioral genetic factors engaged in lifestyle behaviors could potentially enable the classification of individuals into subpopulations that differ in their susceptibility to a particular disease, in the biology and/or prognosis of those diseases they may develop, and/or in responses to a specific treatment with the expectation that preventive or therapeutic interventions can then be concentrated on those who will benefit from them, sparing expense and side effects for those who will not. This would be done by (1) helping to predict a person's susceptibility to adverse lifestyle exposures; (2) facilitating the stratification of type 2 diabetes into subclasses, some of which may be prevented or treated optimally with specific lifestyle interventions; (3) aiding the discovery of prognostic biomarkers that help guide timing and intensity of lifestyle interventions; and, (4) predicting treatment responses.

Symposium 44C

DOPAMINE AND DIFFERENTIAL SUSCEPTIBILITY TO SOCIOECONOMIC, MATERNAL AND OBESOGENIC ENVIRONMENTS IN CHILDREN

Dr. Patricia P. Silveira, MD, PhD

The differential susceptibility model states that the genetic background is associated with an increased risk of pathology in negative environments but greater than average resilience in enriched ones. While this theory was mostly explored in psychiatric-genetic research, it may also help us to unravel the complex ways by which genes and environment interact to influence the behavioral phenotype associated with risk for cardio-metabolic conditions. We reviewed evidence on gene vs. environmental interactions that influence obesity development, aiming to support the applicability of the differential susceptibility model for this condition, and propose that various environmental “layers” relevant for human development should be considered when bearing the differential susceptibility model in mind. Mother-child relationship, socioeconomic status and individual's response are important modifiers of BMI and food intake when interacting with gene variants, “for better and for worse”. While only a few studies to date have investigated obesity outcomes using this approach, we propose that the differential susceptibility hypothesis is in fact highly applicable to the study of genetic and environmental influences on feeding behavior and obesity risk. Moving beyond a “vulnerability” to a “differential susceptibility” approach to explore gene*environment interactions, we found that the interplay between genes and the early socio-economic environment may determine whether one has either increased fat intake or healthier than average eating. We reported a similar effect for maternal sensitivity affecting risk for overweight or obesity. In both cases, children that are the most biologically vulnerable to maladaptive behavior under adverse environments are also likely to be more responsive to improvement in the circumstances in which they are raised. Neighborhood food cues have been inconsistently related to residents' health, possibly due to variations in residents' sensitivity to such cues. Here we show that the degree to which children's predisposition to eat upon exposure to food environment and food cues (external eating and genetic background), could explain differences in strength of associations between their food consumption and the type of food outlets and marketing strategies existent in their neighborhood. In the first study, children with higher external eating scores, healthful food consumption was more positively related to vegetable displays, and more negatively to the display and variety of soft drinks. In the other study we found that the BMI of carriers of DRD4-7Repeat alleles were more sensitive to environmental differences in obesogenic quality of the food environment whereas BMI of non-carriers was insensitive to this contextual difference.

Symposium 45

8:00 AM-9:15 AM

DIABETES: THE OTHER HARD-HITTING EPIDEMIC IN RURAL APPALACHIAN OHIO AND WEST VIRGINIA

Darlene E. Berryman, PhD, RD, LD¹, Anirudh V. Ruhil, PhD¹, Lesli Johnson, MSW, Ph.D¹, Elizabeth A. Beverly, PhD², Marilyn D. Ritholz, PhD³¹Ohio University, Athens, OH; ²Ohio University Heritage College Osteopathic Medicine, Athens, OH; ³Joslin Diabetes Center, Arlington, MA

Diabetes in the United States (US) has reached epidemic proportions, and the people of Appalachia have been disproportionately affected by this disease. Appalachia is a 205,000-square-mile region that encompasses 420 counties in 13 states from New York to Mississippi and includes 32 counties of Ohio and all of West Virginia. The Appalachian Region is 42% rural, compared to 20% of the US as a whole, and predominantly white (94.6%). The people in this region battle a poverty rate 1.5 times that of the US average, and suffer from higher unemployment, lower educational achievement, generally poorer health, and lower access to health care. Moreover, the Appalachian counties located in southeastern Ohio and West Virginia are designated as economically “distressed,” with nearly one-fifth to one-third of residents living below the poverty line. The Centers for Disease Control (CDC) annual Behavioral Risk Factors Surveillance System (BRFSS) has long been the most widely used source for county-level estimates of diabetes incidence rates. Since 2004, the CDC has utilized small area estimation techniques to fill-in information for counties that were either not sampled in a given year or had very few respondents in the diabetes module. However, accurate information about the prevalence of diabetes is needed to design primary and secondary prevention strategies as well as tertiary care protocols. This symposium includes three presentations. The first presentation examines the findings from the telephone survey with items drawn chiefly from the BRFSS diabetes module to gather our localized data. This presentation also will include geographic information system (GIS) mapping data showing diabetes prevalence rates by county, available healthcare resources (e.g., hospitals, pharmacies, Federal Qualified Health Centers), and food deserts in the region. The second presentation explores the patient experience via interviews and focus groups from those living with diabetes in southeastern Ohio and Wood County, West Virginia. Lastly, the third presentation draws on qualitative data from in-depth interviews of health care providers assessing barriers to providing care and system-level challenges unique to this region. The discussant will weave together findings from all three presentations to emphasize the burden of diabetes in southeastern Ohio and Wood County, West Virginia. Finally, the discussant will address the potential influence of Appalachian culture on diabetes rates and offer practice implications for this critical clinical situation.

Symposium 45A

LOCATION, LOCATION, LOCATION: THE RELATIVE VALUE OF DIRECT VS. INDIRECT SURVEY ESTIMATES

Dr. Anirudh V. Ruhil, PhD

The CDC annual BRFSS has long been the most widely used source for county-level estimates of diabetes incidence rates. Since 2004, in particular, the CDC has utilized small area estimation (SAE) techniques to fill-in information for counties that were either not sampled in a given year or had very few respondents in the diabetes module. These estimates allow for some trend analysis for adults 20 years-old or older. Three factors, unfortunately, limit the value of these CDC estimates in comparison to direct survey-based estimates. First, the margin of error for these estimates tends to average around +/- 4 percentage points. Second, detailed analysis of diabetes incidence or prevalence rates by age, sex, and any other demographic, socioeconomic, or comorbidity condition is beyond the reach of researchers interested or service providers working with populations living in small counties typically not sampled by the CDC. This is not surprising because the BRFSS tends to sample the larger counties in a state, virtually guaranteeing that direct BRFSS estimates will be unavailable for most rural counties. Finally, even when available, CDC estimates lag by several years; most recent estimates CDC provides are for 2014. Consequently, one of the best means of securing localized, timely, and detailed information on diabetes prevalence and needs of residents in rural areas is a cost-effective survey. With this goal in mind, we conducted a diabetes prevalence survey in seven southeastern Ohio Counties and Wood County, West Virginia. The survey instrument was designed with items drawn chiefly from the BRFSS surveys that include a diabetes module to gather our localized data. Respondents self-reported (via a screening question on the survey) either that they had been diagnosed with diabetes or that they were the primary caretaker for a household member diagnosed with diabetes. A stratified quota-sampling scheme was employed, with strata defined by the distribution of adult (18 years-old or older) males and females in each county. With an effective sample size of 1,884 respondents, our findings indicate a much higher diabetes prevalence rate in the eight counties surveyed than reflected by CDC estimates. Specifically, the diabetes prevalence rate was 19.9%, and of those reporting they had diabetes 14.0% had nephropathy, 17% had retinopathy, and 24.0% had neuropathy. These findings along with GIS data highlight the diabetes epidemic in rural Appalachia.

Symposium 45B

THE PATIENT EXPERIENCE: LIVING WITH DIABETES IN APPALACHIA

Dr. Lesli Johnson, MSW, Ph.D

The qualitative data for this study is intended to better understand the experiences of individuals living with diabetes in an eight county Appalachian region. The Appalachian region examined in this study included seven southeastern Ohio counties and Wood County in West Virginia. Interviews (10) and focus groups (36) were conducted with patients (44) diagnosed with diabetes and family caregivers (2) for individuals with diabetes. Seventy percent of the participants were female, 29% of the participants were between 55–64 years old and 49% were 65 years old or older. Participants were asked about their experiences with medical professionals, accessibility of resources needed to manage diabetes, and the strategies they use to manage their diabetes. All interviews and focus groups were audio recorded and transcribed. Thematic and content analysis was completed using MAXQDA, a qualitative data management program. The results reveal many barriers including trouble accessing needed resources, financial strain, lack of motivation, difficulty with insurance, and lack of social support. Some participants report lacking access to exercise facilities, grocery stores, endocrinologists, and nutritionists. Many participants struggle to manage the financial burden of having diabetes including the cost of food, insurance, prescriptions, medical care, transportation, and exercise facilities. Despite the barriers, many participants also discuss positive experiences and supportive factors that have helped them effectively manage their diabetes. The majority of participants, who had attended a diabetes education class note that this experience provided many beneficial tools for managing diabetes. Participants articulate a variety of positive and negative experiences with medical professionals; however, there is broad consensus about the qualities that they value in a health care provider. They want physicians to listen to them, treat them with compassion, provide them with clear instructions, and stress the urgency of managing diabetes. Overall, the results of this study provide a better understanding of the experiences of patients in this region. These results can inform healthcare approaches needed to address the needs and strengths of this population.

Symposium 45C

DIABETES FATALISM, MENTAL ILLNESS, AND SOCIAL DETERMINANTS OF HEALTH IMPACT PROVIDERS' ABILITY TO TREAT PATIENTS IN APPALACHIA

Dr. Elizabeth A. Beverly, PhD

In diabetes, patient-provider collaboration is associated with increased self-efficacy, improved quality of life, decreased negative attitudes toward living with diabetes, and improved glycemia. Thus, this collaboration is critical in achieving optimal outcomes in diabetes. Yet little is known about patient-provider collaboration in rural Appalachian Ohio and West Virginia, which may explain why diabetes rates are more than double the national average. The purpose of this qualitative study was to explore providers' perceptions of barriers and needs to treating diabetes in rural Appalachia. A purposive sample of 43 providers (mean age=45.3 ± 12.0, 67.4% female, 95.3% white, 34.9% physicians, 17.3 ± 11.6 years of experience) participated in semi-structured interviews. Interviews were transcribed, coded, and analyzed via content and thematic analyses using NVivo 10 software. Qualitative analysis revealed three themes: 1) Difficulty Communicating the Severity of Diabetes: Providers struggled to communicate the severity of diabetes and its related complications to patients with diabetes. Providers felt that the pervasiveness of diabetes in the region contributed to indifferent and apathetic views toward diabetes. 2) Fatalistic Attitudes and Comorbid Mental Illness: Providers recounted story after story of patients believing that they were predestined to develop diabetes because everyone in their family had it. Further, providers described patients feeling hopelessness and helplessness about their diabetes, which many attributed to the high rates of comorbid mental illness in the region. 3) Social Determinants Affecting Diabetes Care: Providers recited numerous barriers influencing patients' ability to manage their diabetes effectively, including poverty, low education, food insecurity, housing issues, transportation barriers, limited or no insurance, lack of specialists, and minimal social support. Findings indicate that providers struggled to communicate the severity of diabetes and related complications to patients living in rural southeastern Ohio and Wood County, West Virginia. In addition, providers felt that the high prevalence of diabetes in families, persistent poverty, and high rates of comorbid mental illness contributed to fatalistic attitudes toward diabetes. A centralized system to enhance communication and coordinate providers, behavioral health care, community resources, and diabetes education is needed to better serve patients in this rural, underserved region of the country.

MOBILE BEHAVIORAL HEALTH TECHNOLOGY TO EXTEND OUR REACH: APPLICATIONS IN CHRONIC DISEASE, PRIMARY CARE, AND ADOLESCENT HEALTH

Megan Oser, PhD¹, Bonnie Spring, PhD², Charles Jonassaint, PhD MHS³, Jessica S. Yu, Ph.D.⁴, Alina Liao, MBA, MA in Education, Stanford University. BA English & Economics, Yale University⁵

¹Lantern; Research Associate Psychologist, Department of Psychiatry, Brigham and Women's Hospital, San Francisco, CA; ²Northwestern University, Chicago, IL; ³University of Pittsburgh, Pittsburgh, PA; ⁴Lantern, San Francisco, CA; ⁵MindRight, Washington, DC

Individuals who experience higher levels of stress and trauma throughout their life are at increased risk for poor health and early mortality. Several evidence-based interventions exist for the treatment of stress-related disorders; however, availability and access to evidence-based interventions is limited due to the lack of trained mental health professionals, prohibitive costs particularly when lacking insurance coverage, and the inconvenience and time intensive nature of regular psychotherapy. As such, despite the increasing evidence supporting the beneficial effects of psychological and behavioral health treatments for mental and physical health, the uptake of these evidence-based practices has been poor.

Over the past decade, mobile technology ownership has radically increased for people of all ages. The penetration of mobile technology has reached all race/ethnicity groups and socioeconomic strata. The pervasiveness of technology across all populations has led to excitement surrounding the potential for mHealth to improve delivery of evidence-based care, increase utilization and sustainability of these services, and ultimately, positively impact public health. Unfortunately, the implementation of mobile technology-based interventions was not as straightforward as initially perceived resulting in limited evidence that mHealth tools were effective for improving health outcomes. Recently, however, there have been several advances to using mHealth for delivering high quality and evidence-based care.

This symposium reviews three different strategies for delivering psychological and behavioral stress management interventions via mobile technology. There are several critical issues to consider regarding the design and implementation of mHealth to ensure these interventions are maximally effective and sustainable. We present perspectives from both academia and industry showcasing the reach of behavioral health and medicine interventions and the future of mHealth in health care.

Symposium

46A

FEASIBILITY OF IMPLEMENTING MENTAL HEALTH TREATMENT IN ROUTINE ADULT SICKLE CELL DISEASE CARE USING A MOBILE TECHNOLOGY-BASED INTERVENTION

Dr. Charles Jonassaint, PhD MHS

Sickle cell disease (SCD) is a severe hemoglobinopathy that affects approximately 100,000 people in the US but disproportionately affects those of African descent. Patients living with SCD typically suffer from daily chronic pain and recurrent, unpredictable, vaso-occlusive episodes ("pain crises") that are characterized by severe pain and often require immediate medical attention. Sufferers of the disease, most of whom are ethnic minorities from disadvantaged backgrounds, report significant psychosocial stress and are at higher risk for psychiatric disorders. Indeed, a recent review found that 26–57% of patients with SCD report clinically significant depressive symptoms. However, only a small percentage of patients are receiving mental health care. Lack of availability and access to evidence-based behavioral treatment has been a significant barrier to improving the care of these patients. Viable strategies for addressing the mental health of patients living with SCD are needed. Therefore, the objective of this study was to test the acceptability and implementation of an online computerized cognitive behavioral therapy (CCBT) intervention called Beating the Blues that can be accessed on a mobile device.

Methods: All adult patients (age 18–65) with a diagnosis of sickle cell disease and significant symptoms of depression (defined as PHQ-9 score ≥ 10) and/or anxiety (GAD-7 score ≥ 10) were randomized 2:1 to receiving eight sessions of Beating the Blues with care coach support or usual care. Participants in both groups received an iPad mini to enter daily pain and mood symptoms. The treatment group also used the iPad for accessing the Beating the Blues program. Depression and anxiety and pain symptoms were assessed at 1-, 3- and 6-months.

Results: Thirty patients were enrolled, 18 to CCBT and 12 to usual care. All patients completed at least one follow-up visit except for one patient in the CCBT arm. At 6-months follow-up, patients in the CCBT arm reported a marginally greater decrease in PHQ-9 depressive symptoms (-3.82, SE=1.30) than those in the TAU group (-.50, SE=1.60; $p=.06$)(Figure 2). There were no significant effects of treatment group on change in GAD-7 anxiety symptoms or current pain intensity level. In qualitative interview post intervention, patients expressed liking the structure, care coach support, simplicity of the language, homework activities, and practicality ("it really does work once you start listening and paying attention").

Conclusion: As a first step toward delivering effective mental health care to patients with SCD, this study tested computerized cognitive behavioral therapy, delivered via mobile device, to adults living with SCD. The data showed that the intervention modality is feasible in real-world, non-ideal conditions, is relevant to the target population, and has the potential to improve patient reported outcomes.

Symposium 46B

IMPLEMENTATION, ENGAGEMENT, AND EFFECTIVENESS OF LANTERN, A COGNITIVE BEHAVIORAL MHEALTH PROGRAM FOR ANXIETY IN PRIMARY CARE

Dr. Jessica S. Yu, Ph.D.

More mental health visits occur in primary care than in other settings with anxiety disorders being the most prevalent presentation. Thus, expanding the reach of evidence based behavioral health care within primary care is paramount. Cognitive behavioral therapy (CBT) is well established as the gold standard, evidence-based psychological intervention for anxiety. In pace with the digital revolution of the past two decades, CBT can now be provided via interactive, digital platforms that increases access to services. Lantern, a mobile phone app, is one such digital cognitive behavioral program combining evidence-based anxiety management skills with motivational-behavioral skills coaching. A prospective, pragmatic study conducted at the University of Pittsburgh Medical Center (UPMC) evaluated the implementation, user engagement, and early effectiveness of Lantern among patients with elevated anxiety referred by their primary care physicians.

Methods: Two primary care clinics offered Lantern. Adult patients (ages 20–65) with GAD-7 ≥ 5 on routine clinical screening were invited to participate. At active sites, physicians ordered Lantern for eligible patients through the electronic medical record. Anxiety symptoms are assessed at baseline and 2-, 6-, and 12-months. Here, we present preliminary findings from baseline to 2 months.

Results: 633 patients consented to the study and were provided access to Lantern. 218 completed at least 1 session. At time of analysis, 77 had both baseline and 2-months GAD-7 scores available. At 2-months, participants used Lantern an average of 14.8 days (SD=15.6), completed 9.10 sessions (SD=13.5; 24.5% of program), and practiced 13.0 techniques (SD=19.2). Adjusting for age, gender, medical complexity, and physical health quality of life anxious symptomatology (GAD7) significantly decreased from baseline to 2-months ($B=-2.07$, $SE=0.694$, $t(75)=-2.98$, $p=0.004$). Those with GAD7 > 9 at baseline ($n = 44$), which is suggestive of an anxiety disorder, experienced a clinically meaningful reduction in anxiety symptoms (5.75 point reduction on GAD7; $p < .0001$) with a large within subject effect size ($d = .88$) at 2 months.

Conclusion: Our results indicate that digital behavioral health interventions like Lantern can be implemented within real world primary care settings and are effective in helping patients manage their anxiety. Implementation methods and outcomes within primary care clinics will also be discussed.

Symposium 46C

MINDRIGHT: HOW TEXT MESSAGING CAN IMPROVE THE WELLNESS OF YOUNG PEOPLE EXPOSED TO COMPLEX TRAUMA

Alina Liao, MBA, MA in Education, Stanford University. BA English & Economics, Yale University

Research-based interventions for low-income youth with complex trauma exist but are often inaccessible to this population. Proactively outreaching to youth on an ongoing basis is needed. Text messages have a 99% open rate among teenagers. We thus created MindRight, a non-clinical service that provides socioemotional coaching over text message to youth of color impacted by complex trauma. We train volunteers to serve as coaches, who check in with users daily. Our coaching draws from Trauma-Focused Cognitive Behavioral Therapy, Acceptance Commitment Therapy, and positive psychology. We provide a judgment-free space to talk; positive affirmations; psychoeducation; and stress management skill-building.

Method: We are conducting a study comparing those who initiated MindRight and those who did not among a group of students at a Washington, DC high school. 144 students, ages 14–15, were offered MindRight. Before providing the service, students completed the Adverse Childhood Experiences (ACEs), a non-clinical assessment of post-traumatic stress disorder (PTSD) symptoms, and the EPOCH Adolescent Measure of Psychological Well-being. The EPOCH was re-administered at 10 weeks. Here, we characterize students who chose to start vs. those who did not and characterize texting activity among students who engaged with the service and who experienced improvement in EPOCH scores.

Results: Among those who started MindRight ($n = 50$; 58% female), 44% had an ACEs score of 3 or higher, and 10% had 3 or more symptoms of PTSD (out of 4). Of those who did not initiate MindRight ($n = 94$; 49% female), 35% had an ACEs score of 3 or higher, and 46% had 3 or more PTSD symptoms. Qualitative results show that the most common reason for not using MindRight was not believing one needed emotional help. Having someone to talk to or better manage emotions was most common reason for starting MindRight. In the first 2 weeks, 7,965 texts were exchanged, with 58% sent by coaches and 42% sent by students. By the third week, the average chat length per student per day was 9 texts exchanged. The longest text chain comprised 106 texts. Chats included both rapport-building and providing an intervention. Primary outcomes comparing changes in students' EPOCH scores are being collected. Findings on EPOCH changes between groups and differences in texting activity within the MindRight group will be presented. How conversations differ in their extent of "rapport building" vs. intervention and correlations between length of text conversations and usage rates with EPOCH score change will be presented.

Conclusions: Delivering interventions via text message can make interventions more accessible and help reduce mental health stigma as a barrier to adoption. Building a positive rapport and relationship with students over text message contributes to student engagement with intervention content.

Paper Session 23: How Do We Incentivize Physical Activity 10:45 AM-11:00 AM

EFFECTIVENESS OF AN INCENTIVE-BASED MHEALTH INTERVENTION TO PROMOTE SUSTAINED PHYSICAL ACTIVITY IN TWO CANADIAN PROVINCES

Marc Mitchell, PhD¹, Lauren White, MSc², Guy Faulkner, PhD³

¹Western University, London, ON, Canada; ²Carrot Insights, Toronto, ON, Canada; ³University of British Columbia, Vancouver, BC, Canada

Objective: The Carrot Rewards application ('app') was developed as part of a novel public-private partnership to reward Canadians with loyalty points (e.g., movies, groceries) for engaging in healthy behaviors, such as walking. The purpose of this study was to examine whether "micro-incentives" tied to daily step goal achievement (assessed by 'built-in' smartphone accelerometers) could promote sustained physical activity.

Methods: A 32-week prospective cohort (pre-post) study was conducted in which 36,071 participants (26,369 from British Columbia and 9,702 from Newfoundland and Labrador) were enrolled in the Carrot Rewards walking program between June 13 and August 6, 2016. During the two-week baseline (or 'run-in') period, mean steps/day were calculated for each participant. Thereafter, participants earned "micro-incentives" (\$0.04 Cnd) every day they reached their baseline mean (i.e. level of first daily step goal). Participants earned additional points (worth \$0.40 Cnd) for meeting their step goal 10 out of 14 days. Upon meeting the 10-day contingency, participants could increase their daily goal by 500 steps, with the objective of gradually increasing their number of steps by 3,000 each day. The primary study outcome was mean steps/day (baseline vs. Study Week 32), and was analyzed for the whole study population as well as for lower active participants (<5,000 steps/day at baseline) using dependent t-tests.

Results: Among users enrolled in the Carrot Rewards walking program, 15,645 had complete data sets (4 valid days in Study Week 32; 43.37%) and were included in the analysis (34 ± 11 yrs; 65.12% female). The whole study population averaged $5,791 \pm 2,793$ steps/day during the baseline period; 42.05% of users ($n = 6,578$) accumulated less than 5,000 steps/day during the baseline. At Study Week 32, compared to baseline, users accumulated an additional 244 steps/day, representing a 4.21% relative increase (95% Confidence Interval: 186, 301, $p = .000$). For lower active participants an increase of 1,215 steps/day was observed, representing a relative increase of 34.45% (95% Confidence Interval: 1,142, 1,288, $p = .000$).

Conclusions: Providing immediate "micro-incentives" for individualized daily step goal achievement promoted physical activity on a population-scale for 8 months (the theoretical definition of behavior maintenance is 6+ months). The effect was much more pronounced among lower active participants.

Paper Session 23: How Do We Incentivize Physical Activity 11:00 AM-11:15 AM

DELAY DISCOUNT RATE MODERATES A PHYSICAL ACTIVITY INTERVENTION TESTING IMMEDIATE REWARDS

Christine Phillips, PhD¹, Jane C. Hurley, MS², Michael Todd, PhD¹, Siddhartha S. Angadi, PhD., FASCSM², Vincent Berardi, PhD³, Melbourne F. Hovell, PhD, MPH⁴, Marc A. Adams, PhD, MPH¹

¹Arizona State University, Phoenix, AZ; ²Arizona State University - Downtown Phoenix Campus, Phoenix, AZ; ³Chapman University, San Diego, CA; ⁴San Diego State University, San Diego, CA

Financial incentives likely increase physical activity (PA), but individual differences in delay discounting rates (preference for immediate or delayed rewards) and immediacy of reward delivery may explain differential responding. The current study tested whether reward schedule preference moderated effectiveness of smaller immediate vs. larger delayed financial rewards on increasing daily PA. We hypothesized that participants randomized to study arms matching their reward preferences would show greater PA change.

Method: Inactive adults ($N=96$, age 18–60, BMI 25–55 kg/m²) were randomized to receive either smaller, immediate rewards or larger, delayed rewards for meeting PA goals over 4 months. Those who completed the Monetary Choice Questionnaire (MCQ; $N=85$) were classified as Immediate Reward Preference or Delayed Reward Preference based on a median split of MCQ-derived values for proportion of choices favoring immediate rewards (range 0–1; $Mdn=.56$). Interactive effects of reward preference and intervention arm on change in mean steps/day from baseline to intervention and rate of change in steps/day during the intervention phase were tested in linear mixed models adjusting for covariates.

Results: Across all groups, PA increased by 2302 steps/day on average from baseline to intervention ($p<.001$), and declined by 10 steps/day during the intervention phase ($p=.28$). Immediate preference/immediate reward participants showed greater increases in steps/day from baseline to intervention than either delayed preference/delayed reward ($b=-931$, $p=.03$) or immediate preference/delayed reward ($b=-1142$, $p=.008$) participants. Relative to the immediate preference/immediate reward group, delayed preference/immediate rewards group did not differ ($b=-200$, $p=.632$). During the intervention phase, steps/day decreased faster for those preferring immediate rewards than for those preferring delayed rewards. Relative to the immediate preference/immediate reward group, delayed preference/immediate rewards ($b=14.1$, $p=.002$), and immediate preference/delayed rewards groups ($b=7.2$, $p=.058$) had slower declines.

Conclusions: Smaller, immediate financial rewards increased PA irrespective of immediate or delayed reward preference. Over time, incentive potency waned among higher discounters and remained stable among lower discounters. Interventions using financial incentives may be optimized by considering individuals' delay discount rates.

Paper Session 23: How Do We Incentivize Physical Activity 11:15 AM-11:30 AM

EFFECTS OF CONTINUOUS REINFORCEMENT VS. VARIABLE MAGNITUDE AND PROBABILITY REINFORCEMENT ON ADULTS' PHYSICAL ACTIVITY

Marc A. Adams, PhD, MPH¹, Vincent J. Berardi, MA, PhD², Christine Phillips, C.S.C.C., M.S.S., PhD¹, Jane C. Hurley, MS³, Michael Todd, PhD¹, Melbourne F. Hovell, PhD, MPH⁴, Siddhartha S. Angadi, PhD., FASCSM³

¹Arizona State University, Phoenix, AZ; ²Chapman University, San Diego, CA; ³Arizona State University - Downtown Phoenix Campus, Phoenix, AZ; ⁴San Diego State University, San Diego, CA

Background: Financial rewards can increase and maintain health behaviors, but little research has quantified steady-state patterns under different reinforcement schedules for promoting moderate-to-vigorous physical activity (MVPA) among free-living adults.

Purpose: This secondary analysis of data from one arm of an RCT examines the effects of six different reinforcement stages, each characterized by a different positive reinforcement schedule, on participants' MVPA.

Method: Participants (N=187) wore an ActiGraph GT9X daily (32,632 observations) in a one-year intervention. Participants were prescribed MVPA goals (i.e., MVPA bout minutes) and could earn rewards daily for meeting goals. As participants met goals, they progressed through four stages, transitioning from one to the next after meeting 24 goals: 1) continuous fixed reinforcement (\$1 per goal met), 2) continuous variable magnitude (\$0.25 to \$2.50/goal met, all goals earned a reward), 3) variable magnitude and probability (\$0.25 to \$2.50/goal, 8% of goals earned \$0), 4) variable magnitude and probability (\$0.25 to \$2.50, 17% of goals earned \$0). Rewards denominations were randomized and total amounts within each stage summed to \$24 ($M=\$1/\text{goal}$). Participants were paid immediately via electronic gift cards after earning \$5.00. We averaged cumulative MVPA bout minutes/day (bm/d) over all participants on each day in each stage to investigate potential differences between stages.

Results: Rate of growth in cumulative MVPA bm/d increased across stages, with Stage 1 (continuous fixed reinforcement) having the smallest slope. Linear regression indicated that a slope of 23.8 bm/d in Stage 1 increased to 30.1 bm/d in Stage 2 ($= 6.3, p<.001$). The slope increased by an additional 2.1 bm/d at Stage 3 ($p=0.23$) and increased by 12.5 bm/d at Stage 4 ($p<.001$). When repeating this analysis with only the highest-performing participants, the between Stage 1 and Stage 2 was smaller (2.8 bm/d, $p<.001$) and slopes for other adjacent pairs of stages were more similar.

Conclusion: Progression through both variable magnitude and variable probability reinforcement schedules resulted in higher MVPA than observed with continuous fixed reinforcement alone, with leaner probability schedules producing the largest amount of MVPA accrual. Variance was not constant across subjects and was smallest for the highest performing participants. Implications for behavioral maintenance will be discussed.

INCENTIVIZING BEHAVIOR CHANGE SKILLS TO PROMOTE WEIGHT LOSS

Corrine Voils, PhD¹, Sarah L. Hale, PhD², Jane Pendergast, PHD³, Jennifer Gierisch, PhD, MPH⁴, Megan McVay, PhD⁵, Elizabeth Strawbridge, MPH, RD, LDN⁶, Erica Levine, MPH³, Allison C. White, N/A³, William Yancy, Jr., MD, MHS³, Shelby Reed, PhD⁷, Yanhong Li, MS⁷, Gary Bennett, PhD³, Ryan Shaw, PhD RN³

¹University of Wisconsin-Madison, William S Middleton Memorial Veterans Hospital, Madison, WI; ²Duke University, Raleigh, NC; ³Duke University, Durham, NC; ⁴Duke Medical Center, Durham, NC; ⁵Duke University Health, Durham, NC; ⁶Durham VA Medical Center, Durham, NC; ⁷Duke Clinical Research Institute, Durham, NC

Objectives: Financial incentives for dietary self-monitoring (SM) and weight loss may increase weight loss. Previous studies have required attendance at in-person sessions to submit food logs for an incentive, representing a confound, and/or have incentivized people for weight loss at the end of a study. To capitalize on the potential efficacy of incentives for behavior change, we must be able to incent people in real-time without requiring attendance. We developed an information technology solution that automatically collects data from MyFitnessPal and Internet-connected body weight scales, analyzing data weekly to determine if participants qualify for incentives. Each week, participants receive a text message informing them about whether they earned money, and if so, how much. They were given credit on a cash card. In a clinical trial pilot study (R34), we evaluated the feasibility and acceptability of this approach for incenting weekly SM and weight loss.

Methods: All participants received a 6-month, group-based weight loss program. Participants were randomized to one of four conditions represented by a 2 (incentives for SM: yes vs. no) x 2 (incentives for weight loss: yes vs. no) factorial design. The study was conducted in 3 sequential cohorts of approximately 32 participants. For each cohort, we evaluated recruitment and retention rates, session attendance, and weight loss. We conducted qualitative interviews with a subset of participants to inform changes for the next cohort.

Results: In cohort 1, mean weight loss was 9.5%, mean attendance was 8.6/13 sessions, and retention was 85%. For cohort 2, we switched from a low-carbohydrate diet (LCD) to a low-calorie diet, changed advertisements to obtain a more diverse sample, and added twice-weekly campaign-style motivational text messages. In cohort 2, mean weight loss was 3.9%, mean attendance was 7.6/13 sessions, and retention was 77%. For cohort 3, we switched back to the LCD, switched from \$0 to \$2 as the lower bound for a weekly incentive, added an extra group session at week 1 to provide additional instruction on MyFitnessPal, and mailed a retention letter to participants at month 5. Results for cohort 3 will be available at the meeting.

Conclusion: Results of this planning study support the feasibility and acceptability of using an IT solution to incent patients in near real-time for dietary SM and interim weight loss independent of group session attendance. We plan to conduct a multi-site randomized trial to evaluate the efficacy of this approach.

AN RCT OF ONLINE AND SOCIAL NETWORKING INTERVENTIONS IN YOUTH WITH ALCOHOL USE DISORDERS AND COMORBID DEPRESSION

Frances Kay-Lambkin, PhD¹, Sally A. Hunt, BA(Psyc)Hons., M.Psych(Clin), PhD², Jenny Geddes, BA M(Psyc)Clin³, Amanda L. Baker, PhD⁴, Mark Deady, PhD, BPsy(hons)⁵, Maree Teesson, BSc Psych(Hons), PhD⁶

¹The University of Newcastle, Newcastle, New South Wales, Australia; ²University of Newcastle, Newcastle, New South Wales, Australia; ³University of Newcastle, Callaghan, New South Wales, Australia; ⁴The University of Newcastle, Callaghan, New South Wales, Australia; ⁵UNSW, Randwick, New South Wales, Australia; ⁶UNSW Sydney, Sydney, New South Wales, Australia

Aims: This paper will report on the use of novel digital tools (namely Facebook and social networking) in the largest trial to date of online treatments for comorbid depression and alcohol misuse in young Australians. The iTreAD study aimed to examine the effect of combining social networking with online psychosocial treatment for young people with alcohol use disorder and comorbid depression. We hypothesize that the combination of social networking and online psychosocial treatment will be associated with increased use of the online treatment program, and superior reductions in alcohol use and depressive symptoms in young people.

Methods: Participants aged 18–30 years were recruited via Facebook to a study comparing: (1) online monitoring for alcohol use and depressive symptoms, (2) online monitoring combined with online automated cognitive behavior therapy (CBT), or (3) online monitoring combined with automated CBT and a clinician-moderated online social networking application (Breathing Space—a purpose-built social networking site) over 12-months. Following baseline assessment, participants were randomized to treatment conditions, with independent follow-up occurring at 6-, 12-, and 18-months post-baseline.

Results: Of the 3,700 young people who completed screening data for the trial, 426 participants met eligibility criteria and commenced the study. On average, participants who were allocated to Breathing Space accessed the site 51 times over 12 months (5–6 month, maximum 1,320), posted an average of 3 times (maximum 23), provided an average of 12 comments, and made an average of 7 empathic responses per participant. Young people reported that being able to post about their thoughts and feelings in a non-judgmental and “safe” environment was beneficial, and preferred to “real time” support offered via telephone or other modes of delivery. Participants randomized to the Breathing Space also completed significantly more modules of the online automated cognitive-behavioral intervention than participants in the other conditions (48% vs. 28% completed 2 or more modules). Over time, significant reductions in alcohol use were reported by participants in all conditions ($p=0.01$), with the largest effect observed among those in the Breathing Space condition (clinically significant). Significant reductions in depression were also observed across all treatment conditions ($p=0.01$), with no clinical or statistical differences between groups. Twelve-month data relating to treatment outcomes, and satisfaction with treatment will be discussed.

Conclusions: Web 2.0 platforms show promise for delivering treatment to traditionally hard-to-reach populations (young people, and comorbid mental health and addiction), and may enhance uptake of online psychosocial interventions. Online monitoring as a first step also shows promise in this group.

REACHING SMOKERS WHO ARE NOT MOTIVATED TO QUIT: A MOBILE APP TO ENHANCE WELL-BEING AND ENCOURAGE CESSATION

Belinda Borrelli, PhD¹, Yvonne Kiera Bartlett, BSc, MSc, PhD², Gregory Frasco, Bachelors of Science in Computer Science³, Alison Wearden, PhD⁴, Frederick Jansen, N/A⁵, Christopher J. Armitage, BA(Hons), PhD², Andrei Lapets, Ph.D.³, Bethany Gill, BSc (Hons) Psychology, MRes Psychology⁶, Amie Gall, MSc²

Goldman School of Dental Medicine, Boston, MA; ²University of Manchester, Manchester, England, United Kingdom; ³Boston University, Boston, MA; ⁴University of Manchester, Manchester, N/A, United Kingdom; ⁵Boston University, Jamaica Plain, MA; ⁶The University of Manchester, Clitheroe, England, United Kingdom

Behavioral Activation (BA) is an evidence-based treatment for depression that fosters engagement in values based activities (VBA) to increase access to sources of positive reinforcement. Depressed mood has been shown to hinder smoking cessation. The aim of this study is to pilot test a mobile app (ImWell) that uses BA to motivate smokers to quit via engagement in VBAs focused on increasing environmental rewards and keeping smoking cessation in mind through occasional motivational messages to quit smoking. Users were encouraged to set two VBAs per week via the app and received automated weekly feedback on their mood, smoking rate, and progress with setting & completing VBAs. The app also provided smoking cessation resources. We hypothesized that ImWell would smoke fewer cigarettes per day, be more motivated and confident to quit smoking, and have better mood vs. controls. 56 adult smokers (M age =34.5 years, M cigs/day = 13.4) who were not ready to quit smoking within 30 days were randomized to either 8 weeks of ImWell (n=27) or control group (no app; received resources for quitting smoking & completed weekly online assessments n=29). Both groups completed online assessments at baseline and follow-up. ImWell also completed daily and weekly in-app assessments. Four participants did not complete the follow-up survey (2 in each group); there were no dropouts. Among ImWell, 100% planned at least one VBA, 25/27 planned VBAs beyond the initial download and registration, and 24/27 planned VBAs in both months of the trial. A total of 253 VBAs were planned and 109 were completed. Although the sample was not motivated to quit, no one rated the smoking messages as ‘difficult to understand’, ‘unacceptable’ or ‘uninformative.’ 20/25 of ImWell said they would recommend it to ‘several’ or ‘many’ people and 24/25 said the process of identifying VBAs was easy. After controlling for baseline values, at follow-up, ImWell smoked fewer cigarettes per day than controls (10.6 vs. 16.6; Cohen’s $d=0.51$, $F(1,48)=2.89$, $p=.10$), had greater motivation to quit smoking ($d = .20$), greater confidence to quit smoking ($d = .14$), and lower CESD scores ($d = 0.18$). 76% of ImWell viewed in-app smoking cessation resources, 20% of whom reported contacting the resources. These data show that smokers who are not motivated to quit will use the app, that they find the app appealing, and that the app has the potential to improve mood and reduce smoking.

ENGAGING THOSE WITHOUT INTENTIONS TO QUIT: SMOKER ENGAGEMENT IN A MHEALTH TOBACCO CESSATION PROGRAM

Amanda Blok, PhD, MSN,PHCNS-BC¹, Daniel J. Amante, PhD, MPH¹, Rajani Sadasivam, PhD², Ariana Kamberi, MBA³, Angela Patterson, MA⁴, Thomas K. Houston, MD, MPH³

¹UMass Medical School, Worcester, MA; ²UMass Medical School, Worcester, MA; ³University of Massachusetts Medical School, Worcester, MA; ⁴UMass Medical School, Shrewsbury, MA

Background. Motivation phase smokers, i.e. smokers not actively trying to quit, are a difficult population to engage in smoking cessation interventions. Mobile health (mHealth) innovations, including responsive 2-way text messaging and smart phone applications (apps), can be leveraged to address some of the barriers faced when targeting motivation phase smokers. Engagement in mobile health smoking cessation interventions and the subsequent effects on smoking cessation-related behaviors are understudied in this population. The purpose of this analysis is to examine the impact of intervention engagement on smoking cessation goal setting by motivation phase smokers.

Methods. The Take a Break study is a randomized controlled trial evaluating a pre-cessation intervention among motivation phase smokers. Engagement with the intervention was measured by responses to daily text message assessing the number of cigarettes smoked and tobacco cravings and urges. After smokers engaged in the intervention for 1 week, they were asked to set a goal for the number of days to attempt being abstinent during the following 2 weeks. The relationship between engagement with the intervention and subsequent cessation goal setting during the following 2 weeks was analyzed using Pearson's chi2 test. Daily self-reported cigarettes smoked and reductions in CO readings taken at the end of 3 weeks compared to baseline are reported.

Results. Thirty-two smokers engaged in the text messaging system. These smokers were on average 53 years old, 56.2% female (N=18), and 90.0% white (N=28). Smoker engagement with the texting system was high, at 77.0% (N assessments responded=188, N assessments possible=244). Engagement varied by smoker, ranging from 0 to 14 responses to assessments with a median of 12 responses. The majority of smokers (N=25/32, 78.1%) set an abstinence goal for the challenge. Abstinence goals ranged from 0 to 14 days, with a mean of 4.2 days (SD: 5.2). The relationship between engagement in week 1 and goal setting was insignificant (chi2=8.7568; p=.271), yet the relationship between engagement and goal setting was significant in weeks 2 and 3 (chi2= 100.318; p=.000). Self-reported cigarettes smoked per day (week 1 versus 2 and 3) declined by 17.7% (week 1 N=2571; week 2 and 3 N=4232.5/2). 58.6% (N=17) smokers had reduced CO readings after 3 weeks and were under.

Conclusion. In this population of smokers who declare they are not interested in quitting, a mobile health smoking cessation intervention did result in daily engagement with the intervention, setting of abstinence goals and a reduced number of cigarettes smoked in 3 weeks. Despite stated intentions not to quit, several smokers were not smoking after 3 weeks per CO validation. Mobile health interventions can engage smokers in smoking cessation trials, even if they initially identify as being not interested in quitting.

USE OF AUTOMATED TOOLS TO TEST DIGITAL PRODUCTS AND IMPROVE THE ENGAGEMENT OF A SMOKING CESSATION WEB INTERVENTION

Brian Keefe, MA, David Vaughan, N/A, Taylor Brown, N/A
ICF, Rockville, MD

Introduction: Many health communication programs struggle to evaluate their digital products, primarily due to budgetary or time constraints. Formative and evaluative research on digital interventions are fundamental to improving usability and efficacy. The goal of this study was to use an automated testing tool to assess and enhance the performance of a digital smoking cessation website.

Methods: Smokefree.gov is the National Cancer Institute's smoking cessation website. Using Google Optimize, automated testing software that integrates into Google Analytics, two distinct versions of the Smokefree.gov Homepage were compared in a concurrent A/B test. The "new" homepage was designed to be easier to navigate on mobile devices (than the "original" homepage), and its content offerings were informed by the typical pathways users took on the website (e.g., the sequence of pages users visited). Users visiting the Smokefree.gov Homepage were automatically directed to one of two versions of the Homepage (original homepage or a newly designed homepage). Data was collected over a 16-day period encompassing nearly 14,000 sessions on Smokefree.gov. A set of 12 key performance indicators, collected in Google Optimize and Google Analytics, were examined to determine the better performing Homepage.

Results: The newly designed Homepage outperformed the original design across all engagement metrics (bounce rate: 28% versus 33%, pages per visit: 2.80 versus 2.64, average session duration: 2:45 versus 2:42, time on homepage: 1:14 versus 1:03) for mobile users, which are the primary users of the Smokefree.gov website. Additionally, users who visited the newly designed homepage were more likely to opt-into SmokefreeTXT programs (e.g., .70% versus .06% conversion rate for the Practice Quit text messaging program), a core offering of the Smokefree program.

Conclusion: Automated A/B tests provide a quick and easy way to optimize digital products, free of cost. This study led to the launching of the newly designed homepage on Smokefree.gov and spurred a line of new research studies to optimize user experience and message delivery.

Paper Session 25: Improving Diabetes Care Among Underserved Populations 10:45 AM-11:00 AM

USING FAITH COMMUNITY ENGAGEMENT TO INCREASE REACH AND IMPACT OF A DIABETES/CVD HEALTH PROMOTION INTERVENTION IN BLACK CHURCHES

Jannette Berkley-Patton, PhD, MA, BSEE¹, Carole Bowe-Thompson, BS², Alexandria Bauer, MA², Marcie Berman, PhD², Andrea Bradley-Ewing, MPA, MA³, Delwyn Catley, PhD³, Kathy Goggin, BA Psychology, MA Psychology, PhD Clinical Psychology⁴

¹Department of Biomedical and Health Informatics, School of Medicine, University of Missouri-Kansas City, Kansas City, MO; ²University of Missouri-Kansas City, Kansas City, MO; ³Children's Mercy Hospital, Kansas City, MO; ⁴Children's Mercy Hospital Kansas City, Kansas City, MO

Background. Wide-reaching health promotion interventions are needed in influential accessible community settings to address African American (AA) diabetes and CVD disparities. Yet, rarely are AA community members fully engaged the research process for improved intervention delivery and impact. Using a faith community engaged approach, this study examined feasibility and outcomes of Project Faith Influencing Transformation (FIT), a diabetes/CVD screening, prevention, and linkage to care intervention pilot study to increase weight loss in AA church-populations.

Methods. The urban Kansas City AA faith community identified diabetes/CVD as a priority health promotion focus with weight loss as the primary outcome. Faith leaders then assisted with FIT intervention development, implementation, and evaluation. Key multilevel, religiously-tailored church-based FIT intervention components included: a) self-help print materials (e.g., risk checklists, pledge cards); b) YMCA-facilitated group weekly weight loss classes; c) church service activities (e.g., sermons, responsive readings); and d) text/phone messages to promote healthy eating and physical activity. Six churches were matched/randomized to multilevel FIT intervention or a standard education control arms. At baseline and 8-months, health screenings were held during church services to identify participants at risk for diabetes/CVD, refer them to their church's weight loss class, and link them to needed health services. We assessed feasibility and outcomes with church liaisons' reports on intervention delivery and participants' weight loss and intervention exposure at 8 months.

Results. 352 church members and community members using the churches' outreach ministries were recruited. Participants (mean age=54, SD=13) were primarily female (67%). Most were overweight/obese (86%; mean BMI=33, SD=7.5). Trained church liaisons assisted with weight loss classes and delivered 2–3 FIT materials/activities/month, primarily print materials, text/phone messages, and responsive readings. Intervention participants were significantly more likely to achieve a ≥5-lb weight loss (OR=1.6; CI=1.24, 2.01) than controls at 8 months. Odds of intervention weight loss class participants achieving a ≥5-lb weight loss was 3.6 times more likely than controls (p<.07). Exposure to print materials, text/phone messages, sermons, and pledge cards was significantly related to ≥5-lb weight loss.

Conclusion. AA faith communities can feasibly assist in developing and increasing reach and impact of church-based diabetes/CVD health promotion interventions with intensive weight loss components among at-risk AA church-community populations.

METABOLIC SYNDEMIC: THE STRESS-DISEASE CONNECTION AMONG RURAL AFRICAN AMERICANS

Idethia Shevon. Harvey, DrPH¹, Rahma Mkuu, MPH², Tamika D. Gilreath, Ph.D.³

¹Texas A & M University, College Station, TX; ²Texas A&M University, College Station, TX; ³Texas A&M University, Houston, TX

Introduction: Mid-life racial and ethnic minorities have disproportionately higher rates of obesity-related chronic conditions compared to their racial counterparts. Conventional frameworks in public health often overlook the interactive effects of social, political, and ecological factors. Human social environments (i.e., social inequality) and socio-genic environmental conditions (i.e., hazards from the built environment) contribute to the clustering of disease. Syndemics theory posits that adverse psychosocial outcomes cluster to negatively impact health outcomes among vulnerable populations. This study uses a syndemic framework to examine disease–disease and social condition–disease interactions of hypertension and obesity among individuals diagnosed with type-2 diabetes.

Methods: Using a phenomenological study design, we interviewed African Americans (N = 27; average age = 65.1 years) with type-2 diabetes (average years of diagnosis = 15.9 years). Participant's demographics were collected and analyzed using descriptive statistics. Interviews were recorded and transcribed and then coded and analyzed using inductive content analysis.

Findings: Narratives were consistent with syndemics theory, indicating that individuals diagnosed with diabetes experienced magnified health-related and socio-environmental burdens. The main themes identified were 1) the intersectionality of co-morbidities and stress, and 2) chronicity of suffering and 3) socio-environmental influences on disease management. The study found that African Americans experience diabetes through a complex social and medical framework.

Conclusion: Using the syndemics approach for understanding the lived experiences of African Americans with type-2-diabetes contributed to a novel perspective of understanding etiologies and socio-environmental factors influencing their health. We propose that increasingly prevalent chronic diseases, like diabetes, which are closely associated with social disparities in health, may function as precursors to psychological and social suffering. A lack of social and economic resources not only discourages positive diabetes management, but may trigger the clustering of co-morbidities and complications.

SOCIODEMOGRAPHIC AND CLINICAL CORRELATES OF KEY OUTCOMES IN A MOBILE INSULIN TITRATION INTERVENTION FOR UNDERSERVED PATIENTS

Aisha T. Langford, PhD, MPH¹, Lu Hu, PhD², Binhuan Wang, PhD², Natasha Orzeck-Byrnes, BA², Erin Rogers, DrPH², Natalie Levy, MD²

¹NYU School of Medicine, New York, NY; ²NYU School of Medicine, New York, NY

Background: Insulin titration, is typically done face-to-face with a clinician. However, in-person titration can be a burden for patients due to transportation challenges, childcare needs, and lost wages from missing work. Our Mobile Insulin Titration Intervention (MITI) uses basic cell phone technology to help underserved patients with type 2 diabetes find their optimal basal insulin dose (OID), thereby removing the need for in-person clinic visits.

Objective: To evaluate sociodemographic and clinical correlates of reaching OID, text message response rate, and days needed to reach OID.

Methods: Primary outcomes for the present study included: (1) reaching OID (success vs. no success) defined as achieving the dose of once-daily basal insulin required to bring about either a fasting blood glucose (FBG) of 80–130 mg/dL or reaching the maximum dose of 50 units within 12 weeks, (2) having a 100% text message response rate or not, and (3) number of days needed to reach OID. Descriptive statistics were generated for sociodemographic and clinical correlates. Three multivariate regression models were performed. The first two models were logistic regressions to quantify relationships between various correlates and (1) reaching OID or not, and (2) having a 100% text response rate or not. The third model was a negative binomial regression to quantify the relationship between correlates and days needed to reach OID.

Results: The sample included 113 patients with a mean age of 50 years old (SD=10), 45% female, 79% Hispanic, 43% unemployed, and 46% uninsured. Approximately 59% of patients chose Spanish for their text language, while 41% chose English. Across the three regression models, only baseline FBG was significantly associated with the key primary outcomes. Specifically, higher baseline FBG was significantly associated with lower odds of reaching OID (OR=0.991, 95% CI: 0.984–0.999, p-value=0.03), lower odds of a 100% text message response rate (OR=0.993, 95% CI: 0.986–0.999, p-value=0.03), and more days needed to reach OID (RR=1.005, 95% CI: 1.002–1.008, p-value=0.0004). No sociodemographic correlates were associated with outcomes in the regression models.

Conclusions: Patients with higher baseline FBG levels were less successful across all outcomes and may need additional supports in future mHealth diabetes programs. None of the sociodemographic correlates were significant, suggesting that MITI is efficacious across diverse populations.

EARLY RESULTS OF A CULTURALLY-TAILORED DIABETES RISK REDUCTION INTERVENTION FOR HISPANIC WOMEN

Sonia Vega-López, Ph.D.¹, Nangel M. Lindberg, PhD², Michael C. Leo, PhD³, Mayra Arias-Gastélum, MS¹, Meagan Shaw, MS³, Katherine Vaughn, BA³, Elizabeth Shuster, MS³, Erin S. LeBlanc, MD, MPH³, Ann Turner, MD⁴, Victor J. Stevens, PhD³, Richard T. Meenan, PhD³, Sara Gille, MPH, PMP³

¹Arizona State University, Phoenix, AZ; ²Kaiser Permanente Northwest Center for Health Research, Portland, OR; ³Kaiser Permanente Center for Health Research, Portland, OR; ⁴Virginia Garcia Memorial Health Center, Hillsboro, OR; ⁵Kaiser Permanente - Center for Health Research, Portland, OR

Background: Hispanic women have the highest estimated risk of developing type 2 diabetes of all ethnic/gender groups in part due to high prevalence of overweight and obesity. Weight loss has become the first-line treatment for overweight diabetic and pre-diabetic patients to improve glycemic control and reduce cardiovascular risk.

Objective: To assess the effects of a culturally-tailored weight-loss behavioral intervention implemented at a Federally Qualified Health Center (FQHC) on weight and cardiovascular risk factors.

Methods: In this two-arm randomized control trial, 200 low-income Hispanic women (age=43.8 ± 10.1 y; weight=86.8 ± 16.5 kg; BMI=36.5 ± 6.5 kg/m²) with diabetes or elevated diabetes risk were randomized to *De Por Vida* or a usual care control group. *De Por Vida* is a 12-month group-based culturally-tailored weight loss intervention based on approaches from successful weight-loss trials with English-speaking populations. Usual care participants received printed materials. Changes in weight, A1c, and fasting blood glucose (FBG) and lipids from baseline to 6-months were compared between groups using generalized estimating equations.

Results: For participants with complete laboratory data (n=197), mean baseline concentrations were 6.5 ± 1.5% for A1c, 134 ± 45 mg/dL for FBG, 183 ± 94 mg/dL for triglycerides, 198 ± 40 mg/dL for total cholesterol, 111 ± 38 mg/dL for LDL, and 47 ± 12 mg/dL for HDL. There was a significant difference in weight loss from baseline to 6-months between arms (-2.9 kg, p<.001), with control participants going from 86.3 kg to 86.0 kg and intervention participants going from 87.2 to 84.1 kg. There were no significant differences in changes in A1c and FBG from baseline to 6-months (-0.18%, p=.24 and -2.0 mg/dL, p=.65, respectively). Though the difference between arms in change in fasting triglycerides from baseline to 6-months was not significant (-22.3 mg/dL, p=.09), the observed change was in the expected direction; control participants had an increase in triglycerides from 184 to 202 mg/dL, whereas intervention participants had a reduction from 181 to 177 mg/dL. There were no significant differences in the change from baseline to 6-months in total cholesterol (2.0 mg/dL, p=.77), LDL (0.3 mg/dL, p=.95) or HDL (1.9 mg/dL, p=.14).

Conclusion: *De Por Vida* has the potential to reduce diabetes risk in this underserved high-risk population in community health centers through achieving successful weight loss.

MEDIA BIAS IN U.S. NEWS COVERAGE OF HEALTH POLICY CONTROVERSIES AROUND THE EARLY DETECTION AND PREVENTION OF CANCER

Loren Saulsberry, PhD, Robert Blendon, ScD

Harvard TH Chan School of Public Health, Boston, MA

Background: Public health guidelines promoting the early detection and prevention of cancer are intended to inform health behaviors. Mass media filter information presented on public health practices, thus having a critical position in communicating health recommendations on the early detection and prevention of cancer. We investigate the political bias in U.S. news coverage of the 2009 USPSTF mammography guidelines and state HPV vaccination mandates.

Methods: We analyzed news content to determine the position towards these controversial cancer prevention practices expressed in print news. We compiled a dataset from Lexis Nexis Academic of 650 news articles and opinion pieces from 60 distinct U.S. newspapers on the 2009 USPSTF mammography guidelines and state HPV vaccination mandates debated from 2006–2008. Intercoder reliability met the criterion for Cohen's kappa of greater than or equal to 0.60. We standardized an ideological slant index for newspapers to measure political bias (i.e. conservative or liberal leaning), which categorized 28 newspapers as liberal-leaning and 32 newspapers as conservative-leaning.

Results: News coverage of the 2009 USPSTF mammography guidelines and state HPV vaccination mandates disproportionately mirrored the political attitudes aligned with that news outlet's political leaning. Liberal-leaning newspapers were slightly more likely than conservative-leaning newspapers to publish news supporting the mammography guidelines (22% vs. 17%), but these differences were not statistically significant ($X^2 = 1.23$, $p = 0.54$). Conservative-leaning newspapers (43%) were significantly more likely than reports published in liberal-leaning newspapers (22%) to convey an opposed position towards state HPV vaccination mandates ($X^2 = 9.32$, $p < 0.01$). The types of sources frequently authoring opinion pieces on both health policy controversies significantly differed between conservative-leaning and liberal-leaning newspapers. Researchers/academics were largely unrepresented among the authors of opinion pieces on both controversies.

Conclusions: Political positions towards debated health practices may not be evenly distributed across the media landscape. Working alongside potentially influential sources that differentially appeal to diverging political ideologies could assist in defining messages about health that resonate with multiple segments of the population. We conclude that policymakers and public health agencies that determine and communicate health recommendations may consider developing a political communication and media strategy, especially when government health authorities are involved in contentious health debates.

THE RELATIVE PERSUASIVENESS OF NARRATIVE VERSUS NON-NARRATIVE HEALTH MESSAGES IN PUBLIC HEALTH EMERGENCY COMMUNICATION

Mesfin Bekalu, PhD^{1,2} Cabral Bigman, PhD^{2,3} Rachel F. McCloud, ScD, MPH³, Leesha Lin, MPH⁴, K. Vish Viswanath, PhD¹

¹Harvard T.H. School of Public Health, Boston, MA; ²University of Illinois at Urbana-Champaign, Champaign, IL; ³Dana-Farber Cancer Institute, Barrington, RI; ⁴Harvard Chan School of Public Health, Boston, MA

Literature shows that narrative health messages are more effective than non-narrative messages in influencing health outcomes. However, this body of evidence does not account for differences in health domain, and little is known about the effectiveness of this strategy in other health domains. In this study, we examined the relative persuasiveness of narrative versus non-narrative message formats in public health emergency communication. Specifically, we examined the relative effectiveness of the two formats in influencing knowledge and perceptions related to pandemic influenza, and determined whether effects of message format vary across population sub-groups. Data for the study come from an experiment fielded in 2013 involving a nationally representative sample of 627 American adults. Participants were randomly assigned to view either a narrative ($n = 322$) or a non-narrative ($n = 305$) video clip containing closely matched information about knowledge and preventive actions related to pandemic influenza, and completed pre- and post-viewing questions assessing knowledge and perceptions related to pandemic influenza. Results indicated that participants in the non-narrative condition reported greater knowledge and rated pandemic influenza prevention measures as more effective compared with those in the narrative condition. Message format effects did not vary across population sub-groups; post-viewing scores of knowledge and perceptions related to pandemic influenza were consistently higher in the non-narrative condition compared with the narrative condition across five socio-demographic groups: age, gender, education, race/ethnicity and income. We concluded that didactic, non-narrative messages may be more effective than narrative messages to influence knowledge and perceptions during public health emergencies.

Paper Session 26: Social Media and Broadcast Messaging for Health 11:15 AM-11:30 AM

USING TARGETED FACEBOOK AND TWITTER CAMPAIGNS TO RECRUIT AFRICAN AMERICAN ADULTS INTO AN ONLINE ORGAN DONATION INTERVENTION

Nakeva Redmond, MPH¹, Carol Leighton, MBA BPharm², Hy Tran, MS³, Steven D. Binns, BSW, MPH⁴, Chris Kalb, N/A⁵, Kimberly J. Arriola, PhD, MPH⁶

¹Emory University, Rollins School of Public Health, Atlanta, GA; ²NORC at the University of Chicago, marina del rey, CA; ³NORC at University of Chicago, Chicago, IL; ⁴NORC at the University of Chicago, Forest Park, IL; ⁵NORC at the University of Chicago, Gulf Breeze, FL; ⁶RSPH of Emory University, Atlanta, GA

There is a need to increase public commitment to organ and tissue donation (OTD), particularly for African Americans (AAs) who are disproportionately represented on organ waitlists. Internet-based, behavioral interventions can be effective, however recruiting AAs for research studies poses unique challenges, particularly for stigmatized health topics such as OTD. The reach and accessibility of social media platforms offer a potentially low cost and efficient way of recruiting participants into interventions, yet developing targeted digital ads is relatively undefined for AA populations. This study tested the effectiveness of targeted Facebook and Twitter campaigns in recruiting AA adults into an online, OTD intervention.

Eligible participants were AA adults in Georgia (GA) who were not registered on the state donor registry. Data mining strategies were informed by previous studies noting altruism, educational attainment, and religion as correlates of AAs' decisions to donate. Facebook and Twitter accounts interacting with pages of historically Black colleges and large churches in GA were identified and used to create an initial target user list. A machine learning model was used to further target by age (18+), location (GA), language (English) and account activity (>20 tweets). A total of 40,000 Twitter and 100,000 Facebook accounts were included in the final targeted user list. Ad campaigns were deployed for a total of 60 days, and directly linked participants to the external study website.

The ad campaigns generated 154,060 impressions, 1,481 clicks and an overall cost of \$1000 (\$.68 per click). A total of 1,021 individuals completed the study eligibility screener, 482 were found eligible (47%) and 245 completed the study (51%). Ad costs averaged \$4.10 per eligible, consented participant who completed the study. The final study sample included 115 participants who indicated that they learned of the study from a personal referral, suggesting a social media network effect.

Our strategy in developing a targeted Facebook and Twitter user list and associated ad campaigns was cost efficient, and effective in recruiting eligible participants into our study. Easy message sharing on social media encouraged snowball recruitment among participants' social networks, and an added bonus of increased participation in our study. More research is needed to determine how to reach AAs about sensitive topics through social media-based recruitment strategies.

THE FEASIBILITY OF USING FACEBOOK TO OFFER SOCIAL SUPPORT TO AYA WITH SARCOMA AS PART OF A MOBILE-BASED PSYCHOSOCIAL INTERVENTION

Elizabeth Donovan, PhD¹, Couisneau M. Tara, PhD², Lonnie K. Zeltzer, MD³, Laura Payne, PhD⁴, Sarah Martin, PhD⁵, Laura Seidman, BS³, Meredith Trant, MSW⁵, Weiman Margie, RN, MSN⁶, Marla L. Knoll, MSW⁷, Joe Burton, N/A⁸, Noah Federman, MD⁹

¹Simmons College, Boston, MA; ²BodiMojo, Inc., Milton, MA; ³University of California, Los Angeles, Los Angeles, CA; ⁴David Geffen School of Medicine at UCLA, Los Angeles, CA; ⁵BodiMojo, Inc., Bedford, MA; ⁶Geffen School of Medicine at UCLA, Los Angeles, CA; ⁷UCLA Medical Center, Los Angeles, CA; ⁸Whil Concepts, Inc., San Francisco, CA; ⁹UCLA, Los Angeles, CA

There is an emerging interest in identifying and meeting the unique needs of adolescents and young adults (AYA) with cancer. Roughly 700,000 AYA are diagnosed with cancer each year in the United States, and the incidence in this cohort has increased steadily over the past 30 years. Recent work has documented significant levels of unmet needs among AYA with cancer, particularly psychosocial challenges during the transition to adulthood, (e.g., abrupt disruption to school and social life, and social isolation). Given that adolescents and young adults drive mobile app use, Facebook may be an ideal way to introduce a social support component to a mobile-phone based psychosocial intervention.

Participants: Seventeen AYA with sarcoma, 7% female; Mean age 19.1 years (range 13–24), recruited from UCLA Pediatric Bone and Soft Tissue Sarcoma Program.

Design and Methodology: A 28-day intervention was created. Organization of the Facebook group involved four steps: (1) Creating a schedule of varied and interactive daily content designed to elicit responses and promote social interaction between participants; (2) Recruiting an advisory board of two AYA cancer survivors to review content; (3) Recruiting a young adult cancer survivor to moderate the Facebook group; (4) Enlisting two research staff members (a clinician and a research associate) to monitor the Facebook group. The Facebook group was an accompaniment to a mobile-phone based mindfulness intervention, delivered through a mindfulness app (Whil Concepts, Inc.), which includes a program for youth called "Grow". Modifications to the existing content included creating a four-week "Mindfulness for Resilience in Illness" program, with 28 relaxation exercises, and the addition of videos featuring two sarcoma survivors as program hosts.

Main findings: Sixteen of 17 people in the group posted at least one reply to the moderator's prompts. On average, participants responded to about half (49.0%) of the moderator's prompts, ranging from 0%–96.8%. Daily response rate ranged from 23.5%–75.0% (average 49.9%). When asked "Would you recommend that this type of online social group be part of a future support program for youth with cancer?", 100% responded "yes." Participants also offered qualitative feedback about ways to improve future online social support programs for AYA.

Discussion: Facebook may be a feasible way to offer social support to AYA with sarcoma as a component of a mobile-based psychosocial intervention.

COST-EFFECTIVENESS OF YOGA FOR CHRONIC LOW BACK PAIN

Lin Liu, PhD¹, Laura Schmalzl, PhD², Erik Groessl, PhD³

¹UC San Diego, La Jolla, CA; ²Southern California University of Health Sciences (SCU), Seal Beach, CA; ³VA San Diego, San Diego, CA

Yoga interventions can improve function and reduce pain in persons with chronic low back pain (cLBP). Using data from a recent trial of yoga for military veterans with CLBP, we analyzed the incremental cost-effectiveness of yoga versus the study comparator. Participants (n=150) had been randomized to either 2x weekly, 60-minute yoga sessions for 12 weeks, or to a delayed treatment (DT) control receiving usual care. Outcomes were measured at 6 weeks, 12 weeks, and 6 months. Clinically meaningful improvement (CMI) was defined as a 30% improvement on the Roland-Morris Disability Questionnaire (RMDQ). Preference-based quality of life was measured using the EQ5D scale. Actual intervention costs including personnel, materials, and transportation were tracked during the study. Health care utilization and costs were estimated using self-reported use of back pain-related health services and adverse events. The analysis used a 1-year time horizon and a healthcare organization perspective. Outcomes were compared using a multivariable random effects model controlling for covariates. At 6-months, 43 (57%) yoga participants had a CMI compared with 18 (24%) of the DT group (p = 0.003). The yoga group had significantly greater increases in EQ5D scores than the DT group (mean change difference = 0.063; p = 0.047). Adjusting for lead-in effects and diminishing effects from 6- to 12 months, QALYs gained over 1 year were estimated as 0.041. Total intervention costs including estimated overhead were \$550 per yoga participant and \$85 per DT participant. Health care costs were assumed to be equal based on very similar utilization and AE data. The incremental cost-effectiveness ratios (ICERs) were \$1,395 per clinically improved patient at 6-months, and \$11,341/QALY over one year. To adjust for inflated intervention costs resulting from conducting an RCT in a limited timeframe, a sensitivity scenario estimated that costs for an ongoing yoga intervention could be delivered at about half the cost, or \$287/participant. In this scenario, ICERs are lowered to \$606 per clinical improvement at 6-months, and \$4,927/QALY. The results suggest that yoga, which is typically delivered in a group format, is a relatively low-cost intervention and has a favorable cost-effectiveness ratio. Using intent-to-treat data, yoga was delivered for about \$23 per session/participant and has been shown to produce equivalent benefits to physical therapy which is often reimbursed at \$100 per 60-minute session.

ACCEPTABILITY AND FEASIBILITY OF HATHA YOGA FOR CHRONIC PAIN IN PATIENTS RECEIVING OPIOID AGONIST TREATMENT

Lisa Uebelacker, PhD¹, Donnell Van Noppen, N/A², Ana Abrantes, Ph.D.³, M Stein, M.D.⁴

¹Brown University and Butler Hospital, Providence, RI; ²Butler Hospital, Providence, RI; ³Butler Hospital/Alpert Medical School of Brown University, Providence, RI; ⁴Boston University School of Public Health, Providence, RI

Chronic pain is a significant problem for more than half of people receiving opioid agonist treatment (OAT) for opioid use disorder (OUD). Given its efficacy in reducing pain interference or pain severity in other pain populations, hatha yoga may be a useful adjunctive treatment people taking OAT. In order to create a yoga program, we conducted 4 focus groups with people (n=24) enrolled in OAT. They provided feedback: they were interested in yoga as a way to cope with chronic pain, but any class should be very gentle and not more than one hour in length. We adapted existing yoga programs for pain to develop a manualized, 12-week hatha yoga class series to take place at the drug treatment program. The yoga was gentle and chair-based, with focus on slow meditative movements. We then conducted a pilot RCT of yoga (n=5) compared to a health education contact control (n=5) in a cohort of people receiving OAT. We compared our results to a priori benchmarks for feasibility and acceptability. We recruited 10 participants in 6 weeks, exceeding our target recruitment rate. We completed an endpoint assessment at 3 months on all 10 participants. There were no serious adverse events related to study participation. Self-report measures of credibility, acceptability, and satisfaction all exceeded pre-set cut-off for both conditions. However, we did not meet the benchmark set for class attendance – i.e., that 70% of participants would attend 8 out of 12 possible classes. In the yoga group, 2 of 5 participants met the target, whereas in the health education arm, 3 of 5 did. We used qualitative data to understand the reasons for poor attendance. In the yoga arm, one woman stopped attending class due to an exacerbation of back pain and subsequent fear of movement. A second person was unable to attend classes due to health problems such as influenza and gastrointestinal distress. The third person attended one class but then stated that yoga was not a good match for him, noting that he felt pain while engaging in some of the postures. In contrast, the two men who did attend class regularly expressed strong enjoyment of class, reported regular home practice, and had decreased pain interference or decreased pain severity. Thus, fear of pain may contribute to poor attendance at yoga classes in this population. We are modifying our intervention to address this concern in our next pilot RCT.

CHRONIC PAIN SYMPTOMS AND WELL-BEING IN MIDLIFE: EVIDENCE FROM THE NATIONAL LONGITUDINAL STUDY OF HEALTH AND WELL-BEING

Shin Ye Kim, Ph.D.¹, Ashley Neduveilil, B.S.², Yuki Shigemoto, M.A.³, Nancy A. Hamilton, Kansas⁴

¹Texas Tech University, Lubbock, TX; ²Texas Tech University, Irving, TX; ³Texas Tech University, Memphis, TN; ⁴University of Kansas, Lawrence, KS

More than 100 million Americans suffer from chronic pain, which is four times than people with diabetes and 10 times more than cancer patients (Institute of Medicine Report, 2010). Despite a large body of research suggesting that chronic pain is related to physical and psychological illness (Boonstra et al., 2013; Estevez-Lopez et al., 2015; McNamee & Mondolia, 2014), little is known about the longitudinal association between chronic pain and psychological health, including the impact of recurring symptoms of chronic pain on an individual's well-being. Likewise, little is known about the association between chronic pain and positive psychological functioning as well as the bidirectional relationship between the two.

This study aims to extend this line of research using two waves of national longitudinal data collected 9 to 10 years apart (Midlife Development in the United States (MIDUS)-II and III dataset). We tested three models: The cross-sectional relationship between chronic pain symptoms, well-being and psychological distress in MIDUS-III, second, longitudinal bidirectional effects of chronic pain symptoms on well-being and psychological distress, and third, the longitudinal relationship between recurring chronic pain symptoms at two time points 10 years apart and well-being. We included only participants who experienced pain in both time points. This resulted in 473 adults (61.1% women, 38.9% men). Ages ranged from 34 to 84 ($M = 56.34$, $SD = 10.71$) at MIDUS-II.

Multiple-group longitudinal structural equation modeling analyses revealed evidence for significant negative association of chronic pain symptoms and SWB and EWB. In addition, chronic pain symptoms at Time 1 were found to be a significant predictor of future EWB ($B = -.078$, $SE = .036$, $p = .030$). When examining the cross-lagged paths, significant negative associations were found between recurring pain and SWB at Time 2 for both gender ($B = -.086$, $SE = .024$, $p < .001$) and between recurring pain and EWB at Time 2 for women ($B = -.065$, $SE = .023$, $p = .004$). Recurring pain was also positively related to distress for both genders ($B = .094$, $SE = .027$, $p < .001$).

Findings suggest that chronic pain symptoms have a strong negative relationship to individuals enjoying life and perceiving that one has a meaningful life. Additionally, the experience of recurrent chronic pain symptoms at 2 time points is particularly detrimental to one's well-being. Implications for research and practice are discussed.

FREQUENCY, CONSISTENCY AND CORRELATES OF PHYSICAL ACTIVITY-RELATED PAIN WORSENING DURING MIGRAINE ATTACKS

Samantha G. Farris, Ph.D.¹, J. Graham Thomas, PhD², Ana Abrantes, Ph.D.³, Richard Lipton, Jelena Pavlovic, MD/PhD⁴, Todd Smitherman, PhD⁵, Megan Bennett. Irby, PhD⁶, Donald B. Penzien, PhD⁷, Julie Roth, MD⁸, Kevin C. O'Leary, MS⁹, Dale S. Bond, PhD¹⁰

¹Alpert Medical School of Brown University / The Miriam Hospital, Providence, RI; ²Brown University School of Medicine & The Miriam Hospital, Providence, RI; ³Butler Hospital/Alpert Medical School of Brown University, Providence, RI; ⁴Albert Einstein College of Medicine, Bronx, NY; ⁵University of Mississippi, University, MS; ⁶Wake Forest School of Medicine, Winston Salem, NC; ⁷Wake Forest School of Medicine, Winston Salem, NC; ⁸The Warren Alpert Medical School of Brown University, Providence, RI; ⁹The Miriam Hospital, Providence, RI; ¹⁰The Miriam Hospital/Brown Alpert Medical School Weight Control and Diabetes Research Center, Providence, RI

Background: Migraine is a neurological disease involving recurrent attacks of moderate-to-severe and often disabling head pain. Worsening of pain with routine physical activity (PA) during attacks is a migraine defining symptom; however, the frequency, individual consistency, and correlates of this symptom are unknown. Given potential of this symptom to undermine daily PA and exercise participation, an effective migraine prevention strategy, further research is warranted. The current study is the first to prospectively evaluate 1) frequency and individual consistency of PA-related pain worsening during migraine attacks, and 2) potential correlates, including other migraine symptoms, anthropometric characteristics, psychological symptoms, and daily PA.

Methods: Participants were women ($n=132$) aged 18–50 years with neurologist-confirmed migraine and overweight/obesity ($BMI=25.0–49.9$ kg/m²) seeking treatment to lose weight and reduce their headaches in the Women's Health and Migraine (WHAM) trial. At baseline, participants used a smartphone diary to record migraine attack occurrence, severity, and symptoms (i.e., worsening of pain with activity, photophobia, phonophobia, and nausea) for 28 d. Participants also completed questionnaires and 7 d of objective PA monitoring before and after diary completion, respectively. Patterning of PA's effect on pain was summarized within-subject by calculating the proportion (%) of attacks in which PA worsened, improved, or had no effect on pain.

Results: Participants reported 5.5 ± 2.8 (mean \pm SD) migraine attacks over 28 d. The intraclass correlation coefficient ($ICC=.71$) indicated high consistency in participants' report of PA-related pain worsening or not. On average, PA worsened pain in $34.8 \pm 35.6\%$ of attacks, had no effect on pain in $61.8 \pm 34.6\%$ of attacks and improved pain in $3.4 \pm 12.7\%$ of attacks. Few participants (9.8%) reported PA-related pain worsening in all attacks. Attacks where PA worsened pain were associated with more severe nausea, photophobia, phonophobia, and allodynia ($r^2=.18-.22$, $p's<.05$). Pain worsening due to PA was not related to psychological symptoms or total daily PA.

Conclusions: There is large variability in the impact of PA on pain during migraine attacks that can be accounted for by individual differences. For a minority of participants, PA consistently contributed to pain worsening. More frequent PA-related pain worsening was related to greater severity of other migraine symptoms and pain sensitivity, which supports the validity of this diagnostic feature.

POTENTIAL BENEFITS OF MIND-BODY PRACTICES FOR COLORECTAL CANCER: PRELIMINARY RESULTS FROM A RANDOMIZED-CONTROLLED TRIAL

Rainbow T. H. Ho, Prof¹, Adrian Wan, PhD Candidate²

¹Centre on Behavioral Health, The University of Hong Kong, Hong Kong, N/A, Hong Kong; ²The University of Hong Kong, Hong Kong, N/A, Hong Kong

Background: Depression and anxiety symptom are risk factors to psycho-social-spiritual well-being of cancer survivors. Mind-body practices, such as mindfulness-based stress reduction program and Qigong practice have reported potential benefits in alleviating depressive and anxiety symptoms. This study explores the comparative benefits of a mindfulness-based self-compassion training and a qigong training in improving depressive and anxiety symptoms of colorectal cancer. This study presented the preliminary results of an ongoing study of colorectal cancer patients.

Methods: The present study adopts a randomized-controlled trial study design. Participants are colorectal patients diagnosed of Stage I, II, III and non-metastatic colorectal cancer, who had completed primary treatment at least 6 months ago, but not more than 5 years. Participants were randomly assigned to a mindfulness group, qigong group, and a wait-list control group. All participants surveyed on an inventory of depressive symptoms at baseline and 8 weeks later. A total of 54 participants had completed the study in this ongoing study.

Results: Primary data analysis reported significant *Time x Group* difference between the three conditions. Post-hoc repeated measures ANOVAs demonstrated the 8-week mindfulness-based self-compassion training has a statistically significant effect on depressive symptoms with compared with the control ($F(1, 38) = 4.47, p \leq .05$), as well as with the banduanjin group ($F(1, 33) = 4.98, p \leq .05$); and that the mindfulness-based self-compassion training reported the most reduction in depressive mood among the three groups. However, the preliminary data reported no significant *Time x Group* difference on the measure of anxiety ($F(2, 49) = .70, p = .499$).

Conclusions: Preliminary data suggested that both mindfulness-based self-compassion training and qigong practice are effective in reducing depressive symptoms of colorectal cancer survivors, when compared with the wait-list control. However, their effectiveness in improving anxiety symptoms remained inconclusive. This ongoing study targets to recruitment a total of 198 colorectal cancer survivors, with a larger sample size this study will contribute to our knowledge in psycho-social intervention in the field of psycho-oncology.

BRIEF STRESS MANAGEMENT INTERVENTIONS REDUCE RAGE-ASSOCIATED S100A8/A9 LEVELS IN BREAST CANCER PATIENTS

Chloe Taub, M.A.¹, Hannah M. Fisher, B.S.¹, Erica R. Nahin, B.A., B.S.¹, Bonnie B. Blomberg, Ph.D.², Marc E. Lippman, MD³, Barry I. Hudson, PhD³, Alain Diaz, Ph.D.⁴, Suzanne Lechner, PhD⁵, Tae Kyoung Kwak, PhD³, Gyong Ha Hwang, B.S.³, Charles S. Carver, PhD¹, Michael H. Antoni, PhD¹

¹University of Miami, Coral Gables, FL; ²University of Miami Miller School of Medicine, Miami, FL; ³University of Miami, Miami, FL; ⁴University of Miami School of Medicine, Miami, FL; ⁵University of Miami Miller School of Medicine, Coral Gables, FL

INTRODUCTION. Women undergoing treatment for breast cancer often experience heightened inflammation and increased inflammation has been linked to poorer disease outcomes. The s100 protein family plays an important role in the inflammatory response through interaction with the receptor for advanced glycation end products (RAGE), and has been identified as a biomarker for breast cancer due to associations with tumor development and metastasis. Prior work has demonstrated the ability of stress management interventions to reduce levels of leukocyte inflammatory gene expression and circulating cytokines in women undergoing treatment for breast cancer; however, the impact of such interventions on s100A8/A9 has yet to be examined.

METHODS. Breast cancer patients (Stage 0 – IIIb) who were 4 – 10 weeks post-surgery but had not yet started adjuvant therapies (mean age = 54.28) were enrolled and randomized to one of three 5-week intervention conditions: cognitive behavioral training (CB), teaching cognitive restructuring and interpersonal skills; relaxation training (RT), teaching muscle relaxation, deep breathing, and imagery exercises; or attention-time matched health education control (HE). At baseline and at 12-months follow-up, 121 women provided blood samples from which s100A8/A9 levels were determined by ELISA. We hypothesized that participants assigned to either the CB (N = 41) or RT (N = 36) condition (CBRT) would show significant decreases in s100A8/A9 over the first year of primary treatment compared to the HE (N = 44) condition.

RESULTS. A 2 (Condition: CBRT, HE) by 2 (Time: T1, T4) general linear model repeated measures analysis controlling for age, stage of cancer, time since surgery, chemotherapy treatment, and radiation treatment revealed a significant effect of condition on s100A8/A9 levels from T1 to T4, $F(6, 114) = 4.363, p = .039$, with s100A8/A9 in CBRT reducing over time compared to HE.

CONCLUSION. These results suggest that brief group-based stress management programs teaching either cognitive behavioral or relaxation techniques may reduce levels of the RAGE-associated s100A8/A9 ligand in women with breast cancer during the first 12 months of primary treatment. Future work should investigate how changes in this biomarker in the present cohort relate to longer-term disease outcomes.

EFFECTS OF PHYSICAL ACTIVITY ON QUALITY OF LIFE IN YOUNGER VS OLDER BREAST CANCER SURVIVORS: ROLES OF COGNITION AND MENTAL HEALTH

Diane Ehlers, PhD¹, Susan Aguiñaga, PhD², Josh Cosman, PhD³, Joan Severson, MS⁴, Arthur Kramer, PhD⁵, Edward McAuley, PhD⁶

¹University of South Carolina, Columbia, SC; ²University of Illinois at Urbana-Champaign, Aurora, IL; ³Pfizer Inc., Cambridge, MA; ⁴Digital Artefacts, Iowa City, IA; ⁵Northeastern University, Boston, MA; ⁶University of Illinois at Urbana-Champaign, Urbana, IL

In the present study, we examined the roles of cognitive function and mental health along the pathway from physical activity to global quality of life (QoL) in younger (less than 60 years-old) versus older (60+ years-old) breast cancer survivors (BCS). We hypothesized a direct effect of physical activity on cognitive function and indirect effects of physical activity on mental health and QoL.

BCS (n=167 young, M age=50.92 \pm 6.85 years; n=133 old, M age=65.92 \pm 4.58 years) wore an accelerometer for seven consecutive days to measure their physical activity and completed iPad-based cognitive tests and questionnaires assessing their executive function (Flanker incongruent reaction time, Mazes drawing time, Task-Switch switch reaction time, Trails B time), demographics, breast cancer history, mental health (Hospital Anxiety and Depression Scale, Pittsburgh Sleep Quality Index [daytime dysfunction]), and QoL (Functional Assessment in Cancer Therapy–Breast [FACT-B], Satisfaction with Life Scale [SWLS]). Structural equation modeling was used to create latent factors representing executive function and mental health and to compare the hypothesized pathway from physical activity to QoL between young and old BCS. Models were adjusted for overweight/obesity status and months since diagnosis.

In the full sample, more daily minutes of moderate-to-vigorous physical activity (MVPA) were associated with faster performance on executive function tasks ($\beta=-.21, p=.003$), which was associated with greater mental health ($\beta=.21, p=.01$). Greater mental health was, in turn, related to greater QoL on the FACT-B ($\beta=.93, p<.001$) and SWLS ($\beta=-.75, p<.001$). Further, the indirect effects of MVPA and executive function on FACT-B and SWLS were significant (all $p<.04$). The indirect effect of MVPA on mental health was also significant ($p=.04$). However, when comparing age groups, effects were evident in young BCS only. Among older BCS, only the direct pathways from mental health to FACT-B ($\beta=-.91, p<.001$) and SWLS ($\beta=-.76, p<.001$) were significant.

Physical activity interventions targeting cognitive function may also confer mental health and global QoL benefits in younger BCS. However, as the vast majority of BCS are ≥ 60 years-old and likely facing age- and cancer-related symptoms, further efforts are needed to: (1) understand the long-term trajectory of QoL in BCS; (2) identify factors that explain differences observed between age groups; and (3) test physical activity interventions aimed at improving cognitive function, mental health, and QoL in BCS.

SUBSTANCE ABUSE AS A MODERATOR OF NEUROCOGNITIVE FUNCTIONING IN OLDER ADULTS WITH HIV

Laurel Weaver, MA¹, H. Jonathon Rendina, PhD, MPH², Brett M. Millar, PhD³, Jeffrey T. Parsons, PhD²

¹Graduate Center of the City University of New York (CUNY), New York, NY; ²Hunter College of the City University of New York (CUNY), New York, NY; ³Graduate Center CUNY, New York, NY

Substance Abuse as a Moderator of Neurocognitive Functioning in Older Adults with HIV

Background: As HIV treatments continue to improve, people with HIV are living longer, healthier lives. However, HIV-associated neurocognitive disorders (HAND) remain a common health burden, and disentangling the precipitating and perpetuating factors of HAND – specifically, the role of substance abuse – presents a complex challenge for research. The present study aims to explore the association between substance abuse and neurocognitive functioning in older adults with HIV.

Method: A total of 107 older (≥ 50 years of age) HIV-positive adults with chronic drug and alcohol issues completed neuropsychological testing as well as self-administered surveys. Digit Span Forward (DF) and Backward (DB) tasks assessed working memory, and D-KEFS Trails 2–4 (number and letter sequencing tasks) measured cognitive flexibility. Drug and alcohol disorders were evaluated with the Drug Abuse Screening Test (DAST) and the Alcohol Use Disorders Identification Test (AUDIT), respectively.

Results: The sample had a mean age of 54.8 ($SD=4.1$) and was largely comprised of unemployed (83.5%), low-income (82.5%) men (67.0%) of color (90.3%). On average, participants had been living with HIV for 17 years ($SD=7.1$). Bivariate analyses revealed correlations between AUDIT and DB scores ($r = -.20, p = .05$), while DAST scores correlated with DF scores ($r = -.21, p = .03$) and number sequencing errors ($r = -.22, p = .02$). When adjusting for demographic covariates and the other neuropsychological test scores, regression analysis showed continued, independent effects of DF scores ($\beta = -.26, p = .03$) and number sequencing errors ($\beta = -.25, p = .03$) on DAST scores, while the impact of DB scores on AUDIT were no longer significant.

Conclusions: These results suggest that substance abuse is highly interrelated with neurocognitive impairment in aging HIV-positive adults. More severe alcohol problems were associated with poorer DB performance, whereas more severe drug problems were associated with lower DF recall, indicating that different substances may differentially affect executive functioning domains. This study adds to growing evidence that substance abuse is related to neurocognitive decline, but future research is needed to measure the nature and magnitude of this relationship. Improved understanding of the association between substance abuse and neurocognitive impairment in aging HIV-positive adults will ultimately help facilitate improved prevention and treatment strategies for HAND.

Life expectancy for people living with HIV has increased because of highly effective antiretroviral medications. The long-term effects of these medications and inflammatory changes associated with HIV infection in older adults result in cellular changes that can impact physical performance and neurocognitive function. This analysis explored cross-sectional predictors of neurocognitive function (NCF) and physical function (PF) among Black and non-Black women 50 years and older. Based on the Socio-Ecological Model, multiple analytic procedures were conducted. Bivariate regression analyses of NCF and PF included: age, history of sexual abuse, social isolation, socio-economic status, depressive symptoms, substance use, alcohol use, and social support. PF was measured using the Lawton Instrumental Activities of Daily Living (IADL) scale. NCF was measured using a battery of eight tests. The sample comprising these analyses included: 612 HIV women (HIV+, n=440; 231 Black, 209 non-Black) and at-risk HIV- (n = 172; 110 Black, 62 non-Black). Blacks who were HIV+ had slightly higher mean PF scores, but they were not statistically significant. HIV+ Black women demonstrated poorer verbal learning and memory compared to HIV+ non-Blacks (30.22 vs 28.30, $p < .05$). No direct associations were found between key predictors and the PF and NCF outcomes. Among Blacks who were HIV+, number of comorbidities, and substance use contributed to limitations in PF yet accounted for only 4% of the variance. Black women who reported being isolated ($\beta = -0.01$) and drinking more alcohol ($\beta = -0.006$; interaction: $\beta = 0.002$, $p < .05$) had worse IADL. In terms of NCF, among Black HIV+ women, substance use predicted verbal ability ($\beta = -10.7$), working memory and attention ($\beta = -4.89$), psychomotor speed and information processing ($\beta = -1.79$) and reading level and learning ability ($\beta = -11.01$). Alcohol use was associated with attention and executive function ($\beta = -.001$, $pp = .05$). While findings were inconclusive among HIV- women, significant associations were observed in HIV+ women. Among this group of aging HIV+ Black women, substance and alcohol use, depressive symptoms, current smoking, and number of comorbidities are important considerations when designing behavioral interventions to maximize overall physical and neurocognitive functional abilities.

LIFESTYLE MODIFICATION AND NEUROCOGNITION: EXAMINING THE INFLUENCE OF NORADRENERGIC FUNCTION

Patrick J. Smith, PhD, MPH¹, Andrew Sherwood, PhD¹, Alan Hinderliter, MD², James Blumenthal, PhD¹

¹Duke University Medical Center, Durham, NC; ²UNC-CH, Chapel Hill, NC

Background: Cardiovascular risk factors (CVRF) have been associated with increased risk of cognitive impairment, with particularly detrimental effects on tests of frontal lobe functioning (e.g. Executive Function and Working Memory).¹ Although CVRF are believed to increase risk of cognitive impairment through microvascular damage, many individuals with elevated microvascular burden do not develop impairments, suggesting that additional, indirect neural mechanisms may play an important role in maintaining cognitive health. Central nervous system catecholamine levels are strongly associated with cognition,² integrally tied to frontal lobe structures adversely impacted by CVRF, and correlate with cognitive changes following pharmacotherapy.³ We therefore examined the associations between CVRF, catecholamines, and cognitive function in a previously published randomized trial consisting of 133 middle-aged, overweight or obese adults with CVRF participating in a 6-month lifestyle intervention.^{4,5}

Methods: Participants with high blood pressure were randomized to Weight Management (WM, n = 55), Exercise (EX, n = 54), or a Usual Care control (UC, n = 24). Prior to randomization and again following 6-months of treatment, participants underwent testing of Executive Function (Trail Making Test and Digit Symbol Substitution Test) and Working Memory (Digit Span Forwards and Backwards); additional assessments included CVRF using the American Heart Association 10-year ASCVD risk score and 24-hour urinary assessment for catecholamines including dopamine (DA) and norepinephrine (NE). Statistical analyses controlled for age, gender, ethnicity, education, and body surface area (catecholamines only).

Results: Greater baseline CVRF ($\beta = -0.24$, $P = .007$) and higher NE ($\beta = -0.21$, $P = .024$) were associated with poorer Executive Function, and greater CVD risk was associated with higher NE ($\beta = 0.20$, $P = .031$). In addition, greater BMI levels were associated poorer Working Memory ($\beta = -0.18$, $P = .036$), higher DA ($\beta = -0.31$, $P < .001$), and tended to be associated with higher NE ($\beta = -0.14$, $P = .073$). Participants in the WM and EX groups showed reductions in CVRF, which were associated with decreased NE ($\beta = -0.19$, $P = .047$). Although we did not observe a treatment main effect for cognitive performance,⁵ the effects of treatment on Working Memory were moderated by baseline NE levels ($P = .008$), such that participants with higher NE experienced additive benefits in the WM and Ex groups experienced compared with Usual Care (Figure 1). In addition, improvements in Working Memory were associated with reduced peripheral levels of DA ($\beta = -0.13$, $P = .038$) and tended to be associated with reduced SBP ($\beta = -0.12$, $P = .070$).

Conclusions: Peripheral catecholamine levels are associated with both CVRF and cognitive function. Improvements in cognitive function following lifestyle modification may depend on baseline levels of catecholamines.

PERSONALIZED MEDICATION ADHERENCE DIGITAL INTERVENTIONS

Syed Haider, PhD¹, Hongda Shen, PhD²

¹Johnson & Johnson, New Brunswick, NJ; ²Johnson and Johnson Health and Wellness Solutions, New Brunswick, NJ

Care4Today® Mobile Health Manager is a commercial medication management mobile app developed by Janssen Healthcare Innovation part of Johnson & Johnson Health and Wellness Solutions. It's been commercially available for four years and generated enormous amount of users' medication adherence data. There are 124,742 registered users globally with reminders for 525,552 medications. The application delivered digital interventions, Behavior Change Techniques (BCTs), viz., Action Planning, Prompt-Cues, Social Support Incentive, and Social Support Reward.

We selected last six months of data in the app, which included 6,694 medications for 1,524 patients with a total number of 721,964 records for analysis. The data includes user interactions with the app, and the medication adherence behavior, a sequence of "taken" or "missed" over time. It's worth noting that some BCTs are optional while the others are mandatory. Among optional BCTs, we find adherence behaviors of users with family support is statistically different from that of users without.

Our interest is to Personalize the BCT's to create a broader impact. Therefore, we have used Machine Learning techniques to discover patterns of behaviors, and their relation to BCT exposures and the determinants of behaviors. Unsupervised learning technique is applied on the features, such as basic statistics, polynomial-fit coefficients, and wavelet coefficients derived from adherence behavior to discover subgroups of users. In each subgroup, we look for insights about users' medication adherence and the performance of BCTs. With these insights, we inform the product design and tailor BCTs to target subgroups to improve the behavior.

In addition to pattern analysis, we developed a predictive model using Random Forest Classifier to predict the outcome of next dose, whether missed or taken. We achieved over 0.9 AUC score with bootstrapping. The advantage of predicting a potential miss, in advance, will help us to maximize health outcome by adapting intervention in time. Additionally, we are also building causal model to understand the determinants of poor adherence behavior using Big Data technology.

Overall, the research aims at using machine learning techniques to build a data-driven health behavior advanced analytic loop. We will continue to develop further by leveraging well established statistical techniques and new machine learning algorithms, including deep learning.

Paper Session 30: Towards Precision Behavioral Medicine: Advancing Analytic Techniques 11:00 AM-11:15 AM

ANALYSIS OF A HYPERTENSION BEHAVIORAL TRIAL INCORPORATING NEWLY RECOMMENDED MISSING DATA METHODS

Stephanie Rettig, MPH¹, Sundar Natarajan, MD, MSc², Binhuan Wang, PhD¹

¹NYU School of Medicine, New York, NY; ²VA NY Harbor Healthcare System, New York, NY

Background: Missing data, a common issue in clinical trials, can compromise study inferences. In order to obtain valid conclusions, it is important to use appropriate missing data methods in the analysis. Recently, formal recommendations on analysis have been disseminated but few behavioral trials report results using them.

Purpose: To use recommended missing data methods to analyze a 3-arm randomized controlled trial that evaluated two behavioral interventions among patients with uncontrolled blood pressure (BP).

Methods: We compared the effectiveness of the behavioral stage-matched intervention (SMI) or a non-tailored health education intervention (HEI), to the usual care (UC) group with the traditional complete case method, and two missing data methods: missing at random using multiple imputation and sensitivity analysis using a pattern mixture model. The outcome measures were systolic BP (SBP) or BP control. Since we were comparing 2 interventions, the Bonferroni-corrected p-value to achieve statistical significance was 0.025.

Results: A total of 533 subjects were randomized in this study: 176 in SMI, 180 in HEI, and 177 in UC. At the 6-month follow-up, there were 22 missing values for the outcome measure in SMI, 12 in HEI, and 18 in UC. Compared to UC, SMI led to a lower SBP at 6 months by 3.51 mmHg (CI -6.16, -0.87) for the complete-case analysis ($p = 0.0093$), by 3.28 mmHg (CI -6.26, -0.31) using the missing at random by multiple imputation ($p = 0.0310$) and by 3.52 (CI -6.20, -0.84) for the pattern mixture model ($p = 0.0101$). The odds of having better BP control at 6 months were significantly greater in SMI compared to UC with an odds ratio (OR) of 2.16 (CI 1.39, 3.35) for the complete case ($p = 0.0008$), OR 2.32 (CI 1.52, 3.54) for missing at random by multiple imputation ($p = 0.0001$) and OR 2.02 (CI 1.32, 3.09) for the pattern mixture model ($p = 0.0013$). HEI did not lead to lower SBP or have better BP control at 6 months compared to UC using the complete-case analysis, the missing at random by multiple imputation or using the pattern mixture model (all p-values > 0.025).

Conclusions: The traditional complete-case analysis and the recommended missing data methods, the missing at random by multiple imputation and pattern mixture model are valuable complementary approaches for analyzing missing data in clinical trials. Missing data methods should be utilized more frequently within clinical trials in order to provide robust study inferences.

Paper Session 30: Towards Precision Behavioral Medicine: Advancing Analytic Techniques 11:15 AM-11:30 AM

USING NATURAL LANGUAGE PROCESSING TO UNDERSTAND THE ANTECEDENTS OF BEHAVIOR CHANGE

April Carcone, PhD¹, Alexander Kotov, PhD², Mehedi Hasan, MI², Ming Dong, PhD², Susan Eggly, PhD³, Kathryn Hartlieb, PhD⁴, Gwen Alexander, PhD⁵, Mei Lu, PhD⁵, Sylvie Naar, PhD⁶

¹Wayne State University School of Medicine, Detroit, MI; ²Wayne State University, Detroit, MI; ³Wayne State University/Karmanos Cancer Institute, Detroit, MI; ⁴Florida International University, Miami, FL; ⁵Henry Ford Health System, Detroit, MI; ⁶Florida State University, Royal Oak, MI

Motivational Interviewing (MI) is a communication framework to increase intrinsic motivation for behavior change. There is strong empirical evidence linking patient motivational statements (i.e., “change talk”) to behavior change. A growing evidence base supports the link between “MI-consistent” provider behaviors and patient change talk, but the specific provider behaviors responsible for the elicitation of patient change talk are less clear. The Minority Youth Sequential Coding of Process Exchanges (MYSCOPE) is a code scheme to characterize communication during MI. MYSCOPE coding is iterative and resource-intensive; thus, its utility is limited. Rapid development of artificial intelligence techniques (e.g., machine learning) allows the automation of time-consuming cognitive tasks, such as behavioral coding. We examined the feasibility of machine learning-based classification models to identify communication behaviors in 38 transcribed audio-recordings from weight loss counseling sessions with African American adolescents with obesity and their caregivers. Eight models were tested and the Support Vector Machines (SVM) model demonstrated the best performance in recognizing MYSCOPE behaviors based on lexical features with 70.8% accuracy (%correct/all codes), 70.5% precision (%correct within code), and 70.8% recall (true positive rate) of adolescents’ statements. Analysis of caregiver statements was similar at 66.4% accuracy, 65.3% precision, and 66.4% recall. The addition of contextual (previous code) and semantic (Linguistic Inquiry and Word Count dictionaries) features improved model performance to 75.1% accuracy, 75.0% precision, and 74.2% recall of adolescents’ statements and 73.8% accuracy, 73.3% precision, and 73.8% recall of caregivers’ statements, accuracy comparable to that of human coders ($k_{SVM}/human=.696-.715$ vs $k_{human}/human=.696$). We then validated the model using a data set composed of 80 medical encounters with young adults with HIV. The HIV model achieved 68.8% accuracy, 66.3% precision, 68.8% recall, and $k_{SVM}/human=.628$ vs $k_{human}/human=.715$. Limitations of the HIV validity sample included a smaller data set (i.e., fewer model training examples) and semantic differences between weight loss counseling sessions and HIV medical care visits. These findings demonstrate the utility of machine learning-based classification models to perform the complicated cognitive task of behavioral coding. This technology has the potential to dramatically accelerate the pace of behavioral science research to test intervention theory and improve clinical efficacy by facilitating intervention tailoring to discrete populations. Ultimately, these methods could greatly extend the reach of behavioral medicine via automated, real-time counseling.

Paper Session 30: Towards Precision Behavioral Medicine: Advancing Analytic Techniques 11:30 AM-11:45 AM

REVEALING MEANINGFUL ENGAGEMENT IN MHEALTH INTERVENTIONS USING MACHINE LEARNING

Angela F. Pfammatter, PhD¹, Robert Bell, Senior Undergraduate (B.S. in Electrical Engineering)², Nabil Alshurafa, PhD³, Bonnie Spring, PhD³

¹Northwestern University Feinberg School of Medicine, Chicago, IL; ²Northwestern University, Evanston, IL; ³Northwestern University, Chicago, IL

Decreased engagement with mHealth interventions over time is a significant barrier to sustained behavior change effects. While increasing and maintaining engagement over time has received much attention, the hallmarks of what constitutes effective engagement have not been clearly defined. Technology has advanced as of late such that participant behaviors such as opening an application, clicking a button, entering information, and use time can be tracked and analyzed to gain further insight into how and when participants use an app. Further, these actions over time can be linked to outcomes so as to define patterns of what could be considered effective engagement. The NUYou trial recruited 303 freshmen who were asked to use a smartphone application designed to promote and improve 4 health behaviors. Participants were randomized to a cardiovascular health (CVH) group focused on smoking, physical activity, weight, and diet or a whole health (WH) group focused on hydration and sun, sex, and travel safety. The app asked participants about their level of their target behaviors as well as stress and happiness on a weekly basis. For the purpose of defining patterns of engagement, we analyzed 26 consecutive weeks of app use for all participants. Results of unsupervised k-means clustering of weeks of use indicated that 7 distinct weekly time series patterns emerge which generally centered around a primary day of week use. Clustering of app use demonstrated stark differences between groups, thus, for the purpose of defining effective engagement, the CVH group was analyzed. 4 clusters of participants emerged: healthy and steady; unhealthy and steady; decliners, and improvers. Clusters that were more behaviorally static had higher density of short interventions (49% and 51% of participants in healthy steady and unhealthy steady, respectively) compared to the more variable clusters (38%). Those clusters exhibiting more positive health behaviors used the app approximately 2 more times per week than the clusters that did not. Improvers demonstrated a pattern of engagement with high overall use ($M=17.49$ seconds) where interaction times were longer per use (7–61 seconds per use) compared to the declining cluster that had high overall use ($M=18.06$ seconds) but with interaction times shorter per use (0–7 seconds per use). This is indicative of a pattern consistent with use spent more in reviewing information or feedback on the app, rather than simply checking, glancing, or brief self-monitoring as more conducive to positive behavior change. These results suggest that total app use time is not a reasonable target for interventions, but rather reviewing progress or reflecting on feedback is an important mediator of proximal behavior change. These findings will be discussed as having important implications for passive sensing technologies and design of mHealth interventions.

Panel Discussion 16 12:45 PM-1:45 PM**HARNESSING DESIGN THINKING TO ENHANCE BEHAVIORAL INTERVENTIONS**

Molly L. Tanenbaum, PhD¹, Jessica Y. Breland, PhD², Myra Altman, PhD³, Sara F. Krugman, MA, BA⁴, Bryan Gibson, DPT, PhD⁵, Leah Yingling, BS⁵, Lisa S. Miller, PhD⁶, Olga Perski, BSc, MSc⁷, Korey K. Hood, PhD¹

¹Stanford University School of Medicine, Palo Alto, CA; ²VA Palo Alto Health Care System, Menlo Park, CA; ³Stanford University, San Francisco, CA; ⁴sarakrugman.com, Oakland, CA; ⁵University of Utah, Salt Lake City, UT; ⁶University of California, Davis, Davis, CA; ⁷University College London, London, England, United Kingdom

Design Thinking, often called “user-centered design”, is a powerful way to build innovative health interventions and improve existing ones. Design Thinking is a human-centered, iterative approach that conceptualizes users as experts in their own experience and engages potential users from inception to development and testing to ensure that the end product (e.g., behavioral intervention, mobile app) will be acceptable, useable, and engaging. As such, Design Thinking methods - such as empathy building, ideating, and prototyping - can help improve effectiveness and extend the reach of evidence-based behavioral interventions by promoting the development of interventions that are based on what users want and need. While elements of Design Thinking have conceptual and methodological overlap with qualitative methods, quality improvement and other research approaches, Design Thinking methods provide a unique user-centered approach that is underused in the development of health interventions.

This panel of behavioral scientists and designers will help attendees consider how to incorporate Design Thinking methods into the development of digital and analog interventions. First, panelists will define Design Thinking and present results from a systematic review on the added value of applying Design Thinking methods in health interventions. We will then provide four examples of Design Thinking in action: 1) an academic-design partnership to create an evidence-based mHealth tool to increase uptake of technology for type 1 diabetes; 2) the process of identifying and interviewing end-users and experts beyond the academic sphere to refine and test a nutrition literacy e-tool; 3) the multi-method design and development of a technology-based type 2 diabetes self-management intervention; and 4) the use of Design Thinking to promote increased user engagement with a smartphone app for alcohol reduction. In the second half of the session, a moderated discussion will address challenges, recommendations and potential points of collaboration between designers and behavioral scientists to advance the development of interventions that are simultaneously user-centered and evidence-based. Attendees will also have the opportunity to ask questions and troubleshoot their own health-related Design Thinking challenges.

Panel Discussion 18 12:45 PM-1:45 PM**NOVEL USES OF DECISION SUPPORT TOOLS FOR PATIENTS AND CLINICIANS: BLENDING HEALTH TECHNOLOGY AND HEALTH COMMUNICATION**

Aisha T. Langford, PhD, MPH¹, Tannaz Moin, M.D., M.B.A., M.S.H.S.², Margaret M. Byrne, PhD, MS³, Jamie L. Studts, PhD⁴

¹NYU School of Medicine, New York, NY; ²David Geffen School of Medicine at UCLA, Los Angeles, CA; ³Moffitt Cancer Center, Tampa, FL; ⁴University of Kentucky College of Medicine, Lexington, KY

Chair. The chair will give a brief overview about decision support tools and how they can be used to promote (1) informed decision making -- equipping patients with accurate, unbiased information needed to make health decisions, and (2) shared decision making -- patients and clinicians working together to make health decisions. The chair will also discuss the emerging role of health technology in supporting health decision making.

Presenter #1. In a practice level, cluster-randomized, intention-to-treat trial in one large academic health system, we tested the effectiveness of using trained pharmacists embedded in primary care to deliver a shared decision-making (SDM) intervention to engage patients in diabetes prevention, using a prediabetes decision aid. Presenter #1 will share the early trial findings which indicate that a prediabetes SDM intervention can be used to enhance patient engagement in evidence-based therapies to prevent diabetes and weight loss at 4 months and how discuss how this model may be disseminated to enhance type 2 diabetes prevention efforts among patients at highest risk.

Presenter #2 will review the development and testing of a web-based lung cancer screening decision aid. The overall goal of the decision aid is to improve individuals' decision making about being screened for lung cancer. The decision aid has been developed to be used by individuals in the community who are potentially interested in being screened for lung cancer, as well as by individuals who are exploring lung cancer screening with a health care provider and/or a lung cancer screening program. Besides increasing knowledge about lung cancer screening, the decision aid has several interactive components which go beyond just knowledge increases to try to improve decision making. These components include: 1) an algorithm which will inform individuals about their own risk of developing lung cancer risk; 2) an algorithm that will determine if the individual meets the USPSTF and NCCN guideline criteria for lung cancer screening; 3) question prompt lists to facilitate individuals discussions about lung cancer screening with the health care provider; 4) animated videos which help individuals understand informed decision making; and 5) a conjoint valuation exercise to elicit individuals' preference for lung cancer screening.

Presenter #3 will review the development and testing of a web-based tool to facilitate integration of evidence-based tools to support tobacco treatment efforts in a variety of clinical settings. The platform supports clinician-driven assessment and intervention but also provides several strategies to support patients. Presenter #3 will also discuss collaborations with a health IT company and a practice-based network to conduct iterative usability testing, pilot testing, and a large scale feasibility and acceptability trial to evaluate this intervention in dental care settings.

LEVERAGING THE MEDIA TO IMPACT PUBLIC HEALTH

Katherine D. Hoerster, PhD, MPH¹, Jamie Bodenlos, Ph.D.², Cindy Kuzma, N/A³, Sherry Pagoto, PhD⁴

¹VA Puget Sound Healthcare, Seattle and University of Washington, Seattle, WA; ²Hobart and William Smith Colleges, Geneva, NY; ³freelance, Chicago, IL; ⁴University of Connecticut, Storrs, CT

To optimally impact public health, behavioral medicine researchers must effectively communicate behavioral science research priorities, findings, and implications to the public, clinicians, organizations, and decision-makers. The broad public reach of mass media offers a communication vehicle with a high return on investment. This panel will cover the rationale, challenges and solutions, recommended practices, and benefits to self, field, and society of leveraging the media to impact public health. Practical guidance regarding media outlet selection, writing style, institutional resources, and dissemination approaches will be provided. This panel will draw on panelists' varied and extensive relevant experiences, including prior media-related collaborations. One panelist has written approximately 20 op-eds and health advice articles in local and national media outlets; has provided comment across numerous media outlets regarding health-related research; and writes two health-focused blogs. She also leads a health-related, university-based media center, and advocates for policy and public health by writing letters to the editor to academic journals. Another panelist's relevant work includes op-ed writing, speaking at local marches, including the recent March for Science and Climate Change marches, and teaching op-ed writing to students and trainees. The panel's moderator recently drew on prior public health legislative advocacy and media interview experience by writing an op-ed, and used it as a platform to advocate for various healthcare, research, and policy changes. Two panelists published in SBM's Outlook newsletter on the importance of op-ed writing for advancing behavioral medicine, and tips for successful publishing. The fourth panelist is a widely published health and wellness freelance journalist, who has written for outlets such as Runner's World, SELF, Prevention, and Women's Health magazines. She previously worked in media relations for the Journal of the American Medical Association (JAMA). She has interviewed another panelist for prior media pieces and through her work with JAMA. The panel will be moderated and will utilize interactive, discussion-based learning with attendees. Attendees will have ample opportunities to ask questions of panelists and share ideas and experiences. Panelists will share a range of useful tips and perspectives so that attendees leave inspired and equipped to work with various media formats to enhance public health.

BUILDING PHYSICIAN COMPETENCY IN LIFESTYLE MEDICINE: THE LIFESTYLE MEDICINE CORE COMPETENCIES PROGRAM

Danielle 'Dani' Pere, MPM¹, Liana Lianov, MD, MPH²

¹American College of Preventive Medicine, Washington D.C., DC; ²HealthType LLC, Fair Oaks, CA

Lifestyle medicine is a scientific approach to decreasing disease risk and illness burden by utilizing lifestyle interventions such as nutrition, physical activity, stress reduction, rest, smoking cessation, and avoidance of alcohol abuse. Lifestyle medicine is the recommended foundational approach to preventing and treating many chronic diseases. Lifestyle medicine is a core component of preventive medicine and its practices and programs are based on proven and effective methods of preventing and controlling disease. Lifestyle medicine is an innovative way to improve the well-being of individuals and communities.

The American College of Preventive Medicine (ACPM) and the American College of Lifestyle Medicine (ACLM) convened a blue ribbon panel of representatives from several major physician/health professional organizations to develop a consensus statement that was published in the Journal of the American Medical Association in 2010. The article was titled "Physician Competencies for Prescribing Lifestyle Medicine". The 15 competencies fall into five categories including: Leadership, Knowledge, Assessment Skills, Management Skills and Use of Office and Community Support.

In September 2016, ACPM and the ACLM released the Lifestyle Medicine Core Competencies program (LMCC), a culmination of over 4 years of work to create a first-of-its kind evidence-based online program. This 30-hour program is designed to provide a comprehensive foundation for doctors as well as nurses, nurse practitioners, physician assistants, dietitians, health coaches, and other allied health professionals with an interest in learning the basic foundational principles of lifestyle medicine. The curriculum teaches how to incorporate lifestyle medicine into practice and establishes a new standard for primary care focused on disease prevention, health promotion, and care coordination.

The nine modules comprising the 30-hour program cover basic and advanced information on: 1.) Core Competencies of Lifestyle Medicine, 2.) Nutrition, 3.) Physical Activity, 4.) Coaching Behavior Change, 5.) Sleep Health, 6.) Tobacco Cessation, 7.) Alcohol Use Risk Reduction, 8.) Emotional Wellness/Stress Reduction and 9.) Electives (choose 3 hours from 5 options). This curriculum comprehensively addresses the knowledge and skill gaps doctors themselves cited as major barriers to counseling patients about lifestyle interventions. The presentation will address why the curriculum is needed, who benefits from it, and how individual clinicians as well as the private sector health systems and residency programs in the U.S. are using it, and how it is utilized by the U.S. Federal Government.

THE ACCUMULATING DATA TO OPTIMALLY PREDICT OBESITY TREATMENT (ADOPT) PROJECT

Susan M. Czajkowski, Ph.D.¹, Alexander Rothman, Ph.D.², Christine Hunter, Ph.D.³, Deborah L. Young-Hyman, Ph.D.⁴, S. Sonia Arteaga, Ph.D.⁵, Leslie A. Lytle, Ph.D.⁶, John M. Jakicic, Ph.D.⁷

¹National Cancer Institute, NIH, Bethesda, MD; ²University of Minnesota, Minneapolis, MN; ³National Institutes of Health, Bethesda, MD; ⁴NIH, Bethesda, MD; ⁵National Heart, Lung, and Blood Institute, Bethesda, ME; ⁶University of North Carolina at Chapel Hill, Chapel Hill, NC; ⁷University of Pittsburgh, Pittsburgh, PA

Being overweight or obese significantly increases the risk of developing chronic diseases, including cancer, cardiovascular disease and diabetes. Weight loss trials in adults have documented considerable variation in the amount of weight lost and maintained over time in response to behavioral and pharmacological treatments. The identification of variables that predict treatment success can lead to insights into how psychosocial, behavioral, environmental, and biological factors operate and interact during weight loss and maintenance, ultimately enabling us to predict which weight management strategies work best for which individuals. However, the lack of standardized, multidisciplinary phenotyping across studies has hampered efforts to identify predictors of weight loss and regain that are replicable across studies. To facilitate the identification of a standard array of variables, the Accumulating Data to Optimally Predict obesity Treatment (ADOPT) Core Measures initiative, a trans-NIH effort led by the National Heart, Lung, and Blood Institute (NHLBI) and the National Cancer Institute (NCI) in collaboration with other NIH Institutes, Centers and Offices, is identifying a set of key variables and measures related to weight loss to determine potential predictors of successful weight loss and maintenance. Following an initial meeting in May of 2016, the ADOPT Core Measures Working Group – consisting of NIH and extramural scientists -- launched an effort to identify key variables and measures by entering potential moderators and mediators into the NCI's Grid-Enabled Measures (GEM) Database (<https://www.gem-measures.org/>). Constructs and measures related to weight loss and maintenance were identified for the following domains: behavioral, biological, environmental and psychosocial. The ultimate product of the Working Group is a core set of measures that are recommended for use in adult weight loss and maintenance trials. In this panel discussion, NIH and extramural scientists will describe the goals, process and products of ADOPT, including the ADOPT working model/framework and the core list of constructs and measures recommended by the ADOPT Working Group for inclusion in weight loss/maintenance trials. In addition, opportunities for investigators to engage in ADOPT, including potential funding opportunities to allow adding ADOPT measures to weight loss/maintenance trials, will be discussed. Following these presentations, panel members will engage in a discussion with audience members concerning the ultimate goals and utility of the ADOPT framework, constructs and measures in enabling more targeted, precise and effective treatments for obesity.

CAREERS IN CARDIOVASCULAR BEHAVIORAL MEDICINE

Carly M. Goldstein, Ph.D.¹, Rachel A. Millstein, Ph.D, MHS², Anne L. Saltzman, PsyD³, Joel W. Hughes, Ph.D⁴, Jeffrey J. Lauzon, M.A., Ph.D⁵

¹The Miriam Hospital/The Alpert Medical School of Brown University, Providence, RI; ²Massachusetts General Hospital, Boston, MA; ³UCLA Medical Center, Los Angeles, CA; ⁴Kent State University, Kent, OH; ⁵Aurora Health Care, St. Luke's Medical Center, Milwaukee, WI

The Society of Behavioral Medicine's Student Special Interest Group (Student SIG) and the American Association of Cardiovascular and Pulmonary Rehabilitation (AACVPR) are proud to jointly present a panel on careers in cardiovascular behavioral medicine. Cardiovascular disease (CVD) is the primary cause of death for adults in the United States, and many of the risk factors and treatments are behavioral, and therefore potentially modifiable. Consequently, CVD prevention and treatment represents an excellent career opportunity for behavioral medicine scientists and practitioners. AACVPR is a multidisciplinary professional organization aimed at improving quality of life in individuals with CVD or pulmonary diseases and their families. Members of AACVPR's Psychosocial and Nutrition Expert Group and colleagues will join in this panel discussion for individuals considering a career in this broad and exciting field. The panel will feature: a junior scientist with funding from the National Institutes of Health (NIH) to study cardiac rehabilitation (CR), technology, and weight loss who is also the course co-director of a National Heart, Lung, and Blood Institute-sponsored fellowship in cardiovascular behavioral medicine; a junior investigator with expertise in public health and clinical psychology with a K23 targeting physical inactivity through multilevel interventions for patients with CVD and diabetes; a clinician who created a psychology service within a major academic medical center's CR program; a senior scientist who has conducted ground-breaking NIH-funded research in CR and CVD patients who also established research programs in two CRs; and a mid-career health psychologist who works closely with cardiac rehab to detect, receive, and manage referrals for anxiety, depression, and recovery adjustment to medically traumatic events from pre-surgical/heart transplant evaluation through recovery. Attendees will leave with knowledge of how to establish a career in this field, seek grant-funding for CVD research, how to find CR programs to collaborate with, how to establish a program of research or clinical service within CR, current policy-level issues that affect this field, and what training to pursue to be successful.

CAN HEALTH EQUITY & SOCIAL JUSTICE IDEALS BE ACHIEVED IN TRANSLATIONAL RESEARCH? REACHING PEOPLE EXPERIENCING MARGINALIZATION

Lucie Levesque, PhD¹, Colin PT. Baillie, MSc¹, Erica Soltero, PhD², Scherezade Mama, DrPH³, Rebecca E. Lee, PhD⁴¹Queen's University, Kingston, ON, Canada; ²Arizona State University, Phoenix, AZ; ³The Pennsylvania State University, University Park, PA; ⁴Arizona State University, Phoenix, AZ

Community-engaged research (CEnR) often seeks to share all aspects of research with community members. Cast as a transformative research paradigm, CEnR intrinsically seeks to increase health equity and social justice by “empowering” community members to take an active role in decision-making and research tasks. Although laudable ideals, researchers typically work within institutions that perpetuate settler-colonial, or Euro-centric, values that are at least partially related to the dominance of positivist knowledge systems that dictate which “products” are valued as research outcomes, as well as which guidelines are used to determine what is considered ethical research. Translational scientists have a responsibility to challenge unequal power structures in relationship building, data collection, data analysis and dissemination of findings. Challenging these power structures involves actions by researchers within the academy and within the community. Researcher advocacy efforts may need to address university based research ethics’ policies, internal research funding structures, criteria for student admission and retention, criteria for faculty tenure and promotion, etc. Within the community, actions may involve researchers exploring how their positionality or personal characteristics, such as social status and ethnicity, influence their ability to work with marginalized populations. This panel will share examples of strategies that we have used to uphold the ideals of CEnR in ways that challenge the academic status quo, redress power imbalances among community and academic partners, and promote reciprocal knowledge translation consistent with health equity and social justice ideals. We will discuss the role that researcher identity plays in the development and implementation of community-engaged physical activity research involving Indigenous peoples in Canada, Hispanic populations in the United States, and Mexican populations in Mexico. We will highlight actions inside and outside of the academy that catalyze change and facilitate a researcher’s ability to connect with marginalized populations.

HUMAN SUBJECTS PROTECTIONS, NIH CLINICAL TRIALS POLICY, AND IMPLICATIONS FOR YOUR RESEARCH

William N. Elwood, Ph.D.¹, Catherine Stoney, PhD², Dana L. Wolff-Hughes, PhD¹, Dawn A. Morales, Ph.D., Experimental Psychology³¹National Institutes of Health, Bethesda, MD; ²NHLBI/NIH, Bethesda, MD; ³National Institutes of Health, BETHESDA, MD

Scientific disciplines can differ on what qualities constitute a *clinical trial*. NIH defines the term broadly, “A research study in which one or more human subjects are prospectively assigned to one or more interventions (which may include placebo or other control) to evaluate the effects of those interventions on health-related biomedical or behavioral outcomes.” NIH finalizes the implementation this definition with newly formatted FOAs, grant application segments, training certification requirements, and reporting requirements for funded projects as part of the agency’s ongoing efforts to enhance rigor and reproducibility.

For example, NIH defines *intervention* as a manipulation of a person or a person’s environment to modify **one or more** health-related biomedical or behavioral processes and/or endpoints. Principal and co-investigators who work on NIH-funded projects require Good Clinical Practice certification. Basic researchers in social-behavioral sciences may find that their projects now fall within the rubric of NIH clinical trials. NIH changes also pertain to submission and reporting requirements for applied/clinical researchers.

This session will include a brief overview of the current definitions and policies and spend more time orienting participants to the newly-implemented categories of NIH FOAs to help ensure that investigators submit applications that make their way through the peer review process and not be returned for applying through an incompatible FOA. Panelists also will address timing and content issues for grantee reports to clinicaltrials.gov, and orient participants to online resources they can access at home and their respective institutions.

Panel Discussion 25

12:45 PM-1:45 PM

ENGAGING MILITARY VETERANS THROUGH HEALTH, GENUINE RELATIONSHIPS, & PURPOSE: PERSPECTIVES FROM TEAM RED, WHITE & BLUE LEADERS

John Pinter, BS¹, Caroline Angel, Ph.D., R.N.², Sarah Holzhalb, MS, MPS³, David E. Goodrich, EdD, MA, MS⁴¹Team Red, White and Blue, Floyds Knobs, IN; ²Team Red, White & Blue, Westfield, NJ; ³Team Red White and Blue, Covington, LA; ⁴VA Ann Arbor HCS, Ann Arbor, MI

The transition from active military service to civilian life is a critical period for psychosocial challenges that can predispose veterans to increased health risks. Loss of leadership, camaraderie, sense of purpose, military identity and a physically active lifestyle can compromise resiliency developed through active duty service. Team Red, White & Blue (RWB) is a 120,000+ member intergenerational veteran service organization (VSO) founded in 2010 to enrich veterans’ lives by connecting them to their communities through physical and social activities. Team RWB’s 220 local chapters in the US aim to enrich members’ lives by providing opportunities for physical, social, service, and leadership activities. A conceptual model called the “Engagement Funnel” is the basis for programming. The Funnel was designed to engage veterans through positive experiences that foster close, genuine, personal relationships within a broader social network to facilitate reintegration with local communities. This network creates a safe environment for veterans to share adjustment challenges and to mobilize the social support of teammates to link at-risk members to community resources, acute care services, and to prevent psychosocial decline.

This panel discussion is a partnership between the SBM Scientific and Professional Liaison Council and Team RWB to introduce the audience to a non-for-profit that has successfully used evidence-based behavioral strategies in local communities to improve veterans’ lives. The Chair will summarize the challenges faced by veterans reintegrating into civilian life and the opportunities for behavioral medicine to address these needs. The first panelist will discuss the founding of Team RWB, how the Engagement Model and programming developed over time, and highlight current national initiatives. The second panelist will present how Team RWB has successfully translated theory into programming to improve veteran outcomes as well as current efforts to measure and evaluate the organization’s programming including, the psychometric validation of an Enriched Life Scale. The third panelist will describe local Team RWB activities and cultural context of the New Orleans Chapter. Ample time will be provided for an interactive discussion with the audience with a focus on identifying future opportunities in which both organizations can collaborate to support the other’s mission to reach at-risk populations through psychosocial community interventions

Panel Discussion 26**12:45 PM-1:45 PM****EXTENDING OUR REACH: USING PATHWAYS TO ADDRESS PERSISTENT PAIN**Patricia Robinson, PhD¹, Kathryn Kanzler, PsyD, ABPP², Christopher L. Hunter, Ph.D.³, Jeff Reiter, PhD, ABPP⁴¹Mountainview Consulting Group, Inc., Portland, OR; ²University of Texas Health Science Center San Antonio, San Antonio, TX; ³Defense Health Agency, Arlington, VA; ⁴Swedish Medical Group, Seattle, WA

While there are a number of empirically supported interventions for persistent pain, most people challenged to cope with chronic pain do not receive them. In the health care world of today, little thought is given to prevention of chronic pain and early interventions, and most resources are delegated to caring for patients with the greatest complexity. Barriers to dissemination of behavioral interventions for coping with pain and seeking a higher quality of life include lack of knowledge and training among clinicians, over-reliance on medication treatments, a mismatch between where patients seek care and where behavioral clinicians work, and prohibitive costs for specialized treatment programs. Increasingly, behavioral health clinicians are re-locating their practice to primary care clinics where they work as fully integrated team members. In this panel discussion, four primary care behavioral health clinicians (PC BHCs) describe their experience with development, implementation, and evaluation of pathway strategies for addressing acute and chronic pain complaints among primary care patients. Pathway strategies rely on a population-based care, as opposed to case-based care, approach where the attempt is to provide “a small intervention for a lot of people” to improve outcomes for all. The panelists will include PC BHCs working in the Department of Defense, rural health care, urban commercial systems, and academic health care training clinics. Each panelist will respond to prompts concerning pathway work, such as defining the population, selecting interventions, and engaging team members and patients. Participants will be encouraged to share experiences and pose questions to the panelists. The session will conclude with each panelist describe “lessons learned” and “three wishes” for change in training and research approaches to improve the reach of interventions for patients with persistent pain.

Panel Discussion 27**12:45 PM-1:45 PM****PUBLIC/PRIVATE PARTNERSHIPS FOR PUBLIC HEALTH: LESSONS FROM THE SANTA MONICA WELLBEING PROJECT AND AIR LOUISVILLE**Ernesto R. Ramirez, PhD, MS¹, Douglas Yeung, N/A², Meredith Barrett, PhD³, Lisa E. Parson, MPA⁴, Grace Simrall, N/A⁵¹Fitabase, San Diego, CA; ²RAND Corporation, Santa Monica, CA; ³Propeller Health, San Francisco, CA; ⁴City of Santa Monica, Los Angeles, CA; ⁵Louisville Metro Government, Louisville, KY

The rise of personal and patient-generated health data has fundamentally changed the way researchers think about understanding numerous health behaviors. With the advent of technology for tracking, sharing, and analyzing health behaviors, there has been an emphasis on understanding behavioral patterns, outcomes, and new intervention methodologies. However, another use case for this type of data has also emerged: the ability for citizens to share this data with their local communities and government organizations in order to impact public health.

Representatives from RAND (Douglas Yeung) and the City of Santa Monica (Lisa Parsons) will discuss their in-progress physical activity and wellbeing study being conducted with 200 current Santa Monica residents. These residents have been provided with Fitbit devices to remotely track their physical activity and sleep behaviors. The data is shared with RAND and the City of Santa Monica through a partnership with Fitabase. The panelists will discuss the project, offering insight on lessons learned and preliminary data.

Meredith Barrett, VP of Research at Propeller Health, and Grace Simrall, Chief of Civic Innovation and Technology, will discuss the successful AIR Louisville project, which leveraged Propeller Health's remote asthma inhaler sensor technology to track where and when rescue medication use occurred among 1000 residents in Louisville, KY. These data generated novel insights to inform Louisville Metro's municipal interventions. Insights from the project, including improved asthma outcomes, enhanced civic engagement, and implications for urban planning policy at the local and national level, will be shared.

Audience members will learn about ongoing and new models for public/private partnerships to leverage citizen health data in order to make a positive impact in local communities.

Panel Discussion 28**12:45 PM-1:45 PM****MIND-BODY APPROACHES TO BEHAVIORAL CHANGE - DO THEY WORK AND HOW?**Elena Salmoirago-Blotcher, MD, PhD¹, Beth Bock, PhD², Crystal Park, CT³¹The Miriam Hospital, Alpert Medical School of Brown University, Providence, RI; ²Brown Medical School, Webster, MA; ³University of Connecticut, Storrs Mansfield, CT

Physical inactivity, smoking, and poor dietary habits are major contributors to a range of medical conditions including obesity, the metabolic syndrome, type II diabetes, cancer, and cardiovascular disease (CVD). Promoting and maintaining change in these behaviors is a challenging and yet unresolved public health problem. Clearly, we need creative approaches to promote lasting changes in these important behavioral risk factors.

Self-regulation is central to the processes of behavioral change and maintenance of healthy behaviors and interventions supporting the development of this capacity represent an opportunity to promote behavioral change and improve clinical outcomes. Mind-body approaches have been shown to enhance self-regulation, but whether they may promote change in health behaviors is still unknown.

Using evidence from the literature and novel research findings this panel discussion will focus on this novel and controversial topic, namely, whether mind-body approaches can promote behavioral change. We will examine this topic from experimental and theoretical perspectives with a particular focus on smoking cessation and on the promotion of physical activity.

Dr. Bock will begin by examining the role of yoga in smoking cessation. Traditional aerobic exercise has been shown to enhance quit rates among women. Yoga represents a mind-body practice that includes physical activity, meditation and mindfulness – practices that may further enhance the ability of men and women to quit smoking.

Dr. Salmoirago-Blotcher will use findings from a study of tai chi for physically inactive individuals with CVD and data from a school-based mindfulness intervention for teenagers to discuss the possible effect of tai chi and mindfulness training, respectively, in the promotion of physical activity in these populations.

Dr. Park will address hypothesized mechanisms, existing research gaps, and challenges to the clinical application of mind-body approaches to behavioral change. For example, yoga may improve individuals' comfort with their bodies and movement, serving as a “gateway” to other forms of exercise.

We will conclude with a discussion and Q&A session to obtain panelists' and audience's feedback and input on this novel approach to behavioral change.

Symposium 47**2:00 PM-3:15 PM****(MIS)PREDICTING AFFECTIVE REACTIONS IN THE FUTURE SELF AND AMONG OTHERS: CONSEQUENCES FOR PALLIATIVE CARE DECISION MAKING**Rebecca Anne. Ferrer, PhD¹, Michael Hoerger, PhD, MSCR², Caitlin Drummond, PhD³, Jennifer M. Taber, PhD⁴¹National Cancer Institute, Rockville, MD; ²Tulane University, New Orleans, LA; ³Erb Institute, University of Michigan, Pittsburgh, PA; ⁴Kent State University, Kent, OH

Incorporating care aimed at comfort rather than cure (i.e., palliative care [PC]) into primary care for cancer and other advanced illness with high symptom burden is an important component of patient-centered care. However, PC is underutilized; many patients do not receive PC until end-of-life, when it may be too late to substantially alter quality of life. For patients to receive timely PC, the provider must decide to recommend PC – or provide PC or a PC referral at a patient request – and the patient must decide to accept (or request) PC services. Thus, understanding psychological and decisional processes among patients and providers is critical to developing evidence-based interventions to improve PC uptake. In particular, psychological and decisional theory suggests that inaccurate affective predictions – forecasts an individual makes about how he or she will feel in the future, or about how another person feels in the present – may be an important barrier to PC referral and uptake. This symposium examines how biases in affective predictions contribute to communication and coordination of PC among patients and providers. Three speakers will show that 1) medical providers may be biased in predicting patient PC preferences and affective responses to PC; 2) patients make errors in predicting how they will feel in response to their future illness trajectory; and 3) patients' and providers' decision making can be influenced by biased affective forecasts. A discussant will then synthesize presentations and discuss the value of incorporating social psychological and decisional theory into PC research and interventions.

Symposium 47A

INTRAPERSONAL AND INTERPERSONAL AFFECTIVE (MIS)PREDICTIONS IN PALLIATIVE CARE DECISION MAKING

Dr. Rebecca Anne Ferrer, PhD

Research suggests that individuals have difficulty predicting how they, themselves, will feel in the future, as well as in predicting how others feel (either at present or in the future). Predictions are most likely to be inaccurate when the individual predicting how they will, or how others do, feel in an emotional (i.e., hot) state when the predictor is in an unemotional (i.e., cold) state – termed the hot-cold empathy gap. We translated decision science theory on affective forecasting and the hot-cold empathy gap to understand patient and provider barriers to palliative care. We uncovered *interpersonal* empathy gaps in a nationally representative U.S. sample of medical providers (Study 1, $n=502$). Empathy gap between providers' own preference for PC and their perceptions of patients' preference was associated with feeling threatened when they cannot cure disease and with less willingness to provide/refer to PC. We also uncovered *intrapersonal* empathy gaps (Study 2) among PC-naive ($n=166$) patients and nonpatients ($n=289$) compared to ratings among PC-experienced ($n=33$) in their predictions of how discussing PC would make them feel. Empathy gap was associated with PC information avoidance, less positive beliefs about PC, and less endorsement of PC as standard-of-care. These findings suggest that affective mispredictions about others preferences, and affective mispredictions about one's own feelings and preferences in the future, may be important barriers to PC referral and uptake.

Symposium 47B

AFFECTIVE FORECASTING AND PALLIATIVE CARE AVOIDANCE IN ADVANCED CANCER

Dr. Michael Hoerger, PhD, MSCR

Background: Palliative care benefits quality of life and is recommended for all patients with advanced cancer. Affective forecasting theory could explain aversion to palliative care.

Method: We ran 5 studies ($N=1,583$) involving cancer patients, non-patients, family caregivers, and oncologists. Following social psychology methods, participants made affective forecasts about living with advanced cancer. These were compared to patients' actual experiences. Patients also made forecasts about palliative care visits, and rated their desire for help with affective forecasting.

Results: Non-patients, family caregivers, and oncologists underestimated patients' quality of life in advanced cancer (Studies 1 & 2). Patients overestimated future quality of life (Study 2). Patients overestimated the emotional distress of palliative care visits (Studies 3 & 4). Most patients wanted help with affective forecasting (Study 5).

Discussion: Patients' challenges in affective forecasting may foster avoidance of palliative care. Non-patients may lack awareness of these biases. Actionable research on fundamental mechanisms underlying affective forecasting and health-care decision making is warranted.

Symposium 47C

BEHAVIORAL INFLUENCES ON CLINICIAN DECISION MAKING IN END-OF-LIFE SITUATIONS

Caitlin Drummond, PhD

Behavioral approaches have increasingly appeared in the health decision making literature in recent years, yet have infrequently focused on clinician decision making. In exploratory research with 8 oncologists, 1 intensive care doctor, and 4 cardiologists, we applied the mental models methodology of in-depth interviewing and analysis to understand how clinicians judge and communicate end-of-life prognosis to patients, and how they decide if and when to consult palliative care specialists. A thematic frequency analysis and corresponding mental model diagram leverage social psychological theories (e.g., terror management theory, intergroup dynamics, self and identity) to elucidate previously unidentified behavioral factors influencing clinician judgment and decision making. We find that mortality salience, affective and relational biases, and intergroup or identity dynamics within the clinical setting can contribute to delayed prognostic conversations and palliative care referrals. While differences appear to exist between specialties, data also suggest a strong role for individual differences within specialty. We conclude with a discussion of potential affective interventions for further testing in experimental or survey settings.

Symposium 48

2:00 PM-3:15 PM

SITTING LESS AND MOVING MORE: EMERGING METHODS AND STRATEGIES FOR REDUCING SEDENTARY BEHAVIOR

Matthew P. Buman, PhD, FACS¹, Meynard John L. Toledo, MS¹, Sarah L. Mullane, PhD¹, Michelle L Takemoto, PhD², Dori E. Rosenberg, PhD, MPH³

¹Arizona State University, Phoenix, AZ; ²University of California, San Diego, La Jolla, CA; ³Kaiser Permanente Washington Health Research Institute, Seattle, WA

Sedentary behavior has emerged in recent years as an independent risk factor for cardiovascular disease, diabetes, and premature death, yet evidence-based strategies for reducing sedentary time are scarce. The science of sedentary behavior change is complex given the ubiquitous, habitual, and socially-reinforced nature of the behavior. While macro-level interventions exist that target sedentary time in youth, older adults, and office workers, careful formative work that identify intervention strategies to uniquely address the complex nature of sedentary behavior are not common. In this symposium we present a set of formative studies using cutting-edge methods and technologies to identify feasible and efficacious strategies for reducing sedentary time in work and home environments. Mr. Meynard Toledo will present intensive ecological momentary assessments of contextual factors to inform optimal moments for intervention delivery in office workers. Dr. Sarah Mullane will follow with a presentation of a micro-randomized trial testing the efficacy of content-specific email-based prompts in sedentary office workers with sit-stand workstations. Dr. Michelle Takemoto will present feasibility and acceptability results from a recent randomized controlled trial testing the impact of prompts, sit-stand workstations, and counters on two distinct sitting interruption modalities (i.e., sit less, increase sit-to-stand transitions). Finally, Dr. Dori Rosenberg will highlight promising strategies, emerging technologies, and future directions required to significantly advance the field of sedentary behavior interventions.

Symposium 48A

MOMENTARY AFFECTIVE PREDICTORS OF SEDENTARY AND ACTIVE BEHAVIORS IN THE WORKPLACE

Meynard John L. Toledo, MS

Background: Understanding the “in the moment” affective states that precede and follow sedentary behaviors (SB) could inform development of interventions to reduce SB.

Purpose: To examine the bi-directional relationship between momentary affective states and objectively-measured workplace SB.

Methods: Sedentary office workers with sit-stand workstations were recruited to participate in a 20-workday observational study. Participants completed ecological momentary assessments (EMA; total of 60 per participant: 3 per day x 5 workdays/week x 4 weeks) of stress, productivity, calmness/energy, sadness, intention to stand/move in the next hour. Participants also wore an activPAL sensor. Each EMA response was time-matched with the activPAL outcomes (i.e., total time spent in sedentary, standing, and moving behaviors and total sit-stand transitions one hour preceding and proceeding each EMA response). Multilevel models were used to examine the bi-directional associations of sitting, standing, and moving behaviors and affective states. All models were adjusted for age, gender, race and job type.

Results: A total of 18 participants (age = 48.9 ± 9.9 years; 44% male; 83% white) completed the study. Four hundred ninety-three EMA responses ($M=27.4 \pm 13.3$ EMA responses/participant) were analyzed. Overall (i.e., between-person associations), individuals reporting higher stress, calmness and energy engaged in less sitting ($b[SE]= -20.1[6.1], -15.7[5.4], -17.7[5.5]$, respectively, $p<.01$) and more standing ($b[SE]= 20.8[5.5], 12.0[4.9], 20.4[5.0]$, respectively, $p<.01$) in the next hour. Individuals reporting higher sadness, productivity and intent to stand/move engaged in more sitting ($b[SE]= 14.3[4.9], 21.5[5.4], 23.0[5.2]$, respectively, $p<.01$) and less standing ($b[SE]= -11.7[4.4], 19.0[4.9], -18.8[4.8]$, respectively, $p<.01$) in the next hour. When examining momentary relationships (i.e., within-person associations), individuals sat less ($b[SE]= -3.9[1.8]$, $p=.02$) and stood more ($b[SE]= 3.5[1.6]$, $p=.02$) in the hour following higher than usual energy and sat less ($b[SE]= -2.8[1.4]$, $p=.04$) and moved more ($b[SE]= 1.2[0.4]$, $p<.01$) following higher than usual intentions to stand/move.

Conclusion: Affective states significantly influence workplace sedentary and active behaviors in complex ways. Information regarding context (i.e., location in the office, nature of job tasks) may complement these findings in developing just-in-time interventions.

CORRESPONDING AUTHORS: Sarah Mullane, Arizona State University; smullan@asu.edu; Sayali Phatak, Arizona State University; sphatak1@asu.edu; Eric Hekler, Arizona State University; ehkler@asu.edu; Matthew Buman, Arizona State University; mbuman@asu.edu

Symposium 48B

EMAIL-BASED PROMPTS TO REDUCE SEDENTARY TIME IN OFFICE WORKERS WITH SIT-STAND WORKSTATIONS: A MICRO-RANDOMIZED TRIAL

Sarah L. Mullane, PhD

PURPOSE: To test the proximal effects of email-based prompts on workplace sedentary behavior.

METHODS: A 20-workday micro-randomized trial was conducted in office workers using sit-stand workstations. Prompt delivery was sequentially randomized to be sent (ST) or not sent (NST) to all participants (probability of 0.5), at eight decision points per day (between 9am and 5pm), resulting in a total of 2400 randomizations across participants. Among prompts per person, half encouraged standing more (*stand*; N=80) and the other half encouraged moving more (*move*; N=80). Participants wore an activPAL3c sensor and completed a retrospective usability survey. General estimating equations were used to examine the effect of prompt delivery by modeling the mean likelihood of a response (i.e., transition from sitting to standing or sitting to moving) as an odds ratio, over the next 5-min and 30-min periods. Mixed model analyses were used to examine the association between prompt type and total sedentary time over the next 30-min period. All models were adjusted for age, race, gender, day of intervention and minutes of sitting 30-mins prior to a prompt. Decision points where the participant was standing or moving at the time of delivery (ST) or scheduled (NST) time were excluded from analyses.

RESULTS: Among participants (N = 15; 67% female; age = 50.9 ± 9.5 yrs), 1147 decision points occurred when seated (ST = 543; NST = 604). Participants were 42% more likely to transition from sitting to standing or sitting to moving within 5-mins when a prompt was sent (OR[95%CI] = 1.4[1.1, 1.8], $p<.01$). Stand prompts were 25% more likely to elicit a transition (OR[95%CI] = 1.6[1.2, 2.0], $p<.01$) than move prompts (OR[95%CI] = 1.3[1.0, 1.7], $p<.05$). Sending a prompt was associated with less sitting ($b[95%CI] = -2.0[-2.9, -1.0]$) and more standing ($b[95%CI] = 1.8[1.0, 2.5]$) over the next 30-mins ($p's<.01$). Participants who stood within the first 5-mins of receiving a prompt exhibited significantly less sitting ($b[95%CI] = -8.3[-9.8, -6.9]$) and more standing ($b[95%CI] = 6.5[5.3, 7.8]$) over the next 30-mins ($p<.01$). Mean usability ratings were higher for *stand* ($68 \pm 1.9\%$) compared to *move* messages ($60 \pm 2.6\%$).

CONCLUSIONS: Prompts may be an effective complementary strategy to encourage sit-stand workstation use. Specificity of the behavioral target (*stand* rather than *move*) may be necessary to maximize prompt effectiveness and should be considered in future prompt based sedentary behavior reduction interventions.

CORRESPONDING AUTHORS: Meynard JL Toledo, MS, Arizona State University; mltoledo@asu.edu; Marios Hadjimichael, Arizona State University; marioshadj@gmail.com; Eric B Hekler, PhD, Arizona State University; ehkler@asu.edu; Matthew P Buman, PhD, Arizona State University; Matthew.Buman@asu.edu

Symposium 48C

THE SEARCH FOR THE EJECTING CHAIR: A MIXED METHODS ANALYSIS OF TOOL USE IN A SEDENTARY BEHAVIOR INTERVENTION

Dr. Michelle L Takemoto, PhD

Background: There are negative associations of excessive sitting and health. Research is needed on interventions targeting sedentary behavior (SB) with appropriate behavior change tools. The current study used convergent sequential mixed methods (QUAN+qual) to explore how tool use during a pilot intervention impacted SB to inform future long-term interventions.

Methods: Data came from a two arm randomized-controlled pilot trial designed to test the feasibility and acceptability of a SB intervention. Participants were between 50 and 70 years of age (N=30) with an equal number of workers and non-workers. During the intervention, participants were presented with a number of intervention tools (e.g., prompts, standing desks, counters) and asked to report which tools they used as well as the frequency of use. Separate mixed effects regression models explored associations between change in number of tools and frequency of tool use with the two intervention targets: change in sitting time and number of sit-to-stand transitions overtime. Qualitative data explored participants' attitudes towards intervention tools and explained the quantitative results.

Results: There was a significant relationship between mean tool use and sitting time. With a one-unit increase in frequency of tool use, participants reduced daily sitting time by 75 minutes. Sit-to-stand transitions were not associated with frequency of tool use. There were no significant relationships between total tool use and sitting time or sit-to-stand transitions. Twenty-four semi-structured interviews were coded and a thematic analysis revealed 4 themes related to tool use: 1) prompts to disrupt behavior; 2) tools matching the goal; 3) tools for sit-to-stand were ineffective; and 4) tool use evolved over time.

Conclusions: Participants who honed in on effective tools were more successful in reducing sitting time. Tools for participants to change sit-to-stand transitions were not effective. Devices with real-time feedback that accurately track SB are needed.

Symposium 49

2:00 PM-3:15 PM

AN UPDATE ON THE COST-EFFECTIVENESS WORKING GROUP ON METHODOLOGY, COLLABORATIVE CARE AND DISSEMINATION

Dawn K. Wilson, Ph.D., FSBM¹, Robert M. Kaplan, Ph.D., FSBM², Paul Jacobsen, PhD³, William Riley, PhD⁴

¹University of South Carolina, Columbia, SC; ²Clinical Excellence Research Center, Stanford, CA; ³National Cancer Institute, Bethesda, MD; ⁴NIH Office of Behavioral and Social Sciences Research, Bethesda, MD

This symposium will provide an update and overview of a special working group on the applications of cost-effectiveness analysis for behavioral and psychological interventions. Although standardized methods for cost-effectiveness have been developed and have been widely applied in medicine, we have seen few applications in Health Psychology and Behavioral Medicine. The purpose of this symposium is to provide information from the working group based on their reviewed of the current recommendations for cost-effectiveness analysis and appraisal of whether they are appropriate for studies in the field of Health Psychology and Behavioral Medicine. The group will develop four white papers that will be covered in this session on standards of cost-effectiveness in the areas of methodology, prevention, collaborative care and dissemination. After each presentation the group will answer questions as a panel. The working group and symposium leaders represent the Society for Health Psychology, the National Cancer Institute, and the Office for Behavioral and Social Sciences Research at the National Institutes of Health.

Symposium 49A

STANDARDS FOR COST-EFFECTIVENESS ANALYSES FOR THE FIELD OF HEALTH PSYCHOLOGY AND BEHAVIORAL MEDICINE

Dr. Robert M. Kaplan, Ph.D., FSBM

This year, the United States will spend over \$3.2 trillion on health services, making US healthcare the largest sector in the biggest economy in the history of the world. Despite these large expenditures, health outcomes in the United States are not exceptional. In contrast to other rich economies, life expectancies in the United States have been systematically losing ground over the last 35 years. Finding ways to spend resources more efficiently is an important national objective. However, achieving scientifically based resource allocation remains difficult. Different sectors of the healthcare system compete for the same resources. Yet the competing sectors measure their productivity in different outcome units. This paper reviews progress toward the development of a generic tool kit that can be used to evaluate the cost/effectiveness of a wide range of healthcare services. A variety of well-validated outcome measures are available. Most of the measures integrate measures of morbidity and mortality into a common unit. The common outcome unit is necessary to make comparisons between services as different as orthopedic surgery and depression management. The assessment tools typically measure outcome using standardized questionnaires that capture patient reported functioning and symptoms. Preference weights are used to place levels of wellness on a continuum ranging from 0 (for dead or about the same as being dead) to 1.0 for complete wellness. Each year of life is weighted by level of wellness. Summing values across years yields a measure of Quality-adjusted life expectancy. Although these measures have become common in medical clinical research, there have been very few applications in behavioral medicine. As a result, behavioral programs may be neglected in discussions of resource allocation. The presentation will summarize existing measurement methods and will offer examples of how behavioral interventions can be compared with other health services in terms of cost-effectiveness.

Symposium 49B

STATUS OF FINANCIAL AND ECONOMIC ANALYSES OF COLLABORATIVE CARE

Dr. Paul Jacobsen, PhD

A robust evidence base exists for the efficacy of variety of mental health and psychosocial interventions in improving quality of life outcomes for people receiving medical care. A notable example is collaborative care management of depression, a multi-component intervention to treat depression that typically uses case managers to link patients and medical care practitioners with mental health professionals. Numerous randomized trials have demonstrated that collaborative care is more effective than standard care in improving depression outcomes for patients seen in primary care settings as well specialty settings such as outpatient oncology clinics. Despite considerable evidence for their efficacy, implementation of collaborative care and other forms of psychosocial care in medical care settings has been limited. Among the oft-cited concerns are unanswered questions about the financial and economic impact of providing mental health and psychosocial services in a routine manner in medical settings. This presentation will review the state-of-the science regarding research on financial and economic aspects of introducing collaborative care and similar interventions in medical settings. Examples will be provided of studies that have enumerated the costs of these interventions as well as studies that have evaluated costs in relation to indices of effectiveness. The presentation will conclude with identifying directions for future research in this area as well as a consideration of how studies incorporating financial and economic outcomes can help foster broader adoption of mental health and psychosocial interventions in medical care settings.

Symposium 49C

STANDARDS FOR COST-EFFECTIVENESS ANALYSES IN THE CONTEXT OF DISSEMINATION

Dr. William Riley, PhD

Despite considerable research support for various social and behavioral interventions to improve health, both at the individual and population level, the dissemination and implementation of these interventions in real world settings has lagged. Implementation science studies the methods by which the systematic adoption of evidence-based practices into routine practice can be promoted. There have been a number of important and emerging advances in implementation science including novel research methods better suited to practice settings, increased integration of research methods within practice settings (e.g., learning health systems), technological delivery of interventions, and planned adaptations of interventions to address the unique needs of a variety of practice settings and resources. Implementation research on how economic or cost-benefit considerations influence adoption, however, are limited. In large part, the relative lack of economic and cost-benefit consideration in the implementation of social and behavioral interventions is the result of a scarcity of cost-effectiveness research for these interventions. This presentation will discuss the various health economics approaches, including cost-benefit analysis, cost-effectiveness analysis including cost utility and incremental cost-effectiveness ratio (ICER) and distributed cost-effectiveness analysis, and how these approaches can be applied to and adapted for social and behavioral interventions. The outcomes commonly considered in these cost-effectiveness analyses (illnesses prevented, life years added, quality-adjusted life years) are often quite distal from the outcomes of most behavioral intervention studies; therefore, methods for estimating and modeling these cost-effectiveness values from the outcomes of these studies will be considered. Further, because technology-based interventions often incur more fixed than variable costs, estimates of reach or scalability also need to be considered. The impact of these various cost-effectiveness approaches on facilitating implementation of social and behavioral interventions will be discussed.

Symposium 50

2:00 PM-3:15 PM

DELIVERING HEALTH PROMOTION INTERVENTIONS ON SOCIAL MEDIA: ENGAGEMENT AND METHODOLOGICAL CONSIDERATIONS

Sherry Pagoto, PhD¹, Molly E. Waring, PhD¹, Danielle E. Jake-Schoffman, PhD², Wen-ying Sylvia Chou, PhD, MPH³

¹University of Connecticut, Storrs, CT; ²University of Massachusetts Medical School, Worcester, MA; ³National Cancer Institute, Rockville, MD 20892, MD

The majority of US adults have at least one social media account and most users log in on a daily basis to interact with family and friends, read news/online articles, and/or participate in topic-focused communities. Given the near ubiquity of use, social media platforms can engage large audiences on nearly any topic. Not surprisingly, evidence is now mounting for social media as a delivery modality for health promotion interventions. The use of commercial social media platforms to deliver health promotion programming sidesteps technology costs of developing a unique website or platform and eliminates barriers to participation in clinic or community programs (e.g., geographical barriers, transportation, scheduling, childcare). Along with the benefits come significant challenges which we address in this symposium. First, very little research has explored how to develop intervention content that engages participants in discussions in a social media setting. Dr. Molly Waring will present her work exploring the characteristics of intervention posts that engaged the most and least participants in a Facebook post-partum weight loss intervention. A second challenge is that we know little about the types of participant engagement associated with behavior change in these programs. Dr. Danielle Jake-Schoffman will present her work exploring how participants discuss their behavioral goals in a Facebook weight loss intervention and the relationship between aspects of the language they use to articulate goals and end-of-treatment weight loss outcomes. A third challenge relates to attracting and engaging individuals who are not motivated to change or seeking help to change. Social media platforms can expand our reach to people who are not actively seeking help to change but how to leverage it to engage such populations is not well studied. Dr. Sherry Pagoto will present methodological challenges relating to recruitment, intervention content development, and intervention delivery for a Facebook intervention targeting mothers of teen daughters who engage in indoor tanning. Findings of all three studies will be informative to researchers designing social media-delivered health promotion interventions. Dr. Sylvia Chou, a social media expert at the National Cancer Institute will put these findings into perspective of the broader field of NIH-funded research on social media and health and make recommendations for important directions for future research.

Symposium 50A

METHODOLOGICAL CHALLENGES OF SOCIAL MEDIA-DELIVERED HEALTH PROMOTION INTERVENTIONS

Dr. Sherry Pagoto, PhD

Social media platforms can be used to deliver health promotion interventions to wide audiences without the barriers to participation that plague traditionally-delivered programs (e.g., geography, transportation, scheduling, childcare). Because most people access their social media feeds daily, health programming can be delivered to populations who are not necessarily seeking help or motivated to change. Despite these promising features, designing studies to evaluate social media-delivered interventions involves unique methodological issues that can impact. We present data regarding these issues from a pilot feasibility trial (N=90) and a randomized controlled trial (N=97) evaluating a Facebook-delivered intervention to mothers of teen daughters to reduce indoor tanning. The pilot study was conducted to refine recruitment and intervention procedures. The first 97 participants have been enrolled in the randomized trial and were included in the present analyses. Mothers who enrolled were similar in health risk factors relative to state averages (41% vs 35% obesity rate; 15% vs 20% smokers; 51% vs 48% HPV vaccination rates) which suggests that social media delivered interventions may have the potential to attract representative populations. In terms of enrollment strategies, one major methodological issue is how to enroll participants into an online community. Online social communities are constantly growing in size which in a research setting would produce variability across participants. Our pilot data revealed that our original plan to recruiting groups with a static fixed number of membership (to avoid variability caused by differential group size) resulted in longer wait times between recruitment and intervention start (mean wait time = 6 months vs 1 week) and greater participant loss (16.7% versus 5.2%) relative to the rolling recruitment approach we used in the trial. Another methodological issue was designing an intervention about a health topic for which awareness and interest in the population is low. We embedded indoor tanning content within a feed addressing a variety of health topics of interest to mothers of teen girls as expressed in formative focus groups. This approach resulted in similar engagement in with indoor tanning-related posts relative to posts on other health topics (mean = 1.13, sd = 1.87 engagements vs 1.54, sd = 2.33 engagements), however engagement was low for both. Lessons learned and recommendations for future research will be discussed.

Symposium 50B

TYPES OF INTERVENTION POSTS THAT ENGAGE THE LEAST AND MOST PARTICIPANTS IN A FACEBOOK POST-PARTUM WEIGHT LOSS INTERVENTION

Dr. Molly E. Waring, PhD

Knowledge is nascent about how to optimally engage participants in social media-delivered weight loss interventions. Using data from a pilot study of a post-partum weight loss intervention delivered on Facebook, we examined which types of intervention posts engaged the least and most participants to identify which posts could benefit from modification, and what ways to present intervention content that might be more effective at engaging participants. Over 12 weeks, 19 overweight/obese women received counseling based on the Diabetes Prevention Program via posts, links to articles and recipes, a weekly “weigh-in”, and support from coaches and other women. Women were instructed to use a free commercial app to track their diet and exercise. Retention was 95% at 12 weeks. We downloaded engagement data from Facebook and calculated the percent of participants who replied to each of 151 intervention posts. We categorized intervention posts as no-engagement (no participants replying), higher-engagement ($\geq 25\%$ of participants replying [$n \geq 5$]), or some-engagement ($< 25\%$ replying [$n = 1-4$]). As variables were not normally distributed, we used Wilcoxon rank-sum tests to compare the percent of participants replying by post type. We also described the proportion of low- and higher-engagement posts by post type. A median of 0% of participants (IQR: 0–16%; 0–79%) replied to intervention posts. The proportion of participants replying differed by post type ($p < 0.0001$). Half of intervention posts (51%; $n = 77/151$) were no-engagement and 17% ($n = 26/151$) were higher-engagement posts. Four types of intervention posts were represented among high-engagement posts: weigh-ins ($n = 12$; 83% higher-engagement, 0% no-engagement), posts soliciting challenges ($n = 9$; 44% higher-engagement, 33% no-engagement), posts asking participants to set a goal ($n = 28$; 25% higher-engagement, 29% no-engagement), and posts soliciting thoughts on a topic ($n = 22$; 23% higher-engagement, 45% no-engagement). Conversely, 4 post types included no higher-engagement posts: explaining program logistics ($n = 7$; 100% no-engagement), offering a motivational message ($n = 10$; 90% no-engagement), providing information ($n = 57$; 68% no-engagement), or soliciting a progress report ($n = 6$; 17% no-engagement). Objective engagement data can provide insights into what types of intervention posts are most effective at engaging participants in social media delivered behavioral interventions.

Symposium 50C

GETTING PARTICIPANTS TO SET BEHAVIORAL GOALS IN AN ONLINE WEIGHT LOSS PROGRAM: WHAT KINDS OF GOALS MATTER?

Danielle E. Jake-Schoffman, PhD

Greater participant engagement is associated with weight loss in social media-delivered interventions, but little is known about what types of engagement impact weight loss. Goal setting is an important behavioral strategy emphasized in all weight loss programs. Using data from a Facebook-delivered intervention, we examined the characteristics of participants' posts in which they set a goal to explore the relationship between the characteristics of goals and weight loss. Overweight/obese adults ($n = 53$) received a 12-week Facebook-delivered weight loss intervention based on the Diabetes Prevention Program. We downloaded objective engagement data from Facebook and content analyzed participant posts in which participants set a goal (i.e., expressed an intention to make a healthy lifestyle change). Two coders independently coded whether the goals were quantifiable (e.g., I will track my diet 7 days this week) vs. not (e.g., I'm going to get back on track this week) (84% agreement, $\kappa = 0.58$ [95% CI: 0.38–0.78]) and repeating (e.g., Going to the gym 3 days this week) vs. one-time (e.g., Going for a 30 minute walk today) (83% agreement, $\kappa = 0.49$ [95% CI: 0.25–0.74]). As the number of each type of goal per participant was not normally distributed, we report medians and inter-quartile ranges (IQRs) and assess associations with % weight loss using Spearman correlations. We use t-tests to compare average weight loss and number of goals and 1+ (vs. none) goal of each type. Participants (91% female; 91% non-Hispanic white) were on average 46.2 (SD: 10.5) years old with baseline BMI of 32.4 (SD: 4.8) kg/m². Average 12-week weight loss was 2.6% (SD: 3.5%). Participants posted a median of 4 (IQR 1–7) goals; 77% of participants posted >1 goal. Sharing more goals was associated with greater % weight loss ($p = 0.002$), but participants who shared 1+ goal did not lose more weight on average than those who shared no goals ($p = 0.10$). Of the 255 goals shared, 75% were quantifiable (30% of which were repeating) and 28% were repeating (82% of which were quantifiable). Sharing a greater number of quantifiable goals was associated with % weight loss ($p = 0.001$), and participants who shared 1+ quantifiable goal lost more weight on average ($p = 0.03$) than those who shared none. Sharing a greater number of repeating goals was associated with greater % weight loss ($p < 0.001$), and those who shared 1+ repeating goal lost more weight on average ($p = 0.003$) than those who shared none. Online weight loss programs provide objective data on how participants articulate their goals and intentions. Further research should explore how to best help participants set goals that are quantifiable and repeated in an online environment, and whether doing so improves their weight loss.

Symposium 51

2:00 PM-3:15 PM

PLACE AND CANCER: EXPLORING THE IMPACT OF WHERE WE LIVE, WORK AND PLAY ON CANCER RISK AND OUTCOMES

Kimlin Ashing, PhD¹, Monica L. Baskin, PhD², Sabrina Ford, PhD³, Reginald Tucker-Seeley, ScD⁴, Kassandra I. Alcaraz, PhD, MPH⁵, Scarlett Lin. Gomez, PhD⁶, Chanita Hughes-Halbert, PhD⁷

¹City of Hope, Duarte, CA; ²University of Alabama at Birmingham, Birmingham, AL; ³Michigan State University, East Lansing, MI; ⁴University of Southern California, Los Angeles, CA; ⁵American Cancer Society, Atlanta, GA; ⁶University of California, San Francisco, San Francisco, CA; ⁷Medical University of South Carolina, Charleston, SC

Growing evidence of the impact of place – where people live, work and play – on cancer underscores the urgency of a symposium focused on the relationship between place and population disparities—cancer risk, incidence, prevalence, mortality and burden. In cancer research, examining place offers a necessary and profound opportunity for advancing the science of disease etiology, progression and outcomes -- by revealing a person's potential and actual cancer risk exposure, and barriers to prevention and treatment. Place and residential history significantly define neighborhood quality and resources; stress and quality of life, housing condition; tobacco, alcohol and substance consumption; food environments; chemical contaminants exposures; and accessibility and quality of healthcare resources. However, understanding these linkages can be complex and challenging.

In this symposium, a multidisciplinary panel of experts will highlight the epidemiological data and outcomes literature, as well as explore the underlying pathways, predictors, moderators, and mediators of place and cancer relevant to cancer risk outcomes and burden. Thus, the chair will introduce a broad, behavioral science perspective approach on place and cancer. The first presenter will discuss place and daily living risk, particularly on how place hinders healthy lifestyles. The second presenter will speak on place and cancer environmental risk, focusing on environmental carcinogenic exposure. The third presenter will explore methods and measurement considerations regarding place and financial well-being and how these affect cancer risk and outcomes. The fourth presenter will reflect on place and healthcare access, quality of care and survivorship. Finally, the fifth presenter will highlight the impact of place on risk, morbidity, mortality and survival. The discussant will synthesize and critically examine the state of the science presented, identifying potential challenges and opportunities to advance the field. The EMMH and Cancer SIGs partnered to bring together scientists and behavioral professionals from various disciplines to discuss the latest findings in the field, to foster interdisciplinary interactions, and to stimulate the development of new research in cancer, place and disparities. Discussion will attend to behavioral science inclusion and contribution to team science and multisectoral partnerships to better understand and address the vexing problem of place and cancer.

Symposium 51A

PLACE AND CANCER: EXPLORING THE IMPACT OF WHERE WE LIVE, WORK AND PLAY ON CANCER RISK AND OUTCOMES

Dr. Kimlin Ashing, PhD

Growing evidence of the impact of place – where people live, work and play – on cancer underscores the urgency of a symposium focused on the relationship between place and population disparities—cancer risk, incidence, prevalence, mortality and burden. In cancer research, examining place offers a necessary and profound opportunity for advancing the science of disease etiology, progression and outcomes -- by revealing a person's potential and actual cancer risk exposure, and barriers to prevention and treatment. Place and residential history significantly define neighborhood quality and resources; stress and quality of life, housing condition; tobacco, alcohol and substance consumption; food environments; chemical contaminants exposures; and accessibility and quality of healthcare resources. However, understanding these linkages can be complex and challenging.

Symposium 51B

ROADBLOCKS TO HEALTHY LIFESTYLES ON THE JOURNEY TO BETTER HEALTH

Dr. Monica L. Baskin, PhD

Obesity is associated with 5 of the 10 most common cancers in the US and as many as 1 in 5 cancer deaths are related to excess weight. Poor nutrition and physical inactivity may also increase the risk of several cancers, independent of obesity. While these risks are not unique to any single population, racial/ethnic minorities, socioeconomically disadvantaged, and rural residents experience a greater cancer burden. Maintaining healthy lifestyles for cancer prevention or recurrence may be particularly challenging for these groups. Geographic disparity is explained, in part, by greater poverty and limited access to healthcare and health-promoting environments. Specifically, environments in which African Americans and rural residents live may pose barriers to healthy lifestyles due to the limited number of supermarkets and poor access to safe places to engage in physical activity. Larger food stores are more likely to stock healthy foods at lower cost. Similarly, light traffic, sidewalks, and safety from crime characterize neighborhoods with increased physical activity. This presentation will explore the intersection of race, place and cancer in describing barriers of participants in a lifestyle intervention in the rural Deep South. Participants were part of an academic-community partnership to reduce cancer disparities and involved the use of trained lay staff and volunteers to deliver the intervention in their local communities. A total of 409 African American women from rural communities in Alabama and Mississippi participated with over 27% of the total sample losing $\geq 5\%$ of their body weight at the end of the most intensive phase of the trial (6-months). Average participant weight loss in the multi-level group-based intervention was 3.2kg ($p < 0.001$) vs the traditional group-based intervention (2.2kg; $p < 0.001$). These findings are similar in weight loss magnitude among African Americans as published trials using more highly skilled interventionists; however, session attendance (often inhibited by transportation issues, family obligations, work schedules, etc.), family and friend support, perceived cultural norms, and access to health promoting environments mediated the impact of the intervention. Extending our reach to rural, lower-income, and racial/ethnic minority populations will require careful consideration and elimination of road blocks and potential detours to facilitate a successful journey to better health and cancer prevention.

Symposium 51C

ENVIRONMENTALLY RELATED CANCER IN RURAL “HOT SPOTS”: WHAT CAN WE LEARN?

Dr. Sabrina Ford, PhD

Geographic cancer clusters or “hot spots” are locales where cancer incidence rates are higher than the national averages for the United States (U.S.). Examining environmental toxins can assist us in identifying epidemiological factors related to cancer risk. Environmental toxins are defined as cancer causing agents that can be created or occur naturally in air, water, foods, etc. In the U.S., each state has its own diverse set of environmental risks that contribute to cancer incidence. More specifically, environmental risk factors can be concentrated in rural counties and small towns that affect a defined group of persons. In this presentation, the State of Michigan cancer rates will be explored to illustrate methodology for identifying environmental factors found in rural counties and towns with high rates of cancer incidence and the potential environmental contributors. Using evidence and statistics from the National Cancer Institute (NCI), American Cancer Society (ACS), Centers for Disease Control and Prevention (CDC), and Michigan Cancer Consortium, we will give an overview of rural hot spots in U.S. We will then describe, in detail, five rural counties in Michigan with distinct environmental risks for cancer and how they affect local populations. We will discuss how the delivery of toxins produced by rivers that flow through adjacent rural counties, urban auto factory residue, and chemical manufacturing present distinct differences in cancer risk. Urban toxic exposures are fairly similar across larger cities in the U.S., whereas rural exposure is often unique to geographic locale. Our methodology and findings can be generalized to other states, counties and small towns that are often overlooked because of the small number of cancer cases compared to more populous counties and towns. Understanding and describing environmental cancer risks contributing to cancer hot spots can inform public health providers and policy makers for designing and implementing intervention and prevention programs specific to rural populations.

Symposium 51D

INDIVIDUAL AND NEIGHBORHOOD FINANCIAL WELL-BEING DURING CANCER SURVIVORSHIP

Reginald Tucker-Seeley, ScD

The cost of cancer care is rising faster than other diseases; and research has shown that the experience of recent financial hardship is associated with worse outcomes throughout survivorship, even beyond the negative outcomes associated with poverty. Discussions about the financial burden of cancer care have increased in recent years in the academic literature and popular press, and several terms have been used to describe this “burden.” Yet, the discussion oftentimes conflates the lack of *material* resources to cover medical expenses, the potential *psychosocial* distress accompanying the lack/reduction in financial resources, and the *behavioral* coping responses to address the lack /reduction in financial resources. In addition, the discussion of the neighborhood socioeconomic context is often used as a proxy for individual socioeconomic circumstances without a clear theoretical framework linking neighborhood environment to individual/household socioeconomic circumstances. More specifically, we currently lack adequate conceptualizations and operationalizations of the **material, psychosocial, and behavioral** aspects of individual and neighborhood financial well-being prior to, during, and following cancer care. This dearth in the operationalization of multilevel financial well-being during cancer survivorship impedes efforts to identify modifiable intervention targets of the financial burden of cancer care to ensure that families do not succumb to financial ruin as they manage a chronic disease and navigate the health care system. Research by the presenter and others focused on defining and measuring financial well-being at the individual/household and neighborhood level will be discussed.

Symposium 51E

THE INVISIBLE PLACE: ASSESSING AND ADDRESSING THE SOCIAL ENVIRONMENT TO ELIMINATE DISPARITIES IN CANCER

Dr. Kassandra I. Alcaraz, PhD, MPH

Although not always readily apparent, the social environment exerts significant and persistent influence on cancer-related perceptions, behavior, and outcomes. The unique social environment of socioeconomically disadvantaged or otherwise marginalized populations can be particularly influential in these populations, who often suffer disparities in cancer. Extending our conceptualization of “place” beyond the physical environment can inform and advance a new set of strategies to reduce disparities. The 2018 SBM meeting, focused on “Extending Our Reach,” presents an opportune time to discuss how the social environment can be used to both understand and address cancer disparities—beyond the healthcare sector. Despite strong evidence of social influences on health, we have yet to adequately understand and take advantage of the social environment in developing solutions to eliminate disparities. For example, social isolation is well-established as an independent risk factor for premature death on par with other risk factors such as physical inactivity, obesity, and lack of healthcare access. However, such work has not translated to the development of efficacious and scalable behavioral interventions for the socially isolated. Fortunately, the emergence of new research frontiers, communication technologies, and multi-sectoral partnerships hold promise for overcoming this and other challenges. This presentation will discuss the social environment and cancer disparities across four interrelated domains: 1) framework for assessing, understanding, and addressing the social environment of medically vulnerable populations; 2) evidence of socio-environmental influences on disparities in cancer; 3) innovative cross-sectoral approaches for leveraging and/or enhancing the social environment to develop and disseminate disparity-reducing behavioral interventions; and 4) recommendations for future research. The discussion seeks to stimulate a focused plan of action for proactively considering and integrating socio-environmental factors in efforts to reduce cancer disparities and mortality in the United States.

Symposium 51F

PLACE AND CANCER RISK AND SURVIVAL: DOES CONTEXT MATTER?

Dr. Scarlett Lin. Gomez, PhD

Where people live, work, and play has been shown to impact health behaviors and a number of health outcomes including overall mortality. However, until recently, research on neighborhood factors and cancer risk and survival has been relatively sparse. In recent years, there has been a greater conceptual appreciation for the importance of place on its influences on cancer outcomes across the continuum, from prevention to mortality. The development of geospatial methods and tools, and geostatistical models have also helped to fuel the expansion of research in this area. In this presentation, we will provide an overview of the epidemiological data on neighborhood characteristics, focusing on social and built environment factors, on cancer risk, survival and mortality. We will discuss the methodological challenges and opportunities to advance research in this area.

Symposium 52

2:00 PM-3:15 PM

USING MHEALTH AND EHEALTH INTERVENTIONS TO REDUCE HEALTH DISPARITIES: FROM CANCER PREVENTION TO CANCER SURVIVORSHIP

Shannon M. Christy, PhD¹, Brian D. Gonzalez, Ph.D.², Leah A. Carter, M.Ed.³, Claire A. Spears, Ph.D.⁴, Betina Yanez, Ph.D.⁵¹University of Tennessee Health Science Center, Memphis, TN; ²Moffitt Cancer Center, Tampa, FL; ³Pennington Biomedical Research Center, Baton Rouge, LA; ⁴Georgia State University School of Public Health, Atlanta, GA; ⁵Northwestern University Feinberg School of Medicine, Chicago, IL

Health disparities affect racial and ethnic minorities and medically underserved individuals throughout the United States. Such disparities are evident across the cancer continuum from engagement in cancer preventive behaviors (e.g., cancer screening behaviors, physical activity) and cancer risk behaviors (e.g., smoking) to morbidity, quality of life, and mortality. mHealth and eHealth technologies have the potential to promote cancer preventive behaviors and to reduce cancer risk behaviors prior to the development of cancer as well as to improve quality of life and symptom management among cancer survivors. Using these technologies, interventions can be tailored for an individual, targeted to specific populations, and provided in real time. As the vast majority of adults in the United States use the internet and own a mobile phone, mHealth and eHealth technologies may be a means of successfully impacting cancer health disparities. In particular, these approaches could reduce some of the barriers (e.g., cost and transportation) that often limit access to services for underserved populations. However, few mHealth and eHealth interventions have focused specifically upon populations impacted by health disparities. In this symposium, the speakers will present findings on the development, feasibility, and acceptability of technology-based applications aimed at reducing cancer health disparities as well as offer suggestions and lessons learned. The first speaker will present data on the development of a culturally-targeted mHealth application focused upon encouraging physical activity among African American men. The second speaker will share the findings of a text messaging intervention for promoting smoking cessation among low-income, predominantly African American smokers. The final speaker will present data on the feasibility of an eHealth intervention aimed at improving knowledge and quality of life among Hispanic breast cancer survivors. Finally, the Discussant will provide insight into some of the promises and potential challenges of mHealth and eHealth technologies for reducing cancer health disparities.

Symposium 52A

A MOBILE PHONE-BASED PHYSICAL ACTIVITY MAINTENANCE APP FOR AFRICAN AMERICAN MEN: MOBILEMEN

Ms. Leah A. Carter, M.Ed.

Background: Physical activity (PA) is a modifiable risk factor for those cancers frequently afflicting African Americans. There is a need to tailor PA interventions towards African American men because they have unique gender role beliefs which influence exercise promotion. African American men perceive mobile technology as an acceptable means of intervention delivery. The purpose of this proposal is to develop a PA maintenance mobile phone application for African American men (*MobileMen*).

Methods: The development of the mobile application took place in three phases. First, iterative focus groups with African American men were conducted to determine interest and guide development of *MobileMen* content, design, and aesthetics to fully develop a functioning prototype of the mobile app. Second, lab usability testing was conducted to test the app's functionality and ease of use. Third, field usability was conducted to assess practical usability and satisfaction with the prototype version of the app.

Results: There were 25 African American men who took part in 4 focus groups. The men indicated that an app specifically developed for African American men was appropriate. There was acceptance of the feedback, lesson content, and reward system in the app. Additional components desired included monitoring dietary habits and personal health parameters, as these were seen as consistent with increasing physical activity. There were 18 African American men who took part in 3 usability sessions. Overall, the app was deemed user friendly. A functional app has been developed that includes self-monitoring, rewards, feedback, and behavioral content tailored to African American men. Ten African American men will utilize the app for one month to determine practical usability and satisfaction.

Conclusions: Thus far, the concept of an app designed specifically for African American men is acceptable and the app has been determined to be feasible to fully develop. To our knowledge, no study has utilized mobile phones as a means of effecting PA levels in African American men. In this way, *MobileMen* will address an unmet need as it will be the first smartphone app that is targeted toward PA maintenance in African American men.

Symposium 52B

EXPERIENCES WITH TEXT MESSAGING FOR SMOKING CESSATION AMONG LOW-INCOME, PRIMARILY AFRICAN AMERICAN SMOKERS

Dr. Claire A. Spears, Ph.D.

Mobile health technologies offer tremendous promise for providing personalized, just-in-time support for health behavior change. Accumulating evidence supports the efficacy of text messaging for smoking cessation, and between-session text support could enhance effects of in-person interventions. Research is needed to understand users' experiences with these programs and inform the development of more engaging and effective interventions, particularly for underserved populations affected by tobacco-related health disparities. This feasibility study examined user experiences with text messaging as part of an 8-week smoking cessation treatment among low-income, primarily African American smokers. Thirty-eight adult smokers (45% female, 90% African American, 70% total family annual income <\$24,000) enrolled in a mindfulness-based smoking cessation program that involved 8 weeks of in-person group counseling and between-session text messages (1–7 messages per day, with higher frequency around the quit date). Text messages provided motivation, coping strategies, and personalized reminders of reasons for quitting. The program was designed to be interactive (e.g., participants were asked questions and encouraged to text CRAVE, STRESS, or SLIP keywords as needed for additional support). Participants completed questionnaires each week and at 1-month follow-up to provide feedback about text messages. Most (90%) participants responded via text, and 58% used keywords. The majority (92%) indicated reading all or most text messages. On a scale from 1–10 (1=not at all helpful, 10=extremely helpful), participants' average rating of text helpfulness was 8.1 ($SD=2.4$). Most (62%) indicated receiving about the right number of texts; 27% preferred fewer and 12% preferred more. When asked what was most helpful, participants noted the encouragement, positive feedback, and personalized reminders. When asked what they disliked and suggestions for improvement, most participants responded "N/A" or "nothing." Of those who provided feedback, some suggested sending more frequent text messages, some suggested fewer texts, and some suggested including more personalization. The research team also noted some logistical issues (e.g., participants changing phone numbers or experiencing service interruptions). Overall, results provide support for feasibility and offer practical suggestions for using text messaging to enhance smoking cessation programs among low-income African American smokers.

Symposium 52C

MY GUIDE: AN E-HEALTH INTERVENTION TO IMPROVE PATIENT-CENTERED OUTCOMES AMONG HISPANIC BREAST CANCER SURVIVORS

Betina Yanez, Ph.D.

Background: Breast cancer (BC) is the most commonly diagnosed type of cancer among Hispanic women living in the U.S., and relative to non-Hispanic white women, Hispanic women report poorer quality of life (QOL) after treatment. Smartphone interventions are a viable approach for addressing healthcare accessibility issues and improving QOL outcomes among cancer survivors, especially among Hispanics with documented increased levels of Internet use for accessing health information. This abstract describes the development and preliminary feasibility of My Guide, a patient-centered smartphone application.

Methods: Eligibility criteria for participants included: English or Spanish-speaking Hispanic/Latina women breast cancer survivors, diagnosis of non-metastatic breast cancer, completed active treatment within the past two years. Hispanic survivors were enrolled in a 4-week intervention to assess the satisfaction and demand for the My Guide application. Participants completed measures on user satisfaction and breast cancer knowledge and were encouraged to use the application each week and were assigned to weekly telecoaching calls. The My Guide application was organized into six modules that incorporated psychosocial education and behavioral elements from the literature as well as feedback from community stakeholders, human-computer interaction and Smartphone application design experts, and investigators with ample experience conducting research with Hispanic breast cancer survivors.

Results: Participants were 25 Hispanic breast cancer survivors. Sixty-eight percent of the sample had a high school education or less. Ninety percent of participants enrolled in the My Guide feasibility trial and the retention was also 90%. The mean number of hours spent using the application across the 4 weeks was 9.25 hours ($SD=7.83$). The mean score on the satisfaction survey was 65.91 (range 42–70, $SD=5.89$), in which higher scores reflect greater satisfaction with the My Guide application. Participants' scores on the Breast Cancer Knowledge Questionnaire improved from study baseline ($M = 9.5$, $SD = 2.92$) to the post-intervention assessment ($M = 11.14$, $SD = 2.66$); $t(21) = -3.12$, $p = .002$, $d = .59$.

Conclusions: Study findings provide preliminary evidence for the feasibility of a Smartphone-based intervention for Hispanic breast cancer survivors. Future work is needed to establish the efficacy of My Guide for Hispanic breast cancer survivors.

HOW SERVICE DESIGN UNLOCKS THE POTENTIAL OF DIGITAL HEALTH

Ellen Beckjord, PhD, MPH¹, Emily Lattie, PhD², Kristin McCall-Kiley, MSW, MASD³, Charles Jonassaint, PhD MHS⁴, Eric Hekler, Temp⁵

¹UPMC, Pittsburgh, PA; ²Northwestern University, Chicago, IL; ³UPMC Health Plan, Pittsburgh, PA; ⁴University of Pittsburgh, Pittsburgh, PA; ⁵Temp, Temp, AZ

How are innovations in digital health successfully integrated into a clinical service? Though important work continues on creating and testing digital health tools, many digital health innovations cannot reach their full potential to positively impact health behavior and outcomes until they are integrated into the delivery of health care. Service design is a discipline specifically concerned with this process. It considers care providers as critical users in digital health and surfaces insights required to allow people and technology to interact in ways that elevate the impact of both. Our first presentation will focus on the integration of a digital tool for pain management in a sickle cell clinic. Next, we will discuss the design of a technology-enabled mental health service for integration within a multi-clinic accountable care organization. The third presentation will describe the service design research done to support integration of a mobile application for health behavior change into the health coaching service of a health insurer. Our Discussant will discuss the implications of service design on how to create, optimize, and repurpose useful and usable tools for behavior change and corresponding usable evidence, with a particular focus on discussing linkages between human-centered design, optimization, and implementation science.

Symposium 53A

DESIGNING TECHNOLOGY ENABLED MENTAL HEALTH SERVICES FOR VALUE BASED CARE

Emily Lattie, PhD

Technology-enabled mental health services, such as those delivered via web-based or app-based platforms, offer the possibility of greatly expanding the reach of service provision. These types of programs have demonstrated efficacy in clinical trials, yet efforts to implement these types of programs into care settings have not been successful. There has been a problem with the design of these programs, which has focused primarily on the technology components and not the design of the clinical service. Further, these programs often face implementation challenges in care organizations following a fee-for-service financial model, as this model does not typically incentivize organizations to adopt technology-enabled mental health services.

Our research group recently proposed the Accelerated Creation-to-Sustainment (ACTS) model, which draws upon methods from human-computer interaction and implementation science to iteratively design and evaluate a technology-enabled mental health service within a care setting. In this presentation, we will discuss our initial work towards developing such a service, following the ACTS model, for a value based care organization that serves more than 200,000 patients. The value-based care organization identified their centralized Care Management service, which works closely with Primary Care, as being the best “fit” for a technology-enabled mental health service. The care managers ($n = 13$) already provide remote-delivered services for patients, with a primary focus on identifying potential barriers to care that may impact patients' abilities to achieve their health goals, and then strategizing ways to overcome those barriers. Quantitative and qualitative analyses of surveys and interviews have indicated that care managers work with patients who have a high rate of common mental health problems, and care managers are eager to receive additional training and resources for the management of these mental health problems. Methods for embedding technology-enabled mental health programs into the care management workflow have been identified, and ongoing work is being conducted with administrative and patient stakeholders.

ODYSSEY: A CASE STUDY IN THE UTILIZATION OF SERVICE DESIGN FOR BETTER MEMBER HEALTH & BUSINESS OUTCOMES

Kristin McCall-Kiley, MSW, MASD

Health needs around stress, smoking, and weight effect a vast majority of people in the population that UPMC serves. Traditionally, UPMC served these needs through a paper workbook or a web-based system in which a member looking to manage their stress, smoking, or weight would choose to participate in the type of service with or without a health coach assisting them through the program. UPMC saw the opportunity to both improve the experience and outcomes for those with these health needs while also optimizing the process model for delivering the experience at scale. To do this, UPMC designed an integrated mobile application and service offering using innovation methodologies including: 1) agile, 2) service design, and 3) human-centered design. The team used human-centered design over agile sprints to deeply, yet quickly, understand the experience and needs of those who would benefit from the app and care providers alike (in this case health coaches). Secondary research consisted of analogous situations and environmental scan of digital behavioral health services. The primary service design research consisted of: 1) interviews with health coaches and business leaders to uncover the existing service blueprint and 2) co-design sessions with members and health coaches to collaboratively discover the technology-enhanced service blueprint. The outputs of which were mapping the existing experience journey and business processes from these perspectives (i.e., a service design blueprint). This uncovered key moments of opportunity that quickly assessed the organization's ability to deliver. The team then employed lean-startup methodologies to prototype the new service (and its assumptions) in the form of a test run in November. Insights from the monitoring and evaluation of the test run provided the second iteration of the technology-enhanced service. The team then launched a larger service pilot in January with the revised version of the service. Pairing evidence-based practices in behavioral health with innovation methods has increased the ability to scale the life improvement services to our members.

Symposium 53C

ODYSSEY: A CASE STUDY IN THE UTILIZATION OF SERVICE DESIGN FOR BETTER MEMBER HEALTH & BUSINESS OUTCOMES

Dr. Charles Jonassaint, PhD MHS

Pain is the most common medical symptom requiring care. Over 80% of patients presenting for a physician visit report pain as a primary complaint, however, 80% of those patients receive inadequate treatment for their pain. Accurate assessment and diagnosis of pain is necessary to provide appropriate pain treatment and quality care, yet the current methods for assessing pain are sorely inadequate. Pain assessment tools are either too long and complex for point of care or too simplistic to capture the dynamic pain experience. To address this, we developed Painimation, a novel tool that uses graphic visualizations and animations, instead of words or numeric scales, to assess pain quality, intensity, and course. This presentation will provide an overview of the human-centered design approach that led to the concept of using abstract animations to measure pain and the preliminary data examining the utility and validity of Painimation in a chronic pain medicine clinic.

Through a series of interviews that included contextual inquiry, think-aloud protocols and guided story-telling, we identified patient needs and barriers to effectively communicating their pain experience. We developed a preliminary set of animations and a beta version of the Painimation app that went through user testing. The finalized version of the Painimation app was then tested among 207 adult patients receiving treatment for pain and who reported pain more days than not for at least 3 months. Using a tablet computer, participating patients completed the Painimation instrument, the McGill Pain Questionnaire (MPQ), and the PainDETECT questionnaire for neuropathic symptoms. Participants (N = 207), completed Painimation and indicated it was useful for describing their pain (mean=4/5 on a usefulness scale), and 75% agreed or strongly agreed that they would use Painimation to communicate with their providers. Animations selected corresponded with pain adjectives endorsed on the MPQ. Further, selection of the electrifying animation was associated with self-report neuropathic pain ($r=.16$), similar to the association between neuropathic pain and PainDETECT ($r=.17$). Painimation was associated with PainDETECT ($r=.35$).

Using animations may be a faster, more patient-centered, and accurate method for assessing pain that is not limited by age, literacy-level, or language. This presentation highlights the advantages of human-centered design in the implementation of health care technologies.

2:00 PM-3:15 PM

THE ANNUAL WELLNESS VISIT: IMPLEMENTATION IN REAL WORLD SETTINGS AND COST BENEFITS

Barbara Resnick, PhD, CRNP¹, Natalia Loskutova, MD, PhD², Sherri Sheinfeld Gorin, PHD³, Debra Ritzwoller, PhD⁴, Barbara Resnick, PhD, CRNP¹

¹University of Maryland, Baltimore, MD; ²American Academy of Family Physicians, Kansas City, MO; ³Columbia University, New York, NY; ⁴Institute for Health Research, Kaiser Permanente Colorado, Denver, CO

The Medicare Annual Wellness Visit (AWV) was introduced in 2011 as part of the Medicare Part B expansion under the Affordable Care Act. The AWV was promoted to encourage preventive care and mitigate health risks in aging patients through required age-appropriate and risk modifying screenings and assessments. It does not include a comprehensive physical exam. Rather it incorporates vital signs such as height, weight and blood pressure, assessments of cognition, mood, balance, vision, hearing, falls risks, immunizations, cancer screenings, and advanced directives. Unfortunately, the implementation of the AWV has been relatively low nationally and relatively little is known about the benefits of the AWV in patient outcomes and costs. The percentage of beneficiaries receiving an AWV increased from 7.5% in 2011 to only 15.6 by 2014. Generally, those who were White, lived in urban, higher-income areas, and had one to two comorbidities were more likely to receive an AWV than others. Challenges to implementation of the AWV include: lack of knowledge among providers about how to perform, document, and bill for the AWV; acute medical problems taking priority over prevention; and lack of interest on the part of patients. Outcomes associated with implementation of AWV have included; medication adjustments; increased adherence to vaccinations; and improved cancer screening and screening for diabetes and hyperlipidemia. For practices, the AWV is revenue-generating and patients seem to respond positively to the AWV experience. While the AWV provides an opportunity to better prevent and manage disease, there is insufficient provider team assessment and followup to facilitate either near-or longer-term behavior change. Moreover, little is being done to apply the findings from the AWV to facilitate physical activity and dietary counseling, to followup on positive findings from cancer screening, or to reduce falls. And, only 10% of older adults who receive an AWV are screened for depression. The purposes of this symposium are to: provide a comprehensive review of the AWV; describe the innovative implementation of the AWV in a real-life setting; summarize AWV cognitive assessments; address the cost implications of the AWV; and to discuss the opportunities for implementing behavior change through the AWV. The findings from this symposium will be developed into a Policy Brief with the Gerontological Society of America.

Symposium

54A

THE COGNITIVE ASPECTS OF THE ANNUAL WELLNESS VISIT

Natalia Loskutova, MD, PhD

Early and timely recognition of cognitive decline shows clear benefits from disease management, ethical, safety and financial planning perspectives. Evidence, however, highlights a significant diagnosis gap in dementia with the majority of dementia patients in primary care never receiving a diagnosis of dementia. Assessment of cognitive impairment is a required component of the AWV. Ultimately, the goals of this AWV component is to improve detection and diagnosis of dementia. We have evaluated 2,999,338 electronic health records of individuals 65 and older for evidence of the AWV and documented diagnosis of dementia of any type from 2011 to 2015. Overall, we identified 3,859 records of completed AWV (G0438 and G0439), that represented 0.08% of all documented visits. Of those, Welcome to Medicare AWV (G0438) constituted on average 22.5% of all AWVs. The overall 5-year average dementia diagnosis rate was $0.51 \pm 0.51\%$ with a demonstrated gradual increased over time. The rates of dementia detection correlated significantly with the total number of visits ($r=0.97$, $p=0.007$) and with the number of AWVs ($r=0.90$, $p=0.04$). Despite a relative paucity of evidence on the performance of the AWV approach on improved dementia detection and subsequent care and several implementation barriers, the AWV provides the only sustainable and regular opportunity to establish a baseline measurement and identify changes in cognitive status over time. Several recommendations and resources have been developed to address the implementation challenges of cognitive assessment during the AWV including algorithms for assessing cognition in primary care, recommendations on screening tools and documentation and reimbursement guides for services and procedures related to cognitive impairment. Health care providers should make a greater effort to identify patients who skip the annual AWV and encourage them to utilize this benefit, otherwise they miss the opportunity to conduct regular cognitive assessments. Additionally, underutilization of AWV may lead to lost opportunities to alter behaviors that can help optimize cognitive function such as exercise and other healthy behaviors such as smoking cessation and moderation of alcohol intake.

Symposium 54B

DISCUSSANT THE ANNUAL WELLNESS VISIT: IMPLEMENTATION IN REAL WORLD SETTINGS AND COST BENEFITS

Sherri Sheinfeld Gorin, PHD

The discussant will provide a synthesis of the presentations around the Annual Wellness Visit.

The AWV was promoted as a way to encourage preventive care and mitigate health risks in aging patients through required age-appropriate and risk modifying screenings and assessments. Unfortunately, the implementation of the AWV has been relatively low nationally; further, little is known about the benefits of the AWV from either a patient quality of life perspective or by comparing its costs and benefits. The percentage of beneficiaries receiving an AWV increased from 7.5% in 2011 to only 15.6 by 2014. For practices, the AWV is revenue-generating and patients seem to respond positively to the AWV experience. While the AWV provides a critical opportunity to reduce risks for diabetes and hyperlipidemia, for example, through physical activity and dietary counseling, and the detection of cancer, there is insufficient provider team assessment and followup to facilitate either near-or longer-term behavior change. And, only 10% of older adults who receive an AWV are screened for depression. Moreover, little is being done to apply the findings from the AWV to facilitate behavior change through physical activity and dietary counseling, to followup on positive findings from cancer screening, or to reduce falls. The purposes of this symposium are to: provide a comprehensive review of the AWV; describe the innovative implementation of the AWV in a real-life setting; summarize AWV cognitive assessments; address the cost implications of the AWV; and to discuss the opportunities for implementing behavior change through the AWV. The Centers for Medicare and Medicaid Services is evaluating the AWV, so, alongside our GSA partners, the findings of the symposium could have policy impact on enhanced health among older adults.

Symposium 54C

THE ANNUAL WELLNESS VISIT: RESOURCE AND COST IMPLICATIONS ASSOCIATED WITH IMPLEMENTATION

Debra Ritzwoller, PhD

Consensus generally exists regarding the value of broad implementation of USPSTF prevention guidelines for regular screening and counseling of Medicare age-eligible patients who receive care in community settings. However, at both the provider and practice level, resources, costs, and reimbursement issues may generate disincentives for adoption. The ACA's Medicare Part B coverage expansion that included the Annual Wellness Visit (AWV) which includes a Health Risk Assessment (HRA) and a personal prevention plan (PPP), often requires changes in practice workflows, personnel resources, and informatics capacity.

A recent evaluation of the implementation of an HRA known as My Own Health Report (MOHR) across nine geographically dispersed, heterogeneous primary care practices showed that completion rates were highest (75.3%) for practices that employed electronic devices loaded with the questionnaire and given to patients in the waiting area versus mailings with web-based links (26.2%), phone based (64.2%), or paper surveys in the waiting room (33.9%). Costs per patient completing MOHR varied substantially based on the methods used by the practice. However, no long-term follow-up data is available regarding the effectiveness of the use of MOHR.

In order to maximize the HRA completion rates and to generate a patient specific PPP, in 2011 to 2012, Kaiser Permanente Colorado (KPCO) exploited their EHR and information technology infrastructure to comprehensively implement the AWV using methods that included novel EHR and information technology approaches including: 1) use of interactive voice response (patients call a number and are guided through the HRA questions); 2) a secure email is sent with an embedded link to the HRA; 3) an AWV "smart set" is embedded in the EHR and is used at the visit to electronically generate (and email) the PPP. To date, approximately 50% of eligible patients have completed at least one AWV with HRA. Approximately 65% of patients trigger a positive for at least one condition and participation in prevention strategies including the KPCO "Better Balance Class," has been high. No cost-effectiveness data are currently available.

In order to better align reimbursement strategies by payers, comprehensive evaluations associated with effective and feasible implementation strategies for AWV are needed to assess implementation resources and costs and downstream costs. We will address potential ways in which to gather this data.

Symposium 54D

THE ANNUAL WELLNESS VISIT: WHAT IT IS AND HOW IT CAN BE DONE IN PRIMARY CARE

Ms. Barbara Resnick, PhD, CRNP

The Annual Wellness Visit (AWV) includes a health risk assessment and customized wellness or personal prevention plan for Medicare beneficiaries. The AWV supplements the "Welcome to Medicare" preventive visit which is a one-time comprehensive health assessment for those who initially enroll into Medicare. The AWV is provided by a primary care provider (or under the direction of primary care provider) and should include at least a history, basic assessments of height, weight, blood pressure, preventive screening and personalized health planning. The focus is to identify chronic disease, injury risks, modifiable risk factors and urgent health needs of an individual. The focus is on physical function, psychosocial risks, cognitive function, depression, life satisfaction, loneliness, pain, fatigue, behavioral risks (tobacco and alcohol use), physical activity, nutrition, oral health, sexual health, home and motor vehicle safety, activities of daily living, and instrumental activities of daily living. Realistically, to complete an AWV, short screening tools must be used and referrals made as needed for more comprehensive screening or management of problems once identified. Within a Continuing Care Retirement Community primary care practice AWVs are done during the birthday month of the resident and include basic assessments as noted, the Mini-cog, the PHQ-2, review of smoking, alcohol use, driving status, the Barthel Index and Lawton's Instrumental Activities of Daily Living, review of medication, time spent in physical activity, screening for cardiovascular risks and cancer screening as appropriate are reviewed, lastly medications and advanced directives are reviewed and updated as appropriate. Behavior change interventions are implemented using social cognitive theory. Outcomes associated with AWV include 100% adherence to completion of advanced directives, decreased number of inappropriate cancer screenings, increased physical activity and use of the exercise activities within the facility, and increased awareness of mental health issues among the residents and facilitation of treatment such as cognitive training techniques with speech therapy and counseling for depression with psychology. The AWV allows for a focused review of critically important health issues for older adults prior to an acute event occurring such as a motor vehicle accident or an acute delirium.

Symposium 55

2:00 PM-3:15 PM

NOVEL ANALYTIC APPROACHES TO VARIANCE MODELING IN ECOLOGICAL MOMENTARY ASSESSMENT STUDIES OF PHYSICAL ACTIVITY

Jaclyn P. Maher, Ph.D.¹, Genevieve F. Dunton, PhD, MPH², Chih-Hsiang Yang, PhD³, David Williams, Ph.D.⁴

¹University of North Carolina at Greensboro, Greensboro, NC; ²University of Southern California, Los Angeles, CA; ³University of Southern California, STATE COLLEGE, PA; ⁴Brown University School of Public Health, Providence, RI

The use of Ecological Momentary Assessment (EMA) in physical activity research is growing rapidly as real-time data capture methods supply novel insights into antecedents and consequences of this behavior in naturalistic settings. EMA is particularly well-suited to address these questions because it collects real time information on time-varying constructs multiple times per day. By doing so, EMA is able to capture changes in time-varying variables (e.g., mood, stress), which may be concealed by retrospective summary measures. Time-varying variables can also be aggregated into conceptually and theoretically relevant indicators at the level of the person, including subject-level variances (e.g., how erratic is a subject's mood across occasions?), and subject-level slopes (e.g., is a subject's mood related to physical activity across occasions?). However, little is known about the effects of subject-level parameters (i.e., variances and slopes) of time-varying variables on overall subject-level health outcomes and behavior. The presentations in this symposium will describe a novel analytic approach to variance modeling in EMA research. This approach tests a joint statistical model through the standalone software program, MIXWILD, that allows the random effects of time-varying psychological and contextual factors (i.e., subject-level variances and slopes) to influence overall subject-level health-related outcomes and behavior such as usual physical activity levels and weight status. The first presentation will explore associations between subject-level variability in negative affect with body movement and posture in college students. The second presentation will examine the extent to which subject-level variability daily physical activity is associated with mental health profiles among normal weight, overweight, and obese adults. The third presentation will focus on the degree to which affective responses to physical activity (i.e., subject-level slopes) and subject-level affective variability influence weight status among children and adults. Overall, these presentations will show that applying novel analytic approaches to EMA data facilitates the advancement of theoretical frameworks to explain health behaviors as well as identifies opportunities for tailoring interventions. The discussant will address both the specific contributions of these presentations and the broader role of modeling subject-level variances and slopes in physical activity research.

Symposium 55A

GREATER DAY-TO-DAY VARIABILITY IN PHYSICAL ACTIVITY IS ASSOCIATED WITH POORER MENTAL HEALTH PROFILES AMONG OBESE ADULTS

Jaelyn P. Maher, Ph.D.

U.S. Federal Physical Activity Guidelines outline specific recommendations regarding the duration and intensity of aerobic physical activity (PA) accumulated across the week to gain substantial health benefits, but guidelines are less clear about the recommended frequency of aerobic PA. Research is mixed about whether PA should be performed every day or whether it can be done less frequently, but in longer bouts. To address these questions, research is needed on the physical and mental health effects of day-to-day variability in PA. The current study examined the extent to which day-to-day variability in PA is associated with adults' mental health, and if this association differs by Body Mass Index (BMI). Adults ($N = 116$) completed three waves of data collection (each lasting 4 days) during which participants completed a questionnaire assessing aspects of mental health (i.e., life satisfaction, depressive symptoms, perceived stress), wore a waist accelerometer, and had height/weight measured. This study employed a novel two-stage data analysis approach using the standalone program, MIXWILD. The first-stage model predicted mean level as well as between-subject and within-subject variances in daily PA. This first-stage model estimated a random location (i.e., subject-level means) and a random scale (i.e., subject-level variability) effect for daily PA. In the second stage, these random subject effects (i.e., location and scale) for daily PA, along with their interactions with BMI, predicted subject-level mental health outcomes. Results from the two-stage approach revealed that the association between subject-level variability (i.e., random scale) in daily PA and mental health outcomes significantly differed depending on adults' BMI (i.e., life satisfaction: $\beta = -0.05$, $p < 0.05$; depressive symptoms: $\beta = 0.03$, $p < 0.05$; perceived stress: $\beta = 0.04$, $p < 0.01$). Greater day-to-day variability in PA levels was associated with poorer mental health to a greater extent in obese adults as compared to non-obese adults. For obese individuals, inconsistent activity patterns may have consequences (e.g., muscle soreness, intermittent mood benefits) that ultimately detract from mental health profiles. Behavior change strategies that promote consistency in daily PA may be particularly useful for obese individuals to not only increase PA but to enhance mental health.

Symposium 55B

AFFECTIVE RESPONSE TO PHYSICAL ACTIVITY AND AFFECTIVE INSTABILITY PREDICT OBESITY RISK

Dr. Genevieve F. Dunton, PhD, MPH

Background: Research is growing on the role of affective processes in physical activity and obesity risk. However, research is lacking on whether affective response to physical activity (i.e., association between physical activity and subsequent momentary positive affect) and levels of affective instability (i.e., variability, fluctuation) contribute to obesity risk.

Objective: The current study used Ecological Momentary Assessment (EMA) to examine whether having (1) a greater positive affective response to physical activity and (2) lower positive affective variability reduce obesity risk.

Methods: This analysis pooled data from four EMA studies (age range: 8–73 years) with objective ambulatory monitoring via waist-worn accelerometry ($n=589$). Momentary positive affect was assessed through randomly-prompted EMA surveys occurring several times per day across 4–7 days. Positive affect levels were matched to moderate-to-vigorous physical activity (MVPA) measured by accelerometer in the 30 min. before each EMA survey to capture affective response. Height and weight were measured. This study employed a novel two-stage data analysis approach using a new software program called MIXWILD. In the first stage, a multilevel model (occasions nested within people) estimated random location (i.e., subject-level mean), random scale (i.e., subject-level variability), and random slope (i.e., subject-level association with past 30-min MVPA) effects for momentary reports of positive affect. In the second stage, a single-level logistic regression model tested whether the random subject effects (i.e., location, scale, and slope) of momentary positive affect predicted the odds of being obese (vs. not obese) after controlling for age and sex.

Results: Subject-level mean (i.e. location) of positive affect was not associated with obesity risk ($\beta=-0.05$, $p=0.67$). Lower subject-level variability (i.e., scale) in positive affect ($\beta=0.30$, $p=.02$) and greater positive affective response to physical activity (i.e., slope) ($\beta=-0.84$, $p=.01$) were associated with lower obesity risk.

Conclusion: Fluctuating levels of positive affect were shown to be more obesogenic than chronically low levels of positive affect. Having a greater momentary positive affective response to physical activity may also reduce obesity risk by reinforcing the motivation to be physically active.

Symposium 55C

EXAMINING THE INTERPLAY BETWEEN MEAN AND VARIABILITY OF MOMENTARY NEGATIVE AFFECT IN PREDICTING EVERYDAY ACTIVITY AMONG COLLEGE STUDENTS

Chih-Hsiang Yang, PhD

Behavioral patterns developed during college have profound influence on health consequences in later adulthood. Previous research among college students has indicated that both usual (between-person) and momentary (within-person) levels of negative affect are associated with physical activity. To date there has been limited work investigating the interaction between variability and overall levels of momentary negative affect in predicting daily time spent in different daily activities/postures. Students experiencing similar fluctuations in momentary negative affect may have different time allocations in daily activities/postures depending on their average levels of momentary negative affect. This study aimed to examine the moderation effect of average negative affect on the relation between variations in negative affect and time spent in daily activities/postures. College students ($N = 158$) completed a consecutive 14-day ecological momentary assessment (EMA) study rating their real-time activities/postures (i.e., sitting/standing/moving) and their contemporary levels of negative affect (i.e., stress/anxiety/displeasure) via a smart-phone application. This study employed a novel two-stage data analysis approach using the standalone program, MIXWILD. The first stage model estimated a random location (subject-level average) and a random scale (subject-level variability) for momentary negative affect. In the second stage, the random subject effects and the interaction between them were used as regressors in predicting proportions (%) of sitting, standing, and moving responses in separate subject-level regression models. After controlling for age and gender, the interaction between mean (location) and variability (scale) of momentary negative affect was significantly associated with the proportion of moving responses ($\beta = -1.44, p = .04$). High variability in negative affect was negatively associated with behavior when college students experienced high mean levels of momentary negative affect. This interaction effect remained robust after 500 times of resampling ($\beta = -1.90, p = .05$). None of the main or interaction effects were significant in predicting proportion of sitting or standing responses. The unfolding of intraindividual variations in momentary negative affect may improve our understanding of the role of affect in regulating physical activity in the context of everyday life. Results from this study also may provide useful information for health professionals in developing affective strategies to promote health and well-being among college students.

Symposium 56

2:00 PM-3:15 PM

WHAT DRIVES PROBLEMATIC EATING IN ADULTS WITH OBESITY OR BINGE EATING? A SERIES OF EMA INVESTIGATIONS

Leah Schumacher, MS¹, J. Graham Thomas, PhD², Kathryn Smith, Ph.D.³, Stephanie Manasse, PhD¹, Kathryn Godfrey, PhD¹

¹Drexel University, Philadelphia, PA; ²Alpert Medical School of Brown University & The Miriam Hospital, Providence, RI; ³Neuropsychiatric Research Institute; Department of Psychiatry and Behavioral Science, University of North Dakota School of Medicine and Health Sciences, Fargo, ND

Obesity and binge eating are common among American adults and are associated with poorer physical and mental health. Many individuals with binge eating and obesity report eating in response to affective and internal physical states (e.g., hunger, fatigue), yet research on the relations between these experiences and eating has been mixed. This is true even for studies that use ecological momentary assessment (EMA) to assess participants' internal experiences and eating episodes in real-time and in participants' natural environments. It is critical to improve our understanding of the relationships between internal experiences and eating episodes to optimize interventions for weight management and binge eating. This symposium features three presentations that elucidate important considerations in understanding the link between affective/internal physical states and eating behavior among adults with obesity and binge eating. Dr. Kathryn Smith will begin by discussing how the valence (i.e., positive versus negative) and stability (i.e., state versus trait) of affect differentially predict binge eating and dietary restraint among adults with obesity. Dr. Stephanie Manasse will then discuss how the relationship between internal states and dietary lapses may be moderated by important person-level variables, such as one's degree of impulsivity and the presence of loss-of-control eating. Finally, given the potential limitations of participant self-reports of both affective/internal states and the occurrence of potentially problematic eating episodes, Dr. Kathryn Godfrey will present results from a study that assessed the feasibility of incorporating psychophysiological measures of stress and a smartphone application for photographing food into EMA among a sample of individuals with binge eating. Dr. J. Graham Thomas will conclude the symposium by discussing how the present studies expand on and help to clarify the complex relationships between internal experiences and eating among individuals with binge eating and obesity. Key next steps for utilizing EMA and other technology to assess and ultimately intervene on triggers of problematic eating behavior in these populations also will be discussed.

Symposium 56A

STATE AND TRAIT NEGATIVE AND POSITIVE AFFECT DIFFERENTIALLY PREDICT BINGE EATING AND RESTRAINT IN OBESITY

Dr. Kathryn Smith, Ph.D.

Negative affect (NA) has been implicated in the onset and maintenance of binge eating, a behavior that is also common among individuals with obesity. While dietary restraint (i.e., cognitive effort to restrict caloric intake) is often conceptualized as maladaptive with respect to eating disorders, in the context of obesity, moderate restraint may facilitate weight loss and improve physical health. It is therefore important to elucidate affective predictors of binge eating and restraint among individuals with obesity, which may inform treatment approaches that concurrently target binge eating and maximize health promoting behaviors. This study examined relationships between trait and state levels of NA and positive affect (PA), binge eating, and restraint among 50 adults with obesity (BMI ≥ 30). Participants completed baseline assessments and a two-week ecological momentary assessment (EMA) protocol. Structural equation modeling assessed a trait model of affect in relationship to overall levels of binge eating and restraint, while general estimating equations (GEEs) assessed state models examining relationships between momentary affect and subsequent binge eating and restraint. The trait model indicated higher overall NA was related to more binge eating episodes, Estimate=.49, SE=.18, 95% BC CI [.21, .86] but was unrelated to overall restraint, Estimate=-.001, SE=.02, 95% BC CI [-.03, .03]. Higher overall PA was related to higher overall restraint, Estimate=.04, SE=.02, 95% BC CI [.01, .07] but was unrelated to binge eating. State models indicated momentary NA was associated with a greater likelihood of subsequent binge eating, Estimate=.05, SE=.02, $p=.01$, and lower restraint, Estimate=-.01, SE=.003, $p=.02$. Momentary PA was unrelated to subsequent binge eating or restraint. Taken together these findings demonstrate important distinctions between the valence (i.e., positive versus negative) and stability (i.e., state versus trait) of affect in relationship to binge eating and restraint among individuals with obesity. While NA is a more salient predictor of binge eating than PA, both overall PA and momentary NA appear to be relevant predictors of restraint.

Symposium 56B

DO IMPULSIVITY AND LOSS-OF-CONTROL EATING MODERATE THE RELATIONSHIP BETWEEN INTERNAL STATES AND DIETARY LAPSES? AN EMA STUDY

Dr. Stephanie Manasse, PhD

Empirical tests of the prediction that changes in internal states would lead to dietary lapses (unintended breaks of eating restraint) have yielded mixed results, potentially because this relation would only be evident for those high in impulsivity or with loss-of-control (LOC) eating. The current study examined impulsivity (inhibitory control, the ability to withhold an automatic response, and negative urgency, the tendency to act rashly while in distress) and LOC eating as moderators of the relation between affective and physical states and the likelihood of dietary lapses in overweight and obese adults ($N=190$) completing 2 weeks of ecological momentary assessment at the beginning of an obesity intervention. Generalized estimating equations indicated that for those without LOC, overall greater levels of irritation, loneliness, and boredom were associated with higher lapse likelihood, while for those with LOC eating, likelihood of lapse was elevated regardless of overall levels of negative affect ($bs = -.74$ – $-.45$, $ps < .001$). The relation between momentary increases in stress and lapse was more pronounced for those with poorer inhibitory control ($b = .001$, $p = .01$), and the relation between increases in loneliness and subsequent lapse likelihood was strongest for those higher in negative urgency ($b = .32$, $p = .03$). Interestingly, the relation between increases in hunger and subsequent lapse was strongest for those lower in negative urgency ($b = -.23$, $p < .01$). Results suggest that those with LOC appear to be at greater risk for dietary lapses even if overall levels of negative affect are low. Impulsivity may strengthen the relationship between affective states and subsequent lapses, while increases in physical states may be predictive of lapses for those lower in impulsivity. With replication, results could point towards tailoring the provision of weight control strategies based on LOC status and impulsivity level.

Symposium 56C

STRESS AND BINGE EATING: INTEGRATING ECOLOGICAL MOMENTARY ASSESSMENT WITH PSYCHOPHYSIOLOGY

Kathryn Godfrey, PhD

Advances in mobile technology have created the potential to improve the reach and capacities of weight management interventions. Smartphone applications (apps) for dietary logging are growing in popularity as they allow real-time tracking of eating behaviors in a naturalistic setting with devices already in users' hands. Given the enthusiasm for these technologies and their possible clinical utility, more research is needed in populations with disordered eating. This study examined the relationship between self-reported stress and binge eating using smartphone-based ecological momentary assessment (EMA) and explored the feasibility of incorporating psychophysiological measures of stress. Sixteen male and female community-recruited participants with obesity who binge eat completed a seven day at-home EMA protocol to capture stress and eating behaviors. Participants also took photos of their food, and a chest-worn device measured their heart rate variability (HRV) before eating. Results of longitudinal multilevel mixed effects models show that higher self-reported stress was linked to increased probability of overeating and loss of control overeating ($p = 0.011$ to $p < 0.001$) but not of eating non-nutritious, high calorie foods, or breaking dietary rules. Inspection of HRV data demonstrated substantial limitations of ambulatory HRV data quality. Participants generally reported ease and satisfaction with taking photos of their food. Validation of these photos reveal that participants, even after in person training, were somewhat inaccurate at rating their eating behavior. Taking photos of food may be feasible but more training is needed to improve ratings of disordered eating behaviors. Findings further establish stress as a trigger for overeating and loss of control overeating. Research incorporating psychophysiological measures of stress with EMA may require improved devices to capture HRV through a chest-worn monitor. This work informs future EMA research on stress and eating and builds foundations to develop just-in-time adaptive interventions and smartphone apps enhancing and delivering evidence-based interventions for binge eating and weight management.

COMMUNAL COPING 20 YEARS LATER: ADVANCES IN THEORY, MEASUREMENT, AND APPLICATION

Vicki Helgeson, Ph.D.¹, Kelly Rentscher, Ph.D.², Bonita Sur, M.S.³, Tracey A. Revenson, Ph.D.⁴

¹Carnegie Mellon University, Pittsburgh, PA; ²UCLA, Los Angeles, CA; ³University of Arizona, Tucson, AZ; ⁴Hunter College & The Graduate Center, City University of New York, New York, NY

Over the past two decades, a variety of approaches have been taken to the study of how couples cope with chronic disease. The focus of this symposium is on one interpersonal approach referred to as communal coping. Twenty years ago, communal coping was defined by Lyons, Mickelson, Sullivan, and Coyne (1998) as occurring when “one or more individuals perceive a stressor as ‘our’ problem (a social appraisal) vs. ‘my’ or ‘your’ problem (an individualistic appraisal), and activate a process of shared or collaborative coping” (p. 583). The goal of this symposium is to review the current theory, measurement possibilities, and applications of communal coping to individuals who face chronic disease. The first presenter, Vicki Helgeson, will focus on the two components of communal coping—illness appraisal and collaboration. She will identify antecedents of the two components of communal coping, examine the relation of illness appraisal to collaboration, and explore the implications of illness appraisal and collaboration for the interpersonal exchanges between couple members in which one person has type 1 diabetes. The second presenter, Kelly Rentscher, will examine novel measurement approaches to communal coping. In expanding beyond self-report, she will present data on a new observational measure of communal coping as well as data on we-talk in the context of couples coping with alcohol use disorders and heart or lung disease. Finally, the third presenter, Bonita Sur, will examine the application of communal coping to the prevention of type 2 diabetes. Specifically, she will describe the FAMCON intervention and the interpersonal mechanisms that are targeted to inspire behavior change in the areas of diet and physical activity. Our discussant, Tracey Revenson, is a renowned leader in the field of health psychology with specific expertise in interpersonal coping. She will offer her insights into the progress that has been made over the past 20 years on dyadic coping in light of these presentations and suggest directions for future research.

Symposium 57A

COMMUNAL COPING: AN EXAMINATION OF SHARED ILLNESS APPRAISAL AND COLLABORATION IN THE CONTEXT OF ADULTS WITH TYPE 1 DIABETES

Vicki Helgeson, Ph.D.

Communal coping is a dyadic approach to coping with chronic disease that was defined by Lyons et al. (1998) as consisting of shared illness appraisal (our problem vs. my problem) and collaborating (i.e., working together) to manage the illness. In a study of 199 couples in which one person was diagnosed with type 1 diabetes (52% female, 91% white, average 47 [range 26–75]), we explored both shared appraisal and collaboration and their implications for patient-partner interactions. We asked patients and partners separately whether they viewed diabetes as (1) the patient's issue, (2) the patient's issue with effects on partner, or (3) a shared issue. Partners were significantly more likely than patients to view the illness as a shared issue (69% vs. 24%; $p < .05$). Those for whom independence was central to their self-concepts were less likely to view the illness as shared. Patients who were older, had been married longer, and reported lower physical functioning were more likely to view the illness as shared (all p 's $< .05$). However, the relation to physical functioning disappeared when age was statistically controlled. Importantly, shared illness appraisal was related to collaboration ($p < .001$). Shared illness appraisal was also related to more emotional and instrumental support receipt from partners, higher relationship quality, and lower levels of diabetes distress (all p 's $< .01$). These findings held when age was statistically controlled. Shared illness appraisal was not related to diabetes self-efficacy or self-care behavior, but did interact with whether the patient was diagnosed with diabetes before (76%) or after the partner relationship was established (24%). Patients who reported the highest self-efficacy ($p < .10$) and the best self-care behavior ($p < .05$) were those who were diagnosed with diabetes after the relationship was established and perceived the illness as shared. Collaboration was related to reports of emotional and instrumental support from partners and couple interaction behavior during a videotaped diabetes discussion (all p 's $< .05$). When discussing diabetes difficulties, collaboration was related to observations of joint coping, patients' being receptive to partner support, and partners providing more support and being engaged in the discussion. In sum, patients who appraise diabetes as a shared issue and collaborate with partners to manage the illness are more likely to have supportive exchanges that could benefit diabetes care.

Symposium 57B

MEASUREMENT CONSIDERATIONS FOR THE ASSESSMENT OF COMMUNAL COPING IN A THERAPY CONTEXT

Kelly Rentscher, PhD

Communal coping—a relational process in which partners view a problem interdependently as *ours* rather than *yours* or *mine* and take collaborative action to address it (Lyons et al., 1998)—has emerged as an important correlate of relationship quality and predictor of partner health. Despite recent advances in communal coping theory and research, it has proven challenging to develop well-validated measures. Given social desirability concerns inherent in self-report scales and the evaluative nature of the communal coping construct, observational and behavioral measures have strong potential from a measurement perspective. Several studies link partners' first-person plural pronoun use (*we-talk*), as a behavioral (i.e., linguistic) measure of communal coping, to favorable health outcomes. We present findings from a pilot study that aimed to develop an observational measure of communal coping in a therapy context and further validate *we-talk* as a behavioral measure. 56 couples in which one partner abused alcohol or continued to smoke cigarettes despite having heart or lung disease participated in a couple-focused intervention for health problems. We developed a 4-item rating scale based on Lyons et al.'s conceptualization and previous self-report measures of communal coping. Trained raters observed a therapy session in which increases in communal coping were expected to occur and rated communal coping behaviors for each partner in 1-minute intervals. We obtained pronoun measures via computerized text analysis from transcripts of partner speech during the session. Psychometrically, results provided evidence of construct validity as partners showed significant within-session increases in communal coping behavior ($t_{patients} = -7.74$; $t_{spouses} = -6.78$, $ps < .01$). Results also provided evidence of internal validity, with excellent consistency of scale items (Chronbach α : .93–.97) and inter-rater reliability (ICCs: .54–.82) across segments. With respect to external validity, communal coping behavior correlated with *we-talk* ($r_{patients} = .52$ and $.45$; $r_{spouses} = .43$ and $.49$, $ps < .01$) and a global measure of constructive communication during most segments ($r_{patients} = .17$, $p = .23$ and $r = .51$, $p < .01$; $r_{spouses} = .31$ and $.53$, $ps < .05$). Findings provide preliminary evidence for an observational measure of communal coping in a therapy context and further validate *we-talk* as a behavioral measure. We also discuss considerations for capturing communal coping in therapeutic as well as laboratory and real world settings.

Symposium 57C

COMMUNAL COPING AS A MECHANISM FOR HEALTH BEHAVIOR CHANGE IN THE FAMILY CONSULTATION (FAMCON) PROGRAM FOR T2 DIABETES PREVENTION

Bonita Sur, M.S.

A large and growing literature points to the importance of marriage and marriage-like relationships in promoting health behaviors and for predicting health outcomes. As estimates of pre-diabetes prevalence and disease burden associated with type 2 diabetes escalate, novel prevention programs that have the potential to be widely disseminated and implemented would be of immense public health benefit. The FAMily-based CONSultation (FAMCON) intervention program is an evidence-based treatment for modifying a range of health behaviors (e.g., alcohol abuse, smoking) by leveraging relationship dynamics. We have recently adapted the FAMCON program to target the prevention of diabetes using close relationships as a vehicle for increasing physical activity and maintaining a healthy diet. FAMCON does not target relationship discord per se, but rather uses a systemic perspective to identify and modify couple-level interaction patterns (e.g. communal coping). In this talk, we describe three couple-level behavioral targets that serve as the putative mechanisms of the FAMCON intervention, and discuss how we assess and target each mechanism in the applied intervention. These targets include (a) symptom-system fit, the intimacy-promoting relationship dynamics that reinforce physical inactivity or unhealthy eating; (b) ironic processes, where one person's efforts to encourage physical activity or healthy eating reinforce physical inactivity or unhealthy eating in the partner; and, (c) communal coping, the degree to which couple views the health behavior problem as shared communally within the relationship. We will present results from an initial feasibility and acceptability trial and preliminary pilot outcome data from three couples.

Symposium 58

2:00 PM-3:15 PM

TRANSLATIONAL RESEARCH ON THE ROLE OF FORECASTED HIV STIGMA IN THE CONTEXT OF HIV PREVENTION

H. Jonathon Rendina, PhD, MPH¹, Kristi E. Gamarel, PhD², Sarit A. Golub, PhD, MPH³, John Pachankis, PhD⁴¹Hunter College of the City University of New York (CUNY), New York, NY; ²University of Michigan, Ann Arbor, MI; ³Hunter College/Graduate Center, City University of New York, New York, NY; ⁴Yale University, New Haven, CT

Researchers, clinicians, and policy makers have increasingly recognized the role of HIV stigma on the health and well-being of people affected by HIV and how HIV stigma undermines engagement and retention in HIV treatment and care. To date, however, there has been limited research on the impact of forecasted HIV stigma; that is, the discrimination, rejection, or negative self-image that HIV-negative individuals expect to experience in the event of seroconversion. Data indicate that forecasted HIV stigma is prevalent (i.e., HIV-negative people anticipate they would experience high levels of HIV stigma upon seroconversion) and negatively impacts prevention behavior (e.g., testing behavior). This symposium brings together cutting-edge empirical research to foster greater understanding of forecasted HIV stigma, describe its associations with HIV prevention behaviors among at-risk communities, and discuss the ways that this research could be translated to impact the uptake of biomedical HIV prevention strategies, such as HIV testing and pre-exposure prophylaxis (PrEP). The first talk will present a study of 373 gay and bisexual men that found that, in line with the *impact bias* from the affective forecasting literature, HIV-negative men forecasted significantly higher levels of HIV stigma than HIV-positive men actually experienced, yet experienced HIV stigma was more strongly linked to mental health outcomes for HIV-positive men than forecasted stigma was for HIV-negative men. The second talk presents a study exploring ways in which forecasted HIV stigma is associated with delaying HIV testing among a sample of 753 young men and transgender women who have sex with men ages 15–24. The third talk presents data from a PrEP demonstration-implementation project illustrating how forecasted HIV stigma negatively predicts PrEP uptake among HIV-negative gay and bisexual men, with the association mediated by PrEP stigma beliefs and PrEP adherence self-efficacy. Taken together, these talks draw on affective forecasting and existing HIV stigma frameworks to advance research on how forecasted HIV stigma may undermine HIV prevention behaviors among the highest priority populations. The discussion will be led by a researcher and clinician with extensive expertise in stigma-ameliorating interventions, and will focus on future directions for research, practice, and policy related to reducing HIV stigma to successfully engage people in HIV prevention.

Symposium 58A

FORECASTED VERSUS EXPERIENCED STIGMA AND THE IMPACT BIAS: COMPARING THE IMPACT OF HIV STIGMA BY HIV STATUS

Dr. H. Jonathon Rendina, PhD, MPH

Background: Building upon work on affective forecasting, researchers have examined the extent to which HIV-negative individuals may anticipate or *forecast* the ways HIV stigma might feel were they to seroconvert. The purpose of the present analyses was twofold. First, we sought to examine evidence for the *impact bias* in stigma forecasting, whereby HIV-negative individuals would report greater *expected* levels of stigma upon diagnosis than HIV-positive men report actually experiencing post-diagnosis. Second, we sought to support the hypothesis that forecasted stigma can take a negative toll on mental health and examine differential effects of stigma on mental health by HIV status.

Method: We examined data from 373 gay and bisexual men (GBM) who completed an online survey on stigma and mental health and whose self-reported HIV status was confirmed via testing. We used 13 items from the original Berger HIV Stigma Scale intended to capture internalized stigma and adapted them for HIV-negative participants; anxiety and depression were measured using the Brief Symptom Inventory.

Results: The sample was nearly half HIV-negative ($n = 206$, 55.2%) and nearly half HIV-positive ($n = 167$, 44.8%). HIV-negative GBM forecasted significantly greater levels of HIV stigma ($M = 34.3$, $SD = 8.0$) than HIV-positive GBM experienced ($M = 27.7$, $SD = 8.3$). HIV stigma had a significant impact on increased anxious ($\beta = 0.16$, $p = 0.04$) and depressed ($\beta = 0.21$, $p = 0.004$) symptomology. Moreover, stigma's impact on anxious symptoms was moderated by HIV status such that experienced stigma was more strongly associated with HIV-positive GBM's anxious symptoms than was forecasted stigma for HIV-negative GBM ($\beta = 0.37$, $p = 0.04$), though the moderation was only marginally significant for depressive symptoms ($\beta = 0.33$, $p < 0.07$).

Conclusions: The present study supported the notion that forecasted HIV stigma can be considered in a way that is consistent with affective forecasting and provided evidence of the impact bias. HIV stigma exerts a negative impact on the mental health of both HIV-negative (i.e., forecasted stigma) and HIV-positive (i.e., experienced stigma) GBM, though the effect is stronger for positive men. Future studies examining within-person changes using pre-post data on HIV diagnosis are warranted to further examine stigma forecasting and its association with subsequent experiences of stigma among HIV-positive individuals.

Symposium 58B

FORECASTED HIV STIGMA AND DELAYS IN HIV TESTING BEHAVIORS AMONG YOUNG MEN WHO HAVE SEX WITH MEN AND TRANSGENDER WOMEN

Dr. Kristi E. Gamarel, PhD

Background: Young gay, bisexual, and other men who have sex with men and transgender women are disproportionately affected by HIV/AIDS. The success of biomedical prevention strategies is predicated on regular HIV testing; however, there has been limited uptake of testing among these groups. Forecasted or anticipated HIV stigma—expecting rejection as a result of seroconversion—may serve as a significant barrier to testing.

Methods: A cross-sectional sample of young men and transgender women (N=753, ages 15 to 24) were recruited to participate in a one-time survey through the Adolescent Medicine Trials Network for HIV/AIDS Interventions. In total, 4.4% identified as transgender women and 90% youth identified as a person of color (59.9% Black, 26.4% Latina, and 13.7% other race/ethnicity) and 36.8% reported a lifetime history of unstable housing. Bivariate and multivariate GEE models were fit to examine associations between forecasted HIV stigma and delays in regular testing (i.e., within the past 6 months based on CDC recommendations). Adjusted odds ratios (AOR) and 95% Confidence Intervals (95%CI) were estimated.

Results: Approximately one-third of youth had not tested within the last 6 months. In a multivariable model, greater levels of forecasted HIV stigma (AOR = 1.04, 95% CI: 1.02, 1.07) was associated with an increased odds of delaying regular HIV testing; whereas, reporting a gay sexual identity compared to a bisexual or other sexual identity (AOR = 0.69, 95% CI: 0.49, 0.97) was associated a decreased odds of delaying regular HIV testing over and above sociodemographic characteristics, substance use, and sexual risk behaviors.

Conclusions: Findings highlight the importance of considering the ways in which stigmatizing contexts impact young men who have sex with men and transgender women's testing behaviors, and consequently their uptake and use of appropriate prevention strategies. Future research and interventions approaches will be discussed on how to address HIV stigma in order to increase regular HIV testing among at-risk youth.

Symposium 58C

FORECASTED HIV STIGMA NEGATIVELY IMPACTS PREP UPTAKE: FINDING FROM A COMMUNITY-BASED PREP DEMONSTRATION PROJECT

Dr. Sarit A. Golub, PhD, MPH

Background: Previous research has demonstrated that forecasted or anticipated HIV stigma, i.e., HIV stigma that HIV-negative individuals expect they would experience were they to become HIV-positive, is negatively associated with prevention behavior. However, the mechanisms behind this ironic relationship are not well understood. This analysis tested the hypothesis that forecasted HIV stigma would be associated with increased PrEP stigma beliefs and decreased PrEP-related self-efficacy (mediating variables), thereby reducing PrEP uptake.

Method: Data were collected as part of SPARK, an NIH-funded PrEP demonstration project conducted in collaboration with a community-based health center in New York City. Health center participants who were eligible for PrEP (n = 431; age 18–76; 49% PoC) completed an online survey and were offered PrEP at their next clinic visit. This analysis compared the 300 participants who accepted PrEP to the 131 who declined it.

Results: Individuals who declined PrEP reported significantly higher forecasted HIV stigma, compared to those who accepted PrEP ($p < .01$). Forecasted HIV stigma was positively associated with PrEP stigma beliefs ($r = .30$, $p < .001$) and negatively associated with PrEP adherence self-efficacy ($r = -.13$, $p < .01$). Using the PROCESS macro in SPSS, we tested a mediation model in which the negative association between forecasted HIV stigma and PrEP uptake was mediated through these two variables. Bootstrapping revealed significant indirect effects of both PrEP stigma beliefs ($b = -.16$, 95% CI -0.36, -0.02) and adherence self-efficacy ($b = -.28$, 95% CI -0.52, -0.06) and indicated that both variables contributed significantly to the model.

Discussion: These data add to the literature on the negative impact of forecasted HIV stigma on prevention behavior, indicating that forecasted HIV stigma may be a barrier to PrEP uptake. These data also support the hypothesis that forecasted HIV stigma impacts prevention behavior by fostering negative attitudes toward HIV prevention (e.g., PrEP stigma beliefs) and one's perceived ability to successfully engage in it. Providers, advocates, and policy makers must recognize HIV stigma as a barrier to prevention efforts, and address stigma as a critical component of comprehensive prevention strategies.

Symposium 59

2:00 PM-3:15 PM

FREQUENCY AND IMPACT OF ALCOHOL, OPIOID, AND MARIJUANA CO-USE IN OPIOID-PRESCRIBED INDIVIDUALS

Kevin Vowles, PhD¹, Katie Witkiewitz, PhD¹, Mark a. Ilgen, PhD²¹University of New Mexico, Albuquerque, NM; ²University of Michigan, Ann Arbor, MI

In the past 20 years, there have been significant increases in opioid prescriptions for chronic pain. There are now well-established relations between the proliferation of available opioids and contemporaneous increases in opioid-related morbidity and mortality. As the available data has highlighted these opioid-related issues, it has become clear that opioids are often co-used with other substances, frequently including those that are legally obtainable such as alcohol and medical marijuana. The scope and impact of this co-use, however, remains unclear. The present symposium will therefore present data on substance co-use in those who use opioids for pain treatment. The first presenter, Dr. Katie Witkiewitz will review findings from a large national dataset, the 2015 National Survey on Drug Use and Health ($N = 57,146$) indicating significant patterns of co-use and significant associations between heavy drinking, marijuana use, and misusing pain relievers to manage pain. Next, Dr Mark Ilgen will describe the longitudinal associations between frequency and quantity of marijuana use and opioid misuse as well as pain and functioning in adults who use medical marijuana for the treatment of pain ($N=801$). Finally, Dr Kevin Vowles will present data on the frequency of opioid and alcohol misuse in a sample of opioid-prescribed individuals with chronic pain, as well as the impact of misuse of one or both of the substances on physical and psychosocial functioning. Overall, the presentations will highlight new findings in the area of substance co-use in those prescribed opioids for the treatment of chronic pain, as well as co-use in population data. They will highlight an intensely practical issue as well – historically, pain treatment providers have rarely been trained in treatments for problematic substance use and addiction treatment providers have rarely been trained in principles of pain management and rehabilitation. These data suggest that such cross training is necessary and that future work examining integrated treatments that seek to both identify and treat problematic substance use within those who have chronic pain is urgently needed. Each presentation will highlight areas of need and opportunity within this domain.

Symposium 59A

ALCOHOL AND OPIOID USE IN CHRONIC PAIN: A CROSS-SECTIONAL EXAMINATION OF DIFFERENCES IN FUNCTIONING BASED ON MISUSE STATUS

Dr. Kevin Vowles, PhD

A number of studies have indicated that opioid misuse is associated with disrupted functioning in those with chronic pain. Less work has examined whether misuse of alcohol has similar problematic influences. The present study examined frequency of opioid and alcohol misuse in a sample of 131 individuals (61.1% female) prescribed opioids for the treatment of chronic pain. Participants completed an anonymous survey on-line, consisting of standardized measures of pain, physical and emotional functioning, and risk of opioid and alcohol misuse. Published cut-scores were used to categorize individuals according to misuse status for opioids and alcohol. In total, 35.9% ($n=47$) were below the risk threshold for both substances, 22.9% ($n=30$) were above the risk threshold for both substances, 38.2% ($n=50$) were above the risk threshold for opioids alone, and only 3.0% ($n=4$) were above the risk threshold for alcohol alone. A multivariate analysis of variance was next performed to examine differences in pain and pain-related functioning between groups (after excluding individuals in the alcohol misuse group due to the small sample size). Measures of functioning included usual pain intensity, pain-related distress, depression, physical and psychosocial disability, pain acceptance, engagement in valued activity, and adaptive pain behaviors. Group comparisons indicated that individuals who did not report misuse for either substances reported less distress and greater healthy functioning in comparison to those who reported opioid misuse alone or misuse for both substances. No differences in distress or functioning were indicated for the latter two groups, suggesting that alcohol plus opioid misuse was not associated with more disrupted functioning in comparison to opioid misuse alone. Overall, the frequency of opioid misuse in this sample was somewhat higher in comparison to previous work, although the findings that such misuse can be associated with problems is consistent. Misuse of both alcohol and opioids was observed in approximately 1 out of 5 participants, suggesting co-morbid misuse may be rather common and also disruptive. While these data are preliminary, and further work is necessary, they do suggest that issues of substance misuse in those with chronic pain extends beyond opioids alone. Further, treatment efforts may benefit from combining rehabilitative interventions with those addressing problematic substance use.

Symposium 59B

ALCOHOL, MARIJUANA, AND OPIOID CO-USE IN THE 2015 NATIONAL SURVEY ON DRUG USE AND HEALTH: IMPLICATIONS FOR THE OPIOID EPIDEMIC

Dr. Katie Witkiewitz, PhD

Rising rates of opioid misuse, opioid use disorder (OUD), and opioid overdose deaths in the United States have been described as an “opioid epidemic.” These trends have largely been attributed to dramatic increases in opioid prescription rates and long-term prescription opioid treatment for chronic pain. Alcohol misuse and alcohol use disorder (AUD) are also prevalent public health problems associated with considerable individual and societal costs. Marijuana use is also increasing in the United States, and changing marijuana policies (e.g., legalized recreational marijuana) are likely to be associated with further increases in use. Alcohol, marijuana, and opioids are commonly used in combination, and this pattern of polysubstance use is associated with poor clinical prognosis. For example, alcohol is a contributing factor in many opioid overdose deaths and the continued use of alcohol and marijuana may interfere with OUD treatment, particularly medication-assisted treatment. Further, the concurrent use of alcohol, marijuana, and opioids may interfere with treatment for chronic pain, which impacts at least 1 in 10 adults in the United States. Yet, research on the association between alcohol, marijuana, and opioid co-use is lacking. The current presentation will examine the association between alcohol, marijuana, and opioid co-use in a general population sample using data from the 2015 United States National Survey on Drug Use and Health (NSDUH; $N = 57,146$). The NSDUH is an annual nationwide survey using in-person interviews conducted with randomly selected individuals aged 12 and older. The current presentation focuses on adults, ages 18 and older ($n= 43,561$). In the 2015 survey, 73.2% reported past year use of alcohol, 33.4% reported past year use of any prescription opioid, and 19.0% reported past year use of marijuana. With respect to problematic levels of use, 7.9% met criteria for current alcohol abuse or dependence, 4.7% reported misuse of a prescription opioid in the past year (1% met criteria for current pain reliever abuse or dependence), and 2.3% met criteria for current marijuana abuse or dependence. Regression analyses, adjusting for sampling weights, indicated significant co-use of all three substances ($p < 0.001$), significant associations between misuse of all three substances ($p < 0.001$), and significant associations between heavy drinking, marijuana use, and using pain relievers to manage pain ($p < 0.001$). Results will be discussed within the context of the opioid epidemic and the treatment of chronic pain.

Symposium 59C

ASSOCIATIONS BETWEEN MEDICAL CANNABIS USE, PAIN, FUNCTIONING AND OPIOID MISUSE AMONG ADULT MEDICAL CANNABIS PATIENTS

Mark a. Ilgen, PhD

Background: Pain is the most commonly endorsed reason for medical cannabis use. Several recent state-level epidemiological studies have found a link between the passage of medical cannabis legislation and reductions in opioid-related adverse outcomes. However, very little is known on an individual level about the real-world use of cannabis for pain and how this relates to pain-related outcomes (pain level and pain interference) and opioid misuse.

Methods: A cohort of adults seeking either initial or renewal of certification for medical cannabis for pain management from one of four clinics in the state of Michigan (N = 801) were recruited into this cohort study. These participants were administered measures of the quantity and frequency of cannabis use, pain severity, pain interference and opioid misuse every six months for two years. Follow-up rates exceeded 80% for each of the four follow-up assessments. The present analyses focus on the first year of data collection and examine prospective relationships between frequency of cannabis use and subsequent measures of pain and opioid misuse.

Results: The frequency of daily or almost daily cannabis use among medical cannabis patients increased from 74% to 82% over one year; the frequency of opioid misuse decreased from 31% to 21%. There was no association between frequency of cannabis use at 6-months and the likelihood of opioid misuse at 1-year. Frequency of cannabis use at 6-months was not associated with 1-year pain severity and was associated with greater 1-year pain interference.

Conclusions: Adults who use medical cannabis for pain report very frequent use of cannabis and approximately one third report misuse of opioids. Despite recent findings suggesting state-level associations between medical cannabis laws and fewer opioid-related harms, the present study found no link between the extent of cannabis use and likelihood of opioid misuse on an individual level. No evidence was seen for prospective associations between the extent of cannabis use and pain severity, with some suggestion that greater cannabis use was associated with greater subsequent pain interference. The design of this observational study prevents the determination of causal links between these variables. However, these analyses did not reveal clear benefits of medical cannabis use and underscore the importance of examining the impact of medical cannabis use on positive and negative outcomes at the individual patient level.

2:00 PM-3:15 PM

UNDERSTANDING AND HARNESSING SOCIAL INFLUENCES ON WOMEN'S HEALTH BEHAVIORS: SOCIAL PERCEPTIONS, STIGMA, AND SOCIAL MODELING

Danielle Arigo, Ph.D. in Clinical Psychology¹, Emily Panza, M.S.², Deirdre Dlugonski, PhD³, Tricia Leahey, PhD⁴

¹The University of Scranton, Scranton, PA; ²Alpert Medical School of Brown University, Providence, RI; ³East Carolina University, Greenville, NC; ⁴University of Connecticut, Storrs, CT

Women experience unique challenges to engaging in behaviors such as healthy eating and physical activity, and have specific needs with respect to improving these behaviors that may begin early in life. Of particular importance for women's health behaviors are impressions of and experiences with their social environments, which can influence women's behaviors through a variety of social processes. At present, however, the majority of research focuses on the individual in isolation and does not take into account social processes or perceptions. Additional attention to this set of influences on women's health behaviors may improve intervention efforts tailored for women. Toward these ends, the goal of this symposium is to describe several types of social influence on women's health behaviors: perceptions of the quality of social interactions, self-evaluations relative to others (i.e., social comparison), stress associated with being a member of a minority group (i.e., minority stress as a form of stigma), and shared health behaviors between mothers and daughters. Speakers in this session will present empirical evidence from ambulatory assessment and intervention studies that investigate these processes and their associations with women's health behaviors. First, Dr. Danielle Arigo will describe daily social perceptions (of interaction quality and social comparison), and relations between perceptions and objectively assessed physical activity, from a daily diary study among college women. Emily Panza will then present findings on relations between minority stress experiences and overeating behavior from an ecological momentary assessment study among overweight sexual minority women. Finally, Dr. Deirdre Dlugonski will share the results of a pilot study testing a physical activity intervention designed to promote shared physical activity between mothers and daughters. Each speaker will emphasize the theoretical underpinnings of relations between social processes and women's health behaviors. The discussant, Dr. Tricia Leahey, will integrate the speakers' findings and discuss their implications for understanding and improving health promotion efforts for women.

Symposium 60A

RELATIONS BETWEEN DAILY SOCIAL PERCEPTIONS AND OBJECTIVELY ASSESSED PHYSICAL ACTIVITY AMONG COLLEGE WOMEN

Dr. Danielle Arigo, Ph.D. in Clinical Psychology

Background: Women engage in less physical activity (PA) than men across the lifespan, and there is need for an improved understanding of barriers and facilitators of PA among college women in order to entrench PA habits early in life. College women's perceptions of their social environments, including the quality of their social interactions and the occurrence of social comparisons (i.e., self-appraisals relative to others), are known to influence physical activity. To date, however, the nature of these relations and their potential utility for informing PA interventions are unclear. The present daily diary study was designed to (1) characterize college women's perceptions of their social interactions and comparisons in daily life, and (2) examine time-sensitive, within-person relations between daily social perceptions and PA outcomes.

Method: Participants were women in their second through fourth years of college who did not have regular exercise routines ($n=62$, $M_{Age}=21$, $M_{BMI}=23.1$ kg/m²). For 7 days, participants responded to a nightly electronic survey; they categorized the number and quality (positivity/negativity) of that day's social interactions and social comparisons made each day. Participants also wore Fitbit wristbands to capture their steps and engagement of moderate-to-vigorous physical activity (MVPA) and reported on their motivation and intentions for PA in each survey. Multilevel mixed models were used to differentiate stable, between-person trends from day-to-day (within-person) changes.

Results: More than 75% of the variability in number and ratings of social interaction quality was attributable to within-person change between days (ICC = 0.19–0.25). Social comparisons were reported on 50% of assessment days and were predominantly based on appearance (71% of days with comparisons). Participants were twice as likely to report making comparisons on days with increased negative interactions (95% CI 0.82, 5.55); participants also engaged in 1145 fewer steps and 10 fewer minutes of MVPA on days with +1SD ratings for negative interactions. Conversely, they engaged in 780 additional steps and 10 additional minutes of MVPA on days with +1SD ratings for positive interactions. Steps and MVPA did not differ between days when participants reported (vs. denied) that comparisons occurred. However, on days with reports of comparison occurrences, participants showed a 40% decrease in motivation for PA and a 50% increase in the likelihood of endorsing an intention to exercise the following day.

Conclusions: Findings suggest that daily social perceptions are associated with meaningful changes in PA outcomes. Additional work is necessary to determine the mechanism(s) of these relations, as well methods for harnessing the benefits (or buffering against the negative influences) of social perceptions in PA programs for college women.

Symposium 60B

MINORITY STRESS AND EATING BEHAVIOR AMONG OVERWEIGHT AND OBESE SEXUAL MINORITY WOMEN: AN ECOLOGICAL MOMENTARY ASSESSMENT STUDY

Emily Panza, M.S.

Sexual minority women are nearly three times more likely to be overweight or obese than their heterosexual counterparts, yet little research has investigated *why* or *how* sexual minority status confers risk for obesity in women (Boehmer, Bowen, & Bauer, 2007). The current study examined the relevance of one factor, minority stress, as a mechanism for this weight disparity. Sexual minority women belong to multiple socially stigmatized groups: being non-heterosexual, being female, and for 60%, being overweight. This *triple oppression* exposes sexual minority women to unique and chronic minority stressors, including repeated experiences of external stigmatization (Meyer, 2003). Social rejection is stressful, causing chronic elevations in stress and negative emotion that some sexual minority women may try to regulate by overeating and/or binge eating. Over time, these behaviors may promote weight gain and risk for obesity.

To test this proposed model, the current study used Ecological Momentary Assessment (EMA) to examine whether lifetime and acute minority stress increased risk for overeating and binge eating in sexual minority women. 55 overweight or obese (BMI>25) sexual minority (e.g., lesbian, bisexual) women were recruited from the community to complete baseline assessments of eating behavior and minority stress due to sexual orientation, weight, and gender. For the following five days, participants used a smartphone application to report experiences of stigmatization, overeating and binge eating five times daily.

Findings revealed promising support for the proposed model. As expected, women who reported greater lifetime heterosexist, gender, and weight-based stigma reported higher baseline levels of disordered eating and binge eating. Stigma events during the EMA period were associated with greater concurrent overeating at the same time point, and being stigmatized on any given day was associated with more overeating and binge eating on that day.

The current study provides preliminary support for minority stress as a mechanism of the obesity disparity among sexual minority women. Given the paucity of research in this area and this study's preliminary nature, findings justify future research to unpack the relevance and significance of minority stress as a risk factor for obesity in this group. This will be essential for developing effective, informed, and tailored interventions to reduce obesity and to improve health among sexual minority women.

Symposium 60C

MOTHERS AND DAUGHTERS MOVING TOGETHER: A PILOT INTERVENTION TO PROMOTE SHARED PHYSICAL ACTIVITY

Deirdre Dlugonski, PhD

Many young children are not engaging in enough physical activity to accumulate health benefits. Parents are primary role models for young children and should be involved in interventions to increase physical activity among young children. Previous evidence suggests that children are more likely to be physically active when a parent engages in physical activity with the child.

Purpose: The goal of the Mothers and Daughters Moving Together (MDMT) intervention was to increase shared physical activity participation among mothers and their 2–5-year-old daughters.

Methods: In this quasi-experimental design, mother-daughter dyads self-selected into either the intervention ($N=21$ dyads) or control ($N=10$ dyads) group based on their availability for intervention sessions. Mothers and daughters in the intervention participated in 12-weekly physical activity sessions and received a manual and equipment to facilitate increased shared physical activity. The control group participated in pre- and post-intervention testing sessions and then received the manual and equipment upon study completion. At pre- and post-intervention mothers and daughters wore accelerometers for 1-week and mothers completed demographic, family physical activity, and shared physical activity questionnaires. A series of 2 (Group: Intervention versus Control) x 2 (Time: Pre- versus Post-Intervention) ANOVAs were conducted to determine the impact of the intervention on physical activity, mother-daughter shared physical activity, and family physical activity.

Results: There were no statistically significant main ($F(1, 23)=.53, p=.47$) or interaction ($F(1, 23)=.85, p=.37$) effects for accelerometer-measured moderate-to-vigorous physical activity (MVPA) for mothers. Similarly, there were no statistically significant main ($F(1, 23)=.02, p=.89$) or interaction ($F(1, 23)=1.28, p=.27$) effects for daughter MVPA. There was a statistically significant group by time interaction for mother-daughter shared physical activity ($F(1, 25)=8.46, p=.008$). Intervention group mothers reported a large increase ($d=.90$) in frequency of shared physical activity with their daughters and control mothers reported a small decrease ($d=-.20$). There was a statistically significant group by time interaction for shared family physical activity ($F(1, 25)=4.87, p=.04$), with mothers in the intervention reporting a large increase in family physical activity ($d=.84$) and control mothers reporting no change ($d=.03$).

Conclusions: The MDMT intervention successfully increased shared physical activity between mothers and daughters but did not result in increased physical activity for either mothers or daughters. Mother-child shared physical activity could have a long-term impact on child physical activity levels that should be measured in future studies.

Symposium 61

2:00 PM-3:15 PM

DISPARITIES IN BREASTFEEDING AMONG VULNERABLE POPULATIONS IN THE US AND MEXICO - IDENTIFYING PROBLEMS AND EXPLORING SOLUTIONS

Lisette T. Jacobson, PhD, MPA, MA¹, Tessa Swigart, PhD², Anabelle Bonvecchio, PhD³

¹University of Kansas School of Medicine-Wichita, Wichita, KS; ²National Institute of Public Health, Mexico, San Francisco, CA; ³National Institute of Public Health, México, Huixquilucan, Distrito Federal, Mexico

Optimal breastfeeding recommendations include breastfeeding exclusively for the first six months of life and continuing to breastfeed for at least one year. These recommendations are based on evidence that demonstrates prevention of adverse health outcomes for both mother and infant while decreasing mortality and morbidity. Yet rates of optimal breastfeeding are low throughout the world and are due to a number of factors. Stark disparities in the ability to follow recommended practices exist and mothers who breastfeed at lower rates tend to be less educated, earn less income, are younger, reside in marginalized communities, are unmarried, and are racially and ethnically diverse. Yet these same mothers and their children are also more vulnerable to adverse health outcomes that could be prevented or improved by breastfeeding, including the prevention of micronutrient deficiencies and malnutrition in children, prevention of obesity during childhood and the post-partum period, and decreasing the risk of developing type 2 diabetes mellitus, among many others. The purpose of this symposium is to explore the causes of these disparities and their effects on the ability to follow optimal breastfeeding recommendations, and then to explore successful solutions that aim to reduce these disparities and improve breastfeeding practices. Presentations will focus on programs and strategies to promote breastfeeding among targeted, marginalized communities in rural regions of the United States and Mexico. Findings will be synthesized and discussion generated with the aim to inform interventions that could promote, support and protect breastfeeding among vulnerable populations.

Symposium 61A

NOVEL MULTIFACETED COMMUNITY APPROACHES TO PROMOTE, SUPPORT AND PROTECT BREASTFEEDING

Dr. Lisette T. Jacobson, PhD, MPA, MA

Background: The Kansas Breastfeeding Coalition (KBC) manages a multitude of programs to promote, support, and protect breastfeeding across the state. In collaboration with public health departments, regional foundations, public/private organizations, and communities, the KBC aims to improve exclusive breastfeeding rates via: the Communities Supporting Breastfeeding program, Business Case for Breastfeeding, breastfeeding physician practice designation, Breastfeeding 101, “Becoming a Mom” infant feeding session, child care provider education, and building local breastfeeding coalitions.

Objective: The purpose of this session is to cover critical aspects of each program particularly those that are related to narrowing the gap on breastfeeding disparities.

Methods: The Communities Supporting Breastfeeding (CSB) program incorporates features of each standalone program and offers a breastfeeding designation to participating communities after they meet specific criteria within six sectors of their community: local breastfeeding leadership, peer support, maternity care practices, societal support, employer support, and childcare provider support. The KBC provides an assessment, hospital staff education, coalition building assistance, continuity of breastfeeding care, and education to home visitors. The CSB program was effective July 2014 through June 2017. During each program year, a survey to assess progress toward the designation was administered to all mothers who benefited from breastfeeding services.

Results: Since July 2014, 18 communities representing diverse populations have achieved the CSB designation. About 20 mothers in each of the respective communities participated in the survey ($N=343$). Participants were non-Hispanic white (88%), 26–35 years old (65%), some college (39%) or college degree (35%), WIC enrolled (29%), and earned <\$50,000/year (50%). The majority of women believed local breastfeeding leadership, peer support, and hospital support provided adequate breastfeeding support in their community. Women were less familiar with programs that promoted breastfeeding among employers, businesses, and childcare providers. Communities appeared to benefit from improved exclusive breastfeeding rates.

Conclusions: The CSB program along with other initiatives to promote breastfeeding provide communities with the tools to build a culture of breastfeeding support. The CSB program is currently listed as an “emerging practice” on the Innovation Station website of the Association of Maternal & Child Health Programs.

Symposium 61B

THE DEVELOPMENT OF A MASS MEDIA SOCIAL MARKETING STRATEGY TO PROMOTE BREASTFEEDING AMONG LOW-RESOURCE COMMUNITIES IN MEXICO

Tessa Swigart, PhD

Introduction: Optimal breastfeeding practices include exclusive breastfeeding for the first 6 months after birth, and continuing to breastfeed for at least one year. Promotional efforts are important in low-resource settings because of disparities that make these populations more vulnerable to adverse health outcomes that could be avoided with optimal breastfeeding practices. In Mexico, breastfeeding rates are low and decreasing among these populations. To address this problem, the Mexican federal poverty alleviation program developed a strategy that included breastfeeding promotion using interpersonal communication.

Objective: The goal of our study was to develop a corresponding social marketing strategy using mass media for communities with limited resources in Mexico and decrease breastfeeding disparities.

Methods: Our methods were comprised of three stages. For the first stage, we performed a secondary analysis prior research in order to understand our population's breastfeeding practices, beliefs, influences, and social norms and determine the behavioral objectives, target audience, and social marketing platform. In the second stage, we used the social marketing framework to design the marketing mix and strategy components. In the third stage, we pretested our strategy ideas with six focus groups from two Mexican states among our target audience, with a total of 47 informants.

Results: Mothers were motivated to do what was best for their baby. However, there were practices contrary to optimal breastfeeding that included giving water and teas soon after birth and introducing solid food and formula to the baby at about 3 months. Our social marketing strategy included an interactive text messaging service, a free informational hotline, TV spots, and billboards. These channels tested well with our focus groups, but the audience indicated some skepticism toward the message themes we tested.

Conclusion: Our strategy channels were well chosen but our main message themes were not easily believed or trusted, possibly they approached practices and beliefs deeply embedded in tradition and culture. To be more successful, believable, and further reduce breastfeeding disparities, the messaging needs to both work in conjunction with the interpersonal communication and also involve a more multi-pronged approach to maximize consistency and effectiveness in order to improve practices and social norms.

Symposium 61C

ADAPTING A NATIONAL BEHAVIOR CHANGE COMMUNICATION STRATEGY TO INDIGENOUS COMMUNITIES: IMPROVING BREASTFEEDING PRACTICES IN CHIAPAS

Dr. Anabelle Bonvecchio, PhD

Background: Mexico is undergoing a nutritional transition described as malnutrition and micronutrient deficiencies coexisting with obesity and other chronic diseases. Among indigenous groups, this dual burden has grown significantly stunting growth among indigenous children in rural Chiapas by 44% (14% nationally) while the obesity rate is at 8%. These problems are greatly alleviated with optimal breastfeeding practices. As part of the activities of the Mesoamerica Health Initiative 2015, the Health Institute of Chiapas sought a culturally sensitive solution for the state's indigenous population by adapting a national strategy meant to address the nutritional transition, with a strong focus on improving breastfeeding rates.

Objective: The purpose of this project was to conduct formative research with indigenous populations in Chiapas followed by an adaptation of a national interpersonal communication strategy. This approach included developing a mass media communication campaign to positively influence breastfeeding behaviors in indigenous communities of the state.

Methods: The formative research took an iterative approach; first examining behaviors and beliefs about nutrition, breastfeeding and complementary feeding practices, then evaluating the national behavioral priorities in the indigenous context, and pretesting adapted materials based on the findings. The qualitative and quantitative instruments were designed using the social marketing framework and the ecological model and incorporated a mixed methods approach, in which both a quantitative survey was analyzed and integrated with qualitative focus groups and interviews for increased validation.

Results: The results confirmed that the focus of the strategy should remain on the nutritional transition in order to prevent stunting, anemia, obesity, overweight and chronic disease in the future. The behaviors that had been prioritized at the national level should remain but other behaviors that were relevant to Chiapas such as the use of oral rehydration therapy (ORT) and anti-parasites were incorporated. The messages developed for the national strategy had to be adjusted to incorporate local barriers and terminology, and some new messages had to be developed. Additionally, targeted billboards and radio and TV spots were developed based on feedback and adapted to the local indigenous culture and languages.

Conclusions: Indigenous groups in Mexico are widely stigmatized. They receive inadequate healthcare services and are offered culturally insensitive programs. Formative research is needed to determine how to adapt programs in order to better reach these communities and improve breastfeeding behaviors.

Symposium 62

2:00 PM-3:15 PM

OBSERVATIONS AND INTERVENTIONS TO ADDRESS PARENTAL VACCINE HESITANCY, AN INCREASING SOCIAL NORM IN THE U.S.

Austin S. Baldwin, PhD¹, Jasmin A. Tiro, PhD², Melissa B. Gilkey, PhD³, Avnika B. Amin, MSPH⁴, Austin S. Baldwin, PhD¹, Jasmin A. Tiro, PhD²¹Southern Methodist University, Dallas, TX; ²University of Texas Southwestern Medical Center, Dallas, TX; ³University of North Carolina, Chapel Hill, NC; ⁴Rollins School of Public Health, Emory University, Atlanta, GA

Vaccine hesitancy—delay in acceptance or refusal of vaccination despite availability of services—is becoming more normative in the U.S. National surveys reveal that 40% of parents delayed or refused 1+ vaccines in 2009; and more recently, 88% of healthcare providers reported parental requests to delay a vaccine. As a result, more parents are questioning guideline-based vaccination schedules, providers are uneasy during conversations with parents, and vaccination coverage is falling short of Healthy People 2020 goals for the HPV, influenza, and other vaccines. Understanding why this behavioral phenomenon is growing in the U.S. and developing interventions that address hesitancy is a timely and urgent challenge for behavioral medicine researchers. This symposium will highlight three examples of innovative research on vaccine hesitancy. Melissa Gilkey will present her ongoing research on the importance of provider communication, focusing on parental ratings of the best messages from providers for motivating HPV vaccination. Avnika Amin will describe research on the associations between vaccine hesitancy and moral beliefs and discuss why values-based arguments as opposed to information-based arguments are needed for vaccines. Austin Baldwin will share recent findings from a mobile app self-persuasion intervention that helps parents who are undecided about the HPV vaccine think through their own reasons for vaccination. As the discussant, Jasmin Tiro will facilitate a discussion on advancing the science of vaccine hesitancy given the broader healthcare and social context, so that these major public health discoveries – vaccines – benefit the population. Through this symposium, we aim to increase awareness of vaccine hesitancy and its implication among behavioral medicine researchers and encourage innovative ideas to address this pressing behavioral and public health challenge.

Symposium 62A

PARENTS' VIEWS ON THE BEST AND WORST REASONS FOR HPV VACCINATION: A BEST-WORST SCALING STUDY

Melissa B. Gilkey, PhD

Objective. HPV vaccination could prevent most HPV-related cancers, but only about one-third of U.S. adolescents are vaccinated according to guidelines. To inform efforts to counsel parents more effectively, we sought to quantify their views on the best and worst reasons for HPV vaccination. Based on prior research suggesting that vaccine hesitant parents view pro-vaccine messages differently from other parents, we hypothesized that our findings would vary according to parents' confidence in adolescent vaccination.

Methods. We reviewed the research literature and existing provider communication training materials to identify 11 reasons that providers commonly give for guideline-consistent HPV vaccination. We evaluated these reasons using a novel best-worst scaling (BWS) instrument that we administered to a national sample of parents of adolescents ($n=1,177$) via an online survey. Parents completed 11 choice tasks, which used a balanced-incomplete-block design to present repeated subsets of reasons. We calculated a BWS score for each reason based on the number of times it was chosen, with scores ranging from +1 (always chosen as best) to -1 (always worst). We then re-ran analyses stratifying by parents' vaccination confidence (low/high) as measured by the 4-item Vaccination Confidence Scale.

Results. Parents viewed *cancer prevention* as the best reason for HPV vaccination (BWS score=0.65). This reason scored over three times more highly than *preventing a common infection* (.20), having *lasting benefits* (0.19), or being a *safe vaccine* (0.14). Reasons viewed as worst were: *it is a scientific breakthrough* (-0.21); *I got it for my own child* (-0.30); and *your child is due for it* (-0.35). Stratified analyses indicated small differences in the views of parents with low versus high vaccination confidence ($p<0.001$), but the two groups ranked reasons similarly overall.

Conclusions. As recommended by CDC, providers should emphasize cancer prevention when discussing HPV vaccination, as this reason was prioritized by parents regardless of their vaccination confidence. Several other common reasons, including having vaccinated one's own child, were not highly endorsed and may warrant additional testing. This study illustrates the value of using stated-preference methods to understand public health communication strategies. Our findings provide an evidence base for efforts to support providers in more effectively communicating the value of HPV vaccination so as to increase uptake of this potent cancer prevention tool.

Symposium 62B

ASSOCIATIONS OF MORAL FOUNDATIONS WITH VACCINE HESITANCY

Avnika B. Amin, MSPH

Background: Clustering of unvaccinated children can result in outbreaks. Most vaccination interventions focus on targeting vaccine-related attitudes. Moral foundations, a system of six values (authority/subversion, fairness/cheating, harm/care, liberty/oppression, loyalty/betrayal, and purity/degradation), have been associated with attitudes and attitudinal shift on various topics such as climate change and philanthropy. They may be useful to better understand vaccine attitudes but have not been examined to date.

Methods: We recruited parents online in two studies. In our first study, we measured vaccine hesitancy using the Parent Attitudes about Childhood Vaccines (PACV) scale, moral foundation relevance, and demographic information. We used unconditional logistic regression models to examine associations between each moral foundation and hesitancy (low, medium, or high). In our second study, we measured vaccine attitudes, moral foundation relevance, demographic information, and agreement with purity- and liberty-violating vaccine beliefs (e.g. “Vaccines contain poisons/toxins/contaminants.” and “Vaccine mandates are excessive government control.”). We developed a multiple regression model to replicate our first study and mediation models to examine the interplay between moral foundations, foundation violations, and vaccine attitudes.

Results: In our first study ($N = 1,007$), compared to low-hesitancy parents, medium-hesitancy parents were more likely to highly endorse purity (aOR: 2.08, 95% CI: 1.27–3.40). High-hesitancy parents were more likely to highly endorse both purity (aOR: 2.15, 95% CI: 1.39–3.31) and liberty (aOR: 2.19, 95% CI: 1.50–3.21). We saw similar results in our second study ($N = 464$). We found evidence of mediation on the purity-hesitancy association through purity- (b: 0.03, 95% CI: 0.01–0.04) and liberty-violating beliefs (b: 0.03, 95% CI: 0.01–0.04) and evidence of mediation on the liberty-hesitancy association through purity- (b: 0.01, 95% CI: 0.001–0.02) and liberty-violating beliefs (b: 0.01, 95% CI: 0.003–0.03).

Conclusions: Our data suggest that vaccine attitudes are linked with moral concerns. Differences in the emphasis of purity and liberty suggest that these foundations may be factored in more heavily by vaccine-hesitant parents. Our data also suggest moral foundations may shape the beliefs one has on a topic beyond the beliefs directly related to the moral foundation. For example, the purity foundation may influence overall attitudes towards vaccines, which in turn promote beliefs that are in line with these attitudes – even beliefs that have seemingly little to do with purity. Our results provide a promising new direction for development and testing of vaccine communications that are value-based rather than information-based.

Symposium 62C

FEASIBILITY AND EFFICACY OF AN HPV VACCINE APP FOR UNDECIDED PARENTS: A TEST OF SELF-PERSUASION

Austin S. Baldwin, PhD

Objective: Many parents are hesitant about getting the human papilloma virus (HPV) vaccine for their children, and some remain undecided even with a provider recommendation. Self-persuasion – the process of generating one’s own arguments for changing behavior – is potentially an effective approach to address parental hesitancy. However, self-persuasion interventions have not been developed to promote HPV vaccination or for low literacy populations, as they typically have been used among college-educated populations. We developed a mobile app with voiceover narration (in English and Spanish) to elicit parental self-persuasion for adolescent HPV vaccination. In two studies, we evaluated feasibility of self-persuasion tasks (generate and verbalize one’s own HPV vaccination arguments) in a safety-net population (Study 1), and in a randomized trial, we tested the effect of using the app on vaccine decision stage, an interim analysis outcome (Study 2).

Methods: In the feasibility study, we used cognitive interview methodology to solicit feedback on the app and self-persuasion tasks from 45 parents. In the trial, undecided parents ($N=122$) were randomized to one of four app versions with self-persuasion tasks that vary by cognitive engagement (deep vs. shallow) and argument topic choice (yes vs. no). We have currently achieved 75% of target accrual; therefore, we report an interim analysis testing the effect of using the app (any of the four versions) on vaccine decision stage.

Results: In the feasibility study, self-persuasion tasks were rated as easy to complete (M range 1.00 to 2.32 on a 5-point difficult scale), helpful (M range 4.33 to 4.98 on a 5-point helpfulness scale), and 98% successfully completed the tasks. In the trial, results indicate that nearly half of parents (45.9%) moved from being undecided to deciding to get the vaccine, reflecting a medium-to-large effect, $\chi^2(1)=27.03, p<.0001, \phi=.47$. In addition, only 3 parents (2.5%) decided against the vaccine after using the app.

Conclusions: The self-persuasion app was feasible and using it significantly changed parents’ decision stage. We will be (1) identifying which app version is optimal for HPV vaccine initiation and completion, and (2) testing whether basic cognitive and motivational mechanisms (i.e., deep processing, autonomous motivation) hypothesized to underlie self-persuasion mediate the app’s effect.

REACTIVITY TO A LONGITUDINAL SMARTPHONE-BASED TIME-INTENSIVE PHYSICAL ACTIVITY ASSESSMENT

Eldin Dzubur, Ph.D.¹, Genevieve F. Dunton, PhD, MPH², Stephen Intille, PhD³

¹Cedars-Sinai Medical Center, Los Angeles, CA; ²University of Southern California, Los Angeles, CA; ³Northeastern University, Boston, MA

Purpose: Reactivity, the change in behavior as a result of knowing one is being measured, is a phenomenon that is both acknowledged and well-understood in the measurement of physical activity. On the other hand, studies using ecological momentary assessment (EMA), a real-time sampling strategy, generally find little reactivity in participants, despite intensive sampling in free-living situations. However, such studies have been limited to the measurement of psychological constructs (e.g., body image perception) and behaviors unrelated to physical activity (e.g., drinking) as outcomes. There is limited literature on how the use of EMA, as well as both EMA and accelerometers, to measure physical activity as an outcome may induce reactivity (i.e., change in activity levels) in participants. The purpose of this study was to test for reactivity to the application of a longitudinal smartphone-based time-intensive physical activity measurement protocol.

Methods: Adolescents between the ages of 14 and 18 (N=44) completed random EMA prompts at two-hour intervals and context-sensitive EMA prompts after moments of inactivity or activity, while wearing accelerometers and completing an assisted end-of-day recall activity for 14 days. Participants wore accelerometers and carried smartphones without EMA for another 14 days. Participants were randomized into groups receiving the full (i.e., EMA plus accelerometer) protocol in the first two weeks or the last two weeks. Multiple multilevel regressions were used to examine temporal trends and differences in physical activity and sedentary time as measured by accelerometers due to exposure to the EMA protocol and order of exposure.

Results: Participants who received the EMA plus accelerometer protocol in the last two weeks had more light physical activity during the EMA plus accelerometer component than accelerometer only, but had increasing sedentary time throughout the measurement period. Conversely, those who received the EMA plus accelerometer protocol in the first two weeks were more sedentary and had less MVPA during the EMA plus accelerometer protocol, as well as decreasing sedentary and increasing MVPA time throughout the study. EMA compliance did not differ between protocols, but decreased over time.

Conclusions: There was evidence for differential reactivity contingent on the deployment of EMA at the beginning of a study or after a period of accelerometer measurement. Further research is needed to examine how EMA questionnaires alone affect physical activity and sedentary behavior in participants by leveraging onboard smartphone accelerometers to determine whether the effects of reactivity in EMA protocols may be minimized by removing the presence of external sensors.

PATTERNS OF FITBIT USE AND ACTIVITY LEVELS THROUGHOUT A PHYSICAL ACTIVITY INTERVENTION

Sheri J. Hartman, PhD, Sandahl Nelson, MS, Lauren Weiner, BA

University of San Diego, California, La Jolla, CA

Background: There has been a rapid increase in the use of technology-based activity trackers to promote behavior change. However, little is known about how individuals use these trackers on a day to day basis or how tracker use relates to increasing physical activity.

Objective: The aims were to use minute level data collected from a Fitbit tracker throughout a physical activity intervention to examine patterns of Fitbit use and activity, and their relationships with success in the intervention based on ActiGraph measured moderate-to-vigorous intensity physical activity (MVPA).

Methods: Participants were 42 female breast cancer survivors randomized to the physical activity intervention arm of a 12-week randomized controlled trial. The Fitbit One was worn daily throughout the 12-week intervention. ActiGraph GT3X+ accelerometer was worn for 7 days at baseline (pre-randomization) and end of intervention (week 12). Self-reported frequency of looking at activity data on the Fitbit tracker and app/website was collected at week 12.

Results: Adherence to wearing the Fitbit was high and stable, with a mean of 88% of valid days over 12 weeks (SD=14). Greater adherence to wearing the Fitbit was associated with greater increases in ActiGraph measured MVPA ($b_{\text{interaction}} = 0.35, P < 0.001$). Participants averaged 182.6 minutes/week (SD=143.9) of MVPA on the Fitbit, with significant variation in MVPA over the 12 weeks ($F=1.91, p = 0.037$). The majority (67.5%) of participants reported looking at their tracker or looking at the Fitbit app or website once a day or more. Changes in Actigraph measured MVPA were associated with frequency of looking at one's data on the tracker ($b=-1.36, P = 0.07$) but not significantly associated with frequency of looking at one's data on the app or website ($P = 0.36$).

Conclusions: This is one of the first studies to explore the relationship between use of a commercially available activity tracker and success in a physical activity intervention. A deeper understanding of how individuals engage with technology-based trackers may enable us to more effectively use these types of trackers to promote behavior change.

Paper Session 31: Digital Health Innovations in Tracking and Self-Monitoring 4:00 PM-4:15 PM

DIGITAL TRACKER DATA FROM OVER 100,000 INDIVIDUALS SHOW LOWER ACTIVITY LEVELS IN INDIVIDUALS WITH MULTIPLE CHRONIC CONDITIONS

Shefali Kumar, MPH, Tom Quisel, N/A, Luca Foschini, PhD, Jessie Juusola, PhD

Evidation Health, San Mateo, CA

Objectives: Individuals with multiple chronic conditions (CCs) self-report greater disease burden and lower quality of life than those without. Behavioral data can provide additional insight into how CCs impact an individual's health and well-being. We aimed to quantify whether the presence of multiple and different types of CCs are associated with changes in behavior related to physical activity and sleep patterns.

Methods: Members of an online health and activity-tracking community (Achievement, Evidation Health Inc, San Mateo, CA) were asked to participate in a health survey. Participants reported their diagnoses by selecting from a list of 34 CCs. For each participant, we considered the number of CC diagnoses reported, the number of cardiac and metabolic comorbid conditions (CMCC) reported and whether a mental health illness was reported. Data collected from digital trackers over the past year were used to calculate per-participant overall median and Coefficient of Variation (CV) for daily step counts and sleep duration. We examined two cohorts: a Step Cohort of 155,638 individuals who had >10 days of step data, and a Sleep Cohort with 91,995 individuals who had >10 days of sleep data. We considered both median and CV of daily steps and sleep duration as target variables. For each target variable, we ran two models, the first using the number of CCs and the second using the number of CMCCs as explanatory variables. All models controlled for age, sex, education level and race. The CMCC models also controlled for presence of a mental health diagnosis.

Results: On average, participants took 6,708 steps/day and slept 6.8 hours/night. Number of CCs and number of CMCCs were both negatively associated with median daily step count and hours of sleep/night. Each additional CC (any of the 34 conditions) was associated with a decline of 254 steps/day (95% CI [243, 265]; $p < 0.001$), whereas each additional CMCC was associated with almost double that amount, a decline of 493 steps/day (CI [412, 574]; $p < 0.001$). Count of CCs was also associated with less sleep, higher step CV and higher sleep CV, while CMCC count was associated with less sleep and higher sleep CV.

Conclusions: In this analysis, we were able to quantify the decrease in physical activity levels and sleep duration in a population with multiple CCs and CMCCs. Further research should be conducted to determine if this relationship is causal and if tracker-based behavioral data can help detect multiple CCs.

USABILITY TESTING OF A WEB-BASED INTERACTIVE TOOL TO REDUCE CHILDHOOD OBESITY RISK IN URBAN MINORITY YOUTH

Sandra Verdaguer, BS, MS¹, Katrina F. Mateo, MPH², May May Leung, PhD, RD³

¹Hunter College, City University of New York, New York, NY; ²CUNY Hunter College / CUNY School of Public Health, New York, NY; ³Hunter College, New York, NY

Introduction: Childhood obesity is still one of the most serious public health issues in the United States, especially among minority youth. There is evidence that technology-enhanced approaches can be effective for promoting healthy behavior change. The purpose of this study was to test the usability of early prototypes of Intervention INC, an interactive web-based tool promoting healthy dietary behaviors to reduce childhood obesity risk in African-American (AA)/Black and Latino youth.

Methods: AA/Black and Latino children ages 9 to 13 were recruited to participate in two rounds of usability testing conducted in June and July 2017. To inform refinement of the web-based tool prototype, a modified *think-aloud* method was utilized. Self-reported surveys and field notes were collected. Sessions were audio recorded and systematically reviewed to identify usability issues and areas for improvement.

Results: Twelve children, with a mean age of 10.9 ± 1.2 years (33% female; 67% AA/Black) participated. Round 1 consisted of 2 dyad sessions and 2 individual sessions; Round 2 consisted of 6 individual sessions. Testing highlighted overall positive experiences with the interactive tool, especially related to page navigation, sound effects, and color schemes. Opportunities to incorporate additions to increase engagement and improve usability were identified. Specific usability issues were classified into seven themes: appearance, content, terminology, navigation, operational features, special effects, and storyline. Changes to the web tool after Round 1 included adding a navigation guide, making clickable icons more visible, improving graphic designs, such as color scheme, background and pop-up images, and fixing programming errors. In Round 2 of testing, the number of usability issues decreased in five out of the seven themes.

Conclusions: Findings from both rounds of testing will inform further development and finalization of the tool. Preliminary findings of early prototypes suggest that the use of this web-based tool could be an engaging approach to promote healthy eating behaviors among minority youth. The web-based tool will be tested using a two-group pilot randomized study targeting fruit/vegetable and water intake to reduce childhood obesity risk in AA/Black and Latino youth. Future usability testing of web-based tools with youth using a *think-aloud* approach should consider dyad assessments (rather than individual) to facilitate more meaningful feedback in a peer-to-peer environment.

DIETARY SELF-MONITORING WITH NEW TECHNOLOGY: EXAMINING DIFFERENCES IN WEIGHT LOSS USING DIETARY SELF-MONITORING MOBILE APPS

Caroline G. Dunn, MS, RD¹, Gabrielle Turner-McGrievy, PhD, MS, RD², Sara Wilcox, PhD², Destiny Byrd, N/A²

¹USC, Columbia, SC; ²University of South Carolina, Columbia, SC

Background: Dietary self-monitoring (DSM) of foods and beverages is associated with increased weight loss in behavioral interventions; however, DSM may be burdensome and adherence may decrease over time. Novel methods of DSM, including apps that track food using photos, may decrease user burden and increase DSM to improve weight loss outcomes. The purpose of the Self-Monitoring Assessment in Real Time (2-SMART) Study was to compare a commercially-available photo app to a traditional DSM app for weight loss as part of a 6-month randomized behavioral weight loss intervention.

Methods: Overweight or obese adults (n=42; mean BMI=34.7 ± 5.79 kg/m²) were randomized to track their diet with either a traditional mobile app, FatSecret (FS, n=19), or a photo DSM app, MealLogger (ML, n=23). All participants received twice weekly podcasts with identical behavioral weight loss information, and were instructed to track all foods and beverages consumed. Weight (kg) and energy intake (2 dietary recalls) were assessed at baseline and 6 months. Data were analyzed using SPSS software. Intent-to-treat analysis with baseline weights carried forward was used to address issues of missing data.

Results: At 6 months, 74% of participants completed the intervention. Mean weight loss was -1.7 ± 4.1 kg and did not differ by group (FS, -2.1 ± 5.3 kg; ML, -1.3 ± 3.0 kg; p=0.57). There were no significant differences between groups for the number of podcasts downloaded out of 48 possible episodes (FS, 15.0 ± 13.9; ML, 13.6 ± 13.0; p= 0.75) or for the number of days any foods were tracked out of 180 possible days (FS, 69.6 ± 61.0; ML, 44.2 ± 49.9; p=0.15). Weight loss was significantly and positively correlated with the total number of days tracked (r=0.64, p<0.001), but not with the number of podcasts downloaded (r=-0.26, p=0.10).

Conclusions: In this trial, frequency of DSM was significantly associated with overall weight loss regardless of the method of tracking used. However, DSM rates were low for all participants, regardless of group, and participants tracked food less than 30% of days. Weight loss was also fairly minimal (0.28kg/month), and not significantly different between groups. Increasing user engagement with any type of DSM may play an important role in behavioral weight loss interventions to increase frequency of use and improve weight loss outcomes.

Paper Session 32: Improving Quality of Life Among Cancer Patients 3:30 PM-3:45 PM

COORDINATION OF CARE AND HEALTH-RELATED QUALITY OF LIFE AMONG URBAN LATINA BREAST CANCER SURVIVORS

Hayley S. Thompson, Ph.D.¹, David W. Lounsbury, PhD², Maida Y. Herrera, MPH³, Carmen R. Isasi, MD/PhD⁴, Kristin Bright, PhD⁵, Katarina Sussner, PhD, MPH⁶, Heiddis Valdimarsdottir, n/A⁷, Gary Winkel, PhD⁸

¹Wayne State University -Karmanos Cancer Institute, Detroit, MI; ²Albert Einstein College of Medicine, New York, NY; ³Wayne State University School of Medicine - Karmanos Cancer Institute, Sterling Heights, MI; ⁴Albert Einstein College of Medicine, Bronx, NY; ⁵University of Toronto, Toronto, ON, Canada; ⁶xxxx, Seattle, WA; ⁷Mount Sinai school of Medicine, nyc, NY; ⁸Icahn School of Medicine at Mt. Sinai, Brooklyn, NY

A number of studies report lower health-related quality of life (HRQOL) among Latina breast cancer survivors compared to survivors of other ethnic groups. However, few studies have investigated mechanisms that might account for low HRQOL in this group, with some noting that socioeconomic and cultural factors may play a role. Systemic efforts with healthcare settings to improve the quality of care may be vital to improving HRQOL among Latina survivors. One strategy that may be effective is coordination of care (CoC): the incorporation of information from previous healthcare encounters into the current and future healthcare of the survivor. In fact, CoC is among the recommendations for breast cancer follow-up and management offered by the American Society for Clinical Oncology and proposed as a patient self-reported indicator of survivorship care quality by the Institute of Medicine. The current study focused on Latina survivors' perception that their main provider for cancer-related follow-up care communicated with their other healthcare providers and was aware of the range of care the survivor received. Participants were 169 Latina breast cancer survivors between 3 and 48 months post-treatment residing in the metropolitan Detroit and New York City areas. Measures included the CoC domain of the Components of Primary Care Instrument. Participants also completed the Functional Assessment of Cancer Therapy – Breast (FACT-B) which includes physical well-being (PWB), social well-being (SWB), emotional well-being (EWB), functional well-being (FWB), and breast cancer concerns (BCS) subscales. On average, participants reported seeing 4.6 healthcare providers in the past 2 years as part of their cancer-related follow-up care and 75.2% reported that their medical oncologist is their main provider of this care. After controlling for covariates of HRQOL outcomes (specifically, age, household income, employment status, preferred language, study site, and total number of healthcare providers seen for any reason in the past 2 years), multivariate regression analysis revealed that greater CoC was associated with higher scores on PWB (p<.02), EWB (p<.009), FWB (p<.02), and the total FACT-B (p<.009). Results suggest that interventions targeting fragmented systems of survivorship care delivery can have positive effects on outcomes among Latina breast cancer survivors, an especially vulnerable patient population.

“IT DOES ADD UP, EVEN WITH INSURANCE”: A MIXED METHODS STUDY OF LONG-TERM OUT-OF-POCKET COSTS DUE TO BREAST CANCER AND LYMPHEDEMA

Lorraine T. Dean, ScD¹, Yusuf Ransome, MPH, DrPH², Livia Frasso Jaramillo, BA¹, Yuehan Zhang, ScM³, Kevin D. Frick, MA, PhD¹, Lauren Nicholas, MPP, MPhil, PhD¹, SV Subramanian, MA, MPhil, PhD⁴, Kala Visvanathan, MHS, FRACP, MD¹, Kathryn H. Schmitz, MSeD, MPH, PhD⁵

¹Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; ²Yale School of Public Health, New Haven, CT; ³Division of General Internal Medicine at University of Pennsylvania, Philadelphia, PA; ⁴Harvard TH Chan School of Public Health, Boston, MA; ⁵Penn State University College of Medicine, Hershey, PA

Introduction: Economic burden after breast cancer is exacerbated by adverse treatment effects, such as breast cancer-related lymphedema – a chronic condition caused by pooling of lymphatic fluid after lymph node removal during breast cancer surgery -- which patients cite as more distressing than cancer itself. Most studies that have assessed economic burden due to lymphedema used administrative data, and only documented costs in the initial years after cancer. Administrative data misses out-of-pocket expenses thereby underestimating total cost. Moreover, patients' experiences on how economic burden affect them long-term are not sufficiently documented. We therefore conduct a mixed methods study to analyze the role of out of pocket costs among persons with and without lymphedema, among long-term breast cancer survivors.

Methods: In 2015, a prospective sample of 129 breast cancer survivors from Pennsylvania and New Jersey completed: a baseline self-reported survey of demographics, socioeconomic position, checklist of financial challenges since cancer, cancer treatments, insurance, and health; and monthly longitudinal diaries of medical visits and out-of-pocket costs over 12 months. A subset of 40 participants were randomly selected for in-person 30-minute semi-structured interviews to further investigate economic challenges. GLM regression produced dollar amount differences among those with lymphedema and without lymphedema.

Results: 46.5% of participants had lymphedema. Mean age was 63 (SD=8). Average time since cancer was 12 years (SD=5). Over 98% had insurance. Although those with lymphedema cited the same number of financial challenges experienced since cancer, after adjustment for baseline covariates, annual health-related out-of-pocket costs and productivity losses totaled \$2,597 compared to \$1,770 for those without lymphedema ($p<0.001$). Interviews suggested that the cascading nature of economic burden on long-term savings and work opportunities, and insufficiency of insurance to cover lymphedema-related needs drove cost differences. Interviewees reported that higher costs led to delayed retirement, reduced employment, or inability to access lymphedema care.

Conclusion: Long-term breast cancer survivors with lymphedema may experience up to 47% higher annual out-of-pocket costs and sustained impact on savings and productivity that influences their ability to manage lymphedema. Further research should explore patient-driven solutions to reducing economic burden for this population.

Paper Session 32: Improving Quality of Life Among Cancer Patients 4:00 PM–4:15 PM

DEVELOPMENT OF A NOVEL MEASURE OF ADVANCED CANCER PATIENTS' PERCEIVED UTILITY OF SECONDARY GERMLINE FINDINGS

Jada G. Hamilton, Ph.D., M.P.H., Margaux Genoff Garzon, M.A., Joy S. Westerman, B.A., Kechna Cadet, B.S., Jennifer L. Hay, Ph.D., Kenneth Offit, M.D., M.P.H., Mark E. Robson, M.D.

Memorial Sloan Kettering Cancer Center, New York, NY

Background: Treatment decisions for advanced cancer patients can be informed by genetically sequencing their tumor through tumor genomic profiling (TGP). TGP can reveal “secondary germline findings” (SGFs)—information about a patient’s inherited risks for cancer and other disorders. SGFs may have diverse benefits and harms, which may influence patients’ decisions about how to manage this risk information. Little is known regarding patients’ beliefs about the personal and clinical utility of SGFs; therefore, we sought to develop a measure of patient perceptions of the utility of SGFs.

Method: We developed a draft survey (19 items; 5-point response scale: 1=“strongly disagree” to 5=“strongly agree”) based on literature and patient interview data ($n=40$). We evaluated and refined the survey through 2 rounds of cognitive interviews with 10 advanced cancer patients who received SGFs from TGP. Participants were directed to “think aloud” as they answered the items, and share ideas about the utility of SGFs based on their experiences. The final survey (17 items) has been integrated into an ongoing prospective study of advanced cancer patients learning SGFs from TGP; descriptive statistics were calculated from available baseline data ($n=59$).

Results: Cognitive interviews indicated that 2 of the proposed survey items required rephrasing to improve comprehension, 1 item was seen as redundant, and 1 item was irrelevant. Interviewees found the survey easy to answer “all” or “most” of the time (90%), and believed the response scale was “not at all difficult” to use (70%). Preliminary baseline data suggest that the final 17-item scale has high internal consistency (Cronbach’s $\alpha=0.94$). On average, participants most strongly endorsed perceptions that SGFs will help doctors learn to care for future patients ($M\pm SD=4.58\pm 0.89$ on 5-point scale), be useful to doctors (4.46 ± 0.90), and that the meaning of their SGFs may change in the future (4.44 ± 0.93). Participants were least certain that their SGFs will help reduce their family’s chances of getting cancer (2.83 ± 1.33), lessen their confusion about their cancer (3.37 ± 1.07), or be easy to understand (3.42 ± 0.89).

Conclusion: We have developed a novel scale that shows promise for measuring advanced cancer patients’ perceptions of the personal and clinical utility of SGFs. Future research will confirm the psychometrics of this measure, and determine whether and how these beliefs contribute to patients’ decisions and responses in the TGP context.

IMPACT OF OUTPATIENT SPECIALTY PALLIATIVE CARE ON SURVIVAL IN ADULTS WITH ADVANCED CANCER: A META-ANALYSIS OF RCTS

Michael Hoerger, PhD, MSCR¹, Graceanne Wayser, MPH¹, Gregory Schwing, BS², Ayako Suzuki, MD, MPH¹, Laura M. Perry, BS¹

¹Tulane University, New Orleans, LA; ²University of New Orleans, New Orleans, LA

Background: Palliative care refers to care aimed at supporting quality of life, especially for patients with serious illnesses. Increasingly, palliative care programs have formalized, and national oncology guidelines now recommend outpatient specialty palliative care for all patients with advanced cancer beginning early after diagnosis. Two meta-analyses have shown outpatient specialty palliative care to benefit quality of life, but the one meta-analysis of survival outcomes had methodologic limitations and null findings. As patients, families, and clinicians worry that a palliative approach could hasten death, meta-analytic findings on survival have implications for the utilization and dissemination of palliative care.

Method: Following PRISMA guidelines, we conducted a systematic review and meta-analysis of survival outcomes in RCTs of outpatient specialty palliative care interventions for patients with advanced cancer. Unlike prior meta-analyses, results were stratified by key quality criteria, examined a longer follow-up duration, and employed novel methods and software for meta-analyzing survival data, namely the use of composite Kaplan-Meier curves reconstructed from published figures using digital extraction software.

Results: Survival data were available from 8 RCTs of outpatient specialty palliative care, including 5 high-quality studies (n=1,491) – 3 of which had Kaplan-Meier figures with long-term follow-up data (n=680) – as well as 3 lower-quality studies that had methodologic problems (n=580) or few cancer patients (n=21). In the high-quality studies, outpatient specialty palliative care was associated with better 1-year survival relative to usual care (56% v 42%, p<.001). In sensitivity analyses, a survival advantage was also observed at 6, 9, 15, and 18 months. In analyses of composite data reconstructed from published figures, patients receiving palliative care lived 4.56 months longer than those receiving usual care (14.55 v 9.99 months, p=.003), as indicated by a slower rate of mortality (hazard ratio=.743, p=.003).

Discussion: These meta-analytic findings suggest that in addition to supporting quality of life, outpatient specialty palliative care interventions may prolong survival in advanced cancer. Findings have implications for clinical practice and suggest methods psychosocial investigators can use to study mortality outcomes.

Among Cancer Patients 4:30 PM-4:45 PM

PROVIDER-PATIENT RELATIONSHIP: PREDICTORS OF BLACK CANCER PATIENTS PERCEIVED QUALITY OF CARE AND HEALTH OUTCOMES

Matt Asare, PHD¹, Michelle Janelsins, PhD, MPH¹, Luke Peppone, PhD, MPH¹, Karen Mustian, PhD, MPH¹, Ian Kleckner, PhD¹, Calvin L. Cole, PhD¹, Eva Culakova, PhD, MS¹, Lauren M. Hamel, PhD², Gary Morrow, PhD, MS¹, Charles Kamen, PhD, MPH¹

¹University of Rochester Medical Center, Rochester, NY; ²Wayne State University/Karmanos Cancer Institute, Detroit, MI

Introduction: Disparities in quality of care and health outcomes among racial and ethnic minorities are well documented. Compared to white cancer patients, minority patients are more likely to experience poorer quality interactions with their providers, which contribute to health disparities. Research focusing on the interpersonal relationship between providers and black cancer patients and its effects on health outcomes is scant. Thus, we examined whether the Provider-Patient Relationship (PPR) is associated with black patient's overall health outcomes. We also examined whether the association between PPR and health outcomes was mediated by quality of care.

Methods: We used Health Information National Trend Survey (HINTS) data from 2011 to 2014. A sample of 252 black cancer patients (age 64.0 ± 13.0 years) provided evaluable data. The outcome variables were patients' self-reported quality of care and self-rated health. The predictor variable was PPR, calculated from eight HINTS items assessing providers' communication with patients, emotional support, time spent on patients, and involvement of patients in decision making; factor analysis showed that these variables loaded onto a single factor (with factor loadings >0.7). Covariates included marital status, education, employment, gender, age and income. Multivariable linear regression was used to evaluate a mediation model (association between PPR and self-rated health, PPR and quality of care, and the impact of quality of care on the relationship between PPR and health).

Results: Most participants were female (61.1%), unemployed (71.8%), and unmarried (64.3%). The most common cancer types were: breast cancer (23.0%), prostate cancer (19.4%) and colon cancer (8.7%). After controlling for covariates, the multivariable model showed that PPR was significantly associated with both self-rated health (p<0.01) and quality of care (p<0.01). When PPR and quality of care were added to the same model, the analysis showed that quality of care mediated the impact of PPR on self-rated health (p=0.015), and quality of care accounted for 72% of the variance in self-rated health.

Conclusion: Providers' positive interpersonal relationships—including effective communication and involvement in decision making—has a significant positive influence on the health of minority patients, and this influence may be due to increased positive perception of quality of care. Future studies could develop an intervention to enhance provider-patient relationships to help improve patient health.

Paper Session 33: Promoting Physical Activity Among Youth 3:30 PM-3:45 PM

PHYSICAL ACTIVITY AND HEALTH-RELATED QUALITY OF LIFE IN CHILDREN AND ADOLESCENTS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Arwen M. Marker, BA, Ric G. Steele, Jr., PhD, ABPP

University of Kansas, Lawrence, KS

Background: Physical activity is associated with broad physical and psychological benefits in children and adolescents. One construct which may universally characterize functioning across various pediatric populations is health-related quality of life (HRQOL). A number of studies have found positive associations between physical activity and HRQOL; however, to date no systematic review and meta-analysis has quantified the effect of physical activity on HRQOL in children and adolescents.

Methods: A systematic search of PubMed, PsycINFO, and ProQuest Dissertation Abstracts identified 1081 relevant, non-duplicate articles. From these candidate articles, 33 studies, including both descriptive and pre-post intervention designs, met inclusion criteria and were included in the meta-analysis.

Results: Descriptive studies yielded a small, positive effect of physical activity on HRQOL based on child-reports (Hedge's $g = .302, p < .001$) and a negligible effect based on parent-proxy reports (Hedge's $g = .115, p = .101$). Intervention studies yielded a small, positive effect of physical activity intervention on HRQOL based on child-reports (Hedge's $g = .279, p = .014$) and a medium, positive effect based on parent-proxy reports (Hedge's $g = .522, p = .012$). However, effects across two of the models were attenuated by the removal of a single intervention study. Hypothesized moderators, including chronic disease status, weight status, sex, and study rigor, did not significantly moderate the effect of physical activity on HRQOL. Exploratory analyses did not find intervention contact hours or age to moderate the effect of physical activity on HRQOL.

Conclusion: Findings support the primary hypothesis that increased levels of physical activity are related to better HRQOL in youth, although the magnitude of these effects did not represent a minimal clinically important difference (MCID) in most studies. Results suggest that 6–14 youth would need to participate in an existing exercise intervention for one patient to see a beneficial improvement in HRQOL. Future studies are needed to assess HRQOL in youth before and after high-quality exercise interventions to quantify the type, frequency, duration, and intensity of physical activity needed to change HRQOL to a clinically meaningful level. Cross-disciplinary collaborations are indicated to develop more robust physical activity interventions and achieve greater gains in psychosocial outcomes in youth.

Paper Session 33: Promoting Physical Activity Among Youth 3:45 PM-4:00 PM

AN EXERGAMING RCT IMPROVES CARDIOMETABOLIC RISK FACTORS IN CHILDREN WITH OVERWEIGHT AND OBESITY

Chelsea Hendrick, BS¹, Robert L. Newton, Jr., Ph.D.², Daniel Hsia, MD¹, Robbie Beyl, PhD³, Amanda E. Staiano, PhD²

¹Pennington Biomedical, Baton Rouge, LA; ²Pennington Biomedical Research Center, Baton Rouge, LA; ³Pennington Biomedical Research center, Baton Rouge, LA

Background: Exergaming, or video gaming that involves physical activity, can lead to improvements in overall health, specifically in adolescents with obesity. The purpose of the GameSquad study was to test the efficacy of exergaming to reduce adiposity in overweight and obese children.

Methods: The study randomly assigned 46 children ages 10 to 12 years, having a BMI percentile of 85 or greater, to either an exergaming condition or a control condition. Participants attended screening, week 0, and week 24 clinic visits where the following measures were collected: height, weight, DXA scan of fat mass, resting blood pressure, and a fasting blood draw. Children assigned to the exergaming condition were provided an Xbox 360, Kinect, four Kinect games, and a 24-week Xbox Live subscription along with a standardized curriculum to perform three days of 60-minute exergaming sessions with increasing intensity per week in their home over a 24-week period. Participants were also asked to wear a Fitbit Zip throughout the intervention to monitor steps/day and attend video chat sessions with a Fitness Coach through the Xbox weekly for the first six weeks, then biweekly thereafter to assist with intervention retention. Individuals assigned to the control condition were provided the Xbox bundle at no cost following their final clinic visit.

Results: Of the 46 randomized participants, 54% were male and 57% were African American. The average compliance to the intervention, defined as completed days/week versus expected days/week, was 88.5%. Using repeated measures ANCOVA controlling for age and sex, there was a significant effect of the intervention on improving total cholesterol ($p=0.02$) and diastolic blood pressure ($p=0.006$). There was no intervention effect for change in BMI z-score, fat mass or % fat mass, glucose, HDL cholesterol, or systolic blood pressure.

Conclusion: Exergaming at home for 24 weeks improved cardiometabolic factors for children ages 10–12 years without changing body mass or fat mass. Given the high adherence to the exergaming physical activity, further research is needed to explore exergaming as a method of improving childhood health.

Paper Session 33: Promoting Physical Activity Among Youth 4:00 PM-4:15 PM

ASSESSING ACTIVITY ACROSS THE 24-HOUR DAY IN OBESE LATINO YOUTH AT RISK FOR DIABETES

Erica Soltero, PhD¹, Armando Peña, MS², Hanna Rahman, BA², Micah Olson, MD³, Gabriel Shaibi, PhD²

¹Arizona State University, Phoenix, AZ; ²Arizona State University, Phoenix, AZ; ³Center for Health Promotion and Disease Prevention, Arizona State University, Phoenix, AZ

The activity continuum experienced in a 24-hour day includes moderate-to-vigorous physical activity (MVPA), light physical activity (LPA), sedentary behaviors (SBs), and sleep. However, the majority of the research to date has focused on the associations between MVPA and health outcomes. LPA, SBs, and sleep, are associated with reduced type 2 diabetes (T2D) risk in adults, independent of MVPA, yet little is known about these behaviors and diabetes risk in youth. To address this gap, this study examined the associations between time spent in activity levels across the 24-hour cycle and T2D risk in obese Latino youth.

Participants included 160 obese Latino youth ($BMI\%=98.2 \pm 1.4$, $Age=15.3 \pm 0.9$). Anthropometrics were taken to assess height, weight, BMI and body fat (BF%). A 2-hour oral glucose tolerance test (OGTT) was used to assess fasting and 2-hour glucose and insulin resistance (HOMA-IR). Activity was measured using the 3-Day Physical Activity Recall. Compliance with 24-Hour activity guidelines which include daily recommendations for MVPA (≥ 60 minutes of MVPA), screen time (≤ 2 hours), and sleep (> 9 hours), was also assessed. T-tests were used to assess differences in activity by sex and one-way ANCOVAs were used to explore differences in T2D risk by the number of activity guidelines achieved after adjusting for age, sex, and BMI.

Girls reported more MVPA ($M=119.5 \pm 91.0$ vs. 87.2 ± 75.3 , $p=.016$) and LPA ($M=82.7 \pm 42.9$ vs. 62.8 ± 37.8 , $p=.002$) compared to boys. Boys spent more time in VPA and SBs; however, these differences were not significant. 63% of youth met MVPA recommendations, yet boys and girls still averaged ~10 hours of SBs per day. A dose-response pattern between activity guidelines and T2D risk was observed, whereby youth meeting all three guidelines exhibited 11% lower 2-hour glucose and 64% lower HOMA-IR scores compared to youth who did not meet any guidelines.

These findings demonstrate that despite most youth meeting activity recommendations, the excessive amount of time spent in SBs, may still contribute to risk for cardiometabolic disease. These data also suggest that the sum of time spent in activity, screen time, and sleep, can have an impact on T2D risk. This study highlights the importance of assessing activity across the 24-hour cycle in order to increase our understanding of activity patterns in high-risk youth and inform future physical activity promotion and disease prevention strategies aimed at reducing T2D in this high-risk population.

CHILDCARE CENTER REGULATIONS ON FREE PLAY AND OUTDOOR TIME ASSOCIATED WITH CHILDREN'S PHYSICAL ACTIVITY AND SEDENTARY BEHAVIOR

Amanda E. Staiano, PhD¹, E. Kipling Webster, PhD², Andrew T. Allen, MBA³, Corby K. Martin, PhD⁴

¹Pennington Biomedical Research Center, Baton Rouge, LA; ²Louisiana State University, Baton Rouge, LA; ³InHealth Strategies, Baton Rouge, LA; ⁴Pennington Biomedical Research Center, Baton Rouge, LA

Background: The majority of preschool-aged children do not meet national recommendations of 2–3 hours/day of moderate-to-vigorous physical activity (MVPA). Given most children spend time in childcare centers, the purpose of this study was to examine the association of childcare center regulations on children's physical activity.

Methods: This observational trial examined cross-sectional associations among 10 childcare centers' regulations and play environments with 105 preschoolers' in-school MVPA and sedentary behavior (SB). Center directors completed surveys detailing MVPA and SB regulations, and children wore Actigraph GT3X+ accelerometers during the school day. Descriptive characteristics, bivariate correlations, and independent sample *t*-tests were used to examine associations among center regulations with children's activity levels.

Results: Directors reported providing 124.6 ± 81.3 min/day of free play and 78.3 ± 23.0 min/day of outdoor play. Children engaged in an average of 67.7 ± 22.6 min/day MVPA at school including 21 min/day of VPA, plus 226 min/day of SB. Children's MVPA was inversely related with SB at school ($r=-0.83$, $p<.001$). Children in centers with ≥ 120 min/day of free play had higher MVPA (74 vs. 62 min/day, $p=0.004$), higher VPA (25 vs. 17 min/day, $p=0.0004$), and less SB (215 vs. 235 min/day, $p=0.006$) than centers who offered ≤ 120 min/d of free play. In centers with multiple play areas including an open space for running and a path/track, children engaged in higher MVPA (72 vs. 62 min/day, $p=0.03$) and VPA (23 vs. 17 min/day, $p=0.005$) vs. those centers with fewer structures. Children's MVPA and SB did not vary by whether or not the center had a written PA or electronic device policy, whether or not the center withheld PA due to misbehavior, the frequency with which teachers led structured PA, the amount of allowed screen-time, or the variety and amount of portable play equipment.

Conclusion: Identifying ways to support centers and teachers to provide more unstructured free time with supportive play equipment is a priority to increase physical activity levels in young children.

AN AFTER SCHOOL PHYSICAL ACTIVITY INTERVENTION FOR UNDERSERVED ADOLESCENTS: MOVING FROM FEASIBILITY TO THE EFFICACY TRIAL

Nicole Zarrett, Ph.D.¹, Michelle Abraczinskas, M.A.², Lauren H. Law, MA¹, Brittany S. Cook, M.A.³, Stephen G. Taylor, B.S.¹, Dawn K. Wilson, PhD¹, Bethany A. Bell, PhD, MPH¹

¹University of South Carolina, Columbia, SC; ²University of South Carolina, New Haven, CT; ³University of South Carolina, West Columbia, SC

Preliminary data from an afterschool program feasibility trial will provide the evidence-based methods for developing a large-scale efficacy trial of the Connect through Positive Leisure Activities for Youth ('Connect') afterschool physical activity (PA) program. The Connect intervention, which is based on social development theory and the social mechanisms highlighted by Self-Determination Theory and Achievement Goal Theory, aims to increase the PA of underserved (i.e., low income, minority status) middle school youth within pre-existing afterschool programs (ASPs). The intervention is designed to improve several key social mechanisms within ASPs overlooked in previous interventions (e.g., developing friendship and connection to peers and staff through PA; group belonging, including positive peer PA norms and tangible support) that are key predictors of youth PA. The research team recently completed a feasibility trial (NIH R21 HD077357) within 6 ASPs (3 intervention vs. 3 controls) for underserved middle school youth that was the first intervention to date to address youth PA social mechanisms.

A regression model (pooled across imputations), controlling for baseline MVPA, site, bmi, and gender significantly predicted MVPA ($F[5,219]=46.17$, $p < 0.001$, $R^2 = 0.51$), with youth in the social intervention (vs. comparison) showing an increase of 8.61 min of MVPA at post ($B=8.61$, $SE: 3.63$, $pt(118)=2.60$, $p=.01$), praising [$t(118)=1.98$, $p=.05$], participating with youth [$t(118)=5.93$, $p=.000$], youth PA social supports [$t[47]=3.09$, $p=.000$] and connections with peers [$t[118]=3.68$, $p=.000$]. Process evaluation indicated adequate dose and fidelity of all program essential elements, and staff readiness assessments indicated high levels of program acceptability. Findings from the feasibility trial are used to inform the proposed R01 Efficacy trial, which expands on the intervention's novel translational approach by targeting program staff as instrumental for sustainable changes in social mechanisms within the ASP setting for increasing the daily PA of underserved adolescents. We will highlight the importance of community-based participatory approaches, the use of critical process measures (e.g., process evaluation; readiness assessment, systematic observations), and assessment of key findings for developing a large-scale efficacy trial.

THE INFLUENCE OF CHAOS IN THE HOME ON THE HOME FOOD ENVIRONMENT FOLLOWING A WEIGHT-LOSS PROGRAM

Emily Wyckoff, B.A.¹, Talea Cornelius, Ph.D., M.S.W.², Erin Lenz, Ph.D.³, Gary Foster, PhD⁴, Alexis Wojtanowski, CCRP⁵, Amy A. Gorin, Ph.D.¹

¹University of Connecticut, Storrs, CT; ²Columbia University Medical Center, New York, NY; ³Bedford VA Medical Center, Southbridge, MA; ⁴Weight Watchers, Inc, New York, NY; ⁵Weight Watchers Intl, New York, NY

A disorganized, unpredictable home environment can put children at risk for obesity, suggesting a link between the general home environment and an obesogenic home food environment (i.e. lots of high fat foods and few low-fat choices). The effect of home-chaos on weight control in adults and reciprocal effects between general and food environments have not been examined. This study explored the association between a chaotic home environment and participation in a commercial weight loss program as they related to foods kept in the home. It was hypothesized that a more chaotic home environment would be associated with more high-fat foods and fewer low-fat foods in the home. Further, it was expected that the influence of chaos on foods in the home would differentially influence participants in a commercial weight loss program, who would have been directed to change their food environment, compared to those who undertook a self-guided approach to weight loss. Specifically, it was hypothesized that chaos in the home would have a minimal influence on those attempting self-guided weight loss, and for those following a commercial weight loss program high chaos in the home would negatively predict number of low-fat foods and positively predict number of high fat foods, as chaos in the home would make the changes suggested in a structured behavioral weight loss program more challenging to enact.

The Confusion Hubbub and Order Scale (CHAOS) and the Home Food Inventory (HFI) were completed by adults following participation in 6-months of Weight Watchers (WW; n=47) or self-guided weight loss (SG; n=55). Two sequential regressions were performed (outcomes HFI high-fat foods and HFI low-fat foods) including number of children in the home, income, CHAOS, condition, and an interaction between CHAOS and condition.

Both models were statistically significant (Low-fat foods: $F(5,96)=3.55$, $p<0.05$, $R^2 = .16$; High-fat foods: $F(5,96)=2.52$, $p<0.05$, $R^2 = .11$). Neither chaos nor intervention significantly predicted Low-fat foods ($ps>.05$), but the interaction between CHAOS and condition was significant ($Beta=.689$, $p=.03$). In WW, greater CHAOS was associated with fewer low-fat foods in the home. In SG, CHAOS did not predict number of low-fat foods in the home. The interaction between CHAOS and condition was not significant in predicting high fat foods, however WW condition was associated with fewer high-fat food in the home ($Beta=-.74$, $p=.02$).

Findings indicate a chaotic home environment in itself is not associated with a poor food environment, but a chaotic environment may make it difficult for those in a weight loss program to improve their food environment. Future research should examine the changes to the home food environment throughout weight loss treatment and the influence of chaos on making changes to the food environment.

Paper Session 34: Nudging Healthier Food Options 3:45 PM–4:00 PM

DIFFERENCES IN FRUIT AND VEGETABLE INTAKE BETWEEN SCHOOL AND PACKED LUNCHES: THE ROLE OF SCHOOL LUNCH FOOD AVAILABILITY

Jennifer C. Taylor, MS¹, Carolyn Sutter, PhD², Lenna Ontai, PhD¹, Adrienne Nishina, PhD¹, Sheri Zidenberg-Cherr, PhD¹

¹University of California, Davis, Davis, CA; ²University of Illinois, Urbana-Champaign, Urbana, IL

Mounting evidence suggests packed lunches brought from home fall short of school-bought lunches in terms of students' fruit and vegetable intake, although findings are mixed. Given that fruit and vegetable availability is positively associated with intake, and that schools are encouraged to offer a wide variety of these foods, higher intake among school lunches may depend on the extent to which greater variety is available at school. The objectives of this study were to (1) compare fruit and vegetable selection and consumption between school and packed lunches and to (2) examine how day-to-day changes in school fruit and vegetable availability influence these differences. Participants were fourth- through sixth-grade students ($N = 315$) from three elementary schools. Each student was observed over a period of 5 consecutive days ($N = 1,421$ lunch observations). Trained analysts estimated food selection and consumption using digital images and written records collected before and after lunch. School fruit and vegetable availability were defined as the total number of offered fruit and vegetable menu items, respectively, each day. Mixed model logistic regressions assessed odds of selecting and consuming fruit and vegetables as a function of lunch type overall (**objective 1**), and after accounting for fruit availability (for fruit outcomes) and vegetable availability (for vegetable outcomes; **objective 2**). Models controlled for student gender, grade, household income, and school. Overall, on days students had packed lunches they were less likely to select fruit (odds ratio [OR], 0.39; 95% CI, 0.17–0.88), consume fruit (OR, 0.29; 95% CI, 0.14–0.57), select vegetables (OR, 0.55; 95% CI, 0.32–0.94), and consume vegetables (OR, 0.44; 95% CI, 0.26–0.77) compared to having school lunches, suggesting these dietary behaviors are better supported when students have school lunches. Aggregating across all observation days, between 1–5 fruit and 3–8 vegetable items were available and availability was positively associated with selection and consumption ($ps < .05$). Importantly, when availability was at its lowest levels (i.e., 1 fruit item, 3 vegetable items), there were no significant differences between school and packed lunches for fruit selection, vegetable selection, or vegetable consumption. Building on prior research comparing packed and school lunches, these findings suggest lunch type differences depend on the school lunch program's food availability on a given day.

A "DEFAULT OPTION" TO ENHANCE NUTRITION WITHIN A FOOD INSECURE POPULATION

Jaime A. Coffino, B.A., M.P.H.¹, Tomoko Udo, PhD², Julia M. Hormes, Ph.D.³

¹University at Albany, State University of New York, Albany, NY;

²University at Albany, School of Public Health, Rensselaer, NY; ³University at Albany, SUNY, Albany, NY

Introduction: Food insecurity has been associated with an increased risk for obesity. There is a need for sustainable interventions that improve diet-related health within the food insecure community. In behavioral economics, the "default option" is the option a consumer selects if s/he does not make an active choice (e.g., opting out vs. opting in to organ donation programs). We examined if use of a default option would result in the purchase of healthier food items at an online grocery store, compared to psychoeducation.

Methods: 44 participants (age = 45.75 ± 12.83; BMI = 28.59 ± 6.42; 74.4% male) were randomized into two conditions: (1) reading a nutrition "psychoeducational" brochure adapted from current Supplemental Nutrition Assistance Program (SNAP) materials before selecting groceries online with a budget of \$48.50 (typical weekly food stamp allowance) ($n = 21$) or (2) a "default" pre-filled online shopping cart containing a nutritionally balanced selection of groceries selected within the same budget to which they could freely make changes before finalizing their purchase ($n = 23$).

Results: Compared to psychoeducation, the default condition resulted in the purchase of significantly fewer average daily calories ($M = 3581.10$ vs. 2822.31, $p = .02$, $d = .74$), total fat (g) ($M = 182.71$ vs. 101.91, $p < .001$, $d = 1.55$), saturated fat (g) ($M = 59.10$ vs. 30.17, $p < .001$, $d = 1.55$), sodium (mg) ($M = 5113.95$ vs. 3599.17, $p = .002$, $d = .99$), and cholesterol (mg) ($M = 1038.19$ vs. 554.39, $p < .001$, $d = 1.22$), and significantly more average daily fiber (g) ($M = 22.26$ vs. 39.76, $p = .001$, $d = 1.08$) and a greater percentage of the budget allocated towards fruits ($M = 6.3$ vs. 14.43, $p = .02$, $d = .73$) and vegetables ($M = 9.24$ vs. 29.96, $p < .001$, $d = 1.58$).

Discussion: This study suggests that a default approach may help improve food choice behaviors in food insecure individuals with significant financial constraints. Implementation via online platforms could specifically benefit those living in food deserts with limited access to healthy options. As a next step, we plan to conduct a longitudinal, small-scale randomized clinical trial to examine the effect of the default option on actual consumption and diet-related health outcomes.

FRUIT AND VEGETABLE SELECTION AND INTAKE AFTER INSTALLATION OF SALAD BARS IN TITLE I ELEMENTARY SCHOOLS: A PLATE WASTE STUDY

Melanie Bean, PhD¹, Bethany Brady Spalding, MSc², Elizabeth Theriault, MPH MSW³, Kayla-Brooke Dransfield, BA², Alexandra Rachel. Sova, BS⁴, Mary Dunne Stewart, MSW²

¹Virginia Commonwealth University, Richmond, VA; ²Greater Richmond Fit⁴Kids, Richmond, VA; ³Richmond City Health District, Richmond, VA; ⁴Georgetown University, Washington, DC

School salad bars are increasing in popularity as a means to increase fruit and vegetable (FV) intake within the National School Lunch Program. Salad bars foster choice, which might be particularly effective with the “serve” model, requiring children to take a FV with each meal. However, there is little empirical support for their use. This investigation evaluated the short term impact of salad bars on FV selection, intake and plate waste in two randomly selected, Title I elementary schools in a large, urban district in central Virginia. It also examined student perceptions of salad bars in 15 elementary schools within the district. Digital imagery plate waste assessments were conducted (grades 1–5; >95% African American) before (n=276 plates) and one-month after (n=385 plates) salad bars were installed; 4th and 5th grade students from 15 schools (n=1193) responded to surveys. General linear models examined changes in FV selection, consumption, and % plate waste, controlling for school. Frequencies and qualitative analyses were applied to survey data. Results suggested that students selected more types of FV; however, they selected smaller portions and consumed fewer FV at post, compared to when FVs were pre-portioned. FV plate waste (%) increased; yet relative to portions selected, there was less FV waste (cups) at post. Students liked the ability to choose FV from the salad bar. Results suggest that short term exposure to salad bars increases the number and variety of FV children choose. Additional strategies are needed to increase FV consumption.

Paper Session 35: Supporting Physical Activity Among Older Adults
3:30 PM-3:45 PM

CROSS-SECTIONAL RELATIONSHIPS OF PHYSICAL ACTIVITY, SLEEP QUALITY, AND COGNITIVE FUNCTION IN OLDER ADULTS

Ryan S. Falck, MSc¹, John Best, PhD¹, Jennifer C. Davis, PhD², Teresa Liu-Ambrose, PT, PhD¹

¹University of British Columbia, Vancouver, BC, Canada; ²University of British Columbia, Kamloops, BC, Canada

Background: The growing public health problem of cognitive impairment—and the fact a pharmaceutical cure does not yet exist—places increasing need for lifestyle and behavioural approaches that maintain cognitive health. Current evidence suggests physical activity (PA) and sleep quality are important for cognitive health. However, few studies examining the role of PA and sleep for cognitive health have measured these behaviours objectively. Thus, using cross-sectional data, we examined whether 1) higher PA is associated with better cognitive performance independent of sleep quality; 2) good sleep quality is associated with better cognitive performance independent of PA; and 3) whether higher PA is associated with better sleep quality.

Methods: We measured PA, sleep quality (i.e., fragmentation, efficiency, duration, and latency) and cognitive function (i.e., indexed using the Alzheimer’s Disease Assessment Scale-Plus [ADAS-Cog Plus]) in community-dwelling adults (N=137; aged 55+) using the MotionWatch8®. Using latent variable structural equation modeling, we generated separate models for each sleep quality index (i.e., fragmentation, efficiency, duration, and latency). Each model examined the strength of the relationships of 1) PA with cognitive function, while controlling for sleep quality; 2) sleep quality with cognitive function, while controlling for PA; and 3) PA with sleep quality.

Results: Across all four models, greater PA was associated with better ADAS-Cog Plus performance ($\beta = -0.13$; $p < 0.01$). Greater sleep fragmentation was associated with better cognitive performance ($\beta = -0.11$; $p = 0.03$). However, there were no significant relationships between 1) sleep duration; 2) sleep efficiency; and 3) sleep latency and cognitive performance. We also found higher PA was associated with less sleep efficiency ($\beta = -0.19$; $p = 0.04$), but PA was not significantly associated with any other sleep quality index.

Conclusion: While PA was strongly associated with cognitive performance, the relationship of sleep quality with cognition was less consistent, as only one sleep quality index correlated with cognitive performance. In addition, PA was not strongly related to older adult sleep quality, and thus improving older adult sleep health may require interventional approaches which combine PA with other therapies (i.e., bright light, sleep hygiene, etc.).

Paper Session 35: Supporting Physical Activity Among Older Adults 3:45 PM–4:00 PM

FEASIBILITY OF AN OUTDOOR MINDFUL WALKING PROGRAM FOR REDUCING NEGATIVE AFFECT IN OLDER ADULTS

Chih-Hsiang Yang, PhD¹, David E. Conroy, PhD²

¹The Pennsylvania State University, STATE COLLEGE, PA; ²The Pennsylvania State University, UNIVERSITY PARK, PA

Mindful walking has emerged as a potential intervention strategy to improve mental health and promote well-being in adult and clinical populations. This strategy has not been implemented with older adults to date. This study evaluated the feasibility, acceptability, sustainability, and preliminary efficacy of a mindful walking program for reducing negative affect in older adults. Community-dwelling older adults ($n = 29$) completed a one-month, outdoor mindful walking program distributed across eight 30-minute sessions. Overall, 93% of the recruited participants ($n = 27$) completed all walking sessions and assessments. Responses from the post-program and the followup questionnaires revealed that mindful walking was well-accepted, highly-valued, and maintained after the program ended. Open-ended feedback reinforced these findings. Analysis from the pre-walk and post-walk surveys also suggested the preliminary efficacy of mindful walking program for reducing negative affect. In general, the mindful walking program in the current study can be implemented as intended (i.e., feasible) and should be considered acceptable and sustainable by older adults. Positive results identified in the current feasibility study indicate readiness for randomized controlled trials to further examine the efficacy and effectiveness of a mindful walking intervention for promoting health and well-being in older populations.

FACTORS ASSOCIATED WITH ADHERENCE TO ACTIVITY MONITOR-BASED PHYSICAL ACTIVITY INTERVENTION IN OLDER ADULTS

Maria Swartz, PhD, MPH¹, Zakkoyya Lewis, PhD², Michael Swartz, PhD³, Eloisa Martinez, Bachelor of Science in Psychology⁴, Elizabeth J. Lyons, PhD, MPH⁵

¹University of Texas Medical Branch, Missouri City, TX; ²Beachbody, Wilmington, CA; ³The University of Texas Health Science Center at Houston School of Public Health, Houston, TX; ⁴UTMB- Galveston, Texas City, TX; ⁵The University of Texas Medical Branch, Galveston, TX

Purpose: Wearable activity monitors are a promising supplemental tool for increasing physical activity (PA) among older adults, for whom regular PA may help maintain independent living ability and delay development of mobility disability. However, factors that may promote adherence to mhealth interventions (use of activity monitor in addition to counseling calls) are not well understood. We thus examined adherence to a mhealth intervention and identified factors that may be associated with weekly adherence to a 12-week activity monitor-based PA intervention in older adults.

Methods: We conducted a secondary analysis using data from 35 participants (older adults aged 55–79) who completed the intervention. Weekly adherence was defined as the participant wore the Jawbone Up24 wearable activity monitor for ≥ 5 days and completed the weekly phone call to review the previous week's step goal. Variables of interest included: age, gender, race/ethnicity, body mass index (BMI), gave and received virtual support, previous week's step average, achieved step goals, barrier and task self-efficacy, and self-comments. Associations of variables to adherence were examined by generalized linear mixed models.

Results: Participants (61.7 ± 5.7 years, 57% Non-Hispanic White, 83% female, and BMI 30.2 ± 3.34 kg/m²) showed an adherence rate at week 1 of 86%, decreasing to 74% by week 12. Achieved the previous week's goal ($\beta=1.13$, SE=0.41, $p \beta=0.01$, SE=0.004, $p=0.02$) were significantly associated with adherence. Age, gender, race/ethnicity, BMI, gave virtual support, previous weeks' step average, barrier and task self-efficacy, and self-comments were not significantly associated with adherence.

Conclusions: Our results suggest that achieved step goals and received virtual support were important factors to improve adherence to an activity monitor-based PA intervention among older adults. Future interventions may consider setting smaller achievable goals and promoting virtual interactions on the activity monitor applications to encourage long-term PA adherence in older adults.

Paper Session 35: Supporting Physical Activity Among Older Adults 4:15 PM–4:30 PM

DAY-TO-DAY CHANGES IN PHYSICAL ACTIVITY AND SLEEP QUALITY IN OLDER ADULTS: A MULTI-LEVEL ANALYSIS OF BIDIRECTIONAL CONNECTIONS

John Best, PhD, Ryan S. Falck, MSc, Glenn Landry, PhD, Teresa Liu-Ambrose, PT, PhD

University of British Columbia, Vancouver, BC, Canada

BACKGROUND: Maintaining sleep quality and physical activity (PA) have been shown to be important to various aspects of healthy aging. These two behaviours appear to be interrelated, and thus, by promoting one behaviour, it may be possible to improve the other. Examination of within-person day-to-day fluctuations in these behaviours is necessary to better understand the directionality of their association.

METHODS: One hundred fifty-two older adults (mean age = 71 years, SD = 7 years; 67% female) from the community were asked to wear a uni-axial, wrist-worn accelerometer (MotionWatch 8) over 14 days. Three measures of sleep quality were quantified: 1) *fragmentation index*; 2) *sleep efficiency* (time asleep expressed as a percentage of time in bed); and 3) *sleep duration*. Percent of day in PA (>3.0 METS) was assessed. Dynamic structural equation modeling (DSEM) with Bayesian estimation estimated within-subject autoregressive effects (e.g., the person-centered effect of the preceding day's sleep quality on the next day sleep quality), within-subject cross-lagged effects (e.g., the person-centered effect of the preceding day's PA on that night's sleep quality), and between-subject associations between sleep quality and PA. A separate DSEM was constructed for each sleep quality measure. Age, sex, and education were included as between-subject covariates.

RESULTS: Across the 152 participants, 1988 observations of each measure of sleep quality and 1964 observations of PA were collected over the 2-week observation period. In each DSEM, there was a positive autoregressive effect of PA (estimate = .19, 95% CI: .14, .24), suggesting that when an individual engaged in a high amount of PA on one day (relative to her average), she was slightly more likely to engage in a high amount of PA on the next day. In contrast, there was a negative autoregressive effect of sleep duration (estimate = -.09, 95% CI: -.13, -.04), suggesting that nights in which she slept for a long period of time were followed by nights in which she slept relative less than her average. One cross-lagged effect was observed between PA and that night's sleep duration (estimate = .01, 95% CI: .001, .02), which suggests that when an individual engaged in a large amount of PA, she tended to sleep longer that following night. One between-subject correlation was observed between PA and sleep efficiency (estimate = -6.93, 95% CI: -13.88, -.57), suggesting that participants who engaged in large amounts of PA (relative to the sample averaged across all days) tended to have lower sleep efficiency.

CONCLUSIONS: The current study provides evidence that engaging in large amounts of PA might lead to longer sleep duration that night. No measure of sleep quality predicted subsequent engagement in PA. Increasing PA therefore might increase sleep duration in older adults.

Paper Session 35: Supporting Physical Activity Among Older Adults 4:30 PM-4:45 PM

THE ROLE OF MHEALTH IN A TAILORED SELF-MANAGEMENT INTERVENTION TO PROMOTE ADHERENCE TO AN EXERCISE PROGRAM FOR OLDER ADULTS

Taya Irizarry, PhD RN¹, Susan Sereika, PhD², Elizabeth A Schlenk, PhD, RN¹, Annette Devito Dabbs, PHD, RN, ACNS-BC, FAAN¹

¹University of Pittsburgh, Pittsburgh, PA; ²University of Pittsburgh, Pittsburgh, PA

Background: Little is known about how mHealth supported individually tailored self-management interventions (mHealth-ITSMIs) might promote exercise adherence among people living with chronic conditions that impede physical function.

Objective: To generate a contextually rich theory driven assessment of exercise adherence promotion via a mHealth-ITSMI designed specifically for older adults (age 50+) diagnosed with osteoarthritis of the knee and hypertension. The primary research questions are: 1) What is the relationship between extent of tailoring and patterns of adherence over the course of the 24-week intervention period, and 2) What role might mHealth play in tailoring and adherence?

Methods: Quantitative and qualitative data from the intervention arm of the Staying Active with Arthritis (STAR) trial were utilized. Latent trajectories of tailoring and adherence for lower extremity exercise (LEE) and fitness walking (FW) were identified using group based trajectory modeling. Bivariate associations between identified tailoring and adherence trajectory groups were evaluated. Purposive sampling was performed based on adherence and tailoring trajectory group membership. Actor Network Theory guided the descriptive analysis of transcribed audio-recorded participant-physical therapist interactions to examine the role the eDiary played in exercise tailoring and adherence.

Results: Group-based trajectory modeling revealed three distinct trajectories for LEE adherence and tailoring; four for FW adherence and tailoring. A moderate association was observed between LEE and FW adherence trajectories ($p=.001$), and between LEE tailoring and adherence trajectories ($p=.007$), but not between FW tailoring and adherence trajectories ($p=.12$). The eDiary played a role in the participant-interventionist relationship, decision-making, and motivation. Motivation was explained by concepts from social cognitive theory, self-determination theory, and goal-setting theory. The degree of individual fit between how a goal was defined and the way it was measured via the eDiary impacted participants' perceived accomplishment and directly impacted sustained motivation.

Conclusions: mHealth-ITSMIs could further encourage the initiation and maintenance of an exercise routine by offering more individually tailored options for defining goals and measuring achievement. Design consideration include the ability to adjust for changes in health status, physical ability, and life events, and by promoting a personalized balance between extrinsic and intrinsic motivators. Further evaluation of mHealth-ITSMIs should include time-variant measures (both behavioral and physical) that may explain mechanism of effects in the analysis of goal tailoring and adherence at multiple time points over the course of the initial intervention and maintenance phases.

WALKABILITY MODERATES INTERVENTION ON MODERATE-TO-VIGOROUS PHYSICAL ACTIVITY AND BODY MASS INDEX

Jane C. Hurley, MS¹, Lu Hao, BSP², Mohammed Abdullah. Abduljabbar, MAS-GIS³, Siddhartha S. Angadi, PhD., FASCSM¹, Marc A. Adams, PhD, MPH⁴

¹Arizona State University - Downtown Phoenix Campus, Phoenix, AZ;

²Columbia university, New York, NY; ³Arizona State University, Apt# 2009, AZ;

⁴Arizona State University, Phoenix, AZ

Physical inactivity raises the risk of premature morbidity and mortality. The built environment (BE) is consistently linked to physical activity (e.g. walking), yet few studies have examined whether the BE moderates individual-level physical activity interventions. The current study explores how neighborhood walkability moderates change in body mass index (BMI), moderate-to-vigorous physical activity (MVPA), steps per day (Step/d), cardiorespiratory fitness (CRF), and blood pressure (BP) for participants in a 4-month 2x2 factorial RCT using mobile health (mHealth) technology (e.g. accelerometers and text messages) in adults (i.e. the WalkIT Trial).

Methods: Participants received a randomly assigned mHealth intervention designed to increase Steps/d: Adaptive vs. Static Goals and Immediate vs. Delayed Rewards. Pre- and post-BMI, MVPA, Step/d, CRF, BP were measured. GIS defined 500-m and 1-km street-network buffers (neighborhoods) around participant homes and derived walkability scores (residential, intersection, and transit density; land use mix). Analyses included separate linear step-wise regression of change in BMI, MVPA, Step/d, CRF, and BP on walkability for each buffer size; alpha level=0.15 to explore contextual interactions. Covariates included age, sex, race, smoking status, and baseline value of dependent variable.

Results: Participants ($n = 75$) were 77% female, mean age = 42.3 years. For change in BMI and MVPA, the walkability index significantly moderated group assignment for the 500-m buffer size (BMI: $B = .236$, $p = .03$; MVPA: $B = 0.98$ $p = .13$), but was not significant for Step/d, CRF, or BP. The 1-km buffer detected no significant moderation for any outcome. To probe the interactions, the change in BMI and MVPA by intervention group (Goal x Reward) was explored at high and low walkability (± 1 to 3 standard deviations). For BMI: living in higher walkable neighborhoods, participants receiving Static Goals with Immediate Rewards showed the greatest reduction in BMI compared to the other intervention groups. For lower walkable areas, receiving Adaptive Goals with Immediate Rewards showed the greatest reductions in BMI. For MVPA: living in higher walkable neighborhoods, those receiving Adaptive Goals with Delayed Rewards showed the smallest increase in MVPA compared to the other intervention groups. In lower walkable areas, the Static Goals with Delayed Rewards group showed the smallest increase in MVPA. Across walkability scores, the gain in MVPA was stable for both groups receiving the Immediate Rewards.

Conclusions: Walkability differentially moderated intervention effects on BMI and MVPA. Determining types of interventions best suited for specific forms of BE may improve individual response and better change health outcomes.

OBEISITY AND RACIAL DISPARITIES: EXPLORING SPATIAL DISTRIBUTION BASED ON SOCIOECONOMIC DEPRIVATION

Fabiana A. Brito, PhD, MSPH, BSN¹, zaeema Naveed, MPH², Fabio Almeida, PhD³

¹University of Nebraska Medical Center, La Vista, NE; ²University of Nebraska Medical Center, Omaha, NE; ³University of Nebraska Medical Center, Omaha, NE

Rates of overweight and obesity in the U.S. have increased among people of all racial groups and some are disproportionately affected. However, there is scarce information on how spatial distribution of the socioeconomic status (SES) disparities may influence racial differences. This study examined the relationship between the spatial distribution of study participants in a technology-enhanced weight loss program, socioeconomic vulnerability (characterized by the Area Deprivation Index/ ADI), weight status (BMI), and race in the city and county of Roanoke, Virginia. ADI represents a composite geographic area-based measure of the socioeconomic deprivation experienced by neighborhood. The higher the value of ADI, the higher is the socioeconomic deprivation of the respective block group and these high levels of deprivation have been associated with an increased risk of adverse health and health care outcomes. The prevalence of socioeconomic vulnerability characterized by the ADI was mapped by block group in ArcMap by creating a choropleth map of block group ADI using quartiles as a method of classification. Geographical analyses included the use of three spatial statistics to determine spatial clustering (global Moran's I and Getis-Ord G*). Global Moran's I test revealed statistically significant ($p < 0.001$) clustering of both BMI (Moran's I: 0.02; z-score=3.71) and race (Moran's Index: 0.03; z-score=5.46). Hot Spot analysis by means of the Getis-Ord Gi* statistic, where hot spot was defined as a clustering of high ADI while a cold spot represented the clustering of low ADI, revealed significant hot spots (99% confidence) corresponding with the spatial distribution of African American (AA) participants and no associations for Caucasians. These findings show the existence of clusters with significantly higher rates ('hot spots') of social economic deprivation associated with a participant's BMI and race. In particular, AA were more likely to live in areas of greater socioeconomic vulnerability and present higher BMI. These results suggest that racial differences in obesity risk may be influenced by socioeconomic vulnerability and show the importance to consider social environmental determinants to better understand obesity related racial disparities.

I SAW THE SIGN (AND MIRROR): EFFECTS OF MIRROR EXPOSURE AND PROMOTIONAL SIGNAGE ON STAIR VS. ELEVATOR USE IN COLLEGE STUDENTS

Katie L. Hodgin, MPH, PhD¹, Dan J. Graham, PhD²

¹University of Northern Colorado, Fort Collins, CO; ²Colorado State University, Fort Collins, CO

Objective Self-Awareness (OSA) theory (Duval & Wicklund, 1972) proposes that heightened focus on the self will lead individuals to align their behavior with a personally- or socially-derived standard. Exposure to a mirror may increase self-awareness and has previously been found to induce behaviors that align with a known or implied standard, such as honesty and helping behavior. However, very little research has investigated the influence of mirror exposure on physically active behaviors, which are commonly valued. The present research examined the effects of mirror exposure on the health behavior of stair vs. elevator use, hypothesizing that individuals exposed to a mirror and a stair-promotional sign would have higher odds of taking the stairs than those exposed to a sign only and that descriptive norm messaging on promotional signage would be associated with higher odds of stair use than health-based messaging. University students ($n = 204$) were exposed to either a body-length mirror and a point-of-decision sign promoting stair use (with either a descriptive norm or health-based message), a descriptive norm or health-based promotional sign only, or nothing and were then observed as they chose to take the stairs or elevator to the fourth floor of an enclosed campus parking garage. Participants were also surveyed post-transportation decision on demographic information and their health behaviors including physical activity. Results partially supported hypotheses by indicating that participants' odds of stair use were increased above baseline after exposure to a body-length mirror with a health sign describing caloric expenditure during stair use (OR = 2.99, $p = 0.06$, 95% CI [0.96, 9.31]) and after exposure to a descriptive norm sign on its own (i.e., without a mirror) describing the high stair use of university students (OR = 3.63, $p = 0.02$, 95% CI [1.21, 10.94]). Such findings do not directly support OSA theory but suggest inexpensive new methods for promoting stair use among college students with mirrors and specific messages on point-of-decision signage.

AMAZON MTURKERS VS EXPERT RATERS: CROWDSOURCING MICROSCALE AUDITS OF PEDESTRIAN STREETSCAPES

Marc A. Adams, PhD, MPH¹, Christine Phillips, C.S.C.C., M.S.S., PhD¹, Jane C. Hurley, MS², Hanna Hook, MSc³, Emily Western, B.S.⁴, Wenfei Zhu, PhD⁵, Tsung-Yen Yu, M.C.S.⁶, Vincent J. Berardi, MA, PhD⁷

¹Arizona State University, Phoenix, AZ; ²Arizona State University - Downtown Phoenix Campus, Phoenix, AZ; ³Arizona State University, Gilbert, AZ; ⁴Arizona State University, Maricopa, AZ; ⁵Shaanxi Normal University, Xi'an, Shanxi, China (People's Republic); ⁶Arizona State University, Tempe, AZ; ⁷Chapman University, San Diego, CA

Expert virtual audits of neighborhood streetscape features are a reliable alternative to in-person audits. Major obstacles associated with the scalability of virtual audits are their time-intensive nature and the expertise needed. Internet crowdsourcing combined with Google StreetView offers the potential to virtually audit environments by enlisting large numbers of laypersons, thereby addressing the time intensity of scalability. This pilot study tested the concordance between minimally-trained Amazon MTurk (i.e., an online workforce) workers and expert raters of streetscape features with an online version of Microscale Audits of Pedestrian Streetscapes Mini (MAPS-Mini).

Methods: Participants (N=22) were selected from high and low walkable and socioeconomic status neighborhoods in Phoenix, AZ. GIS was used to identify audit points every 25 meters originating from the home and extending out along the street network in all directions up to 400m (n=540 audit points). We developed a dynamic interface to allow 5 experts and 653 MTurk raters to panoramically view and audit each point via Google StreetView for 7 MAPS-Mini features. Intraclass correlation coefficients tested the average scores of 3 MTurk ratings to an expert rating. Majority rule was used (e.g. if 2 of 3 MTurk ratings were positive for a feature, then it was presumed to exist) for each audit point to evaluate sensitivity and specificity relative to experts.

Results: Expert raters found the following prevalences: sidewalks (95%), bike lanes (17%), parks (16%), sidewalk buffers (10%), public seating (8%), transit stops (4%), and graffiti (3%). Compared to expert raters, MTurk ratings for bike lanes (.83), sidewalk buffers (.70), and transit stops (.73) showed substantial concordance. Benches (.54), sidewalks (.59) and parks (.53) showed moderate concordance and graffiti had poor concordance (.08). Further analyses revealed that MTurkers were sensitive to the presence of all features, yet were inaccurate for sidewalk absence. After accounting for prevalence, positive predictive values were in the acceptable range (i.e. >.70) for all items, except graffiti.

Conclusions: Crowdsourced audits of microscale features showed substantial to moderate concordance with experts. Additional testing across diverse neighborhoods and populations is necessary. Next steps for enhancing a crowdsourced MAPS Mini tool will be discussed along with the promise of scaling up microscale audits.

INFLUENCE OF THE BUILT ENVIRONMENT ON QUALITY OF LIFE IN EARLY-STAGE AFRICAN AMERICAN BREAST CANCER PATIENTS.

Mario Schootman, PhD¹, Maria Perez, MA², Jeffrey C. Schootman, N/A³, John Fu, MD PhD⁴, Allese McVay, MPH³, Donna B. Jeffe, PhD⁵

¹Saint Louis University, St Louis, MO; ²Washington University, Saint Louis, MO; ³Saint Louis University, Saint Louis, MO; ⁴Saint Louis University, Saint Louis, MO; ⁵Washington University School of Medicine, St Louis, MO

Living in disadvantaged neighborhoods may adversely affect breast cancer patients' quality of life (QOL) through various stressors. We examined the extent to which the built environment affected QOL in African American breast cancer patients. We prospectively recruited 227 newly diagnosed African American breast cancer patients (stage 0-III, age 30+) between 12/2009 and 12/2012 from the St. Louis area. Patients completed 5 interviews over 2-year follow-up. Patient-reported QOL was measured using the 8 subscales of the RAND Medical Outcomes Study 36-Item Health Survey. Geocoded residential addresses allowed us to virtually audit the built environment of their streets using Google Street View and the Active Neighborhood Checklist, which assesses land-use characteristics, sidewalk quality (e.g., obstructions, cracks), and physical disorder (graffiti, vacant building/lots). Latent trajectory models allowed for differentiation between systematic change in QOL over time (slope) and stable tendencies of a baseline level of QOL (intercept). Covariates included patient sociodemographics, comorbidity, and smoking status. QOL scores improved over time for emotional wellbeing, role limitations due to emotional problems and due to physical health, energy/fatigue, and social functioning (p<0.05). General health and physical functioning declined over time (p<0.05). Pain was the only subscale that did not change significantly. Women who lived on streets with higher sidewalk quality reported better emotional wellbeing and social functioning, and fewer limitations due to emotional problems at baseline in adjusted analysis (all p<0.05), but these QOL measures did not improve more rapidly over time than women with lower sidewalk quality (all p>0.05). Women who lived on streets with abandoned homes/vacant lots reported more limitations due to emotional problems at baseline but this did not affect their improvement over time. Women who lived on streets with graffiti, litter, or broken/boarded windows had a slower rate of improvement in role limitations due to emotional problems over time (p<0.05). None of the built environment conditions affected other aspects of QOL. In sum, key aspects of the built environment affected baseline emotional wellbeing and social functioning and improvement in role limitations due to emotional problems. QOL interventions should focus on African-American breast cancer patients who live on streets with graffiti, litter, or broken/boarded windows.

NEGATIVE AFFECT, MESSAGE REACTANCE, AND RISK PERCEPTIONS: HOW DO PICTORIAL CIGARETTE PACK WARNINGS CHANGE QUIT INTENTIONS?

Marissa G. Hall, PhD¹, Paschal Sheeran, PhD¹, Seth Noar, PhD¹, Marcella H. Boynton, PhD¹, Kurt M. Ribisl, PhD¹, Humberto Parada, PhD², Trent Johnson, MPH³, Noel T. Brewer, PhD¹

¹University of North Carolina, Chapel Hill, NC; ²San Diego State University Graduate School of Public Health, San Diego, CA; ³Stanford University School of Medicine, Stanford, CA

Objective. It is currently unclear what psychological mechanisms underlie the robust finding that pictorial warnings on cigarette packs increase motivation to quit smoking. Thus, we sought to examine the potential mediating role of negative affect, message reactance (i.e., an oppositional reaction to a message), and risk perceptions in shaping quit intentions.

Methods. In 2014 and 2015, we randomly assigned 2,149 adult US smokers to receive either pictorial warnings or text-only warnings applied to their cigarette packs for four weeks. Longitudinal analyses used structural equation modeling with bootstrapped standard errors to test our theorized multiple mediation model.

Findings. Pictorial warnings increased negative affect, message reactance, and quit intentions (all $p < .001$), but not perceived likelihood of harms from smoking. Negative affect mediated the impact of pictorial warnings on quit intentions (mediated effect = .16, $p < .001$). Message reactance weakened the impact of pictorial warnings on quit intentions, although the effect was small (mediated effect = -.04, $p < .001$). Although pictorial warnings did not directly influence perceived likelihood, the model showed additional small mediation effects through negative affect and its *positive* association with perceived likelihood (mediated effect = .02, $p < .05$), as well as reactance and its *negative* association with perceived likelihood (mediated effect = -.01, $p < .05$).

Conclusions. Pictorial cigarette pack warnings increased quit intentions by increasing negative affect. Message reactance partially attenuated this increase in intentions. The offsetting associations of negative affect and reactance on risk perceptions may explain why pictorial warnings did not lead to observable changes in risk perceptions.

WHY DO SMOKERS AVOID RISK MESSAGES? RESULTS FROM TWO RANDOMIZED CONTROLLED TRIALS

Marissa G. Hall, PhD, Noel T. Brewer, PhD

University of North Carolina, Chapel Hill, NC

Background. Avoidance of risk messages is associated with them being more effective, but the mechanism is not well understood. We hypothesize that message avoidance may be due to fear (which will motivate behavior change) or reactance (which will undermine behavior change). We investigated these two understudied hypotheses in two randomized trials.

Methods. Trial 1 randomly assigned 2,149 adult US smokers to receive either pictorial warnings (intervention) or text-only warnings (control) on their cigarette packs for four weeks in 2014 and 2015. Trial 2 randomly assigned 719 adult US smokers to receive either messages about chemicals in cigarette smoke and their health harms (intervention) or messages about not littering cigarette butts for three weeks (control) in 2016 and 2017. Multiple mediation analyses used structural equation modeling. We report mediated effects as standardized path coefficients.

Results. Stronger risk messages led to greater message avoidance in both trials (both, $p < .001$). Negative affect, including fear, explained most of the greater message avoidance in Trial 1 (mediated effect = .21, $p < .001$). In contrast, reactance explained only a small part of the effect in Trial 1 (mediated effect = .03, $p < .001$). Similarly, in Trial 2, negative affect explained the effect of stronger risk messages on message avoidance (mediated effect = .13, $p < .001$). Reactance explained none of the effect.

Conclusions. In two large trials, smokers avoided messages due to fear and other negative affect, but reactance had little impact. This pattern of findings may explain prior research demonstrating that message avoidance is associated with stopping smoking.

IMPACT OF CIGARETTE PACK DISCLOSURES ABOUT TOXIC CHEMICALS: A RANDOMIZED CLINICAL TRIAL

Noel T. Brewer, PhD¹, Michelle Jeong, PhD¹, Jennifer R. Mendel, MPH¹, Marissa G. Hall, PhD¹, Dongyu Zhang, ScM, MD¹, Humberto Parada, Jr., PhD², Marcella H. Boynton, PhD¹, Seth M. Noar, PhD¹, Sabeeh A. Baig, MS¹, Jennifer C. Morgan, PhD³, Kurt M. Ribisl, PhD¹

¹University of North Carolina, Chapel Hill, NC; ²San Diego State University, San Diego, CA; ³University of Pennsylvania, Philadelphia, PA

Background: Federal law requires public disclosure of information about harmful and potentially harmful chemicals in cigarette smoke, but the impact of these disclosures is uncertain. We sought to assess the impact of putting disclosures about toxic chemicals on smokers' cigarette packs.

Methods: We enrolled a convenience sample of 719 adult cigarette smokers in California, US from September 2016 through March 2017. We placed informational messages on the right side of smokers' cigarette packs for three weeks, a different label each week. We randomly assigned smokers to receive either messages about chemicals in cigarette smoke and their health harms (intervention arm) or messages about not littering cigarette butts (control arm). The labels in the two arms were matched for size, color and word length. The primary trial outcome was intentions to quit smoking in the next month, assessed at the end of the three-week intervention. These results are preliminary until publication of final paper. ClinicalTrials.gov identifier: NCT02785484.

Results: Of 719 smokers randomized to a trial arm, 704 completed the trial. Smokers in the trial were diverse, including a substantial number of African American, sexual minority, low-education, and low-income smokers. In intent-to-treat analyses ($n=719$), smokers whose packs had chemical disclosures did not have higher intentions to quit smoking at the end of the trial than those whose packs had a control message (mean [SD] intentions 2.6 [1.0] vs. 2.6 [1.1], $p = .56$). Compared to the control messages, disclosures led to greater awareness of the chemicals (28% vs. 15%, $p < .01$) and health harms (60% vs. 52%, $p = .02$) that were in the disclosure messages. The trial arms did not differ with respect to awareness of the chemicals and health harms not in the disclosure messages. Chemical disclosures led to greater negative affect, thinking about the chemicals in cigarettes and the harms of smoking, conversations about the disclosures, and foregoing a cigarette (all $p < .05$).

Conclusions: Chemical disclosures on cigarette packs did not lead to greater intentions to quit smoking. Our trial findings suggest that implementing chemical disclosures on cigarette packs in the United States would inform smokers but may not lead to a population-wide reduction in smoking.

HOW CONVERSATIONS ABOUT PICTORIAL CIGARETTE PACK WARNINGS IMPACT QUIT ATTEMPTS: A MULTIPLE MEDIATIONAL ANALYSIS

Jennifer C. Morgan, PhD¹, Shelley Golden, PhD², Seth M. Noar, PhD³, Kurt M. Ribisl, PhD³, Brian G. Southwell, Ph.D.⁴, Michelle Jeong, PhD³, Marissa G. Hall, PhD³, Noel T. Brewer, PhD³

¹University of Pennsylvania, Philadelphia, PA; ²University of North Carolina at Chapel Hill, Chapel Hill, NC; ³University of North Carolina, Chapel Hill, NC; ⁴RTI International, Durham, NC

Background: In the US, cigarette smoking is responsible for 1 in 5 deaths annually. Pictorial warnings on cigarette packs elicit more quit attempts than text-only warnings. Conversations people have about the warnings may mediate this relationship.

Purpose: We sought to establish whether conversations mediate the relationship between exposure to pictorial warnings and quit attempts, and, importantly, to understand whether and how the theoretical mechanisms of cognitive elaboration, injunctive norms, and recall may be influencing quit attempts.

Methods: US adult smokers ($n=2,149$) participated in a controlled trial that randomly assigned them to have their cigarette packs labeled with pictorial or text-only warnings for four weeks. Surveys assessed the number of conversations sparked by pictorial warnings, theoretical mechanisms, and conversational content at each visit. Analyses used structural equation modeling to test our theorized mediational model.

Results: The number of conversations about the warnings mediated the positive relationship between exposure to pictorial warnings and quit attempts ($p < .001$). In serial mediation analysis examining possible theoretical mechanisms, the number of conversations was associated with greater cognitive elaboration, which in turn was associated with more quit attempts ($p < .05$). Examining the role of conversation content showed that conversations about negative emotional reactions to the warnings mediated the path from warnings to quit attempts ($p < .05$), while conversations about other topics did not.

Conclusions: Conversations about pictorial warnings are one way that pictorial warnings influence quit attempts, and these results indicate that cognitive elaboration is a possible theoretical mechanism that explains why. Furthermore, what people say during their conversations about the warnings matters; conversations about negative emotional reactions to the warnings influence quit attempts while other topics do not. These results support designing warnings that increase conversations about the warnings.

MESSAGE CHARACTERISTICS AND DEMOGRAPHIC PREDICTORS OF CONVERSATIONAL TRAJECTORIES ABOUT PICTORIAL CIGARETTE PACK WARNINGS

Jennifer C. Morgan, PhD¹, Brian G. Southwell, Ph.D.², Shelley Golden, PhD³, Seth M. Noar, PhD⁴, Kurt M. Ribisl, PhD⁴, Noel T. Brewer, PhD⁴

¹University of Pennsylvania, Philadelphia, PA; ²RTI International, Durham, NC; ³University of North Carolina at Chapel Hill, Chapel Hill, NC; ⁴University of North Carolina, Chapel Hill, NC

Background: In the US, cigarette smoking is responsible for 1 in 5 deaths annually. Pictorial warnings on cigarette packs elicit more quit attempts than text-only warnings. Conversations about pictorial warnings are one of the ways warnings exert their influence on quit attempts, but the number of conversations often decrease over time. We sought to identify covariates that predicted the trajectories of conversation frequency over time.

Methods: We analyzed data from the intervention group of 1,071 US adult smokers who we randomly assigned to have their cigarette packs labeled with pictorial warnings for four weeks. They completed surveys about demographic characteristics, conversation frequency, and reactions to the pictorial warnings during the baseline visit and at each of the subsequent four weekly visits. We analyzed the data using latent growth curve modeling.

Results: During the first week of having pictorial warnings on cigarette packs, older smokers had fewer conversations than younger smokers. Conversations during the first week were also more common among smokers who were white, low-income, had greater perceived message effectiveness of the warning, and had stronger negative emotional reactions to the warnings (all $p < .05$). Conversations declined during the second week, but these declines were more gradual for minority and older smokers, leading to more conversations throughout the study.

Conclusions: Conversations about cigarette pack warnings decreased over time. Greater perceived message effectiveness of the warnings and stronger negative emotional reactions to the warnings were associated with more conversations during the first week of smoking from packs with pictorial warnings. We should design pictorial warnings that elicit strong negative emotions and high levels of perceived effectiveness in order to spark conversations.

Paper Session 38: Progress in Culturally Appropriate Care and Interventions to Address Health Disparities 3:30 PM-3:45 PM

THE BENEFITS OF A CULTURALLY SENSITIVE BRIEF EXPRESSIVE WRITING INTERVENTION AMONG CHINESE AMERICAN BREAST CANCER SURVIVORS

Qian Lu, M.D., Ph.D.¹, Matthew W. Gallagher, Ph.D.², Alice Loh, BA³, Lucy Young, MS⁴

¹University of Houston, HOUSTON, TX; ²University of Houston, Houston, TX; ³Herald Cancer Association, San Gabriel, CA; ⁴National Herald Cancer Association Alliance, San Gabriel, CA

Background: Research has demonstrated that expressive writing interventions confer physical health benefits for Caucasian cancer survivors. However, few studies reported improved quality of life (QOL) or recruited ethnic minorities.

Purpose: The study aims to evaluate the impact of an expressive writing intervention on quality of life (QOL) among Chinese American breast cancer survivors.

Methods: One hundred and thirty-six Chinese-speaking breast cancer survivors in the U.S. were randomly assigned to one of three writing conditions: a self-regulation condition (SRC), an enhanced self-regulation condition (ESRC), or a cancer-fact condition (CFC) to write three 30-minute weekly essays. The CFC wrote about facts relevant to their cancer experience. The SRC and ESRC differed in the sequence of writing instructions. The SRC wrote about one's deepest feelings at week 1 and stress and coping at week 2. The ESRC wrote about stress and coping at week 1 and deepest feelings at week 2. Both conditions wrote about finding benefits at week 3. QOL was assessed by Functional Assessment of Cancer Therapy (FACT) at baseline, 1-, 3-, and 6-month follow-ups. Effect sizes and growth curve models were used to compare group differences in QOL.

Results: All three conditions increased QOL and the ESRC had the greatest increase from baseline to the 6-month follow-up ($b = 6.47$, 95% CI 1.56: 11.38; $d = .90$, 95% CI .02: 1.687). The ESRC had a statistically higher increase in QOL compared to the cancer fact control condition.

Conclusion: Expressive writing is shown to be an effective intervention to improve QOL for Chinese American cancer survivors. Future efforts are warranted to disseminate and implement this low-dose and brief intervention in community and clinical settings.

VIDA PURA: RESULTS FROM A PILOT RANDOMIZED TRIAL TO REDUCE UNHEALTHY ALCOHOL USE AMONG LATINO DAY LABORERS

India J. Ornelas, MPH, PhD, Vanessa N. Torres, MPH
University of Washington, Seattle, WA

Background: Vida PURA is a culturally adapted intervention that consists of promotores providing screening and brief intervention at a day labor worker center to reduce unhealthy alcohol use among Latino day laborers.

Methods: We conducted a pilot randomized control trial to test the efficacy of the Vida PURA intervention. Participants were screened for eligibility using the AUDIT (n = 181). Those with an AUDIT score ≥ 6 completed a baseline survey (n = 121) and were randomized into an intervention (n = 71) or control group (n = 30). Participants in the intervention group received a brief intervention from a promotor at a day labor worker center. Personalized feedback was provided by promotores, using a tablet screen to display the participants' quantity of daily and weekly drinking. Promotores also used motivational interviewing to discuss the feedback and participants' goals related to reducing their drinking. We conducted follow-up surveys at eight weeks following the baseline to assess changes in AUDIT scores, daily and weekly drinking.

Results: At baseline, mean AUDIT scores were 19.1 for men in the intervention group (n = 71) and 21.5 for those in the control group (n = 30). Both groups had decreased their AUDIT scores at eight weeks (intervention, 15.6; control, 18.2) with no significant differences between groups. Both groups also decreased their average number of drinks per drinking day from baseline to eight weeks (intervention, 2.9 to 1.8; control, 4.5 to 3.8, $p < .05$). Number of drinking days in the past two weeks also decreased in both groups from baseline to eight weeks (intervention, 5.7 to 4.2; control, 7.1 to 6.5, $p < .05$).

Conclusions: Given that there were no significant differences across groups, results may have been due to an assessment effect (promotores discussing alcohol use during the survey) or changes in the social environment at the worker center that led to changes in drinking behaviors among control group participants. Future research should further evaluate culturally appropriate interventions for reducing unhealthy alcohol use in this population.

BORDER STUDENTS ARE SUN SAFE: SKIN CANCER PREVENTION EDUCATION FOR HISPANIC ADOLESCENTS ATTENDING RURAL, BORDER HIGH SCHOOLS

Lois J. Loesch, PhD, RN¹, Gail Emrick, MPH², Sarah Rawdin, Arizona¹, Alice Pasvogel, PhD¹, David O. Garcia, PhD³

¹The University of Arizona, Tucson, AZ; ²Southeast Arizona Area Health Education Center, Nogales, AZ; ³The University of Arizona / Mel and Enid Zuckerman College of Public Health, Tucson, AZ

Background: Skin cancer, the most common cancer in the US, is caused by overexposure to ultraviolet radiation (UVR). Most people living near the U.S.-Mexico border are Hispanic; skin cancer incidence is rising in Hispanics. Youth are prone to UVR overexposure; few skin cancer prevention programs target rural and underserved youth. Project Students are Sun Safe (SASS) has been implemented successfully in urban middle and high schools. Trained university health sciences students (peer leaders) teach a brief SASS PowerPoint lesson that covers skin structure, skin cancer, UVR and UVR protection. The lesson is reinforced by three interactive activities (sun protective fabric, sunscreen ingredients, skin analyzer). A limitation of the model is that university students cannot travel long distances to rural schools to present SASS. Using a CBPR framework, university and community partners adapted the SASS lesson activities for dissemination to underserved rural high schools.

Purpose: To determine the feasibility of implementing Border SASS in classrooms and evaluate the main outcomes of skin cancer knowledge, beliefs, and risk-reducing behaviors in students.

Methods: The partnership team adapted the SASS classroom lesson, considering age level and cultural appropriateness. The team reduced the lesson delivery time to 40 minutes to allow for assessments during a high school class period. Trained high school peer educators (n = 18) delivered (in groups of 3) the Border SASS lesson to 220 classroom students over 4 months. The 17-item pretest and immediate posttest assessed demographics and risk factors along with main outcomes. Students completed the second posttest four months later.

Results: Evaluable cases were students who completed all 3 tests (n = 198 students; 90% response rate). Main outcomes increased significantly from pretest to posttests 1 and 2. The overall correct score on knowledge items increased from 40.61% (SD, 20.8) to 53.33% (SD, 22.62) ($p < .001$). Number of sun protective behaviors increased from mean = 2.45 (SD, 1.33) behaviors to mean = 3.58 (SD, 1.33) behaviors ($p < .001$). On pretest 124 (62.6%) participants thought it was definitely important to examine their own skin, increasing to 179 (90.4%) on posttest 2 ($p < .001$). Students were highly satisfied with Border SASS.

Conclusions: Border SASS was successfully implemented in underserved Hispanic adolescents by using a CBPR approach. Participants sustained skin cancer risk-reducing behavior for 4 months. Knowledge improved but remained low, suggesting the need for potential boosters and continued dissemination in rural high schools.

A QUALITATIVE EXAMINATION OF ATTITUDES TOWARD RETURN OF GENETIC RESEARCH RESULTS AMONG AFRICAN AND LATINO/HISPANIC AMERICANS

Kwesi O. Adjei, N/A¹, Carlos M. Garcia Gonzalez, BS², Jennifer Ridgeway, MPP³, Elizabeth Pantoja, BS⁴, Monica Albertie, MHA⁵, Carmen Radecki Breitung, PhD⁶

¹Washington University, St. Louis, St. Louis, MO; ²University of Puerto Rico, San Juan, N/A, Puerto Rico; ³Robert D. and Patricia E. Kern Center for the Science of Health Care Delivery, Mayo Clinic, Rochester, MN; ⁴Mayo Clinic Florida, Jacksonville, FL; ⁵Mayo Clinic, Jacksonville, FL; ⁶Mayo Clinic, Rochester, MN

Genomic research generates results with implications for individual participants and their relatives. Studies addressing return of genetic research results to participants have focused on people of European descent, as they comprise a majority of participants in genetic research. Calls for racial and ethnic diversity in genomic research (including the Precision Medicine Initiative/All of Us Research Program) necessitate a greater understanding of knowledge, attitudes, and preferences among minorities. Six focus groups (3 with African American (AA) and 3 with Latino/Hispanic American (L) adults) were held in Spring 2017 in Duval County, FL (N=45; 78% female; M age=50 ± 18y). Groups were conducted in English or Spanish, audio-recorded, transcribed, translated into English, and verified. Transcripts were analyzed using thematic analysis; coding was informed by the Information-Motivation-Behavior model. A majority of AA and L participants favored the idea of receiving genetic research results because information was viewed as beneficial for self-care or disease prevention, yet, this was only the case if results were actionable or conclusive: “If there is no remedy, don’t tell me” (L); “If you don’t have enough information to give me, don’t give me anything” (AA). Participants generally said they would share genetic findings with relatives: “seria egoista no compartirla” -it’d be selfish not to share it (L) and that they would allow sharing with family members after their death: “... that would be a part of me still being alive to my family” (AA); “I would want mine shared...I mean I’m dead and gone...” (AA) However, participants preferred control over those decisions; they acknowledged the benefits of sharing information that would be helpful to blood relatives, but there was also concern that genetic information could create the potential for worry and negatively affect family members who were not prepared to handle the information. Some family members were considered more apt to manage genetic information than others. Common across groups was the desire for a questionnaire to outline participant preferences, including how results would be shared with the participant, with family members after participant death, and who would do so (researcher, physician). By extending its reach to genomic research initiatives, behavioral science can contribute to the evidence base regarding preferences and outcomes of return of genetic research results and influence emerging policy and practice.

ETHNIC DIFFERENCES IN ARIZONA HOSPITAL UTILIZATION TRENDS: POPULATION-LEVEL EVIDENCE FOR A BROADER HISPANIC HEALTH PARADOX

John M. Ruiz, Ph.D.¹, Matthew Butler, Ph.D.², Patrick Wightman, Ph.D., MPP¹, Matthias R. Mehl, Ph.D.¹, Melissa A. Flores, MS³, Heidi A. Hamann, PhD¹, Elizabeth Calhoun, Ph.D., MEd¹

¹University of Arizona, Tucson, AZ; ²Mel and Enid Zuckerman College of Public Health, Tucson, AZ; ³The University of Arizona, Tucson, AZ

Background. Despite a significantly worse risk factor profile, Hispanics experience lower incidence of most diseases and live longer than non-Hispanic Whites (NHWs). This epidemiological phenomenon commonly referred to as the Hispanic mortality paradox is robust, replicated, and characterized by relatively large effects. An important question is whether this ethnic advantage in longevity reflects a broader health advantage. The current aim was to examine whether Hispanics experience a broader health advantage by examining state-level hospital utilization.

Method. Inpatient hospital utilization rates per 1,000 and confidence intervals were generated using the American Community Survey (ACS) public use microdata and the Arizona Department of Health Services (ADHS) Hospital Discharge Data for the period of January 1, 2008 through December 31, 2015. In Arizona, there were over 500,000 inpatient admissions per year in the ADHS HDD. The current data exclude mental health hospitals as well as child and pregnancy admissions. Subgroup population estimates by race/ethnicity, age, and payer status and their corresponding confidence intervals were estimated using replicate weights from the ACS.

Results. Overall, NHW adults consistently exhibited significantly greater hospital utilization than Hispanics in Arizona. Accounting for population size differences, the average annual hospital admission rates for NHWs were 130 per 1,000 NHW vs 60 per 1,000 Hispanics; a two-fold difference. These omnibus differences remained when the data was disaggregated to look within 4 insurance status categories (Medicare, Medicaid, private, and uninsured) and within age. In addition to lower utilization, Hispanics did not appear to enter the hospital in worse condition. For example, the average in-patient mortality rate for NHWs was 17.84 per 1,000 NHW admissions versus 15.42 per 1,000 Hispanic admissions. These admission and outcome trends held in Emergency Department (ED) utilization.

Conclusions. Hispanics are more than 2:1 less likely to use the hospital system and have lower mortality when admitted in the state of Arizona. These differences are evident in both in-patient admissions and ED use and hold within insurance and age categories, supporting a broader Hispanic health advantage. Implications for health surveillance and resilience mechanisms will be discussed.

Paper Session 39: The Role of Depression and Anxiety in Shaping Physical Health 3:30 PM-3:45 PM

BREAKING SILENCE: UTILIZATION OF A DIVERSE SAMPLE TO IDENTIFY WOMEN AT-RISK FOR DEPRESSION AND ANXIETY FOLLOWING PREGNANCY LOSS

Victoria A. Grunberg, M.S., Pamela A. Geller, Ph.D.
Drexel University, Philadelphia, PA

One in four U.S. women will experience pregnancy loss in their lifetimes. Pregnancy loss is associated with adverse mental health outcomes. Yet, specific risk factors remain understudied, especially in minority populations and women with limited access to psychological treatment. To address these issues, the present study examined how socio-demographics and coping strategies are associated with depression and anxiety among women who experienced pregnancy loss ($N = 825$; Age: 18 - 66 years, $M = 31.87$, $SD = 8.69$). To capture a diverse sample of women who have historically been excluded from pregnancy loss research, data was collected via online survey through social media outlets (e.g., Facebook, Craigslist, YouTube). This unique method of accessing the target population permitted enrollment of a large proportion of minority women ($N = 391$; 47.40%).

Hierarchical regression analyses were conducted to determine which variables predicted depression and anxiety. Predictors included: years since recent loss, education, income, mental health history, age, marital status, religiosity, race/ethnicity, and positive and negative religious coping. When controlling for years since recent loss, education, and income, mental health history, race/ethnicity, and negative religious coping significantly predicted depression, $F(10, 600) = 18.09$, $p < .001$, $R^2 = 23.1$. Using the same covariates, race/ethnicity, negative religious coping, and positive religious coping significantly predicted anxiety, $F(10, 497) = 45.58$, $p < .001$, $R^2 = 33.2\%$. Follow-up analyses of covariance were conducted to examine how depression and anxiety varied as a function of race/ethnicity. When controlling for covariates and mental health history, women who identified as White reported higher levels of depression ($M = 52.78$) compared to women who identified as Hispanic/Latina ($M = 44.60$) and Black/African-American ($M = 43.16$), $F(4, 641) = 5.23$, $p < .001$. However, there were no significant differences in anxiety among women of different races/ethnicities, $F(4, 499) = 1.78$, $p < .132$. Women with a history of a mental health disorder, lower income, less education, and higher levels of negative religious coping reported higher levels of depression and anxiety. Women who identified as White reported higher levels of depression, but not anxiety. These findings can help inform clinical assessment and intervention on which women should be targeted for additional screening and psychosocial support.

ASSESSING THE BIDIRECTIONAL RELATION BETWEEN SEDENTARY SCREEN BEHAVIORS AND DEPRESSION AND ANXIETY DISORDERS IN ADOLESCENTS

Jennifer Zink, BA¹, Britni R. Belcher, PhD, MPH², Afton Kechter, M.S.³, Matthew D. Stone, B.A.⁴, Adam Leventhal, PhD⁵

¹University of Southern California, Los Angeles, CA; ²University of Southern California, Los Angeles, CA; ³University of Southern California, Keck School of Medicine, Pasadena, CA; ⁴University of California, San Diego, La Jolla, CA; ⁵Usc, Los Angeles, CA

Introduction: Screen time (ST) is linked depression and anxiety in adolescents. Cross-sectional studies suggest that some forms ST are more detrimental to mental health than others; they also indicate that physical activity (PA) levels and sex may moderate this relation. However, few studies have tested whether this relation is bidirectional using longitudinal data. Thus, the aim of this study is to test whether bidirectional associations between ST and depression and anxiety differ by form of ST; and to test potential moderators.

Method: Using in-class paper and pencil surveys, Los Angeles high school students ($N=2701$, baseline mean age=14.1 years) reported average hours per day of TV viewing, average hours per day of computer/videogame usage, days per week of PA, and completed the Revised Children's Anxiety and Depression Scale to indicate symptoms of Major Depressive Disorder (MDD), Generalized Anxiety Disorder (GAD), Panic Disorder (PD), and Social Phobia (SP) at baseline and 12-month follow-up. ST was dichotomized as <4 hours/day or ≥ 4 hours/day. Logistic regression models assessed the relation between ST and mental health. Models were adjusted for age, sex, race/ethnicity, SES, school, PA, and BMI percentile; PA and sex were tested as moderators.

Results: ST and MDD were not related. High (≥ 4 hours/day) computer/videogames at baseline predicted greater likelihood of subclinical or higher GAD at follow-up (OR 1.49, 95%CI: 1.19, 1.87); this was stronger in those not meeting the PA guidelines of being active 5+ days/week (OR 1.94, 95%CI: 1.37, 2.75) compared to those meeting PA guidelines (OR 1.23, 95%CI: 0.91, 1.65). Baseline GAD predicted computer/videogames at follow-up (OR 1.27, 95%CI: 1.004, 1.61). TV at baseline predicted a greater likelihood of PD at follow-up (OR 1.42, 95%CI: 1.07,1.89). However, TV was protective against future SP (OR 0.68, 95%CI: 0.47,0.98) while computer/videogames was a risk factor for SP (OR 1.49, 95%CI: 1.15–1.92) 12-months later. Computer/videogames predicted SP more strongly in those who did not meet PA guidelines (OR 2.17, 95%CI: 1.46,3.22) compared to those who did (OR 1.11, 95%CI: 0.79, 1.58). Sex was not a moderator.

Conclusions: Bidirectionality was only observed between GAD and computer/videogames. Moreover, TV was less detrimental to adolescent mental health than computer/videogames. PA was a buffer against anxiety symptoms, even among sedentary participants. Interventions targeting computer/videogames and increasing PA may result in positive mental health outcomes in youth.

Paper Session 39: The Role of Depression and Anxiety in Shaping Physical Health 4:00 PM–4:15 PM

THE MEDIATING ROLE OF MULTIRACIAL IDENTITY INTEGRATION ON THE RELATION BETWEEN RACISM AND DEPRESSION AMONG MULTIRACIAL ADULTS

Laura R. Marks, Ph.D.¹, Idia B. Thurston, Doctorate¹, Rebecca Kamody, Masters Degree², Michael Schaeffer-Smith, M.S.³

¹University of Memphis, Memphis, TN; ²The University of Memphis, New Haven, CT; ³The University of Memphis, Memphis, TN

Background: As the multiracial population in the United States increases so does the need to understand how unique identity experiences in this population may influence their mental health outcomes. We examined the mediating role of multiracial identity integration (i.e., an individual's level of racial distance and racial conflict) on the relationship between racism and depression among multiracial young adults.

Method: Participants were 437 multiracial young adults aged 18–25 years. Participants were recruited using Amazon Mechanical Turk and through undergraduate psychology and education research courses. Participants completed measures of racism (*Schedule of Racist Events*; Landrine & Klonoff, 1996), multiracial identity integration (*Multiracial Identity Integration Scale*, Cheng & Lee, 2009), and depression (*Depression, Anxiety, Stress Scales*; Lovibond & Lovibond, 1995). Mediation analyses were conducted using SPSS PROCESS to generate 5000 bootstrap samples with 95% CI.

Results: The overall model was significant, $F(2, 434)=41.71, p R^2=.17$. There was a significant direct effect of racism on depression, $b=.02, SE=.002, F(1, 435)=78.55, p<.001$, and a significant indirect effect of racism on depression through multiracial identity integration, $b=.001, CI [0.002, 0.003]$.

Conclusions: Findings suggest that multiracial young adults who experience more racism also have higher levels of depression. Further, higher levels of racial conflict and racial distancing explain some of this association. Aligning with the conference theme to extend the reach of behavioral medicine, these findings highlight the need for culturally tailored interventions for improving the mental health of multiracial individuals.

THE LONG-TERM EFFECTS OF THE DEEPWATER HORIZON OIL SPILL ON WOMEN'S DEPRESSION AND MENTAL DISTRESS

Ariane Rung, PhD, MPH¹, Evrim Oral, PhD², Elizabeth Fonham, DrPH³, Daniel Harrington, ScD, CIH⁴, Edward Trapido, MSPH, MSc, DSC, FACE⁵, Edward S. Peters, DMD, SM, ScD⁶

¹Louisiana State University Health Sciences Center School of Public Health, New Orleans, LA; ²LSUHSC School of Public Health, Biostatistics Program, New Orleans, LA; ³LSUHSC School of Public Health, New Orleans, LA; ⁴LSUHSC-New Orleans, School of Public Health, New Orleans, LA; ⁵LSU Health Sciences Center, New Orleans, LA; ⁶LSU School of Public Health, New Orleans, LA

Objectives: There is a paucity of longitudinal data on the mental health effects of oil spill disasters, in particular the Deepwater Horizon Oil Spill (DHOS) of April 20, 2010. The objectives of this study are to describe changes in mental health among women following an oil spill and to examine the relationship between oil spill exposure and mental health.

Methods: The Women and Their Children's Health Study followed 2038 women in coastal Louisiana in a prospective cohort of the health effects of the DHOS. Subjects were interviewed by telephone in 2012–2014 and again in 2014–2016. Oil spill exposure was characterized as economic impact from and physical/environmental exposure to the spill. Affirmative responses to survey items were summed to give exposure scores. Time since the oil spill was the number of years between each interview date and the date of the DHOS. Outcomes were depressive symptoms (measured by the 20-item Center for Epidemiological Studies Depression Scale) and mental distress (measured by the Kessler-6 scale). Rate ratios were estimated for the association between oil spill exposure, time since the oil spill, and the mental health outcomes of depressive symptoms and mental distress scores using generalized estimating equations.

Results: After adjustment for relevant demographics, depressive symptoms increased over two time points following the DHOS, while symptoms of mental distress decreased in that same time period. For every year increase in time since the DHOS, the expected rate ratio for depressive symptoms increased by a factor of 1.08 (95% CI 1.06–1.11). In contrast, the expected rate ratio for mental distress decreased by a factor of 0.97 (95% CI 0.95–0.99). In addition, initial associations between economic and physical exposure to the DHOS persisted up to 6 years after the spill, with women who were more highly exposed experiencing higher levels of depressive symptoms (expected rate ratios 1.08 [95% CI 1.04–1.13] for economic exposure and 1.11 [95% CI 1.06–1.14] for physical exposure) and mental distress (expected rate ratios 1.05 [95% CI 1.01–1.08] for economic exposure and 1.11 [95% CI 1.07–1.13] for exposure) at each time point.

Conclusions: Different mental health outcomes exhibit different patterns of recovery following an oil spill disaster, but the strength of their association with oil spill exposure remained the same. A better understanding of these patterns can help direct critical mental health response efforts.

DEPRESSION WITH ONSET IN THE PERIPARTUM AND DNA METHYLATION CORRELATES: AN INTEGRATIVE AND CRITICAL REVIEW

Sarah Braun, M.S.¹, Dana Lapato, B.A.¹, Roy E. Brown, MLIS², Timothy P. York, PhD³, Ananda Amstadter, PhD¹, Patricia Kinser, PhD, WHNP-BC, RN⁴

¹Virginia Commonwealth University, Richmond, VA; ²Tompkins-McCaw Library for the Health Sciences, VCU Libraries, North Chesterfield, VA; ³VCU, Richmond, VA; ⁴Virginia Commonwealth University School of Nursing, Richmond, VA

Background: Major depression with onset in the peripartum (MDP) has been overwhelmingly linked to negative birth, infant, and child health outcomes but the pathophysiology is poorly understood. Theoretical and empirical evidence suggests that biologically mediated mechanisms including differentially methylated DNA (DNAm) are, in part, responsible for the relationship between MDP and negative postnatal outcomes. Technological advances in the measurement of the methylome have facilitated these investigations, yet specific challenges remain including inconsistent results, lack of standards in reporting results and defining phenotype, unsophisticated study designs, and poor reproducibility. These limitations continue to hinder scientific progress.

Purpose: This integrative review compiled existing DNAm studies of MDP restricted to onset during pregnancy in order to evaluate the robustness of current results and make specific recommendations for future studies.

Methods: A comprehensive literature search identified studies reporting DNAm correlates of MDP with prenatal onset. A quality scoring rubric was used to quantify how well studies adhered to best practices for study design and reporting. Two raters independently assigned articles scores based on sample size, covariate reporting, phenotype measurement, and other important study design considerations.

Results: Seventeen studies were identified. Quality scores ranged from 8 to 16 out of 24 ($M = 11.9$; $SD = 2.4$), with higher scores indicating higher quality. Use of cross-sectional study design, reliance on candidate gene selection, and poor covariate reporting were the most significant contributors to lower quality scores.

Conclusion: Experimental design flaws undermine the credibility of individual study findings, and the pervasiveness of poor reporting practices hinders cross-study comparisons. The consequences of poor study design choices and recommendations for planning and executing DNAm studies adhering to best practices are discussed. Given that the current limitations cannot be adequately addressed by a single study, specific directions for improvement are provided for researchers, reviewers, and funding agencies to enhance the science overall.

MINDFULNESS AND PSYCHOLOGICAL ADJUSTMENT IN METASTATIC BREAST CANCER PATIENTS AND THEIR FAMILY CAREGIVERS

Kelly Chinh, M.S.¹, Ekin Secinti, M.S.¹, Shelley A. Johns, PsyD, ABPP², Adam T. Hirsh, PhD³, Catherine Mosher, Ph.D.¹

¹Indiana University-Purdue University Indianapolis, Indianapolis, IN; ²Indiana University School of Medicine, Indianapolis, IN; ³Indiana University - Purdue University Indianapolis, Indianapolis, IN

Greater mindfulness, or non-judgmental attention to the present moment, has been associated with better psychological adjustment in cancer survivors, yet little research has examined this association in patient-caregiver dyads facing advanced-stage cancer. This is notable given that many patients and family members cope together as a social unit; thus, mindfulness may be an important protective process that facilitates better dyadic coping. In the present study of women with metastatic breast cancer (MBC) and their family caregivers, we examined relationships between participants' mindfulness and their own/partner's mental health outcomes. Participants ($n=33$ dyads) were recruited from an academic cancer center. MBC patients and caregivers completed self-report measures of mindfulness (nonjudging, acting with awareness, nonreactivity), depression, anxiety, and global mental health. The majority of patients were Caucasian (89%), with a mean age of 56 years ($SD=11.7$). About half of the caregivers were male (49%) and spouses of the patients (55%), with a mean age of 49 years ($SD=15.9$).

Dyadic data were analyzed with actor-partner interdependence models (APIM) using multi-level modeling. Actor effects were observed for the nonjudging facet of mindfulness: higher levels of nonjudging were associated with lower depressive symptoms and anxiety and better global mental health in patients ($B=-.70$, $p<.01$; $B=-.73$, $p<.01$; $B=.50$, $p<.01$, respectively) and caregivers ($B=-.39$, $p=.03$; $B=-.44$, $p=.01$; $B=.60$, $p<.01$). Similarly, higher levels of acting with awareness were associated with lower depressive symptoms and anxiety in patients ($B=-.42$, $p=.02$; $B=-.41$, $p=.02$) and caregivers ($B=-.39$, $p=.03$; $B=-.34$, $p=.05$). Greater nonreactivity was only related to better global mental health in patients and was unrelated to caregivers' mental health outcomes. In contrast to the aforementioned actor effects, partner effects were mostly nonsignificant, with the exception of a positive association between nonreactivity in patients and global mental health in caregivers ($B=.35$, $p=.05$).

Results suggest that MBC patients and caregivers experience mental health benefits from practicing mindfulness. However, these benefits appear to be primarily intrapersonal, and not interpersonal, in nature. Given the widespread adoption of mindfulness-based interventions in cancer, for patients and caregivers alike, it is important to determine whether and how mindfulness affects dyadic adjustment to cancer.

LEISURE ACTIVITIES AND COGNITIVE PERFORMANCE
AMONG OLDER BREAST CANCER PATIENTS AND NON-CAN-
CER CONTROLS

Brent Small, PhD¹, Heather Jim, FL², Tim Ahles, PhD³, George Luta, PhD⁴, Brenna C. McDonald, PsyD⁵, Kelly N.H. Nudelman, Ph.D.⁵, Danielle Tometich, M.S.⁶, Jeanne Mandelblatt, MD⁴

¹University of South Florida, Tampa, FL; ²Moffitt Cancer Center, Tampa, FL; ³Memorial Sloan Kettering Cancer Center, New York, NY; ⁴Georgetown University, Washington, DC; ⁵Indiana University School of Medicine, Indianapolis, IN; ⁶Indiana University-Purdue University Indianapolis, Indianapolis, IN

Background: Participation in leisure activities has generated considerable interest as a way that older adults can lessen age-related declines in cognitive functioning. However, little is known about whether older breast cancer patients can benefit to the same extent as individuals without cancer or whether genetic polymorphisms known to impact cognition may limit ability to profit from participation in leisure activities.

Methods: Participants were patients with newly diagnosed non-metastatic breast cancer and matched friend or community controls aged ≥ 60 years without prior systemic treatment, dementia, or neurologic disease. Participants completed a battery of neuropsychological tests that were classified into 1) learning and memory (LM) or 2) attention, processing speed and executive functioning (APE) domains. They also reported on participation in 11 common cognitively stimulating lifestyle activities (e.g., reading, playing card games) over the past year. Genotyping was conducted for Apolipoprotein E (*APOE*), Catechol-O-Methyltransferase (*COMT*) and Brain Derived Neurotrophic Factor (*BDNF*) and persons were classified as having a risk allele (vs. no risk allele) for worse cognitive performance (*APOE*-e4, *COMT*-any val allele, *BDNF*-any met allele). Moderated regression analyses were conducted and the effects were independent of race, recruitment site, premorbid IQ and comorbid conditions.

Results: The sample consisted of 725 women who averaged almost 68 years of age (range 60–98) of whom over half were diagnosed with breast cancer ($n = 372$, 51.3%) and 80% were White. Participants reported an average of 6.6 activities. The results indicated that participation in leisure activities was associated with better LM and APE performance ($p < .001$). Among the moderators, cancer patients and controls experienced similar leisure activity related gains to performance. Older age was associated with a greater benefit for participation in leisure activities on both cognitive outcomes and *APOE*-e4 carriers exhibited a greater benefit from participating in leisure activities for LM than non-carriers. No moderator effects were seen for *COMT* or *BDNF*.

Conclusions: Cognitively stimulating leisure activities may be an effective way for older adults to maintain cognitive performance, especially in late life. Future research should examine the extent to which leisure activities can buffer longitudinal declines and treatment-related cognitive declines among cancer patients.

DOSE-RESPONSE EFFECTS OF ACUTE AEROBIC EXERCISE ON
COGNITIVE FUNCTION IN BREAST CANCER SURVIVORS

Elizabeth A. Salerno, PhD¹, Kendrith Rowland, MD², Charles H. Hillman, Ph.D.³, Linda Trinh, PhD⁴, Arthur Kramer, PhD³, Edward McAuley, PhD⁴

¹National Cancer Institute, Columbia, MD; ²Mills Breast cancer institute, Urbana, IL; ³Northeastern University, Boston, MA; ⁴University of Illinois at Urbana-Champaign, Urbana, IL

Physical activity is protective against a host of diseases and has been shown to provide many health benefits to breast cancer survivors. Recently, it has been suggested that physical activity may also improve several domains of cognitive function. The purpose of the present study was to examine the effects of varying durations (e.g., 10, 20 and 30 minutes) of physical activity on executive function domains and processing speed in breast cancer survivors in an effort to determine the optimal length of acute exercise for the greatest improvements in cognitive function. It was hypothesized that the relationship between exercise duration and cognitive function improvements would be curvilinear, such that 20 minutes of exercise would provide the largest improvements in cognition (e.g., higher accuracy, shorter reaction time) compared to 10 and 30 minutes. Breast cancer survivors ($N=48$, $M_{age}=56.02$) completed two sessions in counterbalanced order: moderate-intensity treadmill walking and seated rest. Participants were also randomized to one of three session duration groups: 10 ($n=15$), 20 ($n=16$), or 30 ($n=17$) minutes, reflecting the length of time spent both walking and resting. Immediately before and after each session, women completed a battery of cognitive tasks (e.g., inhibition, cognitive flexibility, processing speed). Within- and between-subjects repeated measures analyses of variance revealed several moderately-sized three-way (e.g., time by activity by duration) interactions. On the task switching paradigm, women performed significantly slower after rest compared with after exercise in both the 10- ($d = -.96$) and 30-minute ($d = -.52$) duration groups. On the flanker task, women were significantly less accurate after the rest condition compared with after exercise in the 20-minute duration group ($d = .75$). On the processing speed task, women performed significantly faster after exercise compared with after rest in the 20-minute duration group ($d = -.24$). These findings suggest that acute bouts of exercise, specifically walking, may be employed for maintenance, and possibly improvement, of domains of cognitive function after cancer. While cancer related cognitive impairment still remains largely misunderstood, results from the present study offer preliminary evidence for the positive relationship between exercise and cognition.

THE MEDIATING EFFECT OF CANCER-RELATED FATIGUE
 STEMMING FROM YOGA ON WALKING, GENERAL PHYSICAL
 ACTIVITY, AND QUALITY OF LIFE

Po-Ju Lin, PhD, MPH, RD¹, Eva Culakova, PhD, MS², Luke Peppone, PhD, MPH², Michelle Janelins, PhD, MPH², Kah Poh Loh, MBBCh³, Ian Kleckner, PhD², Chunkit Fung, MD³, Charles Heckler, PhD², James Atkins, MD⁴, Michael Messino, MD⁴, Marianne Melnik, MD⁵, Karen Mustian, PHD, MPH²

Background: Cancer-related fatigue (CRF) negatively affects patients' physical function (e.g. general physical activity (GPA), walking) and quality of life (QOL). We have previously shown that yoga lowers CRF in cancer survivors. However, whether yoga improves physical function and QOL in cancer survivors is not clear. In addition, whether the improvements in CRF mediate the effect of yoga on physical function and QOL is unknown. This study assessed: (1) the effect of yoga on CRF, walking ability, GPA, and QOL and (2) the mediating effects of improved CRF on changes in walking ability, GPA, and QOL.

Methods: We conducted a secondary analysis on data collected from a phase III randomized controlled clinical trial with 2 arms (standard care and standard care + 4-week of Yoga for Cancer Survivors (YOCASSM)). Total 328 cancer survivors (96% female; mean age 54.6 years; 77% had breast cancer) completed a Symptom Inventory (for assessing walking ability, GPA, and QOL, each on scale 0–10) and the Multidimensional Fatigue Scale Inventory (MFSI) for evaluating CRF pre- and post-intervention. Analysis of covariance was used to assess the effect of yoga vs. standard care on CRF, walking, GPA, and QOL. Causal mediation analyses were conducted to estimate the mediating effects of changes in MFSI total scores on the relationship between yoga and walking, GPA, and QOL.

Results: Yoga significantly improved CRF ($p < 0.01$), walking ability ($p < 0.01$), GPA ($p < 0.01$), and QOL ($p < 0.01$), compared to standard care. CRF significantly mediated the changes in walking ability by 0.45 points ($p < 0.01$) in addition to the direct effect of yoga on walking by 0.57 points, suggesting that 44% of the improvement in walking was mediated through reducing CRF. CRF also significantly mediated the changes in GPA by 0.54 points ($p < 0.01$) in addition to the direct effect of yoga on GPA by 0.47 points, suggesting that 53% of the improvement in GPA was mediated through reducing CRF. Similar mediating effect was also found between CRF and QOL where CRF significantly mediated the changes in QOL by 0.43 points ($p < 0.01$) in addition to the direct effect of yoga on QOL by 0.52 points, suggesting that 45% of the improvement in QOL was mediated through reducing CRF.

Conclusions: Yoga improved walking ability, engaging in general physical activity, and overall quality of life in cancer survivors. These effects can be partially explained (mediated) by reductions in cancer-related fatigue. Funding: NCI UGCA189961, R25 CA102618.

GREATER MINDFULNESS ASSOCIATED WITH LOWER PAIN, FA-
 TIGUE AND PSYCHOLOGICAL DISTRESS IN WOMEN WITH META-
 STATIC BREAST CANCER

James W. Carson, PhD¹, Maren K. Olsen, PhD², Linda L. Sanders, MPH³, Francis Keefe, PhD³, Lauren Zimmaro, Ph.D. Candidate³, Blair Puleo, BA³, Laura Porter, PhD³

¹Oregon Health & Science University, Portland, OR; ²Durham VA Medical Center, Durham, NC; ³Duke University Medical Center, Durham, NC

Women with metastatic breast cancer have average life expectancies of about two years, and report high levels of disease-related symptoms including pain, fatigue, psychological distress, and sleep disturbance. Mindfulness is associated with lower levels of these symptoms in early stage breast cancer patients and in other illness populations, but published studies have yet to examine these associations in patients with advanced cancer. Here we report on analyses of baseline associations between mindfulness scales (Five Facet Mindfulness Questionnaire-Short Form) and pain (Brief Pain Inventory), fatigue (Brief Fatigue Inventory), depression and anxiety (Hospital Anxiety and Depression Scale), and sleep disturbance (Pittsburgh Sleep Quality Index) in a sample of 65 women with metastatic breast cancer who participated in a randomized controlled trial of a Mindful Yoga intervention. The mean age of the sample was 57.3 years, 23.4% were African American and 74% Caucasian, 64.1% were married or living with a partner, and their mean years of education was 17.0. The internal consistency coefficients for all measures were adequate. Pearson correlation analyses demonstrated significant associations in the expected direction between all five mindfulness scales and several symptom measures, with the mindfulness non-reactivity and mindfulness non-judging scales showing the most consistent set of associations. Higher scores on the mindfulness non-reactivity scale were associated with lower pain severity ($-0.25, p = .050$), pain interference ($-0.42, p = .001$), fatigue ($-0.32, p = .010$), anxiety ($-0.51, p < .001$), depression ($-0.52, p < .001$), and sleep disturbance ($-0.31, p = .020$). Higher scores on the mindfulness non-judging scale were associated with lower pain severity ($-0.28, p = .028$), pain interference ($-0.32, p = .011$), fatigue ($-0.25, p = .049$), anxiety ($-0.54, p < .001$), and depression ($-0.31, p = .015$). In addition, in this population correlations between mindfulness and depression and anxiety scores were notably stronger than in the population used to develop the Five Facet Mindfulness Questionnaire-Short Form. These findings will be discussed relative to their implications for interventions aimed at increasing mindfulness.

Paper Session 41: Reducing Skin Cancer Risk through Individual- and Policy- Level Approaches 3:30 PM-3:45 PM

THE ASSOCIATION BETWEEN STATE INDOOR TANNING LAWS AND THE PREVALENCE OF INDOOR TANNING AMONG US HIGH SCHOOL STUDENTS

Jin Qin, ScD¹, Dawn Holman, MPH¹, Sherry Jones, PhD, JD, MPH¹, Zahava Berkowitz, MS¹, Gery P. Guy, Jr., PhD, MPH²

¹CDC, Atlanta, GA; ²Centers for Disease Control and Prevention, Atlanta, GA

Objective: Indoor tanning is an artificial and avoidable source of exposure to intense levels of ultraviolet radiation that increases the risk of both melanoma and non-melanoma skin cancers. In recent years, many states have passed new indoor tanning laws or strengthened preexisting laws to protect youth from the harms of indoor tanning. However, evidence to support the effectiveness of youth tanning laws is limited. The purpose of this study is to examine the association between state indoor tanning laws and indoor tanning behavior using nationally representative samples of US high school students aged <18 years.

Methods: Data from the 2009, 2011, 2013, and 2015 national Youth Risk Behavior Surveys were combined (n=41,313) to analyze the association between two types of state indoor tanning laws (age restrictions and parental permission laws) and the prevalence of indoor tanning during the past 12 months. Age restrictions are laws that prohibit minors younger than a certain age from using an indoor tanning device. Parental permission laws are laws that prohibit minors younger than a certain age from using an indoor tanning device without parental consent or accompaniment. We compared prevalence of indoor tanning among high school students affected by either of two types of state indoor tanning laws with students not affected by laws. We estimated adjusted prevalence ratios (aPR) of indoor tanning behavior with 95% confidence intervals (CI) using multivariable logistic regression models stratified by sex and adjusted for student age, race/ethnicity, and survey year.

Results: From 2009 to 2015, prevalence of indoor tanning decreased from 24.1% to 9.5% (P<0.001) among female high school students, and from 5.7% to 3.3% (P<0.001) among male students. Age restriction laws were associated with a 47% (aPR=0.53; 95% CI 0.40–0.71, P<0.001) lower indoor tanning prevalence among female high school students. We did not find a statistically significant association between parental permission laws and indoor tanning prevalence among either female or male high school students (Female: aPR=0.94; 95% CI 0.80–1.11, P=0.49; Male: aPR=0.95; 95% CI 0.75–1.21, P=0.70).

Conclusions: Age restriction laws were associated with reductions in indoor tanning prevalence from 2009 to 2015 among female high school students. Such reductions may reduce the health and economic burden of skin cancer.

UNDERSTANDING THE PRO-TANNING COMMUNICATION ENVIRONMENT: CONTENT ANALYSIS AS A CRITICAL STEP TOWARDS MESSAGE DEVELOPMENT

Dannielle Kelley, PhD, MPH¹, Seth M. Noar, PhD², Andrew Seidenberg, MPH³

¹National Cancer Institute, ROCKVILLE, MD; ²University of North Carolina, Chapel Hill, NC; ³UNC Chapel Hill, Chapel Hill, NC

Background. Tanning bed use increases the risk of several types of skin cancers, including melanoma. To respond to the Surgeon General's call to develop, disseminate, and evaluate messages to reduce indoor tanning (IT) in the 2014 Call to Action to Prevent Skin Cancer, an understanding of the IT communication environment is necessary. Our study sought to identify the types and prevalence of claims in the pro-tanning communication environment around IT to inform the development of skin cancer prevention messages.

Methods. To enable an analysis of pro-IT content an average Google user may encounter, pro-tanning sites (N=78) were identified by entering a series of general search terms (e.g. "indoor tanning benefits") in Google search. Using systematic quantitative content analysis, site characteristics (e.g. site domain, site type - blog vs. industry site) were coded, as well as claims regarding safety, health, appearance/social and mood/relaxation benefits of IT. All text appearing on the sites was reviewed and coded.

Results. Tanning salons made up 56% of pro-tanning sites, followed by blogs (28%) and industry trade sites (13%). Two prominent types of claims emerged: IT safety (90% of sites) and health benefits of IT (86% of sites). Industry trade sites featured the highest number of safety claims (M=3.2, SD=.92), followed by tanning salons (M=3.0, SD=1.97), and blogs (M=2.5, SD=1.61). Within safety, the most common claims were: 1) IT is safe because it is controlled in terms of time and/or UV dose (81%), and 2) government regulation of IT ensures its safety (56%). Blogs featured the highest average number of health claims (M=3.2, SD=2.16), followed by tanning salons (M=3.0, SD=2.98), and industry sites (M=2.9, SD=2.18). Within health, the most common claims were: 1) IT as a good source of vitamin D (69%), and 2) getting a base tan from IT provides protection from the sun (41%). Only 36% of sites mentioned any appearance or social claim and only 21% featured a mood/relaxation claim.

Conclusions. Pro-tanning sites frequently include IT safety and health claims. The majority of claims are misleading, prompting concern from a public health perspective, as tanners may use these claims to justify their tanning behavior. By dissecting and refuting these claims, prevention efforts may be more effective in creating a disruptive association between IT and many advertised "benefits" of engaging in this dangerous behavior.

COUNTERING INDOOR TANNING ARGUMENTS: AN EXPERIMENT USING SKIN CANCER PREVENTION MESSAGES

Dannielle Kelley, PhD, MPH¹, Seth M. Noar, PhD², Bobi Ivanov, PhD³, Francesca R. Dillman Carpentier, PhD⁴, Brian G. Southwell, Ph.D.⁵, Maria Comello, PhD⁴

¹National Cancer Institute, ROCKVILLE, MD; ²University of North Carolina, Chapel Hill, NC; ³University of Kentucky, Lexington, KY; ⁴UNC Chapel Hill, Chapel Hill, NC; ⁵RTI International, Durham, NC

Background. In contrast with declining incidence rates for many cancers, the incidence of skin cancer has been steadily increasing, particularly among young Caucasian women, primarily due to preventable causes such as indoor tanning (IT). A wide array of misinformation about IT has proliferated through media channels for over a decade, embedded with kernels of truth about IT (e.g. a “base” tan may provide an SPF of 4 or less, providing little if any protection against sunburn). Inoculation theory offers a two-sided refutational messaging strategy to acknowledge the kernels of truth, deconstruct and refute the misinformation, and provide a recommended response. To understand the utility of inoculation theory in the context of IT, we conducted an experiment with two-sided refutational, one-sided, and control messages about IT prevention.

Methods. Sorority members ($N = 649$) were recruited into an experiment delivered through an online survey instrument. The sample was all women, age 18–22 ($M=20$, $SD=1.26$), and mostly white (96%; 6% were Hispanic). Participants were randomly assigned to either the two-sided ($n=263$), one-sided ($n=259$), or control ($n=127$) conditions. Outcomes measured were perceived message effectiveness (PME), counterarguing, cognitive processing, IT intentions, and outcome expectations (OEs).

Results. Compared to one-sided and control, participants in the two-sided condition: rated messages 1) higher in increasing their confidence to avoid IT ($p<0.001$) and 2) more convinced that misinformation about IT benefits is untrue ($p<0.01$); 3) were less likely to counter-argue the IT prevention message ($p<0.001$); 4) had a greater net of negative thoughts about IT ($p<0.01$); and 5) reported lower intentions to engage in IT in the next year ($p<0.05$). Compared to control, participants in the two-sided condition reported fewer positive and more negative OEs (both $p<0.05$). No differences in OEs were found between the one-sided condition and the two-sided and control conditions.

Conclusions. Two-sided inoculation messages may be a valuable tool for reducing unhealthy behaviors such as indoor tanning for which an abundance of misinformation exists. Although one-sided messages performed similarly to two-sided messages for some outcomes, two-sided messages were most effective overall, especially on the key outcome of intentions. Message designers should consider developing and disseminating indoor tanning prevention messages based on inoculation theory.

MODERATORS OF IMPLEMENTATION OF OCCUPATIONAL SUN PROTECTION POLICY BY PUBLIC-SECTOR EMPLOYERS IN A RANDOMIZED TRIAL

David B. Buller, PhD¹, Barbara Walkosz, PhD¹, Mary K. Buller, MA¹, Allan Wallis, PhD², Richard T. Meenan, PhD³, Xia Liu, MS¹

¹Klein Buendel, Inc., Golden, CO; ²University of Colorado Denver, Denver, CO; ³Kaiser Permanente - Center for Health Research, Portland, OR

Outdoor workers are at high risk for skin cancer. Organizational and employee characteristics were examined as moderators of implementation of occupational sun protection policy. Public employers ($n=98$) in Colorado participated in a randomized-controlled trial evaluating the *Sun Safe Workplaces (SSW)* intervention. Based on Diffusion of Innovations Theory, project staff promoted sun safety policy adoption and trained workers in sun protection. Line supervisors ($n=3,650$) and workers ($n=1,555$) completed a 2-year follow-up survey at 68 employers (69% followed-up). More line supervisors reported that intervention employers provided free/reduced price sunscreen ($p=0.003$) and communicated about sun safety ($p<0.001$) with workers than control employers. Greater communication also occurred by employers with a policy than without one ($p=0.005$). More workers recalled receiving written sun safety messages at intervention employers ($p<0.001$) and sun safety training ($p=0.009$). Moderator analyses showed that at larger intervention employers, wide-brimmed hats (100 employees: $M=0.472$; 600 employees: $M=0.906$; $p=0.009$), long work or uniform pants ($M=0.288$, $M=0.868$; $p=0.025$), and temporary or permanent outdoor shade structures ($M=0.135$, $M=0.432$; $p=0.028$) were provided more often than at smaller intervention employers. Larger employers with policies also provided more shade than smaller employers (100 employees: $M=0.078$, 600 employees: $M=0.268$; $p=0.033$). At intervention employers, more older workers reported receiving written messages (20 years old: $M=0.649$, 60 years old: $M=0.751$, $p=0.016$) and more longer-tenured workers reported being trained (1 year: $M=0.409$; 25 years: 0.715, 0.002) than younger and newer workers. Size and job tenure did not seem to alter control employers' actions, but fewer older workers reported receiving training at control workplaces (20 years old: $M=0.531$, 60 years old: $M=0.415$) than younger workers. Larger organizations may have the human capital and slack resources to provide sun protection equipment, while smaller organizations with fewer resources may consider policy adoption without implementation sufficient or rely on employees to provide their own precautions. Employers with older workers may feel they are more at risk for skin cancer or feel older workers may see more value in occupational sun safety than those with young workers. Smaller organizations with younger workers may need assistance to take action to implement sun safety policies.

A BRIEF FACIAL MORPHING INTERVENTION TO REDUCE SKIN CANCER RISK BEHAVIORS: RESULTS FROM A RANDOMIZED CONTROLLED TRIAL

Aaron J. Blashill, Ph.D.¹, Benjamin Rooney, B.A.¹, Christina M. Luberto, PhD², Manuel Gonzales, IV, N/A³, Sarah Grogan, PhD⁴

¹San Diego State University, San Diego, CA; ²Harvard Medical School/Massachusetts General Hospital, Jamaica Plain, MA; ³San Diego State University, Palmdale, CA; ⁴Manchester Metropolitan University, Manchester, England, United Kingdom

Objective: Excessive UV exposure is the strongest environmental risk factor for developing skin cancer and is often driven by appearance concerns. Thus, interventions that aim to reduce skin cancer risk via reductions in UV exposure may benefit from overtly addressing appearance-based motives. The current study tested the efficacy of a brief appearance-based facial morphing program to reduce intentional UV exposure among individuals at elevated risk for skin cancer.

Method: A three-arm randomized controlled trial was employed (N = 217) comparing facial morphing + health information to: 1.) mindfulness + health information; and 2.) health information only. Participants were young adults (81% women; *M* age = 19.72, *SD* = 2.50 years) with a history of recent intentional tanning and future intentions to continue to tan. Primary outcomes were indoor and outdoor tanning frequency, with secondary outcomes of tanning intentions, tanning attitudes, body image, and affect.

Results: Participants assigned to the facial morphing condition generally reported less frequent indoor and outdoor tanning, lower intentions to tan in the future, and more negative attitudes toward tanning compared to other participants, displaying small to small-to-medium sized effects. Additionally, facial morphing participants were not at increased risk for developing negative body image, or negative affect.

Conclusions: Facial morphing programs may offer a brief, efficacious, and scalable augmentation to standard of care in reducing intentional UV exposure.

EXECUTIVE FUNCTIONS AND DAILY SELF-REGULATION TO SUPPORT ADHERENCE ACROSS THE TRANSITION INTO EMERGING ADULTHOOD

Deborah Wiebe, PhD, MPH¹, Maria D. Ramirez Loyola, B.A.¹, Daniel Mello, Doctoral Candidate², Ascher K. Munion, NA³, Jonathan Butner, Ph.D.³, Jessica A. Marino, B.A.¹, Cynthia A. Berg, Ph.D.³

¹University of California, Merced, Merced, CA; ²University of California - Merced, Merced, CA; ³University of Utah, Salt Lake City, UT

Type 1 diabetes (T1D) requires complex daily self-regulation such as developing plans for managing diabetes in daily life, preventing daily diabetes problems, and regulating emotions and self-efficacy when diabetes problems occur. These processes draw on neurocognitive skills (e.g., executive function; EF) which may be challenged during the year after high school, a high risk time when youth experience life transitions while managing diabetes more independently. The present study examined whether problems with EF are associated with less effective daily self-regulation and adherence, and whether associations are stronger as youth transition out of high school. Seniors in high school with T1D for at least one year (N = 241; 61.4% female; *M* age = 17.8 years) completed the BRIEF (i.e., self-report measure of problems in EF) and two 14-day daily diaries, one in the senior year of high school and one the following year. At the end of each day, participants completed an on-line survey reporting on whether they had planned for checking blood glucose, the occurrence of diabetes problems, negative affect, self-efficacy, and adherence over the past 24 hours. Multilevel models with repeated measures examined within-person daily associations between diabetes problems and self-regulatory processes (i.e., affect, self-efficacy, adherence), whether between-person differences in EF moderated these associations, and whether associations differed across year. At each time point, individuals with more problems in EF displayed lower daily planning, more frequent daily diabetes problems, and lower daily adherence on average across days (*p*'s < .01). Participants reported fewer diabetes problems on days they planned more (*b* = -.10), as well as higher negative affect (*b* = .10), lower self-efficacy (*b* = -.21), and poorer adherence (*b* = -.08) on days when more diabetes problems occurred (*p*'s < .001). Although the daily association between diabetes problems and negative affect was stronger for those with more EF problems (*b* = .002), EF did not moderate other daily associations. The strength of daily associations also did not differ across years, suggesting late adolescents and emerging adults are equally vulnerable to daily self-regulation challenges. Findings reveal the daily self-regulation processes necessary to support adherence at a high risk time of development. Teaching youth with poorer EF to plan daily for T1D management so as to prevent diabetes problems may be helpful.

BEHAVIOR CHANGE TECHNIQUES IN TRIALS TARGETING WEIGHT MANAGEMENT IN YOUNG ADULTS: RESULTS FROM THE EARLY TRIALS

Steven Belle, PhD, MScHyg¹, Molly A. Diamond, MPH², Kristen Polzien, Ph.D.³, John M. Jakicic, PhD¹, Karen C. Johnson, MD, MPH⁴, Kelsey Leonard, MS¹, Pao-Hwa Lin, PhD⁵, Catherine M. Loria, PhD⁶, Leslie A. Lytle, PhD², Gina Merchant, PhD⁷, Christine M. Olson, PhD⁸, William Riley, PhD⁹, Sara Czaja, PhD¹⁰, Richard Schulz, PhD¹, Deborah F. Tate, Ph.D.²

¹University of Pittsburgh, Pittsburgh, PA; ²University of North Carolina at Chapel Hill, Chapel Hill, NC; ³University of North Carolina, Chapel Hill, NC; ⁴University of Tennessee Health Science Center, Memphis, TN; ⁵Duke Univ Medical Center, Durham, NC; ⁶NIH/National Heart, Lung, and Blood Institute, Bethesda, MD; ⁷UC San Diego, La Jolla, CA; ⁸Cornell University, Ithaca, NY; ⁹NIH Office of Behavioral and Social Sciences Research, Bethesda, MD; ¹⁰University of Miami Miller School of Medicine, Miami, FL

Background: Standardization, rigor, and precision are important to enable study replicability and reproducibility. A taxonomy of behavior change techniques (BCTs) was developed to standardize labels and definitions used in complex behavioral interventions (Michie, 2013). This taxonomy was applied to the 7 studies within the Early Adult Reduction weight through LifeStYle intervention (EARLY) Trials. Use, and degree of emphasis, of the BCTs in the 7 control arms and 10 active treatment comparison arms is described.

Methods: The EARLY studies were randomized clinical trials targeting weight management in 18–35 year old participants, and featured interactive technology and media as important components of the interventions. The BCT taxonomy employed defines 93 BCTs clustered into 16 domains, each including between 3 and 11 BCTs. Multiple raters trained in the BCT definitions determined which BCTs were used by each arm, separately for the first and second years of intervention. The ratings were reviewed with study personnel to reach consensus agreement. The Analytical Hierarchy Process (AHP) was applied to determine the relative emphasis of each domain, and each BCT within domain, for each of the 17 arms.

Results: As expected, the 10 active comparison arms used more BCTs than the 7 control arms. The number of BCTs ranged from 15–45 (median: 26) across active arms and from 2–39 (median:7.5) in the control arms in year 1 and from 17–45 (active arms, median: 29) and 0–39 (control arms, median: 5) in year 2. In one of the studies with a relatively intense control condition there was only 1 more BCT used in the active than in the control arm, but in the other studies the differences in the number of BCTs (active minus control) ranged from 6–22 in year 1 and 6–27 in year 2.

All domains were represented in at least one arm, but 35 of the 93 BCTs were not. Two BCTs, instruction on how to perform a behavior (Shaping Knowledge domain) and credible source (Comparison of Outcomes domain) were used by all 17 arms in year 1 and 16/17 in year 2 with the former emphasized more than the latter.

Though not used in all of the intervention arms in year 1, goal setting, self-monitoring of behavior, and social support tended to be strongly emphasized when used. In year 2, several of the BCTs were emphasized more strongly across the arms that used them than in year 1, among them social support, information about health consequences, credible sources and prompts and cues.

Conclusion: The BCT taxonomy provides a useful framework to describe behavioral interventions and helps to demonstrate the complexity and richness of weight-targeting interventions in young adults. An important strength of this technique is that it will enable us to examine, across studies, the relationship between BCTs used and study outcomes.

ADHERENCE AND AFFECTIVE REACTIVITY TO DAILY DIABETES STRESS AMONG LATE ADOLESCENTS AND EMERGING ADULTS WITH TYPE 1 DIABETES

Maria D. Ramirez Loyola, B.A.¹, Deborah Wiebe, PhD, MPH¹, Cynthia Berg, Ph.D.²

¹University of California, Merced, Merced, CA; ²University of Utah, Salt Lake City, UT

Effective type 1 diabetes (T1D) management requires that individuals regulate their emotions when experiencing the ongoing stress and hassle of managing a serious illness. This may be especially important during late adolescence and early emerging adulthood, when individuals experience heightened negative emotions and deteriorating adherence while managing diabetes in new work and school settings that are increasingly separate from parents. Higher daily stress may disrupt self-care behaviors and impair metabolic control (e.g., checking blood glucose less on stressful days) and may generate affective reactions such as higher negative affect (NA) and lower positive affect (PA). Such affective reactions to daily stress may be tempered by an individual's level of adherence. In other illness populations, poorer treatment adherence has been linked with higher affective reactivity to daily stress. The present study employed daily diary and survey methods to examine whether individuals who exhibited lower levels of affective reactivity to daily diabetes stress displayed better T1D management. Late adolescents with T1D who had been diagnosed for more than one year completed measures during their senior year of high school (Time 1) and again one year later (Time 2) (N=241; 61.4% female; Mage=17.8). At each time point, participants completed a survey measure of adherence and a 14-day end-of-day daily diary, assessing NA, PA, and the total number of daily diabetes stressors experience in the last 24 hours. Hierarchical linear modeling revealed that on days when participants reported more diabetes stressors, they experienced higher NA and lower PA at both time points. Furthermore, participants who reported better adherence on the survey displayed lower NA reactivity ($\beta = -0.431$, p -value < 0.001) and lower PA reactivity ($\beta = 0.272$, p -value = 0.044) to daily diabetes stress at Time 2, but not at Time 1. In other words, early emerging adults with better adherence displayed smaller increases in NA and smaller decreases in PA as they moved from a low stress to a high stress day compared to those with poorer adherence. Importantly, adherence was not related to affective reactivity to daily diabetes stress at Time 1 when participants were seniors in high school. These findings suggest that regulating both PA and NA when dealing with the daily hassles of diabetes management may be an important component of managing T1D as late adolescents transition into emerging adulthood.

Paper Session 42: Advancing the Health of Adolescents and Young Adults 4:15 PM–4:30 PM

IS GUARDIAN PERMISSION A BARRIER TO SEXUAL HEALTH RESEARCH AMONG ADOLESCENT MALES INTERESTED IN SEX WITH MALES (AMSM)?

Kimberly Nelson, PhD, MPH¹, Michael Carey, PhD¹, Celia Fisher, PhD²¹Brown University, Providence, RI; ²Fordham University, Bronx, NY

BACKGROUND: Research is needed to address the disproportionate number of HIV infections among adolescent males interested in sex with males (AMSM). This study examined the extent to which AMSM perceive guardian permission to be a barrier to sexual health research participation.

METHODS: AMSM ($N = 206$; ages 14–17; 47% out to a guardian; 48% racial/ethnic minority; 66% gay-identified) completed an online survey on sexual attitudes/behaviors and pornography use. A waiver of guardian permission was obtained. We assessed whether requiring guardian permission would be a barrier to participating in the *current* survey or *future* sexual health intervention research. Differences by outness to a guardian were determined using logistic regression models adjusted for age, race/ethnicity, and sexual orientation.

RESULTS: Most AMSM would not participate if guardian permission was required (current: 83%; future: 87%). Youth who were not out to a guardian were less likely to participate if guardian permission was required (current: AOR=0.3, 95%CI: 0.1–0.8; future: AOR=0.2, 95%CI: 0.1–0.6). Most felt guardian permission should not be required (current: 94%; future: 98%). Those who were not out were less likely to agree that guardian permission provided opportunities for parents to explain research risks and benefits for the current survey (AOR=0.5, 95%CI: 0.3–0.9). Most agreed guardian permission might lead to questions about their sexual behaviors (current: 92%; future: 91%) and pornography use (current: 89%; future: 90%) or to being outed (current: 80%; future: 78%). Compared to participants who were out, those who were not out were more likely to feel that they would be punished (current: AOR=2.3, 95%CI: 1.3–4.2; future: AOR=3.3, 95%CI: 1.8–6.0), outed (current: AOR=8.7, 95%CI: 3.3–22.9; future: AOR=14.5, 95%CI: 4.8–43.9), kicked out of the house (current: AOR=3.3, 95%CI: 1.6–6.7; future: AOR=2.6, 95%CI: 1.3–5.3), or forced to speak with a counselor/religious person (current: AOR=2.1, 95%CI: 1.2–3.8; future: AOR=1.9, 95%CI: 1.1–3.4) if guardian permission was required.

CONCLUSIONS: AMSM, especially those not out to family, perceive guardian permission as a significant barrier to participation in sexual health research. This information can be used to help investigators and institutional review boards (IRBs) make informed decisions about waiver of guardian permission for HIV research involving AMSM to ensure they have opportunities to participate in research critical to their health.

A PILOT RANDOMIZED CONTROLLED TRIAL OF A GRATITUDE INTERVENTION FOR ADOLESCENTS WITH TYPE 1 DIABETES

Anna Serlachius, PhD, Kiralee Schache, BA

The University of Auckland, Auckland, Auckland, New Zealand

Background: Adolescents with type 1 diabetes are at an increased risk for psychiatric disorders, which are associated with deteriorating glycaemic control. We wanted to examine whether a gratitude intervention based on writing in a gratitude journal on a daily basis for eight weeks would improve their psychological and physical health compared to standard care. Gratitude interventions have previously demonstrated improvements in psychological outcomes including depression, but have never been trialled in a pediatric population with a chronic illness.

Methods: 80 adolescents (aged 10–16 years) with type 1 diabetes were recruited and randomized into the control group (standard care) or the intervention group (gratitude journal). The primary outcome measure was stress and secondary outcomes measures included depression, quality of life, gratitude, self-care behaviours, glycaemic control and parental stress. Sixty participants completed the baseline and follow-up assessments and were included in the analyses. Independent t-tests were used to examine differences between groups at the eight week follow-up, and linear regression was used to examine what factors in the intervention group predicted psychological outcomes and glycaemic control at follow-up.

Results: We found little evidence of any group differences at follow-up in any of the outcome measures ($p > .05$). However, when examining sex differences, we found evidence that the gratitude intervention had improved quality of life, depression, and gratitude for boys in the intervention group compared to boys in the control group (all p -values $< .05$). The linear regression analysis (including both boys and girls) found that gratitude at follow-up was a significant predictor of glycaemic control at follow-up in the intervention group ($\beta = -.389$, $p = .041$), contributing to 15% of the variance in glycaemic control.

Conclusion: This is the first study to examine the efficacy of a gratitude intervention for a pediatric population with a chronic illness, with results demonstrating that the intervention may be effective in improving psychological health for boys but not girls. A gratitude intervention is a cost-effective, safe and clinically usable intervention for patient populations. The present study should be replicated in a larger sample to confirm the sex-specific differences.

Paper Session 43: Reducing Risk of Substance Use Behaviors 3:30 PM-3:45 PM

INTEGRATED BIOBEHAVIORAL APPROACH TO IMPROVE ADHERENCE TO PRE-EXPOSURE PROPHYLAXIS AND REDUCE HIV RISK IN PEOPLE WHO USE DRUGS

ROMAN SHRESTHA, PhD¹, Michael Copenhaver, PhD², Pramila Karki, BS¹

¹University of Connecticut, Branford, CT; ²University of Connecticut, Storrs, CT

To date, HIV prevention efforts have largely relied on singular strategies (e.g., behavioral or biomedical approaches alone) with modest HIV risk reduction outcomes for people who use drugs (PWUD). The bio-behavioral community-friendly health recovery program (CHRP-BB) is an innovative combination HIV prevention approach that we developed in an effort to fill the significant void in primary HIV prevention for high risk PWUD. This study reports the feasibility, acceptability, and preliminary efficacy of the CHRP-BB intervention to improve pre-exposure prophylaxis (PrEP) adherence and HIV-risk reduction behaviors among high-risk PWUD in methadone maintenance program (MMP). We used a within-subjects, pretest-posttest follow-up design to recruit 40 participants between September 2016 and July 2017. Participants were HIV-uninfected, methadone-maintained people who reported HIV-risk behaviors and were currently taking PrEP (n=40). Participants were assessed at baseline (T₀), immediately post-intervention (4 weeks: T₄) and at 1-month post-intervention (T₈). Immediately after completing the four weekly intervention groups, participants underwent a post-intervention assessment including in-depth qualitative interview. Additionally, we administered a one-to-one semi-structured qualitative interview among treatment providers and administrators (n=10) at the MMP to assess overall satisfaction and perceived utility of the intervention with regard to organization-level factors. We assessed feasibility based on participant recruitment and engagement, which was outstanding, with 95% retention. Results showed that participants were highly satisfied and perceived the intervention as valuable and acceptable (mean: 81.3). Significant enhancements in PrEP adherence [F(2,74)=7.500, p=0.001] and PrEP-related knowledge [F(2,74)=3.828, p=0.026] were observed. Drug (e.g., injection of illicit drugs, sharing of injection equipment) and sex-related (number of sexual partners, inconsistent condom use) risk behaviors were significantly reduced. Additionally, significant improvements were also found in HIV risk reduction Information-Motivation-Behavioral Skills model of health behavior change (IMB) constructs, including knowledge, motivation, and behavioral skills. The intervention effect also remained durable from post-intervention to the 1-month follow-up point. The results support feasibility and high acceptability and support further examination of the efficacy of this combination bio-behavioral intervention in a prospective clinical trial.

EXPERIENCES USING PRE-EXPOSURE PROPHYLAXIS FOR HIV PREVENTION AMONG HIGH RISK DRUG USERS

ROMAN SHRESTHA, PhD¹, Michael Copenhaver, PhD²

¹University of Connecticut, Branford, CT; ²University of Connecticut, Storrs, CT

Introduction: Availability of pre-exposure prophylaxis (PrEP) is emerging as an important tool for curtailing the HIV epidemic and a recommended element of integrated HIV prevention approaches. Despite unequivocal evidence supporting PrEP in the US, its scale-up has been gradual overall, and nearly absent among people who use drugs (PWUD). In the present study, we piloted the implementation of PrEP, as a part of an integrated HIV prevention approach, and explored the experiences and attitudes related to PrEP use among PWUD.

Methods: Between September 2016 and July 2017, we recruited 40 HIV-uninfected, methadone-maintained people, who reported HIV-risk behaviors, and were currently taking PrEP. We conducted both quantitative and in-depth, semi-structured qualitative interviews that primarily focused on experiences, attitudes, acceptability, disclosure status, risk compensation-related attitudes, and barriers related to PrEP adherence. Analyses of quantitative data were performed in SPSS using descriptive statistics, whereas, analysis of qualitative data followed a thematic analysis approach, applying several qualitative data analysis procedures.

Results: Participants were mostly in their mid-40s (mean=44.8 years), male (55.0%), and had been taking PrEP for an average of 36 days. Results showed that participants were highly satisfied and perceived PrEP as valuable and acceptable (mean: 77.7) for HIV prevention. Participants reported high adherence to PrEP with a mean adherence score of 87.6 (Range: 0–100). The most highly endorsed facilitators to PrEP adherence were use of memory aids, no out-of-pocket cost, perceived benefit, and support from social network, whereas the barriers to adherence included side-effects, stigmatization, requirement of daily dosing, and difficulty in accessing PrEP-related services. Additionally, participants expressed disagreement with the overall risk compensation-related attitudes (mean: 16.7, Range: 8–40) and indicated no increment in engagement in risk behaviors while on PrEP.

Conclusion: The results from the current study provide preliminary evidence supporting the successful integration of PrEP within the substance abuse treatment setting, where high risk PWUD are concentrated. Overall, our findings have significant implications for future public health research and for health promotion intervention, practices, and policies for PWUD, particularly in treatment setting.

Paper Session 43: Reducing Risk of Substance Use Behaviors 4:00 PM-4:15 PM

THE IMPACT OF HIV AND COCAINE USE ON CARDIOVASCULAR RISK

Deborah L. Jones, PhD, MEd¹, Dushyantha T. Jayaweera, MD, MRCOG (UK), FACP, CIP¹, Suat Babayigit, MSEd¹, Violeta J. Rodriguez, MSEd², Stephen M. Weiss, PhD, MPH¹, Mahendra Kumar, PhD¹

¹University of Miami Miller School of Medicine, Miami, FL; ²University of Georgia, Athens, GA

Objectives: Cardiovascular disease (CVD) is one of the leading causes of death among HIV-infected individuals, and cocaine abuse is a risk factor for sudden CVD death. This preliminary study explored the impact of cocaine (Coc) use on the risk of CVD within the context of both traditional risk factors and HIV specific factors, e.g., immune activation and inflammation.

Methods: Participants (N = 270) were aged 18–50, with no CVD history or symptoms of CVD and not on antiretroviral medication, and were either current cocaine users (HIV-/Coc+; n = 102), HIV-infected individuals (HIV+/Coc-; n = 100), or both (HIV+/Coc+; n = 68). Evaluations included biomarkers of immune activation (interleukin 6 (IL-6)) and inflammation (TNF α), and subclinical atherosclerosis (carotid artery plaques and intima-media thickness; IMT).

Results: Participants' mean age was 37 (SD= 9.63); most (64 %) were African American, 27% were overweight and 41% were obese; 63% were current smokers. Comparing groups, HIV-/Coc+ participants had the lowest incomes and the highest rates of weekly exercise; HIV+/Coc+ were older and had the worst eating habits. IL-6 and TNF α were mean (SD) 1.79 (2.63) and 9.11 (6.92), respectively. Plaques were identified in 28% of participants, and in binomial logistic regression, age (AOR=1.185 [1.121, 1.253], $p = 7.02$, $p = 0.03$), had highest TNF α ($F=19.41$, $pF=37.71$, $pF=6.92$, $p=0.032$). Even when controlling for smoking and body mass, TNF α was highest among HIV+/Coc+ participants (TNF α , $r^2=0.109$, $p=0.002$).

Conclusions: The combination of HIV and cocaine use was associated with a 50% increase in inflammation and plaques, suggesting CVD risk above and beyond that of traditional risk factors, HIV infection or cocaine use alone. Preliminary results suggest that CVD risk associated with HIV infection may be exacerbated by cocaine use, and that clinical recommendations for evaluation of HIV-infected patients' CVD risk should include assessment of biomarkers of inflammation and use of cocaine when appropriate. Future research should examine the risks associated with the clusters of pathology identified among cocaine users, and how they may impact HIV prognosis and mitigation.

Paper Session 43: Reducing Risk of Substance Use Behaviors 4:15 PM-4:30 PM

DEVELOPMENT AND BETA TESTING OF A PROVIDER-LEVEL MOBILE APPLICATION TO IMPROVE HIV AND ADDICTION TREATMENT

Kasey Claborn, PhD¹, Sara Becker, PhD², Sarah Hodsdon, BA³

¹The University of Texas Dell Medical School, Austin, TX; ²Brown University, Providence, RI; ³Dimagi, Boston, MA

Background: Treatment retention is a significant public health concern among people living with HIV with less than half receiving consistent HIV medical care. People who use drugs are at increased risk for treatment drop out. This study aimed to develop a mobile platform to promote care coordination across clinic settings with healthcare providers as the primary user. The resulting application was built upon CommCare, the most evidenced based mobile health tool for frontline healthcare workers.

Methods: In-depth qualitative interviews with 29 community clinicians informed initial design of the technology-based platform. Two working groups and six in-depth interviews were conducted with key stakeholders to identify potential barriers to usage, potential high users of the platform, and key features. The prototype is being refined through an iterative process whereby we are beta testing with up to 8 potential users to inform usability, modification and finalization of the digital platform. Beta testing will be completed by October 2017.

Results: A multifunctional app was perceived as useful across provider disciplines. The iCare app comprised 5 major functions: HIV/PrEP and substance use screening, referral to treatment, dual treatment planning and communication, patient education resources, and provider training resources.

Conclusions: Development of provider-level mobile applications has the potential to improve patient care and clinic workflow. These data informed development of the iCare application, which will be deployed for testing in a local HIV clinic and 5 addiction treatment facilities.

MERITORIOUS AWARD WINNER Paper Session 43: Reducing Risk of Substance Use Behaviors 4:30 PM-4:45 PM

HIV-STIGMA AND DRUG RELATED PROBLEMS AMONG HIV-POSITIVE GAY AND BISEXUAL MEN

Raymond L. Moody, MA¹, Jeffrey T. Parsons, PhD², H. Jonathon Rendina, PhD, MPH²

¹Graduate Center, City University of New York, Brooklyn, NY; ²Hunter College of the City University of New York (CUNY), New York, NY

Background: Sexual minority stress and emotion dysregulation are associated with greater psychological distress but less is known about drug-related problems. For HIV-positive gay and bisexual men (GBM), HIV-related stress may serve as a significant source of stress and increase risk of drug-related problems. The present study examined the association between HIV-related stress and drug-related problems in a sample of HIV-positive GBM, as well as the mediating role of emotion dysregulation.

Methods: Data are from the *day2day* study; a sample of 87 HIV-positive GBM from NYC ($M_{age}=39$, $SD=10.27$). Three measures of HIV-related stress were examined: HIV-related discrimination, HIV-disclosure rejection sensitivity, and HIV-concealment. Emotion dysregulation was assessed using the Difficulties with Emotion Regulation Scale. Drug-related problems were assessed using the Short Inventory of Problems for Drug Use. Each form of HIV-related stress was modeled independently on drug related problems with emotion regulation as a mediator. In our final analyses, all three forms of HIV-related stress were modeled on drug related problems with emotion regulation as a mediator.

Results: The majority of the sample identified as men of color; (41.2% Black, 27.1% Latino, 20.0% White, 11.8% Other), 26.4% had full-time employment, 36.8% made more than \$30,000 a year, and 25.3% were in a relationship. Modeled independently and adjusting for sociodemographics, HIV discrimination was positively associated with emotion dysregulation ($\beta=0.40$, $p<.001$) and had an indirect association with drug-related problems through emotion dysregulation ($\beta=0.21$, $p=.001$). HIV rejection sensitivity was positively associated with emotion dysregulation ($\beta=0.30$, $p=.013$) and had an indirect association with drug-related problems through emotion dysregulation ($\beta=0.17$, $p=.015$). HIV concealment was not associated with emotion dysregulation ($\beta=-0.03$, $p=.769$) or drug-related problems ($\beta=0.005$, $p=.958$). In our final model, only a significant indirect effect was observed for HIV discrimination on drug-related problems through emotion dysregulation ($\beta=0.18$, $p=.014$). The final model accounted for 41% of the variance in drug-related problems.

Conclusions: Findings provide evidence of an indirect effect of HIV-related discrimination on drug related problems through emotion regulation. Emotion regulation therapies focus on teaching more elaborative skills for coping with stressors, and skills may be important in managing the emotional impact of stigma-related stressors, including discrimination. Further, our findings suggest that improved emotion regulation abilities may reduce the risk of problematic drug use among GBM who experience stigma-related stress.

VETERAN CARE IN THE COMMUNITY: OPPORTUNITIES AND CHALLENGES FOR PAY-FOR-PERFORMANCE

Karli Kondo, PhD¹, Jessica Wyse, MPP, MA, PhD², Aaron William Mendelson, MPH Candidate³, Gabriella Beard, BA in Biology⁴, Allison Low, BA⁵, Michele Freeman, MPH⁶, Devan Kansagara, MD MCR⁷

¹Portland VA Health Care System, Portland, OR; ²VA Portland Health Care System, Portland, OR; ³UC Berkeley School of Public Health, Berkeley, CA; ⁴University of Virginia, Portland, OR; ⁵VA Portland Health Care System, Vancouver, WA; ⁶VA Portland Healthcare System, Portland, OR; ⁷VA Portland Health Care System, Portland, OR

Background: Pay-for-performance is commonly used in the Veterans Health Administration system, and is expected to be an important strategy to incentivize quality and appropriate utilization as Veteran care moves into the community. We conducted a systematic review and interviewed stakeholders to better understand relevant challenges and opportunities to P4P in community settings.

Methods: We searched PubMed, PsycINFO®, and CINAHL® through March 2017 for studies of pay for performance or implementation factors (eg, performance metrics) targeting Veterans in community care. Two investigators abstracted data and assessed study quality. In addition, we interviewed 17 key informants with extensive P4P research or administrative experience. Using conventional content analysis to guide protocol development, we drafted a semi-structured interview informed by previous themes while also allowing new themes and concepts to emerge.

Results: Six studies examined P4P or related design features or implementation factors in Veteran populations related to community settings. In general, studies found that a number of survey instruments examining cross-system access and coordination exist, that the relationship between access and patient satisfaction varies by measure, that Veterans, providers, and administrators reported Veterans Choice Program (VCP) related challenges such as fragmented care, poor communication and coordination, additional burden on VHA providers, and barriers to sharing medical records, and that there are differences between providers interested in VCP participation and those who are not. Key themes from interviews included targeting areas known to need improvement such as documentation and coordination, the importance of developing relationships with providers and health systems known to provide quality care, and the importance of providing tools to streamline the process. Areas of concern included the small number of Veteran patients per community provider, how funding expanded care in the community might affect Veterans receiving care in VHA settings, and the potential for differences in standards of care (eg, overtreatment).

Discussion: Research guiding the implementation of P4P for Veteran care in community settings is limited. Findings from studies and key informant interviews highlight current challenges and provide recommendations to overcome barriers and ensure quality care for all Veterans.

Paper Session 44: Improving the Health of Veterans 3:45 PM-4:00 PM

BEHAVIORAL WEIGHT LOSS AND BINGE EATING: SUPPORT FOR A STEPPED CARE MODEL FOR VETERANS WITH OVERWEIGHT/OBESITY WHO BINGE EAT

Cara Dochat, BA¹, Kathryn Godfrey, PhD², Shahrokh Golshan, Jessica Gundy Cuneo, Ph.D.³, Niloofar Afari, PhD⁴

¹San Diego State University/University of California Joint Doctoral Program in Clinical Psychology, San Diego, CA; ²Drexel University, Philadelphia, PA; ³University of California San Diego, Sonoma, CA; ⁴VA San Diego Healthcare System / UC San Diego School of Medicine Department of Psychiatry, La Jolla, CA

Dieting and weight fluctuation are risk factors for eating disorders (EDs), which raises questions about appropriate treatment models and targets for individuals with overweight/obesity who binge eat. There is a scarcity of longitudinal research examining links between weight loss and binge eating during treatment in a stepped care model, especially in mostly male, Veteran samples. The aims of the current analysis were to determine (1) if weight loss during a behavioral weight loss program (VA's MOVE!) is associated with more severe ED symptoms in Veterans who binge eat; (2) if prior weight loss impacts changes in symptoms during and after adjunctive treatment for binge eating; and (3) whether sex is a moderator of this relationship. 90 Veterans (69 male; $M_{age}=57$, $SD=10$) who completed MOVE! reported ED symptoms on the Binge Eating Scale (BES) and Dutch Eating Behavior Questionnaire and were assessed with the Eating Disorder Examination Interview at baseline and at several time points following adjunctive treatments for binge eating. Mean BMI and mean BES scores at baseline for the entire sample were 38.9 kg/m² ($SD=7.6$) and 16.2 ($SD=8.8$), respectively. Mean % weight lost in MOVE! was 2.3% ($SD=4.1$). Regression analyses showed that Veterans who lost more weight had higher dietary restraint on self-report ($p=0.013$) and interview ($p=0.017$) measures. There were no relationships between % weight lost during MOVE! and other ED symptoms at baseline. Mixed effects models supported significant reductions in binge eating symptoms during adjunctive treatment for binge eating regardless of weight lost during MOVE!. Sex was a significant moderator in the weight loss-binge eating relationship during adjunctive treatment for binge eating (p 's=0.003–0.014). In male Veterans, those who lost more weight in MOVE! had less severe binge eating symptoms during and after adjunctive binge eating treatment. Conversely, greater weight loss in female veterans was associated with more severe binge eating symptoms. Thus, among Veterans with overweight/obesity who binge eat, weight loss during a behavioral weight loss program does not appear to be a risk factor for binge eating symptoms or to influence reductions in binge eating symptoms during adjunctive binge eating treatment. However, the association between successful weight loss and binge eating symptoms within a stepped care model is different for female and male Veterans, highlighting the unique needs of these populations.

TRANSLATING THE LOOK AHEAD INTENSIVE LIFESTYLE INTERVENTION AMONG UNITED STATES ACTIVE DUTY MILITARY PERSONNEL

Rebecca Krukowski, PhD¹, Marion Hare, MD¹, Gerald Talcott, PhD², Leslie A. Gladney, MS², Karen C. Johnson, MD, MPH¹, Phyllis Richey, PhD¹, Mehmet Kocak, PhD¹, Patrick Keller, MD³, Ann Hryshko-Mullen, PhD⁴, Robert Klesges, PhD⁵

¹University of Tennessee Health Science Center, Memphis, TN; ²University of Virginia, San Antonio, TX; ³Defense Institute for Medical Operations, San Antonio, TX; ⁴Joint Base San Antonio-Lackland Air Force Base, San Antonio, TX; ⁵University of Virginia, Charlottesville, VA

Objective: Although weight directly impacts military readiness, health care costs, and career success, there have been few randomized behavioral weight management trials conducted with military personnel. Thus, the purpose of this study was to compare a translation of the Look AHEAD intensive lifestyle intervention with a self-paced version of the same intervention in this population.

Methods: Healthy active duty military personnel (N=248, 49% male, 34% racial minority) with overweight/obesity were randomized to a 4-month distance- (i.e., phone and email) and individual-based program that was proactive (i.e., counselor-initiated (CI) condition) or reactive (i.e., self-paced (SP) condition). Interventionists were retired military personnel or had extensive familiarity with the military.

Results: In intent-to-treat analyses, the CI condition had significantly greater weight loss at 4-months (CI: $M \pm SD = -3.2 \pm 3.4$ kg vs. SP: -0.6 ± 2.9 kg, $p < 0.0001$) and a significantly greater percent weight loss (CI: $3.5\% \pm 3.8$ vs. SP: $0.6\% \pm 3.1$, $p < 0.0001$). The proportion of participants who lost 5% or more also differed significantly by condition (CI: 29.8%, SP: 10.5%, $p = 0.0002$). Mean abdominal circumference reduction was significantly greater for the CI arm (3.5 ± 6.0 cm) compared to the SP arm (1.2 ± 4.1 cm for the SP arm ($p < 0.0001$)). CI participants completed 12.4 ± 3.6 sessions (out of a possible 16); only 2 SP participants each requested one session by the 4-month visit. CI participants self-monitored dietary intake and physical activity using the LoseIt app on 66.7 ± 26.5 days (out of a possible 120 days) compared to SP participants who self-monitored on 21.3 ± 40.2 days ($p < 0.0001$). CI participants weighed themselves on a Body Traceelectronic scale on 88.5 ± 27.8 days compared to 55.3 ± 33.0 days for SP participants ($p < 0.0001$). CI participants consumed 38.6 ± 35.0 of the provided meal replacements (out of a possible 360 meal replacements). In analyses examining only those in the CI condition, there were no significant differences in percent weight loss by gender, race, ethnicity, education level, marital status, age category, or military grade.

Conclusions: The CI behavioral weight loss intervention translated from Look AHEAD offers a promising approach for managing weight in an active duty military population.

EVALUATING TREATMENT FIDELITY USING THE BEHAVIORAL CHANGE CONSORTIUM FRAMEWORK IN THE PATRIOT RANDOMIZED CLINICAL TRIAL (RCT)

Lauren Wash, M.A.¹, Kyle Folterman, Master of Social Work², Sangmin Hyoung, Ed.M.³, Maria Pelosi, M.S.Ed.⁴, Maria Antonia Rodriguez, Ph.D.¹, Sarah R. Sullivan, M.S.Ed.⁵, Sundar Natarajan, MD., MSc.¹

¹Dept. of Veterans Affairs New York Harbor Healthcare System, New York, NY; ²Dept. of Veteran Affairs New York Harbor Healthcare System, New York, NY; ³Dept. of Veterans Affairs New York Harbor Healthcare System, New York, NY; ⁴Department of Veteran Affairs, New York, NY; ⁵James J. Peters VA Medical Center, Bronx, NY

Background: Behavioral research relies on treatment fidelity to ensure the reliability and validity of a proposed intervention. The NIH Behavior Change Consortium Treatment Fidelity Workgroup (BCC) conceptualized a framework for treatment fidelity implementation focusing on five domains. The framework provides subdomains and recommended strategies to fulfill each subdomain.

Purpose: Our goals were to: 1) develop a treatment fidelity metric using the BCC framework, and 2) evaluate how our PATRIOT intervention met the BCC recommendations using this metric.

Methods: PATRIOT is a RCT aimed at primary prevention of foot lesions in Veterans with diabetes using a telephone-based behavioral intervention. We compared each BCC strategy with our current practices. Aspects of the BCC recommendations were refined to be applicable for telephone-based interactions. Interventionists and supervisors individually scored our current practices based on the extent to which each BCC strategy is utilized using a 5-point Likert scale: 1-Poor, 2-Fair, 3-Average, 4-Good, 5-Excellent. Averages of ratings were taken for each strategy to present final point estimates showing how our practices meet the BCC strategies.

Results: Results are the average ratings of five individuals with knowledge of the intervention. Our ratings using the BCC framework are: 1) *Study Design*: a) treatment dose within condition – 4.74/5, b) equivalent dose across conditions – 4.62/5, c) Plan for implementation setbacks – 4.75/5; 2) *Training Providers*: a) standardize training – 4.53/5, b) ensure skill acquisition – 4.44/5, c) Minimize “drift” in skills – 4.13/5, d) Accommodate differences – 4.48/5; 3) *Treatment Delivery*: a) Control for provider differences – 4.83/5, b) Reduce differences within treatment – 4.87/5; c) Ensure adherence to treatment protocol – 4.83/5, d) Minimize contamination – 4.89/5; 4) *Treatment Receipt*: a) Ensure participant comprehension – 4.93/5, b) Ensure participant ability (cognitive skills) – 4.95/5, c) Ensure participant ability (behavioral skills) – 4.86; and; 5) *Enactment of Treatment Skills*: a) Use of cognitive skills – 4.93/5, b) Use of behavioral skills – 4.97/5.

Conclusion: The ratings using the BCC framework showed high treatment fidelity ratings. All ratings ranged from good to excellent. This approach has potential to provide a standard metric to evaluate treatment fidelity in telephone-based behavioral interventions.

PATIENT PERCEPTIONS OF MULTI-MORBIDITY

Kyle Murray, BA¹, Jonette Johnson, BA²

¹Medical College of Wisconsin, Wauwatosa, WI; ²Medical College of Wisconsin, Milwaukee, WI

Patterns of multiple, chronic conditions (multimorbidity, MM) and functional status may influence a paradigm shift in the care of older adults, focusing on the complex interplay rather than on individual diseases. Patient perceptions of MM have implications for treatment, education, self-management, and resource utilization. Goals of this study are to describe patterns of MM and functional status among geriatric outpatients and gather pilot data on perceptions of MM.

Methods: Mixed methods are used to conduct interviews with a convenience sample of patients > 65 years attending appointments at a VA Primary Care Clinic. Measures include the Mini-Cog, Activities of Daily Living (ADL), Instrumental Activities of Daily Living (IADL), Self-Assessed Health (SAH), Short Physical Performance Battery (SPPB), and a semi-structured interview of illness perceptions. Medical records are reviewed for MM, and prospectively over 3 years for healthcare utilization.

Results: To date 81 subjects (77.7 ± 8.9 years; range 65–93) have been interviewed. Mean number of conditions is 16.6 ± 7.1 ; most common ($\geq 25\%$ of subjects) are hypertension, hyperlipidemia, diabetes, and heart disease. 18.8% screened positive for dementia. Self-report ADL was $5.7 + 0.6$ (range 0–6), and IADL $6.5 + 1.6$ (range 0–8). Objective function by SPPB was $7.1 + 3.2$ (range 0–12). The 35% who rated SAH poor-fair had significantly more MM ($19.4 + 6.4$) vs. those rating SAH as good-very good by 65% ($15.2 + 7.1$, $t=2.6$, $p < .05$). Qualitative interviews revealed 77% think of their MM as individual conditions, with little-no interrelatedness. About 62% of the group could name 2 or more of their chronic conditions, while 38% named one or none.

Conclusions: The study population has a high burden of MM. Although tending to report high function (ADL and IADL), actual performance on the SPPB suggests greater impairment. Those rating SAH as poor-fair had a greater burden of MM. Most patients perceive conditions as occurring independently, and are more aware of symptoms that affect their daily life (e.g. pain, shortness of breath).

CRITICISMS OF AND ALTERNATIVES TO DSM-5: IMPLICATIONS FOR BEHAVIORAL MEDICINE

Edwin B. Fisher, Ph.D.¹, Allan Horwitz, Ph.D.², Jeffrey S. Gonzalez, PhD³, Edwin B. Fisher, Ph.D.¹, Elaine F. Walker, Ph.D.⁴

¹Department of Health Behavior, Gillings School of Global Public Health, University of North Carolina-Chapel Hill, Chapel Hill, NC; ²Rutgers University, Princeton, NJ; ³Yeshiva University and Albert Einstein College of Medicine, Bronx, NY; ⁴Emory University, Atlanta, GA

The Diagnostic and Statistical Manual, Version 5 (DSM-5) of the American Psychiatric Association and its predecessors have gained considerable dominance regarding the characterization and diagnosis of mental disorders or mental illness. Criticism however has noted a number of issues: 1) Overlap – 50% of those meeting one diagnosis also meet another. 2) Amorphous categories – e.g., two people can both be diagnosed with Major Depressive Disorder with only 1 out of 9 features in common. 3) Reification and tautology – in most cases, there are no identifiable diseases other than the cluster of symptoms defining them; there is no depression or schizophrenia to treat other than the symptoms that comprise depression and schizophrenia. 4) Assumption that disorders are fundamentally biological relative to a variety of socioecologic and psychological determinants. This is naïve vis a vis extensive evidence that early and later experience influences neurobiology so that neurobiology may best be seen as the mediator of environmental effects on behavior, rather than some immutable basis for psychopathology. This symposium will explore emerging criticisms of DSM-5 and alternatives to it. Employing a sociological perspective, Allan Horwitz will describe the symptom-based diagnostic character of DSMs 3–5 including the diverse professional, cultural, and economic influences that encouraged their development and popularity. This raises questions then regarding the adequacy of such symptom-based models to capture and reflect the broad range of psychic ills that comprise “mental illness.” Jeffrey Gonzalez will describe a key example of problems with DSM-5’s broad categories in the confusion of clinical depression with distress associated with diabetes. This has led to large numbers of false positives, excessive and misapplied treatments, failure to develop treatments reflecting the range of problems associated with diabetes distress and depression, stress on available care, and limited availability of care. Edwin Fisher will then describe an alternative to DSM-5 focusing on problem behavior patterns (e.g., suicide, reduced frequency of previously rewarding behavior, difficulty integrating contextual cues in guiding behavior, hypersensitivity to slights, labile attachments), interventions specific to them, and their practical advantages in behavioral medicine and other clinical settings. Elaine Walker, the discussant, has made major contributions to understanding the developmental, psychological, and biological determinants of psychosis from neonatal development through prodromal phases. Her perspective highlights the multiple determinants of mental disorders and provides a vantage point for examining problems with DSM-5 as well as alternatives and their implications for mental as well as general health and well being.

Symposium 63A

THE DSM, DEPRESSION, AND ANXIETY: A SOCIOLOGIST’S PERSPECTIVE

Dr. Allan Horwitz, Ph.D.

Psychiatric diagnoses often reflect a matrix of sociological factors associated with professional prestige, economic forces, and cultural fashions. Diagnostic systems conceptualize the same underlying psychosocial problems in very different ways during various time periods. Since the publication of the *Diagnostic and Statistical Manual (DSM-III)* in 1980, psychological distress resulting from social circumstances and life threats such as health threats that previously were viewed as general problems of nerves, neuroses, and anxiety was transformed into the specific diagnoses of Major Depressive Disorder and a variety of specific anxiety conditions. Several factors including the contrasting ways that the DSM-III defined anxiety and depression, the necessity to use explicit diagnoses to obtain professional legitimacy and reimbursement for services, and the marketing practices of the pharmaceutical industry account for why depression replaced anxiety as the diagnosis most suitable for treated mental health conditions.

In general, the *DSM-5* (2013) exacerbated rather than improved the weaknesses of symptom-based diagnostic models. Beneath the changing veneer of psychiatric labels, however, lie the same mélange of psychic ills that resist the precise labels that current classificatory fashions strive to impose upon them. Regardless of labels and categories, however, the problems of psychological distress they encompass are important issues that emerge frequently in the prevention and management of health problems and patient care. Nevertheless, major questions remain over whether symptom-based categorizations of diverse psychic ills illuminate or obscure problems, how they impact general health, and if they provide the optimal approaches to ameliorate psychic distress.

Symposium 63B

PROBLEMS WITH ROUTINE SCREENING FOR DEPRESSION IN DIABETES: OVERDIAGNOSIS AND MISMATCHED CARE

Dr. Jeffrey S. Gonzalez, PhD

A large body of research documents increased risk for depression among individuals living with diabetes and links depression to problems with self-management, hyperglycemia and poor health outcomes. Based on these relationships, a number of expert recommendations have called for routine screening for depression in diabetes in order to identify cases and initiate treatment, with the reasonable expectation that doing so would improve diabetes health outcomes. However, a critical examination of the evidence base exposes two significant areas of concern. First, although most studies of depression in diabetes aim to identify cases of major depressive disorder (MDD), as defined by the Diagnostic and Statistical Manual of the American Psychiatric Association, they use crude self-report measures to identify cases. These measures produce a high number of false-positives and introduce considerable heterogeneity into the research literature informing these recommendations. A growing body of evidence suggests that non-pathological emotional distress secondary to the burdens of living with diabetes and its demanding management, or diabetes distress, is often misidentified as depression. Diabetes distress is also more common, more chronic and more closely related to problematic diabetes self-management and hyperglycemia than MDD. These distinct constructs require different approaches to intervention. Second, routine depression screening will require considerable resources to differentiate the large number of false-positive cases from the smaller number of true-positives. This would result in increased demands on an already overburdened mental health system that cannot be met by existing capacity. Evidence shows that routine depression screening leads to over-diagnosis and over-treatment with antidepressants, which are associated with side effects that are particularly problematic for individuals with diabetes (e.g., weight gain) and are mismatched with patient preferences. A 'tick-the-box' approach to depression screening in diabetes may seem to be responsive to the research evidence and expert recommendations but nevertheless will likely be insufficient to address the problem of emotional distress in individuals living with diabetes. Patient-centered diabetes care should be more sensitive to the context that explains emotional distress in conceptualizing the problem and in identifying appropriate interventions.

Symposium 63C

CRITICISMS OF DSM-5 AND ALTERNATIVES FOCUSING ON PROBLEMS RATHER THAN CATEGORIES

Dr. Edwin B. Fisher, Ph.D.

Alternatives to the amorphous and overlapping categories of DSM-5 have included statistical analyses of broad underlying dimension such as extraversion, neuroticism, or positive affect. These may account for substantial variance in clinical manifestations but provide little guidance to treatment, unless, e.g., interventions are developed to treat extraversion or neuroticism. A second direction entails specifying "endophenotypes" or specific behaviors according to "Research Domain Criteria." Although intentionally more specific than the DSM-5 categories, these are still seen as steps to improve articulation of those categories. They also retain the assumption that fundamental causes are biological. An alternative is to focus on problematic behavior patterns not as indicators of DSM-5 categories but of interest in their own right along with their diverse social, economic, and psychological, as well as biological determinants. Suicide, often viewed as an expression of depression, is a good example. It is a major problem with yearly worldwide mortality of about 800,000 (cf., yearly HIV mortality of 1,100,000). Its determinants include depressed mood and hopelessness but also anxiety, antisocial and violent behavior patterns, and educational/economic disadvantage. Thus, suicide may be viewed as a problem in its own right not just in connection to depression. Other problematic behavior patterns include patterns related to anxiety (e.g., amorphous fears, post-traumatic distress), patterns related to mood (e.g., sleep disturbance, reduced frequency of previously rewarding behavior), patterns affecting coherence of behavior and its contexts (e.g., difficulty integrating contextual cues in guiding behavior), patterns related to impulse control (e.g., steep discounting of delayed consequences), or patterns related to relationships (e.g., suspiciousness, hypersensitivity to slights, labile attachments). Supporting this approach, the majority of evidence-based psychological interventions address specific problems rather than broad categories, e.g., studies of problem solving interventions in low and middle-income countries that reduce a number of mental health problems. Implications for behavioral medicine are substantial. Problem solving in mental health overlaps considerably with the problem solving in chronic disease management, facilitating its incorporation within clinical and chronic disease care. Interventions focused on specific problems such as disease-related distress, problems integrating complex cues or hypersensitivity to criticism that interfere with patient-provider relationships, or reduced frequency of previously rewarding behavior that reduces adherence to treatment plans may have greater practicality in prevention and clinical settings than treatment plans for the broad categories of DSM-5.

A NATIONAL PROFILE OF MENTAL HEALTH AND SUPPORT SERVICE NEED AMONG FAMILY CAREGIVERS OF ADULTS WITH CANCER IN THE U.S.

Erin E. Kent, PhD, MS¹, James Dionne-Odom, PhD, MA, RN²

¹ICF International, Rockville, MD; ²University of Alabama at Birmingham, Birmingham, AL

Objective: To examine association between caregiving intensity and mental health among U.S. cancer caregivers and potential moderation by caregivers' unmet support service needs.

Methods: Analysis of Center for Disease Control 2015 Behavioral Risk Factors Surveillance System self-reported survey data from 18 U.S. states (N=1574 cancer caregivers). Caregiving intensity included the hours/week caregiving (high hours > 20, low hours ≤ 20) and caregiving duration (high duration > 2 years, short duration ≤ 2 years). Mental health was reported as the number of "mentally unhealthy days" (MUD) in the past 30. Support service needs included: caregiving classes, help getting service access, support groups, counseling, and respite care. Multivariable linear regression adjusting for sociodemographics and sampling weights modeled MUDs regressed on unmet support service needs and caregiving intensity.

Results: 122 (8.3%) cancer caregivers reported caregiving for high hours/high duration, 213 (13.1%) high hours/short duration, 329 (18.4%) low hours/long duration, and 910 (60.2%) low hours/short duration. Most caregivers were female (67%), younger than 55 (66%), non-Hispanic white (71%), and employed (61%). Mean MUDs was 6 (SE=0.5). The highest reported unmet support service needs were help with service access (48.4%) and counseling (15.6%). Higher caregiving intensity and support service need endorsement were both associated with higher MUDs (*p*

Discussion: High intensity cancer caregiving was associated with poor mental health, especially for those reporting support service needs. Having supportive service needs met may result in greatly reducing MUDs. Prioritizing the development of national strategies to optimize assessment and provision of support services for high intensity cancer caregivers is strongly warranted.

DOES EXPERIENCING SIDE EFFECTS OF ACUTE MYELOID LEUKEMIA TREATMENT WORRY PATIENTS AND CAREGIVERS? RESULTS OF A NATIONAL SURVEY

Norah Crossnohere, MHS¹, Ellen Janssen, PhD¹, John F P. Bridges, PhD²¹Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; ²Johns Hopkins University, Baltimore, MD

Background: Treatment for Acute Myeloid Leukemia (AML) is often aggressive and plagued by short- and long-term side effects. While AML treatment side effects create both physical and emotional burden, worry specifically regarding side effects has not been previously explored. We sought to examine whether experiencing short- or long-term side effects of AML treatment impacted patient and caregiver worries about these side effects.

Methods: We recruited AML patients and caregivers through a national advocacy organization in the US. Participants completed an online survey documenting patients' experience with treatment-related side effects and prioritized 13 AML-related worries using best-worst scaling (BWS). Composite short- and long-term experience scores that reflected number of side effects experienced and severity of side effects (range 0 - 3, lowest to highest) were created. Differences in side effect among patients and caregivers were analyzed using t-tests. Regression models explored the effect of predictors (short-term and long-term side effect experiences score) on 1) BWS of short-worries, and, 2) BWS of long-term worries.

Results: Participants were predominately over 50, white, married, college-educated, and privately insured. Caregivers (n=282) reported higher long-term side effects than patients (1.42 vs. 1.07 n=905; $p < 0.001$), but reported similar short-term side effects (1.88 vs. 1.78 $p = 0.052$). Long-term side effects were the second most concerning worry for patients (BWS=70.6) and caregivers (BWS=63.2) after the possibility of dying. Short-term side effects were less worrisome to patients (BWS=48.1) and caregivers (BWS=46.7). Experiencing more long-term side effects was predictive of being less worried about short-term side effects for patients ($p = 0.040$) and caregivers ($p < 0.001$). Among patients, experiencing long-term side effects was positively associated with worrying about long-term side effects ($p = 0.007$). Among caregivers, experiencing short-term side effects was positively associated with worrying about long-term side effects ($p = 0.042$).

Conclusion: Experiencing long-term treatment side effects assuaged worry about short-term side effects for both patients and caregivers, however what predicted worry about long-term side effects varied. These results offer an important foundation to consider how the lived treatment experiences of patients and caregivers impacts worries, which in turn may influence health behaviors and treatment decisions.

FACTORS CONTRIBUTING TO MISCARRIED HELPING AMONG PARENTS OF CHILDREN WITH CANCER

Leah McDiarmid, B.A.¹, Casiana Warfield, B.S.¹, Kristina Brookshire, M.A.¹, Rachel Kentor, M.S.¹, Lauren Ostarello, M.S.¹, Flora Hoodin, Ph.D.¹, Michelle Byrd, Ph.D.¹, Kristen Kullgren, Ph.D.², Gregory Yanik, MD²¹Eastern Michigan University, Ypsilanti, MI; ²University of Michigan Health System, Ann Arbor, MI

Objective. Miscarried helping is a maladaptive process characterized by ineffective communication by well-intentioned parents of children with chronic illnesses. Research suggests miscarried helping contributes to sub-optimal treatment outcomes across diabetic (Harris et al., 2008) and chronic pain samples (Fales, et al., 2014). This study sought to examine the influence of parent-reported child physical and emotional functioning, and parental depression and anxiety on miscarried helping in children with oncologic disorders.

Method. Primary caregivers ($N = 132$), ages 25 - 57 ($M = 41.16$, $SD = 7.05$), of pediatric cancer patients, ages 3 - 17 ($M = 9.80$, $SD = 4.64$), completed an online survey. Caregivers reported on their child's physical and emotional functioning using the PedsQLTM, their own depressive and anxious symptoms using the PHQ-4 (Kroenke, et al., 2009), and their miscarried helping using the Helping for Health Inventory (HHI; Harris et al., 2008). Data analyses included bivariate correlations and hierarchical regression analysis.

Results. Miscarried helping was unrelated to child age at diagnosis, caregiver age, or perceived prognosis. Miscarried helping was then hierarchically regressed onto conceptually relevant variables based on bivariate correlations ($p \leq .05$). The first block, consisting of parental report of child physical and emotional functioning, accounted for 12% of the variance in miscarried helping, $F(2, 129) = 10.08$, $p < .001$. Parental report of worse child emotional functioning was the only significant predictor ($\beta = -.39$). The second block, consisting of parental self-reported anxiety and depression, significantly improved the model ($R^2\Delta = .13$). In the final model (Adjusted $R^2 = .26$, $F(4, 127) = 11.39$, $p < .001$), significant predictors were parent-reported poorer child emotional functioning ($\beta = -.27$) and greater parental anxiety ($\beta = .29$).

Discussion. These results extend previous research in chronic pain samples indicating child depression is related to miscarried helping (Fales et al.). Moreover, these results suggest that in the context of oncologic diagnoses and treatment, miscarried helping may be partially driven by greater parental anxiety and parental perceptions of worse child emotional functioning, rather than their perceptions of child physical functioning. Therefore, to intervene on miscarried helping, clinicians should target child emotional functioning and parental anxiety and reactivity to child emotional responses.

HPV VACCINE UPTAKE AND COMPLETION IN LATINO ADOLESCENTS: THE INFLUENCE OF CLINIC TYPE AND AGE

Angelica M. Roncancio, PhD¹, Danielle Fincham²¹University of Texas Health Science Center at Houston, Houston, TX;²University of Texas at El Paso, El Paso, TX

Introduction: The human papillomavirus (HPV) vaccine prevents types of HPV linked to genital warts and certain cancers. It is approved for use in females and males aged 9–26. In 2015, 41% of Latino females and 36% of Latino males aged 13–15, completed the vaccine series. These rates are far below the Healthy People 2020 goal of 80% coverage. Little is known about how clinic type (public/non-profit vs. private) and age of the adolescent may influence vaccine series initiation and completion in this population. To address this gap, we examined whether the type of clinic mothers reported as their child's usual source of care (public/non-profit vs. private) and adolescent's age, were associated with HPV vaccine series initiation and completion.

Methods: Data were collected as part of a larger study to identify factors related to Spanish-speaking Hispanic mother's decision to vaccinate their children (aged 10–17) against HPV. Mothers (N=332) completed a baseline survey and at six months post-baseline, a follow-up phone survey and a medical record review were conducted to determine the child's vaccination status. Participants were compensated for their participation (\$20 at baseline and \$15 at follow up). Descriptive and multivariate logistic regression analyses were conducted using SPSS version 23.0 (IBM, Armonk, NY). We tested two separate multivariate logistic regression models. The first model regressed HPV vaccine series initiation (no vs. yes) on clinic type (public/non-profit vs. private) and the adolescent's age (9–10 years; recommended age: 11–12 years; and 13–17 years) while controlling for mother's age (≤ 39 vs ≥ 40), education level (< high school diploma vs. high school diploma) number of years in the US, and child's gender. The second model regressed HPV vaccine series completion on the same variables.

Results: We observed that having a public/non-profit clinic vs. a private clinic as a usual source of care was associated with a higher likelihood to *initiate* the HPV vaccine series. Further, children who were in the 9–10 year age group (i.e., pre-recommendation age range) at baseline, were less likely than those in the recommended age group (11–12 years) to have initiated the series at follow up. In the second model, having a public/non-profit clinic vs. a private clinic as a usual source of care was associated with a higher likelihood of vaccine series *completion*.

Discussion: Our findings indicate that age of the child influences initiation of the series, but not completion. Further, the type of clinic that adolescents attend, influences HPV vaccine series initiation and completion. Our results indicate a need to increase HPV vaccine initiation and completion rates among Latino adolescents attending private clinics. This may be best accomplished through intervening with both health care providers and mothers.

INTERACTIVE PATIENT-CENTERED WEBSITE TO PREVENT DYSPHAGIA IN IRRADIATED PHARYNGEAL CANCER PATIENTS

Eileen Shinn, Ph.D.¹, Jeff McLaughlin², Rose A. Trevino-Whitaker, M.P.H.¹, Evalyne W. Kamunyo, B.S.¹¹UT MD Anderson, Houston, TX; ²Radiant Creative Group, LLC, Houston, TX

Purpose: To provide evidence-based preventive speech pathology services (evaluations and swallowing exercises) and an effective adherence program via a mobile health technology application to head and neck cancer patients during radiation.

Methods: We developed a responsive web-based application program to help patients adhere to preventive swallowing exercises and cope with radiation side effects. The website (English and Spanish) features tracking logs for weight loss, trismus and swallowing exercises, how-to-videos, patient's stories and all-inclusive search bar. Participants at community outpatient clinics based in Fort Worth and Galveston, TX are taught how to log in and navigate the secure interactive website before radiation and are given access to new weekly modules every week for 10 weeks.

Results: One hundred and twelve patients have been enrolled into the prevention program; 52 who received a non-interactive pilot version of the web-based program and 60 who have received the full-scale interactive program. Accrual rates are approximately 95%, with the most common reason for refusal is dislike of a computer-based platform. Approximately 38% of the enrolled patients are either uninsured or low-SES patients. Fifteen mobile tablets with monthly data plans have been distributed to patients without access to computers or smartphones. All 112 patients have received preventive and diagnostic speech pathology services, including fiberoptic endoscopic swallowing tests (FEES). Of the 60 patients who have been enrolled onto our full-scale interactive website, 75% have logged in at least once and over 50% log in regularly throughout the course of their radiation; each visit to the website averages 7 min 38 sec and 8.2 different actions (page views, downloads, searches). Most participants are viewing the swallowing and trismus exercise videos, the cooking demonstrations, and "what to expect this week." Patients have rated the program highly on helpfulness in coping with radiation side effects and with adhering to swallowing and trismus exercises.

Conclusion: Head and neck cancer patients are highly satisfied with technology-based intervention designed to help them cope with radiation side effects and prevent long-term swallowing dysfunction.

INTRUSIVE THOUGHTS AND FACILITY OF GOAL ATTAINMENT IN YOUNG ADULT TESTICULAR CANCER SURVIVORS: THE ROLE OF GOAL DISENGAGEMENT.

Sean J. Ryan, Michael A. Hoyt, PhD

Hunter College & The Graduate Center, City University of New York, New York, NY

Background: The diagnosis of testicular cancer during young adulthood can slow or change the course of development, rendering meaningful goals unobtainable. However, the psychosocial predictors of goal attainment have yet to be identified. Individuals who can disengage from unobtainable goals are more likely to experience better psychosocial adjustment, as they can redirect their focus towards more feasible goals. The ability to shift one's focus away from unobtainable goals may be an important moderator of intrusive thoughts about a situational stressor. Disengagement may be particularly important in the presence of intrusive cognitions about cancer. Intrusive thoughts may result in increased perception of goals as unobtainable, thus negatively affecting adjustment.

Objectives: To examine the relationships between intrusive symptoms, goal facility (perceived attainability of goals), and dispositional goal disengagement in young adult testicular cancer survivors.

Research Design: 171 young adult (ages 18–29) testicular cancer survivors were recruited via a state cancer registry and completed measures of cancer-related intrusive thoughts (IES-R), goal facility (CAYA-T), and goal disengagement (GAS).

Results: Multiple regression analyses (controlling for income, education, employment status, physical well-being, and history of either anxiety or depressive disorder) did not reveal a significant main effect of intrusive thoughts ($\beta=-0.43$, $p<0.10$) or goal disengagement ($\beta=0.10$, $p=0.23$) on goal facility. However, the relationship between cancer-related intrusive thoughts and goal facility was moderated by goal disengagement ($\beta=-0.54$, $p<0.05$) such that those with high goal disengagement and more intrusive thoughts reported relatively low goal facility.

Conclusions: The interaction effect of goal disengagement and intrusive thoughts suggests that goal disengagement might be an ineffective strategy to regulate emotions when cancer-related distress is heightened. Although more research is necessary, this result suggests that young adult survivors, particularly those experiencing mild to moderate distress, might benefit from an intervention that facilitates goal navigation skills.

RELATIONSHIPS AMONG AFFECT, MEMORY, PERCEPTIONS, AND MOBILITY IN OLDER ADULTS WITH CANCER

Jason D. Cohen, B.S.¹, Daniel Palac, MA², Tiffany Bullard, B.S.³, Jonathan North, B.S.⁴, Madhura Phansikar, M.A.³, Sean P. Mullen, PhD³

¹University of Illinois at Urbana Champaign, Champaign, IL; ²University of Illinois at Urbana-Champaign, Champaign, IL; ³University of Illinois at Urbana-Champaign, Urbana, IL; ⁴University of Illinois Urbana-Champaign, Monticello, IL

The average age of cancer survivors in the United States is 67, with 60% being over 65 years old. Researchers have identified cognitive and affective impairments as common sequelae among older adult cancer survivors, however considerable variability exists in the measures used to assess these factors, and in the efficacy of available treatments. Herein, we aimed to test a comprehensive measurement model to better understand cognitive and affective functioning in older cancer survivors, and potential focal points for behavioral interventions. Survey data was collected from the National Health and Aging Trends Study-2016 ($n=5714$; 21.5% of sample excluded due to missing responses on all target variables). The sample was primarily White/non-Hispanic (72%), female (57%) and without (94%) cancer diagnosis ($n=327$). Memory (assessed via Immediate and Delayed Word Recall, and Clock drawing), affect (3 questions from the Health Conditions scale), lower-body mobility (*Short Physical Performance Battery* [SPPB]) and perceptions of memory ability ("how would you rate your memory at the present time"), along with demographics (age, gender, race) and cancerDx were analyzed using structural equation modeling (Mplus v.7). Data were assumed to be missing at random, and weighted least squares maximum likelihood estimation was used. Using affect and memory as latent constructs (regressed on age, gender, race and cancerDx) the model fit the data (χ^2 (df=23) = 102.27, $p<.01$, CFI = .99, TLI = .99, RMSEA = .03, SRMR = .01). Results revealed older, minority women, with a cancer diagnosis were more likely to show greater negative affect and poorer memory. Upon adding perceived memory ability and SPPB to the model (χ^2 (df=23) = 102.27, $pp<.01$, CFI = .99, TLI = .99, RMSEA = .02, SRMR = .01) results revealed a similar pattern; however, the effect of cancer on memory was attenuated and no longer significant. The findings from our study replicate and extend the literature, as we modeled multiple cognitive and affective outcomes in a latent variable framework and this suggests functioning may be lower irrespective of assessment used. Also, lower-body functioning and beliefs in one's memory are malleable, and therefore potential areas of focus for interventions. Together, these findings suggest that physical activity interventions and memory training or gain-framing ("with age comes wisdom") could be important components of any future intervention designed to off-set the effects of aging and cancer on cognition, or to independently optimize affective states.

5-WK STRESS MANAGEMENT INTERVENTIONS DECREASE LEUKOCYTE INFLAMMATORY SIGNALING IN DISTRESSED BREAST CANCER PATIENTS

Michael H. Antoni, PhD¹, Alain Diaz, Ph.D.², Chloe Taub, M.A.¹, Hannah M. Fisher, M.S.¹, Lisa Gudenkauf, PhD³, Charles S. Carver, PhD¹, Bonnie B. Blomberg, Ph.D.⁴

¹University of Miami, Coral Gables, FL; ²University of Miami School of Medicine, Miami, FL; ³Mayo Clinic, Rochester, MN; ⁴University of Miami Miller School of Medicine, Miami, FL

INTRODUCTION. A 10-wk group cognitive behavioral stress management (CBSM) intervention showed decreases in distress and leukocyte pro-inflammatory gene expression in breast cancer (BCa) patients over 12 months. CBSM effects were strongest in women presenting with elevated cancer-specific distress. We next showed that 5-wk interventions featuring CBSM components—cognitive behavioral therapy (CBT) or relaxation training (RT)—decrease distress during BCa treatment. Here we examine whether these brief approaches reduce inflammatory signaling among those with elevated cancer-specific distress. **METHODS.** We identified 49 women who participated in the trial of these 5-week interventions and who reported elevated cancer-specific distress on the Impact of Events Scale-Intrusive Thoughts (5wk CBT=23, 5wk RT=13, 5wk Health Education [HE]=13). Cryopreserved blood samples obtained at baseline (4–8 wks post-surgery and before adjuvant therapy) and 12-month follow-up were used for nuclear protein extraction and determination of Nuclear Factor Kappa-B (NFκB) DNA binding by electrophoretic mobility shift assay. Samples were electrophoresed and dried gels were exposed to Kodak x-ray films, scanned and analyzed for integrated areas under the densitometric curves.

RESULTS. Women assigned to the 3 study conditions showed no differences in sociodemographics, disease characteristics or treatments received. Women in either stress management condition (RT or CBT) showed decreases in NFκB expression over 12-months vs those in HE, after controlling for age, stage, time since surgery and adjuvant treatments received ($F = 4.66, p = .037$). Group differences in change were largest between the CBT condition and the HE condition ($F = 5.25, p = .029$). Lower levels of cancer-specific distress at 12-months were associated with lower NFκB expression, in CBT ($r = .44$) and RT ($r = .62$) but not in HE.

CONCLUSION. Brief stress management appears to down-regulate expression of the NFκB nuclear protein—a key upstream regulator of DNA transcription and inflammatory cytokine production. Thus we have identified a mechanism for decreasing inflammation with CBSM which we have previously shown contributes to better survival in breast cancer patients.

ADHERENCE TO SURVEILLANCE GUIDELINES AMONG LATINA BREAST CANCER SURVIVORS

Nicole Senft, PhD¹, David W. Lounsbury, PhD², Maida Y. Herrera, MPH³, Gary Winkel, PhD⁴, Kristin Bright, PhD⁵, Carmen R. Isasi, MD/PhD⁶, Heidis Valdimarsdottir, n/A⁷, Katarina Sussner, PhD, MPH⁸, Hayley S. Thompson, Ph.D.⁹

¹Wayne State University/Karmanos Cancer Institute, Detroit, MI; ²Albert Einstein College of Medicine, New York, NY; ³Wayne State University School of Medicine - Karmanos Cancer Institute, Sterling Heights, MI; ⁴Icahn School of Medicine at Mt. Sinai, Brooklyn, NY; ⁵University of Toronto, Toronto, ON, Canada; ⁶Albert Einstein College of Medicine, Bronx, NY; ⁷Mount Sinai school of Medicine, nyc, NY; ⁸xxxxx, Seattle, WA; ⁹Wayne State University -Karmanos Cancer Institute, Detroit, MI

The American Society of Clinical Oncology (ASCO) developed evidence-based guidelines for post-treatment breast cancer surveillance that include routine mammography, physical examination, pelvic exam/Pap test, and breast self-exam. Past work has identified lower rates of post-treatment surveillance among racial/ethnic minority breast cancer survivors, and Latina survivors may face distinct barriers to adherence to clinical guidelines, including language barriers, access to healthcare, mistrust of medical professionals, lack of knowledge about recurrence and surveillance, and cultural values like familism (strong feelings of loyalty and obligation towards family members) or fatalism (a belief that cancer cannot be prevented or controlled). Determining which of these contributes to Latina survivors' surveillance behavior is necessary to the development of effective interventions aimed at increasing adherence in this underserved population. The current study focused on testing associations between the constructs listed above and adherence to post-treatment surveillance among 169 Latina breast cancer survivors in the metro Detroit and New York City areas. Survivors were between three months and four years post-treatment. Adherence to surveillance guidelines was conservatively operationalized as the proportion of recommended tests (i.e., mammogram, physical exam, pelvic exam, breast self exam) received at least once since completing cancer treatment. A majority (62%) of Latina survivors reported having performed all four tests at least once. An ordinal regression analysis controlling for demographic predictors (i.e., study site, age, education) found that adherence to surveillance guidelines was associated only with survivors' knowledge of breast cancer recurrence and surveillance ($\beta = .04, p = .006$). Neither preferred language, access to healthcare, mistrust, familism, nor fatalism was significantly related to adherence (all p 's $> .05$). These data suggest that efforts to increase adherence to surveillance guidelines among Latina survivors must focus on making information about recurrence and surveillance available and accessible to members of this patient population.

AFFECTIVE, COGNITIVE, AND BEHAVIORAL FACTORS IN TREATMENT DECISIONS AFTER RECEIVING BRCA 1/2 GENETIC TESTING RESULTS

Revis Ann Massey, Psy D¹, Kristen Farrell-Turner, Ph.D.², Samantha Behbahani, Psy.D.²¹Strong Integrated Behavioral Health, Eugene, OR; ²Albizu University, Miami, FL

The purpose of this study is to understand the extent to which emotional and situational factors influence a woman's decision to have a unilateral or a contralateral prophylactic mastectomy (CPM) versus a less-invasive treatment option such as breast-conserving surgery (lumpectomy) or to use active surveillance (no medical treatment). Research shows that the BRCA 1/2 genetic testing process can be an emotionally-salient experience that influences women's treatment decisions, especially if the result is positive for the genetic mutation. In the past 25 years, the incidence of mastectomies has increased even though survival rates among women who have a unilateral or CPM versus breast-conserving surgery (lumpectomy) (especially for DCIS) are not significantly different. That is, having a mastectomy may not confer the outcome a woman hopes for, especially in the light of the many adverse effects (e.g., scars, changes in body image, delay of adjuvant treatment, surgical infection) caused by mastectomies. All subjects in the study were recruited from cancer support groups in South Florida, had breast cancer, and received negative BRCA1/2 results. Measures used were The Hospital Anxiety and Depression Scale (HADS), Psychosocial Aspects of Hereditary Cancer (PAHC) Questionnaire, and a survey consisting of questions pertaining to demographic information and details related to treatment choices. Results ($N=10$) were not statistically significant but showed that women who were younger and who reported higher levels of anxiety were more likely to choose a unilateral mastectomy or CPM versus a less-invasive treatment option such as breast-conserving surgery (lumpectomy) or to use active surveillance (no medical treatment). Additionally, our results suggest / indicate that women with a negative BRCA 1/2 genetic test result tend to choose a more invasive surgical treatment when they do not feel distress related to the BRCA test result, believe that genetics cause breast cancer, and feel guilty and/or fearful that they might pass the BRCA gene to their children. Considering the increasing numbers of breast cancer diagnosis annually world-wide, it is becoming even more important to understand the emotional and cognitive factors that lead to treatment decisions for breast cancer.

ANXIETY, DEPRESSION, BODY IMAGE AND TANNING IN A COHORT OF 17–18 YEAR OLDS

Lori A. Crane, PhD, MPH

Colorado School of Public Health, University of Colorado Denver, Aurora, CO

BACKGROUND: Tanning, especially indoors, is an important risk behavior for skin cancer, and occurs at high rates among teens and young adults. We examined tanning, anxiety, depression, and body image concerns in a cohort born in 1998, currently age 17–18, for which we have collected longitudinal data on sun exposure and risk factors for skin cancer for at least 12 years (the “Colorado Kids Sun Care Program”). Some members of the cohort received previous skin cancer prevention interventions, but they have been followed since 2007 without any intervention.

METHODS: The online survey was conducted between May and August, 2016. Anxiety was measured using a 9-item inventory and depression was measured by a 7-item scale.

RESULTS: Responses were received from 361 respondents (response rate=51%), equally split between males and females. Females were significantly more likely than males to engage in both indoor tanning (10% vs. 1%; $p<.001$) and outdoor tanning (42% vs. 13%; $p<.001$). Signs of anxiety and/or depression were prevalent in this cohort (34%), many of whom completed the survey around the time of their high school graduation, which may be a particularly stressful time. Females were significantly more likely than males to show signs of anxiety and/or depression (42% vs. 22%; $p<.001$). There was some evidence of a relationship between anxiety and indoor tanning ($F=2.61$; $p=.11$) and between depression and indoor tanning ($F=3.84$; $p=.051$), but there was no apparent relationship between outdoor tanning and anxiety or depression. Indoor tanners were less likely to be satisfied with their weight ($p=.03$) and their appearance ($p=.055$), more likely to report that it is important to their friends that they are thin ($p<.001$), and among females, more likely to report that they make an effort to look like girls or women they see in the media ($p<.001$). These results suggest the importance of both mood and appearance norms as determinants of indoor tanning behavior. Interventions that improve mental health, as well as promote a healthy body image, may reduce indoor tanning behaviors.

ASCO GUIDELINES FOR ANXIETY AND DEPRESSION ASSESSMENT AND RISK IDENTIFICATION WITH CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS

Abigail S. Robbertz¹, David M. Weiss, MA², Barbara L. Andersen, PhD²¹The Ohio State University, New Albany, OH; ²The Ohio State University, Columbus, OH

Introduction: Psychological distress is common amongst cancer patients, with 13–40% of cancer patients experiencing symptoms of depression and 10–30% experiencing symptoms of anxiety. The American Society of Clinical Oncology (ASCO) has provided guidelines for screening, assessment, and treatment of anxiety and depressive disorders in cancer patients and has detailed risk factors for greater disorder severity. Patients with chronic lymphocytic leukemia awaiting the initiation of treatment (a recommended time point for assessment) were screened and information on risk factors was obtained. This study sought to describe the anxiety and depression symptomatology and its relationship with relevant risk factors in an understudied cancer population.

Methods: Patients diagnosed with CLL (N= 113) entering three randomized trials were assessed prior to start of targeted therapy. ASCO recommended measures of depressive (PHQ-9) and anxiety symptoms (GAD-7) were completed. Information on psychiatric disease characteristics (cancer-specific stress and negative life events) and demographic risk factors (income, gender, marital status and age) were obtained. A multiple linear regression was used to predict depression and anxiety from select ASCO (income, gender and marital status) and additional risk factors (cancer-specific stress, negative life events, age and fatigue).

Results: At baseline, 29.3% of patients were experiencing symptoms of depression (18.6% mild, 6.2% moderate and 4.5% moderate to severe) and 26.8% were experiencing symptoms of anxiety (17% mild, 8% moderate and 1.8% moderate to severe). The results of the regression indicated cancer-specific stress, negative life events and fatigue explained 55% of the variance in depression scores ($R^2 = .553$, $F(3, 110) = 44.173$, $p < .000$) at baseline. Cancer-specific stress ($b = .138$, $p < .000$), negative life events ($b = 1.023$, $p = .012$), and fatigue ($b = .159$, $p < .000$) significantly predicted levels of depression. Additionally, another regression indicated negative life events and fatigue predicted 40% of the variance in anxiety scores ($R^2 = .399$, $F(2, 111) = 36.14$, $p < .000$) at baseline. Negative life events ($b = .193$, $p > .000$) and fatigue ($b = .080$, $p = .002$) significantly predicted levels of anxiety.

Discussion: Screening all cancer patients for distress is a new, important criterion to provide innovative treatment for cancer patients. Determining which factors are correlated with depression and anxiety will improve preventative measures and enable the use of supportive care for cancer patients with greatest risk.

ASSOCIATIONS BETWEEN CANCER SURVIVORS' CHANGES IN AUTONOMIC INDICES AND CHANGES IN SYMPTOMS AFTER MIND-BODY INTERVENTIONS

Kirsti Toivonen, MSc¹, Linda Carlson, PhD², Tavis Campbell, PhD¹¹Department of Psychology, University of Calgary, Calgary, AB, Canada; ²Department of Psychosocial Resources, Tom Baker Cancer Centre, Calgary, AB, Canada

Background: Cancer survivors commonly experience enduring symptoms including distress, insomnia, and pain. These symptoms are associated with both the disease and its treatment and impair well-being. Although the exact mechanisms are unclear, these symptoms may in part be associated with alterations in autonomic nervous system functioning. Mind-body interventions may alleviate symptom burden during and after active cancer treatment. Exploring the association between changes in autonomic functioning and changes in symptoms associated with participation in mind-body interventions may lead to a better understanding of the mechanisms involved in symptom improvement.

Methods: As part of the Mindfulness And Tai chi for Cancer Health (MATCH) study, 18 distressed cancer survivors (any type of cancer, stage I-III) completed psychophysiological testing and self-report symptom measures before and after participation in Mindfulness-Based Cancer Recovery, Tai Chi/Qigong, or a wait-list control group. The autonomic indices examined were high frequency (HF) and low frequency (LF) heart rate variability (HRV), baroreflex sensitivity, and blood pressure. Questionnaires included measures of mood disturbance (Profile of Mood States), sleep disturbance (Pittsburgh Sleep Quality Index), pain (Brief Pain Inventory), and health-related quality of life (Functional Assessment of Cancer Therapy-General). Analyses were exploratory.

Results: Increases in LF-HRV were associated with increased vigor ($r(14) = .48$, $p < .05$), increased physical well-being ($r(14) = .60$, $p < .01$), decreased depressive symptoms ($r(14) = -.55$, $p < .05$), decreased fatigue ($r(14) = -.48$, $p < .05$), and decreased mood disturbance ($r(14) = -.50$, $p < .05$). Increased HF-HRV was associated with decreased fatigue ($r(14) = -.60$, $p < .01$), and decreased baroreflex sensitivity was associated with increased anger ($r(14) = .48$, $p < .05$) and depressive symptoms ($r(14) = .55$, $p < .05$). There were no changes in symptoms associated with changes in blood pressure.

Discussion: There was a pattern of subjective symptom improvement associated with changes in indices of autonomic functioning, particularly increased LF-HRV. This suggests that changes in indices of autonomic functioning are associated with treatment response to mind-body interventions. Future directions include examining the generalizability of findings in a larger sample and investigating associations between improvements in symptoms and other pathways of the stress response.

COMBINING A UV PHOTO INTERVENTION WITH SELF-AFFIRMATION OR SELF-COMPASSION EXERCISES: IMPLICATIONS FOR SKIN PROTECTION

Charlotte J. Hagerman, B.S.¹, Michelle L. Stock, PhD¹, Brianne K. Molloy, M. Phil¹, William Klein, PhD², Janine B. Beekman, PhD³¹George Washington University, Washington DC, DC; ²National Cancer Institute, Potomac, MD; ³Ipsos Public Affairs, Washington, DC, DC

Young adults who view an ultraviolet (UV) photo of their skin damage report increased perceived risk of skin damage/cancer and increased skin protection intentions (Walsh & Stock, 2011). However, threatening health information such as a UV photo can inspire defensive or reactive responses (van't Riet & Ruiters, 2013). The current study combined a UV photo intervention with self-affirmation and self-compassion writing exercises, which have been shown to mitigate defensive responses to health information (Terry & Leary, 2011; Koningsbruggen et al., 2009). Employing a 2x3 experimental design, college women (N=167) were randomly assigned to: 1) view a UV photo or Black and White (No-UV) photo of their face and 2) write a self-affirmation, self-compassion, or neutral (sleep-related) essay.

ANCOVA analyses controlled for skin tone and past skin protection. Women who viewed their UV photo (vs. No-UV) reported higher perceived risk of skin damage ($p < .001$) and skin cancer ($p < .001$). However, these differences were only significant among those in the neutral writing condition ($p < .001$). Women who saw their UV photo and wrote a self-affirmation essay actually reported lower perceived risk of skin damage than those who saw their UV photo and wrote a neutral essay ($p = .04$).

A different pattern emerged with behavioral intentions for skin protection. In general, women who viewed their UV (vs. No-UV) photo had higher intentions to protect their skin from the sun ($p < .001$); however, this increase in intentions was only significant for women in the self-affirmation ($p = .02$) and self-compassion conditions ($p = .02$).

As a proxy for skin protection behavior, sunscreen packets were available for participants to take at the end of the study. Logistic regression revealed that viewing the UV photo (vs. No-UV) increased the odds of taking sunscreen among those in the self-compassion condition ($p = .02$). Also, within the No-UV condition, women who wrote a self-compassion essay were more likely to take sunscreen than those in the neutral ($p = .01$) and self-affirmation ($p = .04$) conditions.

Results suggest that while self-affirmation and self-compassion reduce the impact of a UV photo on increased perceptions of risk, these exercises actually enhance the impact of a UV photo on increased intentions for skin protection. Further, writing about self-compassion may promote actual skin protection behavior, an effect that is optimized when paired with a UV photo intervention.

DECISION-MAKING AFTER A VARIANT OF UNCERTAIN SIGNIFICANCE FROM GENETIC TESTING FOR HEREDITARY BREAST CANCER: EXPERT OPINIONS

Courtney Scherr, PhD¹, Amy A. Ross, MA², Hannah J. Badal, MPH¹, Charlotte G. Marshall-Fricker, N/A³, Neeha Shrestha, MPH¹, Baruch Fischhoff, PhD⁴, Susan T. Vadaparampil, PhD⁵¹Northwestern University, Chicago, IL; ²Northwestern University, Ciudad de Mexico, Distrito Federal, Mexico; ³Northwestern University, Evanston, IL; ⁴Carnegie Mellon University, Pittsburgh, PA; ⁵Moffitt Cancer Center, Tampa, FL

Background: Next generation sequencing (NGS) is regularly used in the context of hereditary breast and ovarian cancer (HBOC) to simultaneously test for mutations in multiple genes. NGS exponentially increases the likelihood of receiving at least one variant of uncertain significance (VUS) result. Guidelines are lacking for patient decision-making after receiving a VUS result. We used a mental models approach to reveal expert opinions about the types of decisions patients should make and the information (factors) they should consider after receiving a VUS from NGS for HBOC.

Methods: Experts in HBOC were recruited via professional networks and respondent-driven sampling (N = 25) to participate in a three-step data collection process beginning with an online survey. Survey responses informed individual in-depth interviews and the real-time interactive development of a mental model diagram. Following analysis of interviews and diagrams, participants responded to a confirmatory online survey. We analyzed baseline survey data using descriptive statistics. Two coders conducted content analysis on the interview transcripts and mental model diagrams using a consensus approach to coding. We analyzed confirmatory survey data using descriptive statistics and chi-square goodness of fit tests.

Results: Based baseline survey and individual interview results, we identified 8 possible decisions (e.g., medical risk management) and 25 factors patients could consider (e.g., personal medical history). We conducted a goodness-of-fit test for each decision, and the associated factors to determine majority agreement χ^2 (1, N = 24) = 4.17, $p = 0.41$). The final list included 4 decisions patients should consider: medical risk management, enrollment in a research study, sharing results with providers, and sharing results with family. We identified from 3 to 12 factors (e.g., patient preference, patient understanding, and patient medical history) that experts believed patients should consider, depending on the decision.

Conclusion: Our study identified key decisions that patients should consider after receiving VUS from genetic testing for HBOC, and key factors to consider when making them. This information can guide genetic counseling about VUS results, and inform educational interventions for patients who receive VUS results from genetic testing for HBOC.

DEPRESSIVE SYMPTOMS (NOT TYPE D PERSONALITY) PREDICT QUALITY OF LIFE IN SURVIVORS OF DIFFERENTIATED THYROID CANCER

Frances Deavers, PhD¹, Chelsea Wiener, MS², Jeffrey Cassisi, Ph.D., Clinical Health Psychologist², Sarah Fleurestil, N/A²

¹Michael E. DeBaakey VA Medical Center, Houston, TX; ²University of Central Florida, Orlando, FL

Survivors of differentiated thyroid cancer (DTC) report impaired quality of life (QoL) despite long duration of cure. Research regarding predictors of QoL in this population has largely been limited to demographic characteristics. Type D personality (high negative affect and social inhibition) is correlated with QoL in other chronic illness populations, but has not been thoroughly assessed in survivors of DTC. Therefore, the present study assessed Type D personality as a predictor of QoL in survivors of DTC. Participants included survivors of DTC registered in the Patient Reported Outcomes Following Initial Treatment and Long-term Survivorship (PROFILES) registry. Psychosocial functioning questionnaires were mailed to 334 survivors. Data from eligible respondents (N = 284) were used in logistic regressions to assess relationships between Type D personality and QoL domains. Depression was controlled for in analyses to address concerns regarding conceptual similarity of Type D personality to depression. Type D personality did not predict physical ($\beta = .146$, SE = 0.383, $p = .703$, Exp(B) = 1.157), social ($\beta = 0.389$, SE = 0.375, $p = .299$, Exp(B) = 1.476), cognitive ($\beta = -0.326$, SE = 0.400, $p = .415$, Exp(B) = 0.722), or role functioning ($\beta = 0.015$, SE = 0.349, $p = .965$, Exp(B) = 1.015) beyond what was predicted by depression. Type D personality did significantly predict impaired emotional functioning ($\beta = 1.253$, SE = 0.370, $p = .001$, Exp(B) = 3.500). Depression significantly predicted impaired QoL in all measured domains. Clinical implications argue for continued screening for depressive symptoms in survivors of DTC, but do not support screening for Type D personality in this population. Depression screening may identify individuals at risk for impaired QoL and is currently recommended for cancer patients, including during the transition to survivorship. While identification of personality factors related to impaired QoL may arguably facilitate personalized treatment recommendations, aside from the domain of emotional functioning, Type D personality was not predictive of QoL after accounting for depression. Therefore, additional screening for Type D personality in this population would likely be of limited clinical utility. Further, assessing for a theoretically unmalleable personality trait (such as Type D personality) rather than for a mutable mood state more readily targeted in treatment may delay effective case conceptualization and intervention.

DEVELOPING A FAMILY HISTORY-BASED COLORECTAL CANCER PREVENTION AMONG CHINESE AMERICANS: A CBPR APPROACH

Ming Li, M.S., Yulyu Chen, PhD, Lei-Shih Chen, Ph.D.

Texas A&M University, College Station, TX

Background: Colorectal cancer (CRC) is the third leading cause of cancer death among Chinese Americans. Nevertheless, Asian Americans have the lowest CRC screening rates among all racial/ethnic groups. Westernized behaviors also increase Chinese Americans' CRC risk. As CRC has a strong genetic predisposition, family health history (FHH) has been proposed as a preventive tool to stratify CRC risk and guide personalized screening and behavioral modifications. The purpose of this study is to use a community-based participatory research (CBPR) approach to develop the first culturally-tailored and linguistically-appropriate FHH-based CRC prevention program for Chinese Americans in Texas.

Methods: This program involved 11 CBPR steps: (1) identifying the partnership, (2) establishing a multidisciplinary team, (3) reviewing existing literature for CRC prevention and FHH-based education, (4) conducting needs assessment among Chinese communities, (5) refining target population, (6) generating a theoretical framework, (7) determining intervention activities, (8) designing educational materials, (9) developing a program evaluation plan, (10) advertising the study, and (11) piloting test and producing a final product.

Results: Key components of this program included a two-hour FHH-based CRC prevention workshop, a free fecal occult blood test, a personalized CRC preventive phone call consultation, and navigation services to health insurance enrollment and doctor visit (if needed). The pilot study indicated the feasibility of the intervention and showed that participants were overall satisfied with the program.

Conclusion: Using CBPR principals, we developed the first culturally and linguistically appropriate FHH-based CRC prevention program for Chinese Americans. This promising project extends beyond traditional CRC prevention programs by adding CBPR, FHH, and navigation components. Pilot data suggested the feasibility to implement this FHH-based CRC prevention program to a large group of Chinese Americans in the future.

DISTRESS AND BURDEN IN PARENTS OF PEDIATRIC BRAIN TUMORS SURVIVORS: THE ROLE OF TREATMENT INTENSITY AND MEDICAL LATE EFFECTS

Kathryn Balistreri, B.A.¹, Emily Ach, PhD², Mary Hagan, B.A.¹, Jennifer Kelleher, B.A and B.S.¹, Cynthia A. Gerhardt, PhD¹, Mary Jo Kupst, PhD³, Andrea F. Patenaude, PhD⁴, Maru Barrera, PhD⁵, Kathryn Vannatta, PhD¹

¹Nationwide Children's Hospital, Columbus, OH; ²Stanford Children's Health/Lucille Packard Children's Hospital, Stanford, CA; ³Medical College of Wisconsin, Milwaukee, WI; ⁴Dana-Farber Cancer Institute, Boston, MA; ⁵SickKids Hospital, Toronto, ON, Canada

Objective: Intensive treatment has achieved improved survival rates for pediatric brain tumor survivors (PBTS), but may increase chronic medical late effects (MLE). Child MLE may increase demands on families and elevate risk for increased caregiver strain. We hypothesized that 1) parents of PBTS who required adjuvant treatment with radiation and/or chemotherapy would report more family burden and caregiver distress than parents of PBTS who required surgery alone and 2) MLE would account for the impact of treatment intensity on caregiver outcomes.

Methods: PBTS ($N=187$, 52% male), aged 8–16 ($M_{age}=11.3$, $SD=2.3$) 1–5 years post-treatment, were recruited from five sites in the USA and Canada. MLE (i.e. hearing, vision and speech deficits, alopecia, seizures, neuromotor and endocrine problems) were recorded from medical records. Parents reported symptoms of distress on the Brief Symptom Inventory and perceived family burden on the Impact on Family Scale. Independent t-tests evaluated treatment group differences in MLE and caregiver outcomes. Regression analyses with post-hoc bootstrapping examined the indirect effects of treatment group on family burden and caregiver distress via MLE.

Results: PBTS treated with adjuvant therapy had more MLE than those treated with surgery alone ($M_{adjuvant}=2.74$, $SD=1.62$; $M_{surgery-only}=1.06$, $SD=1.04$; $t(177)=-7.97$, $p<.001$). Treatment groups did not differ in parental distress; however, mothers ($M_{adjuvant}=30.07$, $SD=6.38$; $M_{surgery-only}=25.28$, $SD=6.32$; $t(171)=-4.93$, $p<.001$), but not fathers ($M_{adjuvant}=23.76$, $SD=15.93$; $M_{surgery-only}=20.16$, $SD=19.40$; $t(109)=-1.07$, $p=2.86$), of PBTS requiring adjuvant therapy reported higher family burden than parents of PBTS treated with surgery alone. Despite group differences in MLE and mother report of family burden, the indirect effect of treatment on maternal burden via MLE was not significant (Bootstrap CI=-.32–3.12). The direct and indirect effects of treatment group on father report of burden and distress in either parent were not significant.

Conclusions: Treatment intensity may influence subsequent burden experienced by mothers but not fathers after children complete treatment for childhood brain tumors. Interestingly, this does not appear to be explained by the co-occurring elevation in MLEs experienced by these children. Future research should investigate other child impairments due to treatment (e.g. cognitive, emotional, social) that may explain the group differences in caregiver outcomes.

EFFECT OF CULTURAL BELIEFS, FATALISM AND PERCEIVED CANCER RISK ON ADHERENCE TO MAMMOGRAPHY AMONG ETHNIC MINORITY WOMEN

Ifeanyi B. Chukwudozie, MPH¹, Silvia Tejada, PhD², Ganga Vijayasiri, PhD³, Vida A. Henderson, PhD, PharmD, MPH, MFA⁴, DeLawnia Comer-HaGans, PhD⁵, Shirley Spencer, PhD⁵, Karriem S. Watson, DHSc, MPH, MS⁶, Carol Ferrans, PhD², Richard Warnecke, PhD⁷, Kent Hoskins, MD²

¹University of Illinois Cancer Center, Chicago, IL; ²University of Illinois at Chicago, Chicago, IL; ³UIC, Chicago, IL; ⁴University of Illinois Cancer Center, Chicago, IL; ⁵Governors State University, University Park, IL; ⁶University of Illinois at Chicago (UIC), Chicago, IL; ⁷University of Illinois at Chicago, Chicago, IL

Background: Medically underserved minority women bear a disproportionate burden of breast cancer (BC) mortality. Early detection is vital for reducing BC mortality. As mammography is the mainstay of early detection, increasing adherence to mammography is crucial in this population.

Objective: The objective of this study is to examine the impact of cultural beliefs, fatalism and perceived BC risk on adherence to mammography in minority women with average and increased risk for BC.

Methods: Women ($N=346$) were recruited from a Federally Qualified Health Center in the Southside of Chicago that provides care primarily for underserved African American and Latino patients. Women attending an annual wellness visit were invited to participate based on the outcome of BC risk assessment conducted at the time of the visit. The assessment tool categorized women into average or increased risk based on age, family history and reproductive history. All increased risk and 1-in-4 randomly selected average risk women were invited to participate in the study. Sociodemographic factors, a Cultural Beliefs scale with items associated with late-stage diagnosis of BC (culturally-associated misconceptions about BC), fatalism and perceived risk of having BC were collected through interviewer-administered surveys. Bivariate and multivariate analyses were performed to determine the association between the dependent and independent variables. Mammography adherence within the past 2 years (dependent variable) was based on self-report.

Results: The sample ($N=151$) for this analysis was limited to women age > 40 years. Among women at increased BC risk, bivariate analysis showed increased fatalism was associated with a lower odds of mammography adherence ($OR=0.693$; $P=0.010$) and older age with a higher odds of adherence ($OR=1.114$; $p=0.005$). Increased perceived BC risk among increased risk women was also associated with a higher odds of adherence ($OR=4.328$; $p=0.033$) when controlling for age. Endorsing a greater number of misconceptions on the cultural belief scale was marginally associated with a lower odds of adherence ($OR=0.843$ $p=0.05$) for all women in the multivariate model.

Conclusion: Cultural beliefs associated with late stage diagnosis of BC are also associated with mammography adherence in underserved minority women. Screening interventions should be culturally sensitive to address these beliefs.

EFFECTIVENESS OF PSYCHOSOCIAL NEEDS AND EMOTIONAL DISTRESS ASSESSMENT IN AN NCI-DESIGNATED CANCER CENTER

Jessica Hamilton, Ph.D.¹, Danielle Miro, PhD², Kevin Young, Ph.D.¹, Catherine Rowe, Ph.D.³, Bethany Aiena, PhD⁴

¹University of Kansas Health System, Kansas City, KS; ²University of Kansas Medical Center, Kansas City, MO; ³Colorado Health Foundation, Denver, CO; ⁴Southeast Louisiana Veterans Health Care System, New Orleans, LA

Background: Increased emotional distress is frequently reported among persons with cancer and has been found to be associated to poorer outcomes (e.g., decreased quality of life and treatment noncompliance). The CoC mandate 3.2 addresses this issue and states that distress must be measured at least once. This standard was implemented on January 1, 2015. While most accredited institutions are assessing distress, the evaluation of its effectiveness and efficiency to provide care is not well established. Developing and identifying effective measures to improve patient outcomes remains essential, and a pathway may exist by examining staff/provider perceptions of such measures to increase utilization and integration of such measures.

Objectives: We explored provider and staff knowledge and satisfaction of the implementation of the Patient Need Assessment (PNA) and their understanding of the workflow and utility of patients needs within an NCI-designated Cancer Center. The PNA, which is administered to all patients within the cancer center at their second appointment via paper/pencil, is aimed at identifying a patient's current level of distress and examining practical, emotional, nutritional, spiritual, and physical concerns, while offering patients' referral to supportive services.

Method: All providers and staff working within the cancer center were invited to participate in an online evaluation of the PNA implementation. Descriptive statistics and thematic analyses were used to assess provider/staff satisfaction of the PNA.

Results: Roughly 1/3 of all staff completed the online survey with a total 64 staff/provider respondents. Almost half of the staff respondents were nurses or medical assistants. Most staff reported familiarity of the PNA but were unaware of national guidelines for screening of distress and did not find the assessment to be useful in managing patient care.

Conclusions: Amongst staff or providers, many were unfamiliar with the necessity of addressing or assessing psychosocial needs in cancer patients, suggesting a discrepancy in providing holistic care and integration of the PNA to patient care. Exploratory findings suggested that with regard to workflow and administration of the PNA, utilizing tablets and/or having patients complete the PNA prior to their first visit might increase provider/staff valuation of the PNA. Yet, findings suggest an imminent need for how to best evaluate and address psychosocial and emotional distress among patients with cancer to increase health outcomes. Evaluation findings also indicated a need to unify employees via education of the need and utility of the PNA. In addition, positive reinforcement for their effort in administering the PNA effectively may increase its perceived value within the institution. Future research may want to assess how staff knowledge in these mandates is related to values in administration of these quality standards.

ESTABLISHING PATIENT PROFILES TO PREDICT USE OF A PROSTATE CANCER SURVIVORSHIP WEBSITE: IMPLICATIONS FROM A MULTI-SITE RCT

Allison Marziliano, PhD¹, Michael A. Diefenbach, Ph.D.¹, Shawna Hudson, PhD², Sara Fleszar, B.A.¹, Erin K. Tagai, PhD, MPH³, Alicja Bator, MPH², David Y. T. Chen, MD³, Brett Cox, MD¹, Simon Hall, MD¹, Alexander Kutikov, MD³, Curtis Miyamoto, MD⁴, Louis Potters, MD⁵, Adam Reese, MD⁴, Manish Vira, MD¹, Gianna Torre, B.A.¹, Caitlin DeCoster, MPH¹, Roshni Bhat, BS¹, Siu-kuen Azor Hui, PhD, MSPH⁶, Suzanne M. Miller, PhD³

¹Northwell Health, Manhasset, NY; ²Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ; ³Fox Chase Cancer Center, Philadelphia, PA; ⁴Lewis Katz School of Medicine at Temple University, Philadelphia, PA; ⁵Northwell Health, Lake Success, NY; ⁶Dr. Robin Lowey & Associates, LLC, Philadelphia, PA

Background PROGRESS is a web-based resource for prostate cancer (PC) survivors. It has been designed to empower survivors to effectively manage and cope with treatment-related side effects. Prior to release, PROGRESS was pilot tested for ease of use, content, and acceptability. The goal of this study was to examine patient characteristics related to PROGRESS usage, to aid in the future dissemination of this patient resource tool. Methods PC survivors (N=434) were randomly assigned to receive either PROGRESS (intervention group; n=216) or printed educational materials (control group; n=218). Chi-square and independent sample t-tests were used to analyze baseline characteristics of intervention group participants and their PROGRESS website usage at one month. Results The majority of participants were White (n=310, 71.4%), non-Hispanic (n=375, 86.4%), and married (n=346, 79.7%), with an average age of 63.52 (SD=7.12, Range: 42–86). Of the 216 patients randomized to PROGRESS, 87 (41%) reported using the website vs. 125 (59%) non-users. Users, compared to non-users, were more likely to be White (p=.015), older in age (p=.017), and be significantly more knowledgeable of their PSA (p=.047). Website users, compared to non-users, were more health literate (M=4.51, SD=.65 v. M=4.26, SD=.81, p=.016) and demonstrated a greater drive to seek information (M=2.87, SD=1.99 v. M=2.22, SD=2.30, p=.029). Conclusions Non-white, younger patients with less knowledge about their diagnosis, lower health literacy, and a low desire to seek information were less likely to utilize the PROGRESS website. Thus, those currently using the website are the very patients who already have access to and utilize resources and support. To reach and support underserved patients, future studies involving web-based interventions need to incorporate targeted support in the form of website and computer training, pamphlets, and motivational messages through telephone or text reminders. These practices may enhance usage of web-based interventions and increase engagement among those patients who are likely to benefit most from the offered programs.

EVALUATING THE EFFICACY OF A WEB-BASED SUPPORT TOOL FOR PROSTATE CANCER SURVIVORS: RESULTS FROM THE MULTI-SITE PROGRESS STUDY

Michael A. Diefenbach, Ph.D.¹, Shawna Hudson, Ph.D.², Allison Marziliano, Ph.D.¹, Sara Fleszar, B.A.¹, Erin K. Tagai, Ph.D., MPH³, Alicja Bator, MPH², David Y. T. Chen, MD³, Brett Cox, MD¹, Simon Hall, MD¹, Alexander Kutikov, MD³, Curtis Miyamoto, MD⁴, Louis Potters, MD⁵, Adam Reese, MD⁴, Manish Vira, MD¹, Gianna Torre, B.A.¹, Caitlin DeCoster, MPH¹, Roshni Bhat, BS¹, Siu-ken Azor Hui, PhD, MSPH⁶, Suzanne M. Miller, PhD³

¹Northwell Health, Manhasset, NY; ²Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ; ³Fox Chase Cancer Center, Philadelphia, PA; ⁴Lewis Katz School of Medicine at Temple University, Philadelphia, PA; ⁵Northwell Health, Lake Success, NY; ⁶Dr. Robin Lowey & Associates, LLC, Philadelphia, PA

Background PROGRESS is a web-based resource for prostate cancer (PC) survivors aimed at the post-treatment, early survivorship period. Content consists of patient and physician videos, interactive symptom tracking features to document recovery, and information based on the latest behavioral evidence to improve coping skills, physical functioning, and emotional well-being. Methods Data were drawn from one-month post-randomization assessments of patients recently treated for PC and randomized to PROGRESS or a control group (receiving NCI print materials). The purpose of these analyses was to evaluate the efficacy of PROGRESS on outcomes including: coping, depression, mood/affect, and patient-provider interactions. Two sets of mean difference tests on these outcomes were conducted: first, comparing intervention (n=168) and control (n=174), and next, comparing, within the intervention arm, website users (n=76) v. non-users (n=81). Results The majority of patients were White (75%), non-Hispanic (88%) and married (82%), with an average age of 63.61 (Range: 42–85, SD=7.12). There were no significant differences between the intervention and control groups on baseline demographics, nor on one month post-randomization assessments. In light of the potential for dilution of the intervention effect due to a significant proportion of non-users in the intervention group and an enhanced control comparison, we compared PROGRESS users and non-users to more accurately evaluate the intervention. Within the intervention arm, patients who utilized the website, compared to those who did not, were, at one month follow-up, more likely to engage in active coping, (p=.04), had less depression (p=.03) and depressed mood (p=.04), had more positive affect (p=.007), and had fewer difficulties with medical interactions (p=.05). Conclusions For the subgroup of patients who chose to actively use the PROGRESS website, the intervention showed the hypothesized effect on coping and quality of life. However, uptake is not optimal and therefore should be directly addressed in the research design of survivorship aids. Future research involving software based interventions should consider targeting vulnerable patients who are likely non-users but may benefit from such aids and provide motivational support to sustain usage.

EVALUATION OF A COMMUNITY-BASED EXPERIENTIAL NUTRITION AND COOKING EDUCATION PROGRAM FOR CANCER SURVIVORS

Melissa F. Miller, PhD, MPH¹, Alice Bender, MS, RDN², Catrina L. Feeney, RD³, Jill Kaplan, LCSW⁴, Deirdre McGinley-Gieser, BA⁵, Jeanne Petrucci, MS, RDN⁶, Angie Santangelo, LISW-S⁷, Claire Saxton, MBA¹, Beverley Soult, Ohio⁷, Amy J. Sutton⁸, Julie Taylor, BA¹, Alexandra Zaleta, PhD⁹

¹Cancer Support Community, Washington, DC; ²American Institute for Cancer Research, Arlington, VA; ³Fairfield Medical Center, Columbus, OH; ⁴Cancer Support Community of Central New Jersey, Bedminster, NJ; ⁵American Institute for Cancer Research, Arlington, VA; ⁶Living Plate, Far Hills, NJ; ⁷Cancer Support Community Central Ohio, Columbus, OH; ⁸Cancer Support Community Central NJ, Bedminster, NJ; ⁹Cancer Support Community, Philadelphia, PA

Introduction: The Cancer Support Community (CSC) provides psychosocial support to people facing cancer in community settings. The purpose of this study was to evaluate the compatibility, effectiveness, and fidelity of the Coping with Cancer in the Kitchen (CCK) experiential nutrition and cooking education program at CSC Central New Jersey and Fairfield Medical Center in Ohio. The program is designed to increase acceptance and consumption of a mostly plant food diet. Program content is based on American Institute for Cancer Research (AICR) Recommendations for Cancer Prevention and two evidence based programs, “The New American Plate®” and “Foods That Fight Cancer™”. The behavior change approaches in CCK, including group counseling and support, are consistent with CSC’s approach to psychosocial care.

Methods: A Registered Dietitian (RD) and Licensed Clinical Social Worker (LCSW) at each site implemented CCK. Cooking confidence, knowledge, dietary intake (NCI’s Dietary Screener Questionnaire), and health-related quality of life (FACT-G) were assessed before and after the 7-week intervention. We analyzed quantitative results using unadjusted statistical tests and reviewed qualitative comments by participants as well as meeting notes and written reflections of program staff to assess program compatibility and fidelity. Effect size was calculated by dividing the pre-post difference mean by the SD (Cohen’s d).

Results: 21 survivors of breast (n=12), blood (n=3), gynecologic (n=3), esophageal (n=1), colorectal (n=1), and melanoma (n=1) cancers participated, with 16 completing pre- and post-test surveys. Participants reported an increase in cooking confidence (p=.002, d=0.96), perceived control over cancer (p=.034, d=0.58), perception of dietary quality (p=.009, d=0.76), and weekly self-reported skills capacity, including knowledge and ability to prepare plant-based foods (p=.0002, d=1.0). There was a decrease in meals eaten away from home (p=.026, d=0.61). There was a non-significant (NS) trend in increase in fruit, vegetable, and whole grain intake, with desirable effect sizes for intake of beans (d=0.39), vegetables (d=0.41), and cooked whole grains like brown rice and quinoa (d=0.36). Results also suggested a NS trend in increase in health-related quality of life (p=.067). Participants and staff endorsed the intervention as compatible with CSC’s mission and viewed it as feasible to implement with high fidelity.

Conclusion: Cancer survivors participating in the evidence-based nutrition and psychosocial intervention experienced positive cognitive and behavioral changes after 7 weeks. This pilot project demonstrates that community-centered education and support services led by trained providers can address eating and nutrition needs and empower those living with cancer in CSC centers and hospital settings.

EXTENDING THE PHYSICAL ACTIVITY AND CANCER SURVIVORSHIP REACH: THE CASE OF ACTIVEMATCH

Catherine Sabiston, PhD¹, Angela Fong, PhD²¹University of Toronto, Toronto, ON, Canada; ²Queen's University, Toronto, ON, Canada

Background: Physical activity (PA) is a safe and effective strategy to help reduce many acute and chronic side effects of a cancer diagnosis. In spite of the well-known benefits of PA, most women diagnosed with cancer are not physically active, which suggest an apparent knowledge-to-action gap. Drawing on PA knowledge translational science in oncology and knowledge mobilization frameworks, the purpose of this study was to bridge this gap by developing and evaluating a PA resource for improving PA among women diagnosed with cancer.

Methods & Results: In line with a knowledge mobilization plan, five guiding principles were followed to extend PA and cancer knowledge reach. First, a rigorous review of PA resources, programs, and interventions was conducted to “*get to know the audience and issues*”. Low levels of PA, and lack of translational science methods were outcomes. Second, women diagnosed with breast cancer (N=201) completed a needs assessment survey to identify “*preferred and credible sources of PA information*”. Lack of social support, limited access to PA partners, and limited knowledge of cancer among fitness trainers were main barriers to PA among women diagnosed with cancer. Third, through focus groups with N=9 women diagnosed with cancer, “*audience-specific messages and practices*” were developed in the form of ActiveMatch (activematch.ca) - an online and app platform to help women find PA partners. ActiveMatch was launched and women using the platform provided information on preferences for PA. ActiveMatch users (N=165; Mean age = 47, 70% breast cancer, 65% in active treatment) suggest weight loss and emotional health as main goals for PA. Preferences for walking (90%), outdoor PA (53%), and morning PA (38%) have been identified. Nearly all women (95%) wanted one PA partner. Fourth, the “*effectiveness of message conveyance*” was explored using 8 community group discussions with women diagnosed with cancer and fitness trainers. In focus groups, interviews, and informal discussions, over 30 cancer care practitioners have identified ActiveMatch as a credible resource for PA information and support and suggest that ActiveMatch fills a gap in PA service. As an indicator of success, a breast cancer and PA non-profit organization has collaborated with ActiveMatch to continue to build PA and cancer resources, opportunities, and partnerships. The “*evaluation of effectiveness*” step in the knowledge mobilization plan is on-going.

Conclusions: In line with a community partnership, ActiveMatch provides a credible resource for improving PA among women diagnosed with cancer and is an example of successful “extension of reach” for next steps in increasing PA for enhanced well-being and health of the hundreds of women diagnosed with cancer each day.

HOLDING BACK ASSOCIATED WITH CAREGIVER STRAIN AND DISTRESS AMONG CAREGIVERS OF PATIENTS WITH ADVANCED CANCER AND PAIN

Blair Puleo, BA¹, Francis Keefe, PhD¹, Janet Bull, M.D.², Laura Hanson, M.D., M.P.H.³, Stacy Fischer, M.D.⁴, Thomas Leblanc, M.D.⁵, Jennifer Steele, Ph.D.⁶, Laura Porter, PhD¹

¹Duke University Medical Center, Durham, NC; ²Four Seasons Hospice and Palliative Care, Flat Rock, NC; ³UNC School of Medicine, Chapel Hill, NC; ⁴University of Colorado Anschutz Medical Campus, Aurora, CO; ⁵Duke University School of Medicine, Durham, NC; ⁶University of Pittsburgh, Pittsburgh, PA

Background: For patients and their family caregivers, advanced cancer poses significant physical and emotional challenges that can negatively impact both individuals. When patients have pain, the impact on the caregiver can be particularly profound, with caregivers often feeling overwhelmed, frustrated, and helpless. In studies of couples coping with cancer, the ability to communicate openly and effectively with each other about cancer-related concerns has been associated with better psychological adaptation, while holding back from discussing concerns is associated with greater distress. Few studies, however, have examined holding back in the context of family caregivers of patients with advanced disease and pain. The purpose of the present study was to examine associations between caregivers' reports of holding back from discussing cancer-related concerns with the patient and measures of caregiver distress.

Methods: Participants were 99 patients with Stage IV cancer who reported pain ≥ 4 and their family caregivers. The mean age of the patients was 64.5 years, 65% were male, 79% were Caucasian and 15% African American. Most frequent cancers sites were lung (20%), GI (19%), and prostate (13%). The mean age of the caregivers was 59.9 years, 27% were male, 74% Caucasian and 17% African American. Caregivers were primarily spouses/partners (69%) and adult children (13%) of the patients. Caregivers completed the Holding Back subscale of the Emotional Disclosure Scale, the Caregiver Strain Index, the Center for Epidemiology Studies Short Depression Scale, and the Trait Anxiety Index.

Results: Caregivers in this study reported higher levels of holding back (mean=2.00, SD=1.1) than typically reported by spouses in previous studies. Pearson correlation analyses demonstrated significant associations in the expected directions. Higher levels of caregiver holding back were associated with higher levels of caregiver strain (.04, $p = .05$). Additionally, higher levels of caregiver holding back were correlated with higher levels of depression and anxiety (.001, $p = .005$).

Conclusions: These findings suggest that family caregivers of patients with advanced cancer and pain may have difficulty talking about cancer-related concerns with their loved ones, and that holding back is associated with higher levels of caregiver strain and psychological distress. Additional longitudinal data from this ongoing study may provide insight into whether strain/distress is a result or a cause of holding back. These findings will be discussed relative to their implications for interventions aimed at developing more effective ways to help patients and their caregivers cope with cancer and pain.

INVOLVEMENT IN DECISION-MAKING, AND USE OF INTEGRATIVE ONCOLOGY IMPROVE BREAST CANCER SURVIVOR HRQOL IN EARLY SURVIVORSHIP

M. Robyn Andersen, PHD, MPH¹, Erin S. Sweet, ND, MPH, FABNO², Leanna Standish, ND, PhD, FABNO³

¹Fred Hutchinson Cancer Research Organization, Seattle, WA; ²Bastyr University, Kenmore, WA; ³Bastyr University, Kenmore, WA

Objective: This study sought to describe changes in the health related quality of life (HRQOL) of women who do and do not receive integrative oncology (IO) Complementary and Alternative Medicine (CAM) care during and immediately after breast cancer treatment, and explores the predictive role of, demographic characteristics, IO CAM care, and involvement in decision-making on HRQOL.

Methods: Matched cohorts of breast cancer survivors who did and did not supplement their breast cancer treatment with IO care within two years of diagnosis participated. IO users were identified through IO clinics and usual care controls with similar prognosis were identified through a cancer registry. The registry provided information about all participants' age, race, ethnicity, marital status, stage of cancer at time of diagnosis, and use of conventional medical treatments. Participants' self-reported their involvement in decision-making about their treatment, and completed a HRQOL assessment using the SF-36 instrument. Information about involvement and HRQOL was collected at study enrollment and at 6-month follow-up.

Results: Multiple regression analyses examined change in SF-36 scale scores to 6-month follow-up by including baseline scores as a predictor. Additional predictors examined included: study enrollment matching variables, time since diagnosis at enrollment, treatment received (surgery type, use of chemotherapy, and use of radiation) and involvement in decision-making. These analyses revealed self-reported involvement in decision-making about cancer treatment at study enrollment to associated with better Role-Physical, Role-Emotional, and Social-Functional well-being as assessed by the SF-36 scales at 6-month follow-up ($p < 0.05$), in both bivariate analyses and when included in multivariate adjusted models ($p < 0.05$). Cohort also proved to be a statistically significant predictor of change in the General Health subscale of the SF-36 such that women in the IO cohort reported larger improvements over the 6-month interval immediately following the initiation of IO treatment ($p < 0.05$). Race, age, marital status, and congruence of preferred and achieved levels of involvement, also predicted aspects of HRQOL in breast cancer survivors at enrollment and follow-up ($p < 0.05$).

Conclusions: Both involvement in decision-making about cancer treatment, and IO CAM care may be associated with better HRQOL in breast cancer survivors.

LIFESTYLE PATTERNS AND MORTALITY FOLLOWING BREAST CANCER AMONG PARTICIPANTS OF THE CAROLINA BREAST CANCER STUDY

Humberto Parada, Jr., PhD¹, Xuezheng Sun, PhD², Chiu-Kit Tse, MSPH², Andrew F. Olshan, PhD², Melissa A. Troester, PhD²

¹San Diego State University, San Diego, CA; ²University of North Carolina at Chapel Hill, Gillings School of Global Public Health, Chapel Hill, NC

Purpose: To identify distinct lifestyle patterns based on five behavior/dietary exposures among a population-based sample of women diagnosed with breast cancer, and to examine their association with subsequent mortality.

Methods: In the Carolina Breast Cancer Study (Phases I/II), 1,808 women aged 20–74 were interviewed on average within six months of a first diagnosis of invasive breast cancer and followed since diagnosis (median=13.56 years). Vital status was determined using linkage to the National Death Index (717 deaths, 427 from breast cancer). We identified lifestyle patterns using Latent Class Analysis based on five behavior/dietary exposures: never/former versus current smokers; low versus high vegetable (<14 vs ≥14 cups/week) and fruit (<10.5 vs ≥10.5 cups/week) intake; low/moderate versus high (<7 vs ≥7 drinks/week) alcohol consumption; and no versus any (<1 vs ≥1 time/week) physical activity. We used Cox regression to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for breast cancer-specific and all-cause mortality.

Results: We identified three distinct lifestyle patterns: Class 1=healthy behavior-healthy diet (HB-HD, n=916); Class 2=unhealthy behavior-healthy diet (UB-HD, n=233), and Class 3=healthy behavior-unhealthy diet (HB-UD, n=659). Compared to HB-HD pattern, the UB-HD and HB-UD patterns were associated with 33% (HR=1.33, 95% CI=1.04–1.69) and 22% (HR=1.22, 95% CI=1.03–1.46) increases, respectively, in risk of all-cause mortality. The influence of lifestyle on overall mortality was found to vary by follow-up time and race, but not estrogen receptor status. The lifestyle patterns were not associated with breast cancer-specific mortality.

Conclusions: Women diagnosed with breast cancer may adopt varying lifestyle patterns that influence overall mortality.

MEASURING THE CAREGIVER EXPERIENCE IN HEMATOPOIETIC CELL TRANSPLANTATION (HCT): HOW DOES THE CQOLC PERFORM?

Kristina Brookshire, M.A.¹, Casiana Warfield, B.S.¹, Leah McDiarmid, B.A.¹, Rachel Kentor, M.S.¹, Lauren Ostarello, M.S.¹, Tracey Churay, M.S., CCRP², Michelle Byrd, Ph.D.¹, Flora Hoodin, Ph.D.¹, Sung Won Choi, M.D., M.S.³

¹Eastern Michigan University, Ypsilanti, MI; ²Michigan Medicine, Ann Arbor, MI; ³Department of Pediatrics/ School of Medicine/ University of Michigan, Ann Arbor, MI

Measuring the caregiver experience in Hematopoietic Cell Transplantation (HCT): How does the CQOLC perform?

Family CGs of patients undergoing HCT are at risk for significant levels of distress that can also impact patients (Bevans et al., 2011; Bevans & Sternberg, 2012), highlighting the two-fold importance of understanding the caregiving experience. The aim of this study was to examine the CG experience in the context of an ongoing clinical trial of an mHealth tool (BMT Roadmap), and investigate psychometric properties of the Caregiver Quality of Life Index-Cancer (CQOLC; Weitzner et al., 1999) compared with other established measures.

Primarily white female CGs were electronically surveyed at admission, discharge, and day 100: 15 pediatric CGs (PCGs; mean age 37 years) and 16 adult CGs (ACGs; mean age 57 years). All completed the CQOLC. PCGs also completed the Impact of Events Scale-Revised (IES-R; Weiss et al., 1997), assessing post-traumatic distress related to transplant. ACGs completed the Caregiver Cancer Related Distress Inventory (CTXD; Syrjala, 2010).

Internal reliability of the CQOLC total score was high (Cronbach's alpha=.86-.96), but was more variable across subscales (Cronbach's alpha=.56-.91 in PCGs and .71-.92 in ACGs). Overall, the CQOLC improved significantly across time for PCGs, $F(2,28)=3.55$, $p=.04$ ($\eta^2=.20$), but not ACGs. Post-hoc analyses showed improvement in CQOLC between admission and discharge ($p<.01$) for PCGs. The Burden subscale improved over time for both PCGs, $F(2,28)=7.27$, $p<.01$ ($\eta^2=.34$) and ACGs, $F(2,30)=5.75$, $p<.01$ ($\eta^2=.28$). No other subscales changed across time. Correlation analyses indicated divergent validity between CQOLC and the IES-R among PCGs and convergent validity between CQOLC and the CTXD subscales among ACGs ($r=.63$, $p=.03$ to $r=.89$, $p<.001$). ACG CQOLC scores were better than published means of ACGs of patients with various types of cancer, advanced stage cancer, or in palliative care ($p<.001$; Sun Rhee, 2008; Wadhwa, 2011; Weitzner, 1999). The literature lacks relevant comparators for PCGs.

These results support the CQOLC as a valid measure that can monitor change across the acute HCT experience. Although HCT ACGs showed less life disruption than comparable samples, our findings indicate caregiving may have a different trajectory depending on whether caring for an adult or child/adolescent. These outcomes suggest future studies could deploy the CQOLC to investigate the bidirectional effects of caregiving on CGs and patients, and further examine differential effects of caring for an adult or pediatric HCT patient.

ONCOLOGY CLINICIANS' ATTITUDES AND BARRIERS TOWARD THE ENROLLMENT OF UNDERSERVED POPULATIONS INTO CANCER CLINICAL TRIALS

Giselle K. Perez, PhD¹, Elyse Park, Ph.D., MPH², Ryan Nipp, MD, MPH¹, Katharine Quain, B.S.¹, Emily Gorton, MPH¹, Bruce Chabner, M. D.³, Beverly Moy, MD, MPH¹

¹Massachusetts General Hospital, Boston, MA; ²MGH, Boston, MA; ³Harvard Medical School, Boston, MA

Cancer clinical trials represent the "gold standard" for testing the safety and efficacy of novel cancer therapies. Optimizing trial participation is critical to ensuring the generalizability of trial findings across diverse groups. However, trial enrollment rates remain suboptimal, with as few as 2–5% of adult cancer patients participating in NCI-sponsored cancer clinical trials. Notably, racial/ethnic minority, socioeconomically disadvantaged, and rural populations are underrepresented in clinical trials. Although studies demonstrate that clinician support largely influences patients' decisions to participate in trials, few studies have sought in-depth means to elicit oncology clinicians' perspectives for improving trial accrual, particularly among underrepresented groups. To identify factors that informed clinicians' decision to recommend and enroll minority and socioeconomically disadvantaged patients into cancer trials, we conducted in-depth qualitative interviews in 2016–2017 with 17 oncologists (mean age=46, female=38%; White=75%) at a large academic medical center. Content analysis of the interviews revealed several barriers, including 1) clinician burnout; 2) conflicts of interest and ethical dilemmas; and 3) ambivalence about the risks and benefits of clinical trials. Many oncologists reported that trial logistics (e.g., physical risks) conflicted with their commitment to reduce harm and ensure patient well-being. While clinicians acknowledged the value of clinical trials, they struggled with recommending enrollment to patients with literacy, psychiatric, financial, and other socioeconomic vulnerabilities. Concerns about the legitimacy of informed consent, perceived lack of clinical equipoise, and fear of personal bias due to conflicting interests (e.g., own academic advancement from clinical trial enrollment) influenced clinicians' decisions to recommend clinical trials during treatment discussions. Clinicians also identified patient and oncologist-specific needs to address these challenges, including increasing informational and financial support for patients and involving personnel other than the treating clinician (e.g., navigator) to assist with clinical trial enrollment. Findings suggest that clinical trial navigation programs for both the patient and oncologist may help reduce access barriers and increase enrollment of underrepresented patients into cancer clinical trials.

PERCEPTIONS OF THE HPV VACCINE AMONG EAST AFRICAN IMMIGRANT MOTHERS

Linda K. Ko, PhD¹, Vicky Taylor, MD¹, Farah Mohamed, MSW, MPH², Hoai Do, MPH³, Fanaye Gebeyaw, MPH⁴, Anisa Ibrahim, MD³, Lette Hadgu, MA, Guidance and Counseling⁴, Ahmed Ali, PharmD⁵, Rachel Winer, PhD⁴

¹Fred Hutchinson Cancer Research Center, Seattle, WA; ²Department of Epidemiology - University of Washington, Seattle, WA; ³Harborview Medical Center, Seattle, WA; ⁴University of Washington, Seattle, WA; ⁵Somali Health Board, Seattle, WA

Title: Perceptions of the HPV vaccine among East African immigrant mothers: results from formative work to design education materials for mothers and adolescents.

Background: HPV vaccine uptake is lower among adolescents of East African descent than in the overall US adolescent population. We conducted focus groups with Somali, Ethiopian, and Eritrean immigrant mothers in King County, Washington to gather information about their knowledge and perceptions of the HPV vaccine, and identify HPV vaccination barriers and facilitators. Our findings informed the content of a group education module for East African mothers and a comic book for East African adolescents.

Methods: We convened three separate focus groups in Somali, Amharic, and Tigrinya (with 9–11 mothers per group, n=30). Mothers were eligible to participate if they were fluent in one of the three languages and had ≥1 child between the ages of 11–17 years. The focus group guide was informed by the Anderson Behavioral Model of Health Services (predisposition, enabling, and need for care factors) and the Social Context Framework. We coded transcripts and identified themes of relevance to intervention development.

Results: Participants' mean (standard deviation) age was 41.0 (5.6) years, and they had 9.5 (4.5) years of formal education. Most were married (80%), and had 1–2 children between the ages of 11–17 years. Five (16.7%) reported that ≥1 of their children had received the HPV vaccine. Themes emerged around predisposing, enabling, and need for care factors. Predisposing factors included general perception of vaccines, lack of knowledge of HPV vaccine benefits, and concerns around vaccine side effects. Receiving information from trusted sources such as healthcare providers, family members, and friends were enabling factors. Need for care factors included age and gender-specific HPV vaccine information, places to access relevant information, and opportunities to interface with culturally sensitive healthcare providers. Social and religious factors also impacted HPV vaccine uptake.

Conclusion: Through this formative research process we were able to explore knowledge and perceptions of the HPV vaccine, as well as identify barriers and facilitators to HPV vaccination among East African immigrant mothers. Our findings are relevant to the development and implementation of culturally appropriate interventions to increase HPV vaccination rates in East African immigrant communities.

QUALITATIVE EVALUATION OF A PHYSICAL ACTIVITY INTERVENTION FOR SOCIOCULTURALLY DIVERSE ENDOMETRIAL CANCER SURVIVORS.

Amerigo Rossi, EdD¹, Monica Ortiz, MPH, MFA², Leeja Carter, PhD¹, Carol Garber, PhD³, Dennis Kuo, MD⁴, Nicole S. Nevadunsky, MD⁴

¹LIU Brooklyn, Brooklyn, NY; ²NYC Department of Education, Brooklyn, NY; ³Teachers College Columbia University, New York, NY; ⁴Montefiore Medical Center, Bronx, NY

Introduction: Endometrial cancer survivors are the least physically active of all cancer survivors, and are at elevated risk of developing comorbidities. Research exploring perceptions of physical activity (PA) among socioculturally diverse endometrial cancer survivors is in its infancy. The primary aim of the current study was to qualitatively explore endometrial cancer survivors' experiences and perceptions following a 12-week PA intervention to gain a more complete understanding of survivors' experiences.

Methods: Sixteen participants who had completed a 12-week PA intervention based on Social Cognitive Theory volunteered to participate in this study. Inclusion criteria were body mass index ≥ 30 kg·m⁻², English-speaking survivors of endometrial cancer at least six-month post-treatment who had not exercised regularly during the previous six months and lived in Bronx, NY. Participants completed one-on-one semi-structured interviews with one of the two fitness class instructors regarding motivators and barriers to PA, as well as their perceptions of the 12-week intervention. A phenomenological approach was used to interpret participants' experiences.

Results: The sample was older (mean: 64 years, range: 42 – 74 years) and obese (mean BMI: 38.0, range: 30 – 54 kg·m⁻²). The sample was also ethnically diverse, including 7 Hispanic, 4 non-Hispanic black, and 4 non-Hispanic white participants. The primary types of PA included leisure-time physical activity (e.g., doing household chores) or walking (e.g., walking). Participants reported their motivating factors for PA were maintaining or improving health, being able to participate in family life (including for their dogs) and reducing weight and/or waist size. The overwhelming majority of participants reported weather (heat and/or cold) and pain from various injuries to be their greatest PA barriers. The perceived intervention benefit that came up most often was the positive impact of the social interactions with their peers regarding both motivating them to come to class and being able to share with friends.

Conclusion: Future interventions with similar populations should emphasize PA programs with a large social component that focuses on pain attenuation and ways to keep active during poor weather. Furthermore, these programs may incorporate increasing walking and PA during activities of daily living to most effectively improve health.

QUALITY OF LIFE IN PEDIATRIC BRAIN TUMOR SURVIVORS: ROLE OF SPECIFIC AND CUMULATIVE MEDICAL LATE EFFECTS

Jennifer Kelleher, B.A and B.S.¹, Mary Hagan, B.A.¹, Kathryn Balistreri, B.A.¹, Maru Barrera, PhD², Cynthia A. Gerhardt, PhD¹, Mary Jo Kupst, PhD³, Andrea F. Patenaude, PhD⁴, Kathryn Vannatta, PhD¹

¹Nationwide Children's Hospital, Columbus, OH; ²SickKids Hospital, Toronto, ON, Canada; ³Medical College of Wisconsin, Milwaukee, WI; ⁴Dana-Farber Cancer Institute, Boston, MA

Purpose: Aggressive treatment achieves 5-year survival rates for 65% of children with brain tumors; but two thirds experience medical late effects (MLE) including sensory, neuromotor and endocrine dysfunction. Although pediatric brain tumor survivors (PBTS) are also at risk for diminished physical and psychosocial quality of life (QoL), little is known about linkages with specific MLE or the cumulative burden of multiple MLE.

Methods: 187 PBTS (52% male), age 8–16 years ($M=11.3$, $SD=2.2$), and their caregivers participated at 5 sites in the U.S. and Canada. Caregivers completed the Child Health Questionnaire (CHQ) to assess child psychosocial and physical QoL. PBTS completed the Harter Self-Perception Profile for Children (SPPC), assessing psychosocial (social acceptance, behavior, self-worth) and physical (athletic) competencies. Medical records provided data about MLE including sensory (hearing, vision) and speech deficits, alopecia, seizures, neuromotor and endocrine problems. T-tests and correlations analyzed the association of MLE on QoL.

Results: Overall, PBTS' physical ($M=45.2$, $SD=13.0$; $t(186)=-8.3$, $p<.01$) and psychosocial ($M=50.0$, $SD=8.3$; $t(186)=-1.2$, $p<.05$) QoL were lower than CHQ norms. PBTS self-report of physical (athletic) and psychosocial (social acceptance and self-worth) domains of the SPPC were lower than normative data. Most (80%) PBTS had at least one MLE and 52% had 2 or more. Cumulative MLE predicted poorer physical ($r = -.21$, $p<0.01$) but better psychosocial ($r = .17$, $p <.05$) QoL on the CHQ. Children with vision ($t(174)= 3.7$, $p<0.01$), neuromotor ($t(179)= 3.1$, $p<0.01$), hearing ($t(174)= 2.4$, $p=.02$) and endocrine deficits ($t(147)= 4.3$, $p<0.01$) had lower physical QoL than PBTS without those MLE. Although, caregivers reported better psychosocial QoL for children with more MLE, PBTS with an endocrine, sensory or neuromotor difficulty scored lower than other PBTS on at least one psychosocial domain of the child report SPPC. Perceived athletic/physical competence was also linked to MLE.

Conclusion: The association of MLE with QoL for PBTS is complex. Caregiver and self-reports consistently linked physical QoL to MLE for PBTS, but discrepancies emerged in analysis of psychosocial domains. Surprisingly, PBTS, but not their caregivers, reported diminished psychosocial functioning with persistent MLE, suggesting parents either are not aware or reframe expectations for behavioral functioning in the context of longstanding sequela of medical care.

STRESSPROFFEN: PILOT RESULTS OF A STRESS MANAGEMENT APP FOR PATIENTS WITH CANCER

Elin Børøsund, RN, PhD¹, Matthew M. Clark, PhD, ABPP², Shawna L. Ehlers, PhD, ABPP², Michael Andrykowski, PhD³, Jelena Mirkovic, PhD¹, Hilde Renate Sleveland, BS⁴, Anne Bergland, RN, MS¹, Lise Solberg Nes, LP, PhD¹

¹Center for Shared Decision Making and Collaborative Care Research, Oslo University Hospital, Oslo, Norway, Oslo, Oslo, Norway; ²Mayo Clinic, Rochester, MN; ³University of Kentucky, Lexington, KY; ⁴Center for Shared Decision Making and Collaborative Care Research, Oslo University Hospital, Oslo, Norway, Oslo, N/A, Norway

Background: A cancer diagnosis and ensuing treatment can be overwhelming and disruptive, often accompanied by a wide variety of stressors. Psychosocial stress management interventions may support stress reduction, but are not always offered or available to patients. To address this issue, the current study developed an easily accessible app-based cognitive behavioral stress management intervention for patients with cancer, called *StressProffen*.

Aim: To explore usability, use and preliminary effects of *StressProffen* for intervention evaluation and augmentation in patients with cancer.

Method: *StressProffen* was developed using user centered design methods with considerable user involvement. A feasibility pilot tested the intervention with cancer patients (N=25). The intervention contained: a) face-to-face introduction session, b) ten app based modules with educational stress management material and 36 different exercises (e.g., thought challenges, diaphragmatic breathing and mindfulness), and c) one follow-up phone call after 2 weeks. Questionnaires related to *stress* (Perceived Stress Scale), *distress* (Distress Thermometer), *anxiety* and *depression* (HADS) were completed at baseline and post intervention. Following completion all participants were interviewed about their experiences. User log data were also extracted.

Results: Participants were mainly women (84%), ranged 34–71 yrs old (mean 48) and represented a wide variety of cancer diagnoses, but majority breast cancer (40%). Average time spent on the intervention was 62 days. Dependent/paired t-tests showed significant preliminary pre- post intervention effects with significant decrease in *stress* ($p < .008$, mean diff (MD) -3.95, SD 6.35) and *anxiety* ($p < .019$, MD -1.73, SD 3.18). Distress and depression scores also decreased, although not significant; *distress* ($p = .067$, MD -.77, SD 1.88), *depression* ($p = .148$, MD -.73, SD 2.27). In post intervention interviews participants described having obtained a broader understanding of distress and that *StressProffen* had provided them with many new stress management tools for use in their everyday challenges as cancer survivors. The easy accessibility was highly appreciated by the participants as the intervention could be used anytime and anywhere and they "did not have to bother anyone for help". The face-to-face introduction group and phone call was important to establish rapport and to secure adherence.

Conclusion: An app based stress management intervention can provide highly appreciated support for patients with cancer, is easy to use and can provide significant stress reduction and may improve emotional wellbeing for cancer patients. Further testing in a large randomized trial is warranted.

SYMPTOM PROFILES OF ONCOLOGY PATIENTS SEEKING PALLIATIVE CARE: A COMPARISON BETWEEN DIFFERENT DIAGNOSTIC GROUPS

Nicole Arrato, B.S.¹, Dwain Fehon, PsyD²¹Ohio State University, Columbus, OH; ²Department of Psychiatry, Yale School of Medicine, New Haven, CT

Objective: The field of Palliative Care is a growing and increasingly important component of comprehensive cancer care. A greater proportion of cancer survivors are living longer with advanced forms of cancer and are receiving Palliative Care services. Despite gains in the medical management of advanced cancers, the psychosocial needs of patients within specific diagnostic groups receiving these services are largely unidentified. This exploratory study sought to understand the distinct needs and concerns of 167 consecutively evaluated patients with advanced cancers seen within an outpatient Palliative Care clinic.

Methods: A mixed sample of cancer patients (N=167) receiving their first consultation for Palliative Care at an academic medical center completed the Edmonton Symptom Assessment Scale (ESAS) to assess 13 domains, ranging from physical pain, spiritual pain, financial distress, depression, anxiety, and general well-being. Responses from the entire sample, as well as from specific groups (24.5% lung, 19.2% GI, 16.1% genitourinary, 13.2% breast, 11.4% head & neck, 7.2% brain, 5.4% lymphoma, 3.0% gynecological) were compared. Self-reported symptom presentation for each diagnostic group was analyzed using one-way ANOVAs and Pearson's correlations. Data comparing one diagnostic group against the aggregate of the other groups were analyzed via independent samples t-tests and regression analyses.

Results: After controlling for age (M=60.1 years, SD=12.2), gender (51.2% female), and race (80.6% Caucasian), analyses show that patients with GI cancers reported significantly higher levels of depression (p=.004), anxiety (p=.004), and financial distress (p=.005) compared to the remainder of the sample, comprising the aggregate of the aforementioned diagnostic groups. A significant correlation was found between depression and anxiety for the GI cancer group ($r = .437$, $p = .012$).

Conclusions: Patients with advanced GI cancers have psychosocial needs and concerns that distinguish them from other patients with advanced cancers seeking Palliative Care services. A more comprehensive and nuanced understanding of the unique needs and concerns of patients seeking Palliative Care services will aid the development of diagnosis-specific assessment and intervention programs, targeting depression, anxiety, and general well-being. Further research is needed to replicate these findings and to assess the broader psychosocial needs of patients with advanced GI cancers.

THE EFFECT OF OBESITY ON CANCER-RELATED FATIGUE, INFLAMMATORY MARKERS, AND PLASMA FATTY ACID LEVELS IN BREAST CANCER SURVIVORS

Julia E. Inglis, PhD, RD, Karen Mustian, PHD, MPH, Calvin L. Cole, PhD, Sarah Kerns, PhD, MPH, Michelle Janelins, PhD, MPH, Charles Kamen, PhD, MPH, Allison Magnuson, DO, Luke Peppone, PhD, MPH

University of Rochester Medical Center, Rochester, NY

Background: Breast cancer survivors experience a high prevalence (75%) of cancer-related fatigue (CRF). For breast cancer survivors, changes in weight during and after treatment may also affect severity of CRF. Increases in inflammation and plasma free fatty acids related to obesity may contribute to CRF. The aim of this study is to examine whether obese (BMI ≥ 30) breast cancer survivors have greater CRF symptoms, increased inflammation and higher plasma free fatty acid levels.

Methods: A total of N=105 breast cancer survivors (4–36 mos. post-adjuvant therapy) reporting CRF levels ≥ 4 on the Symptom Inventory (0–10 scale) were classified based on obesity status: obese (OB; BMI ≥ 30 ; n=60), overweight (OV; BMI=25.0–29.9; n=28) and normal weight (NL; BMI=18.5–24.9; n=17). CRF symptoms were measured using the Multidimensional Fatigue Symptom Inventory Short Form (MFSI-SF). Inflammatory markers and plasma free fatty acids were assessed by blood draws. All analyses SAS 9.4.

Results: OB survivors had the highest levels of CRF symptoms based on the MFSI (OB=28.8 vs. OV 22.4 vs. NL 19.0; $p < 0.05$). Inflammatory markers, which are positively correlated with CRF, were higher in the OB group: CRP (OB=15.2 vs OV=14.5 vs NL=13.3; $p < 0.01$), IL-6 (OB=1.4 vs OV=1.2 vs NL=0.6; $p = 0.02$), and TNF- α (OB=2.5 vs. NL=2.1 vs OV=2.2 vs; $p < 0.05$). Plasma free fatty acids were also higher in the OB group: total fatty acids (OB=11.79 vs OV=10.57 vs NL=10.10; $p < 0.05$), saturated fatty acids (OB=4.03 vs OV=3.58 vs NL=3.35; $p < 0.05$), palmitic acid (OB=2757 vs OV=2399 vs NL=2213.70; $p < 0.05$) and triglycerides (OB=146.76 vs OV=110.71 vs NL= 85.70; $p < 0.05$). Increased levels of plasma fatty acids are associated with insulin resistance (IR). IR is tied to fatigue, impaired mitochondrial function and functional decline.

Conclusion: OB breast cancer survivors had significantly worse CRF symptoms, increased inflammation, and elevated plasma free fatty acids compared to NL survivors. Higher levels of inflammation and fatty acids may be promote CRF and increase the risk for co-morbid conditions including metabolic diseases. Future research evaluating CRF should consider the impact of obesity, inflammation and plasma free fatty acids on breast cancer survivors.

THOUGHT SUPPRESSION AND SEXUAL FUNCTIONING AMONG MEN WITH PROSTATE CANCER: THE ROLE OF STRESS AND FATIGUE

Katie Darabos, MS¹, Michael A. Hoyt, PhD²¹The Graduate Center, City University of New York, New York, NY; ²Hunter College, City University of New York, New York, NY

Background: Suppressing cancer-related thoughts after male prostate cancer might contribute to declines in sexual functioning over time. According to the ironic processing theory, active engagement in thought suppression paradoxically increases unwanted thoughts. Moreover, such lapses in thought inhibition is shown to be greater under conditions of cognitive load or resource burden, such as fatigue and stress. Thus, unwanted accessibility of cancer-related thoughts might be related to declines in sexual functioning particularly when the individual is physically or cognitively taxed. This study examined the relationship of thought suppression and sexual functioning in male prostate cancer survivors, and the potential influence of load (i.e., fatigue and stress).

Methods: Adult men ($N=66$, M age = 65.76, $SD=9.0$) with a history of prostate cancer completed measures of sexual functioning, thought suppression, fatigue, and salivary diurnal cortisol at study entry (T1) and 4 months later (T2). Physical and cognitive load was measured using the fatigue subscale of the PANAS and by salivary diurnal cortisol (4 samples across the day for 3 consecutive days). Total daily cortisol output was computed using area under the curve (AUCg).

Results: Controlling for age, time since treatment, marital status, and T1 sexual functioning, regression analysis revealed that higher thought suppression at T1 was significantly related to lower sexual functioning at T2 ($\beta=-.27$, $p<.05$). AUCg moderated this relationship ($\beta=-.34$, $p<.01$) with a trend towards significance for fatigue ($\beta=-.19$, $p=.09$), such that higher thought suppression was more strongly associated with sexual functioning impairment at greater levels of cortisol output.

Conclusion: The extent to which men suppress unwanted cancer-related thoughts contributes to declines in sexual functioning over time. Men with more dysregulation in hypothalamic-pituitary-adrenal axis activity, and possible more fatigue, might be at heightened risk. Interventions aimed at reducing overall stress levels and alleviating fatigue might be particularly helpful for men who engage in cancer-related thought suppression.

USING DECISION SUPPORT AND NAVIGATION TO INCREASE COLORECTAL CANCER SCREENING AMONG HISPANIC-LATINO PRIMARY CARE PATIENTS

Ronald Myers, DSW, PhD¹, Brian Stello, MD², Constantine Daskalakis, ScD¹, Randa Sifri, MD¹, Melissa DiCarlo, MPH, MS¹, Melanie Johnson, MPA³¹Thomas Jefferson University, Philadelphia, PA; ²Lehigh Valley Health Network, Allentown, PA; ³Lehigh Valley Health Network, Allentown PA 18105, PA

Background: CRC screening rates are low (<50%) in Hispanic/Latino primary care patients who are 50 to 75 years of age.

Methods: We identified Hispanic/Latino patients who were eligible for, but not up to date with CRC screening in five primary care practices in the Lehigh Valley Health Network (LVHN) in southeastern Pennsylvania. The research team consented and randomized 400 patients either to an SI Group ($n=203$) or a DSNI Group ($n=197$). A bilingual informational booklet, a stool blood test (SBT), and colonoscopy instructions were mailed to both the SI and DSNI groups. The DSNI Group also received a telephone call from a bilingual patient assistant who reviewed the screening materials, verified the participant's preferred CRC screening test and likelihood of completing his/her preferred test, and guided the participant through a test specific screening plan. A 6-month survey and 6- and 12- month medical records review data were used to assess participant screening adherence.

Results: At 12 months, CRC screening adherence was significantly higher in the DSNI Group than the SI Group (OR = 4.83, 95% confidence interval, CI: 3.08 to 7.58, $p < 0.001$). The DSNI Group, compared to the SI Group, also displayed a higher SBT screening rate (OR = 4.20, 95% CI: 2.63 to 6.70, $p < 0.001$), and a higher colonoscopy screening rate (OR = 8.79, 95% CI: 4.13 to 8.74, $p < 0.001$).

Conclusions: Among Hispanic-Latino primary care patients, a DSNI strategy achieved substantially and significantly greater positive effects on CRC screening adherence and test-specific screening adherence than an SI strategy.

WHAT HELPS PARENTS PROTECT THEIR CHILD FROM MELANOMA RISK?

Tara Coffin, PhD¹, Deborah Bowen, PhD¹, Yelena P. Wu, PhD², Darren Mays, PhD³, Christine Rini, PhD⁴, Kenneth P. Tercyak, PhD⁵¹University of Washington, Seattle, WA; ²Huntsman Cancer Institute, University of Utah, Salt Lake City, UT; ³Lombardi Comprehensive Cancer Center, Georgetown University Medical Center, Washington, DC; ⁴John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, NJ; ⁵Lombardi Comprehensive Cancer Center, Georgetown University Medical Center, Washington, DC, Washington, DC

Melanoma is the most serious and potentially fatal form of skin cancer, ranked among the top five most prevalent cancers in the United States. Sun exposure during childhood can increase an individual's risk of melanoma in adulthood. Unfortunately, sun protection behaviors are often not pursued by parents and children. We developed and evaluated a web-based intervention to promote family communication and information exchange about risk reduction in melanoma families, with the objective of improving familial transmission of helpful information to encourage health behavior change. This paper presents baseline variables associated with parental enactment of sun exposure prevention and protection among children in families with a history of melanoma. Parents ($n=313$) were recruited and surveyed about their melanoma risk reduction behaviors and efforts to protect one of their randomly selected children from melanoma risk. Questions targeted sun exposure and screening behavior of parents, and exposure reduction variables in the selected child. Analyses focused on linear regressions associating risk reduction behaviors in children with parental behaviors, perceptions, and demographic variables. We created a scale by dichotomizing variables and performing a principal component analysis with varimax rotation, selecting a scale with six risk reduction variables ($\alpha = .85$). The resulting dependent variable focused on if children wore adequate sun protective clothing. Among parents surveyed, 80.5% reported inadequate protection and 19.5% reported adequate sun protection for their child. Of those who reported sufficient protection, 28.4% of parents practiced adequate protection across all domains explored. Multivariate regressions identified multiple variables about the parent that were associated with child protection and screening, including if the parents ever use sunscreen ($p<0.001$), use sunscreen of SPF 15 or greater for the past 12 months or when they knew they would be in the sun for at least 15 minutes ($p=0.024$ and $p=0.035$, respectively), how thickly and frequently they apply sunscreen ($p<0.001$); how confident parents felt in their ability to take note of abnormal skin marks through self-exam ($p=0.020$); how confident they were that they could make sunscreen application a regular part of their daily routine ($p=0.038$); how certain they were to use sunscreen while doing outdoor activities in the winter ($p<0.000$); and whether they wore protective clothing, such as long-sleeves or pants, when outdoors ($p=0.032$ and $p=0.003$, respectively). No demographic variables, other parental choices, or family history were significantly associated with child protection. These data have clear implications for targeting parents' child-protective behaviors. If parents use strong protective measures for themselves, they are more likely to use them for children.

WHO USES VITAMIN D DURING BREAST CANCER TREATMENT AND SURVIVORSHIP AND THE EFFECTS OF USE ON HEALTH RELATED QUALITY OF LIFE.

M. Robyn Andersen, PHD, MPH¹, Erin S. Sweet, ND, MPH, FABNO², Leanna Standish, ND, PhD, FABNO³¹Fred Hutchinson Cancer Research Organization, Seattle, WA; ²Bastyr University, Kenmore, WA; ³Bastyr University, Kenmore, WA

Background: Vitamin D supplements may prevent recurrence, prolong survival, and improve mood for women with breast cancer, although evidence for these effects is preliminary. Systemically, D may influence activation of the vitamin D receptor (VDR) in ways that correlate with increased survival in patients. The mechanism by which vitamin D might influence mood is less clear, but there is consistent evidence that there are receptors for vitamin D in the brain and that depression and a variety of mood disorders are associated with low levels of D in the blood.

Methods: This report describes D supplement use by 553 breast cancer patient/survivors: 193 who used an Integrative Oncology (IO) provider and 360 who did not (usual care; UC). Who participated in a matched cohort study of breast cancer outcomes.

Results: We found that more than half of breast cancer patients reported using vitamin D supplements at any specific time. In total almost 90% (n = 130) of patients in the IO and 73% (n = 262) of the patients in the usual care cohort reported ever using vitamin D supplements, excluding multivitamins, at the time of their enrollment in the study. Women in the IO cohort reported more use of D prior to diagnosis (n = 88, 60.7% vs 141, 39.2%; $p < 0.001$). Women who received care from Integrative Oncology providers in early survivorship also appear to be more likely to use vitamin D supplements than are women who use only conventional providers ($p < 0.05$). Approximately 30% of breast cancer patients with blood levels recorded in their medical chart were potentially D deficient (< 30 ng/mL). Multi-variate analyses controlling for cohort, time since diagnosis stage and other relevant variables found that D supplement use at study enrollment was associated with higher levels of self-reported health related quality of life (HRQOL) assessed using the SF-36 questionnaire at enrollment ($p < 0.05$). D use at enrollment also predicted better HRQOL at 6-month follow-up ($p < 0.05$) again controlling for a variety of potential confounders. Sufficient blood levels of D were also associated with better HRQOL ($p < 0.05$).

Conclusions: D supplementation by breast cancer patients is common both during and after treatment for breast cancer, but deficiency may also be common. Most supplement users use less than 2,000 IU daily, and our results suggest that this level of vitamin D supplementation improves HRQOL among women with breast cancer in early survivorship.

TESTOSTERONE MODERATES THE RELATIONSHIP BETWEEN POSITIVE AFFECT AND HEALTH BEHAVIOR

Mariam Ter-Petrosyan, M.S., Ashley Peak, M.S., Luci Martin, Ph.D.

University of La Verne, La Verne, CA

Testosterone is a hormone released as the end product of the hypothalamic-pituitary-gonadal (HPG) axis. Testosterone is released in both men and women, and likely plays an important role in social functioning and motivation. Testosterone has been suggested as the reason for sex differences in behavioural dysregulation, which may explain sex differences in health outcomes. The purpose of this study was to examine the contribution of testosterone, positive and negative affect, and demographic variables on family history of cardiovascular disease and health behaviors. The sample (mean age 21.25, $SD = 6.08$) consisted of 89 female university students asked to complete self-report measures and a saliva sample. Participants self-identified as Latina (37.1%), European American (31.5%), Asian American (5.6%), African American (4.5%), or Mixed/Other (21.3%). For health-related behaviors and history, 44% of the sample endorsed eating 3–5 fruits/vegetables per day, 61% endorsed having a regular exercise program, reporting an average of 2.84 ($SD=1.75$) days exercised per week, and 46% endorsed getting an average of 7–8 hours of sleep per night. Related to substance use, 93% endorsed less than 3 caffeinated beverages per day, 67% denied use of any alcoholic beverages, and two participants endorsed smoking one cigarette per day. For history of medical conditions for self or family, 62% endorsed hypertension, 25% heart attack/myocardial infarction, 23% stroke, 67% diabetes, 56% high cholesterol, and 37% obesity. Hierarchical regression analyses found that testosterone moderated the relationship between positive affect and a composite health behavior score ($t = -2.33, p = .02, \text{Adj. } R^2 = .20, F(5, 81) = 5.38, p < .001$), such that the healthiest behaviors were observed in participants with high positive affect and low testosterone. Furthermore, analyses found that negative affect ($t = 2.68, p = .009$) and testosterone ($t = 2.04, p = .045$) predicted family history of cardiovascular disease ($\text{Adj. } R^2 = .12, F(5, 81) = 3.29, p = .009$). Findings remained after adjusting for oral contraceptive use, income level, relationship status and ethnicity. The Positive Affective Neuroendocrinology perspective proposed by Welker, Gruber and Mehta (2015) provides a synthesis of research on the connection between testosterone and behavioural dysregulation via reward motivation, but few empirical studies have examined these relationships in females. These results provide a preliminary foundation for future research examining the interplay of neuroendocrine function, psychological factors, and behavior. Further empirical studies can focus on expanding this research in larger, representative samples.

ASSESSMENT OF EARLY CHILD CARE AND EDUCATION NEEDS AND PLANNING IN A RURAL REGION

Judy A. Johnston, MS, RD, LD¹, Lisette T. Jacobson, PhD, MPA, MA², Benjamin Anderson, MBA, MHCDS³, Krysta Harvey³

¹University of Kansas School of Medicine - Wichita, Wichita, KS; ²University of Kansas School of Medicine-Wichita, Wichita, KS; ³Kearny County Hospital, Lakin, KS

Background: Young children who have mastered skills in three core areas—regulation of emotion, behavior, and attention; language, reasoning, and problem solving; and relating well to others and forming friendships—experience greater success when compared with those failing to develop such capacities. Poverty and geographic remoteness present unique challenges to families in many rural communities including limited availability of a trained early childhood workforce, low wages for child care and early education professionals, and changing demographics.

Objective: The purpose of this study was to identify community health/wellness needs with a specific focus on child care and education as these were identified as critical priorities in a 2016 community health assessment study.

Methods: Seven focus groups were conducted with parents, grandparents, older adults, and child care providers in a very rural county of a Midwestern state. The purpose of the discussions was to identify perceptions of the availability of current child care, characteristics of “ideal” child care providers/settings, and input regarding inter-generational shared site care. Key informant interviews conducted with employers assessed their perceptions of the impact of current early child care and education on their businesses. Data were collected in July/August 2017.

Results: Fifty nine people participated in focus groups. They identified characteristics of “ideal” child care as: licensed, CPR and First Aid certified, with specific training in early child care and education, structured educational activities, and availability of evening, weekend, drop-in, and sick care. Discussion of inter-generational shared site care among all groups focused on shared time, shared space, and participation choice. Child care providers expressed concerns about perceived state “over-regulation.” Thirteen employers completed phone interviews, identifying absenteeism, lost productivity, and scheduling as negative impacts on lack of reliable child care. The majority thought increased access to flexible child care would improve recruitment (69%), reduce absenteeism (54%), increase productivity (54%), and reduce turnover (62%). The majority (93%) stated that early child care and education should be a concern for their company and the county.

Conclusion: Early child care and education is a community issue with multiple stakeholders who need to be engaged in planning. Follow-up studies in very rural communities are needed to identify viable models.

EFFECTIVENESS OF A BREASTFEEDING SUPPORT INTERVENTION AMONG WOMEN WITH HIGH-RISK PREGNANCIES

Lisette T. Jacobson, PhD, MPA, MA¹, Liuqiang Lu (Kelsey) Lu, Master of Science², Milan Bimali, PhD¹, Darren Farley, MD, FACOG¹, David A. Grainger, MD, MPH¹

¹University of Kansas School of Medicine-Wichita, Wichita, KS; ²KU Medical School-Wichita, Wichita, KS

Evidence suggests that breastfeeding duration is associated with reducing maternal postpartum weight; however, there is limited evidence of effective programs that aim to improve length of breastfeeding among high BMI women. High BMI women experience low breastfeeding rates due to an increased likelihood of high intervention births, delayed lactogenesis II, postpartum edema, polycystic ovarian syndrome, gestational diabetes, and psychosocial factors (e.g., body image concerns). In Kansas, even though 79% of women with a BMI ≥ 25 initiate breastfeeding, only 29% still breastfeed at 6 months postpartum. This is a reduction of 63%, or nearly 2 out of every 3 women no longer breastfeeds at 6 months. Given current recommendations that infants be exclusively breastfed for the first 6 months, a two-hour breastfeeding class was offered during the 2nd trimester to high BMI pregnant women. The purpose of the study was to determine breastfeeding self-efficacy, and to determine knowledge retention after completing the breastfeeding class. Study design was a single-sample, pre-post design with two data collection points. The breastfeeding curriculum was based on the Office on Women’s Health “Your Guide to Breastfeeding” and aligned with nutritional requirements set by the U.S. Department of Agriculture’s Special Supplemental Nutrition Program for Women, Infants, and Children (WIC). Preliminary findings indicate that participants’ average BMI was 32.4, average age was 28, 50% were non-Hispanic white followed by 25% Hispanic, 50% had some college or less, and 56% earned $< \$50,000/\text{year}$. Breastfeeding self-efficacy increased and retention of knowledge improved on the following factors: breast milk composition and infant growth, supply and demand, nursing positions, establishing a milk supply, identification of hunger cues, infant weight loss, engorgement, understanding growth spurts, benefits of exclusive breastfeeding, and the effect of substance use on breast milk. Participants had limited knowledge regarding breastfeeding pain, actions to take when baby has trouble breastfeeding, and the impact of formula use in the early days on breast milk supply. Study results present opportunities for additional education and will help enhance the breastfeeding curriculum. Additional follow-up studies are underway to assess breastfeeding behaviors after birth, with a specific focus on nutrition counseling and physical activity guidance for high BMI women.

IMPACT OF THE BABY-FRIENDLY HOSPITAL INITIATIVE ON BREASTFEEDING AND MATERNAL AND INFANT HEALTH IN THE UK: A SYSTEMATIC REVIEW.

Vicky Fallon, PhD, BSc, FHEA

University of Liverpool, Liverpool, England, United Kingdom

The Unicef UK Baby Friendly Initiative (BFI) is designed to support women to initiate and continue to breastfeed and maximise maternal and infant health outcomes. Global evidence demonstrates that adherence to BFI has a positive impact on short and long-term breastfeeding (BF) outcomes, but this evidence has not been comprehensively stratified by country according to income. In particular, studies examining the efficacy of BFI in high-income countries have yet to be synthesised. Given prolonged, and very low breastfeeding rates in the UK, establishing the impact of BFI in this setting is important. The primary aim of this narrative systematic review was to examine the impact of BFI implementation on breastfeeding and other maternal and infant health outcomes in the UK. Electronic searches were performed using specific keywords and hand searches of reference lists of included articles were conducted. All study designs were considered if they assessed breastfeeding outcomes and/or maternal and infant health outcomes in a UK hospital or community setting with full or partial implementation of BFI steps. 176 studies were identified, of which 13 were eligible. Two authors independently extracted data including study design, participants, and results. Preliminary findings highlight a paucity of robust evidence to support the impact of BFI on improved breastfeeding and maternal and infant health outcomes in a UK setting. Only two trials have been conducted in BFI settings and both indicate that the benefits of the current strategy for breastfeeding outcomes are transient and not sustained. There was no evidence available examining the impact of BFI on physical health outcomes for mother or infant. However, qualitative data indicates that the current approach to infant feeding promotion and support in higher-income countries may be paradoxically related to significant issues with maternal mental health and may need to be situationally modified. There is urgent need for further evaluation of BFI in UK settings to identify barriers to breastfeeding success and eliminate risks to maternal emotional wellbeing. Studies examining the impact of BFI-UK on broader maternal and infant health outcomes, alongside breastfeeding indicators, are also necessary. Conclusions point to tensions with BFI-UK in its current form and provide evidence-based suggestions for modification of the initiative to enhance care for mothers and infants in the UK.

PIONEER BABY: BUILDING COMMUNITY INFRASTRUCTURE TO IMPROVE MATERNAL-CHILD HEALTH IN A RURAL MIDWESTERN REGION

Lisette T. Jacobson, PhD, MPA, MA¹, Judy A. Johnston, MS, RD, LD², Benjamin Anderson, MBA, MHCDS³, Liuqiang Lu (Kelsey) Lu, Master of Science⁴

¹University of Kansas School of Medicine-Wichita, Wichita, KS; ²University of Kansas School of Medicine - Wichita, Wichita, KS; ³Kearny County Hospital, Lakin, KS; ⁴KU Medical School-Wichita, Wichita, KS

Background: A health collaborative called “Pioneer Baby” was established in response to an alarming number of pregnancies complicated by gestational diabetes mellitus in a rural region of a Midwestern state. Gestational diabetes is associated with increased maternal and neonatal morbidity and mortality. Partners include a medical school, local healthcare providers, a regional health system, and the state’s health department.

Objective: The purpose of this study was to identify community health/wellness priorities in a three-county area. This presentation will identify strategies to improve maternal-child health outcomes.

Methods: First, to learn about the characteristics and health behaviors of reproductive age women in the catchment area, a pilot health assessment was completed (N=175). Half of respondents were Hispanic of low socio-economic status. During pregnancy, three-quarters of women were overweight/obese, did not exercise, and had a family history of diabetes. Findings from a qualitative follow-up study within this same community indicated that women had limited access to health promotion programs. Second, to further guide the design for intervention programming aimed at promoting healthy behaviors, a comprehensive survey targeting a three-county area was conducted to identify barriers to improving community health.

Results: More than 50% of all households in each county responded to the survey. Preliminary findings indicate that of the female respondents (N=1,224), nearly two third (64%) were non-Hispanic white followed by 25% Hispanic, average age was 45, and 40% earned less than \$50,000/year. Women reported that they wanted the following healthcare/public health services in their respective counties: diabetes prevention support (59%), diabetes management support (56%), diet counseling (48%), weight management coaching (73%), pregnancy care (56%), specialized breastfeeding support (71%), peer breastfeeding support (65%), and breastfeeding support through a clinic at the health department (65%) or hospital (76%). Within their places of work, women wanted access to exercise facilities (41%), access to healthy food options (59%), access to a private breastfeeding space at work (81%), and health education (55%). Women also reported a need for high-risk obstetrical care (83%). Follow-up focus group sessions were conducted and preliminary findings confirm survey results.

Conclusion: Collectively, Pioneer Baby and its partners use study results to plan and implement community health improvement strategies leading to improved maternal and child health outcomes.

EXAMINING UNCERTAINTY IN ILLNESS IN PARENTS AND CHILDREN WITH CHRONIC KIDNEY DISEASE AND SYSTEMIC LUPUS ERYTHEMATOSUS

Jennifer Petrongolo, MSW, PsyD¹, Nataliya Zelikovsky, Ph.D.², Rachel Keegan, MA³, Susan Furth, MD, PhD⁴, Andrea Knight, MD, MSCE⁵

¹La Salle University, Bordentown, NJ; ²La Salle University, Philadelphia, PA; ³La Salle University, Somerset, NJ; ⁴Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA; ⁵The Children's Hospital of Philadelphia, Philadelphia, PA

Children with chronic kidney disease (CKD) and systemic lupus erythematosus (SLE) have uncertain prognoses and unpredictable cycles of remission and relapse, which may result in parent and child uncertainty, which can be appraised as an opportunity or a danger. Children tend to negatively appraise uncertainty, leading to distress. Children with CKD/SLE often experience internalizing symptoms and low health related quality of life (HRQOL), but the factors influencing adjustment are not fully understood. Child and parent uncertainty relate to child anxiety and depression, and to each other. Illness uncertainty is also related to HRQOL. One study of other pediatric conditions found maternal uncertainty to have an indirect effect on child depressive symptoms through child uncertainty, suggesting a potential mechanism of child adjustment.

This study expanded previous research by examining child uncertainty as a mediator between parent uncertainty and child outcomes of depression, anxiety, and HRQOL in the CKD/SLE population, which has not yet been explored. Participants were 31 parent-child dyads with CKD (N=9; Stage 1, 2 or nephrotic syndrome) or SLE (N=22) recruited from nephrology and rheumatology outpatient clinics. Using a secure online database, parents completed a demographic form and The Parents' Perception of Uncertainty in Illness Scale. Youth (ages 9–18) completed The PROMIS Depression and Anxiety Short Forms, The Child Uncertainty in Illness Scale, and The Pediatric Quality of Life Scale.

Significant correlations were found between child and parent uncertainty ($r=.47$, $p=.007$) and child uncertainty with anxiety ($r=.50$, $p=.005$) and HRQOL ($r=-.51$, $p=.004$). The percentile bootstrapping method generated 10,000 samples to derive the indirect effect; confidence intervals set at 95%. Results found child uncertainty mediated the relationship between parent uncertainty and all three child outcomes: depression ($b=.267$; CI=.01, .34), anxiety ($b=.304$, CI=.05, .34), and child-reported HRQOL ($b=-.26$, CI=-.52, -.06). Results extended previous research to understudied conditions (CKD/SLE) and to variables not previously studied as indirect outcomes of parent illness uncertainty, namely anxiety and HRQOL. Findings allow health care professionals to understand the impact of parent and child uncertainty on child adjustment. It is important to address the appraisal of ambiguity in illness through cognitive interventions with both the parent and child, as both ultimately impact the child's wellbeing.

SOCIOECONOMIC ADVERSITY, SOCIAL RESOURCES, AND ALLOSTATIC LOAD: RESULTS FROM THE STUDY OF LATINO YOUTH

Kimberly L. Savin, B.A.¹, Julia I. Bravin, B.A.¹, Scott C. Roesch, PhD², Carmen R. Isasi, MD/PhD³, Krista M. Perreira, PhD⁴, Mercedes R. Carnethon, PhD⁵, Alan M. Delamater, PhD⁶, Christian R. Salazar, PhD⁷, Maria D. Lopez-Gurrola, MPH⁸, Linda C. Gallo, PhD²

¹San Diego State University/UC San Diego Joint Doctoral Program in Clinical Psychology, San Diego, CA; ²San Diego State University, San Diego, CA; ³Albert Einstein College of Medicine, Bronx, NY; ⁴University of North Carolina at Chapel Hill, Chapel Hill, NC; ⁵Feinberg School of Medicine, Northwestern University, Chicago, IL; ⁶University of Miami Miller School of Medicine, Miami, FL; ⁷Albert Einstein College of Medicine, New York, NY; ⁸South Bay Latino Research Center, Chula Vista, CA

Childhood socioeconomic adversity negatively impacts physical and mental health across the lifespan. Resilience models posit that some individuals continue to thrive despite significant adversity, because they benefit from individual or contextual protective factors. The current study examined associations among socioeconomic adversity, social resources, and allostatic load in N=1324 Hispanic/Latino youth (50% male; ages 8–16) from the Study of Latino youth (SOL Youth), who are at high risk for obesity and related cardiometabolic risks.

The Hispanic Community Health Study/Study of Latinos (HCHS/SOL; 2008–2011) is a population-based study of 16,415 self-identified Hispanics/Latino adults from four urban US communities. SOL Youth recruited youth offspring of HCHS/SOL participants and their primary caregivers between 2012–2014. Youth participants underwent a fasting blood draw and anthropometric assessment, and youth and caregivers provided social and demographic information. A composite indicator of allostatic load represented dysregulation across general metabolism, cardiovascular, glucose metabolism, lipid, and inflammation/hemostatic systems. Socioeconomic adversity was a composite of caregiver education, employment status, economic hardship, family income relative to poverty, family structure, and receipt of food assistance. Social resources was a composite of family functioning, parental closeness, peer support, and parenting style variables.

Multivariable regression models that adjusted for sociodemographic factors, design effects, and sample weights revealed a positive relationship between socioeconomic adversity and allostatic load ($\beta=.10$, $p=.035$). Further, greater socioeconomic adversity related to lower social resources ($\beta=-.10$, $p=.013$). Neither the association of social resources with allostatic load ($p>.05$) nor the compound paths comprising the indirect effect from socioeconomic adversity to allostatic load via social resources were statistically significant (MacKinnon's 95% Asymmetric CI -.002 to .008).

Statistically significant, but modest associations of socioeconomic adversity with both allostatic load and social resources were identified in the current study. This may partially reflect range restriction given overall high adversity and high social resources among our Hispanic/Latino youth cohort. There is an urgent need to examine social risk and protective factors shaping health risks in Hispanic/Latino youth, to inform prevention and intervention efforts that can disrupt health-damaging trajectories before initiation of chronic diseases.

THE IMPACT OF PILOT STUDIES TO INFORM META-ANALYSES:
A CASE STUDYDecker Lindsay, MPH, Glenn Weaver, M.Ed. Ph.D., Michael W. Beets, M.Ed.,
M.P.H., Ph.D.

University of South Carolina, Columbia, SC

Meta-analyses quantify and summarize the results from multiple studies on a specific topic to create a more robust understanding of the state of a given field. These aggregate analyses are often used to as the foundation to develop public policy and evidence-based recommendations for public health interventions. The studies included in meta-analyses, therefore, should only be of the highest methodological quality to produce results with the highest validity and reliability. Pilot studies, which can be a single study or group of studies designed to test the feasibility of an intervention and/or provide initial evidence of an effect in the hypothesized direction, are commonly conducted prior to a well-powered higher quality randomized trial. Pilot studies are often of lower methodological quality, include small sample sizes, are short in duration, and delivered by highly trained interventionists. Within the last 10 years, the publication of pilot studies has accelerated; resulting in pilot studies populating meta-analyses. The purpose of the current study is to reanalyze two published meta-analyses that informed the recommendations for family-based activity interventions and intensive behavioral interventions for pediatric weight management that included pilot studies. The first study analyzed by Brown et al. included family based interventions (n=19, n=15 pilot). The effect size reported from the analysis was 0.40 (0.22, 0.57). When reanalyzed and the pilot studies were removed, the non pilot studies did not reach statistical significance with effect size 0.51 (-0.28, 1.30). The second study reanalyzed included interventions that were focused on child BMI reduction in health care settings (n=37, n=21 pilot). The reported effect size -0.36 (-0.51, -0.21) was similar to the non pilot only effect size in this case, -0.36 (-0.68, -0.41). The inclusion of these pilot studies leads the authors to one conclusion, where if the studies were left out, we reach a different result entirely. Pilot studies, if included in analyses, need to be held separately from full powered trials.

A LONGITUDINAL EXAMINATION OF ADOLESCENT MEDIA USE
AND SEXUAL SOCIALIZATION

Magaela C. Bethune, MS, MPA

Vanderbilt University, Nashville, TN

While the rates of some STIs and unplanned pregnancy among youth have stabilized, or at best, undergone a modest decline over the past few years, the incidence, transmission, and prevalence of STI/HIV, unintended pregnancy and other negative sex-related outcomes still comprise a significant, complex and costly social and public health issue for youth in the United States. Across various disciplines, multiple theorists have attempted to describe the factors that shape sexual behavior, health and sex-related outcomes in youth, as they develop over the life course. Biological, psychological, and social factors – including socialization – all contribute the development of adolescents, as they transition from childhood to early adulthood. During this critical developmental period, media functions as a salient socializer for youth. Myriad studies have described the link between the use of conventional forms of media (i.e., television, radio, video, print media) and youth sexual attitudes, intentions, behaviors, and health statuses.

Drawing on a conceptual framework for adolescent media sexual socialization and using nationally-representative, longitudinal, public-use data from the National Longitudinal Study of Adolescent Health (Add Health) (N=3,126), this study critically examines the influence of media use on sexual socialization across adolescence, and if this relationship is moderated by race and gender. To address the research question, multiple linear regression was conducted to assess if media use during adolescence predicted sexual socialization across five measures (i.e., sex knowledge, perceptions of sex risk, beliefs about pregnancy, perceived birth control efficacy, myths about birth control) later at follow-up at wave 2.

Media use remained a statistically significant predictor of sexual socialization across the five domains examined, when controlled for race and gender. After data were dis-aggregated by race/ethnicity (e.g., non-Hispanic White, non-Hispanic Black, Hispanic, Asian/Pacific Islander, Native American/American Indian, and Hispanic) and gender (e.g., male, female), the effect remained for White youth and both males and females.

As media is a conduit, conveying images, messages and representations about society, and as youth are embedded in the hegemonic context of greater society in the U.S., youth's experiences with media and sexual socialization are gendered and racialized. This differentiated socialization has potential ramifications for the emergence and development of sexual behavior across adolescence. Adolescents, while seeking out information to make sense of their evolving sexual worlds, may turn to media for self-socialization in order to support their transition to adult roles and behaviors. Policy, practice, and research implications of findings are discussed.

ANALYSIS OF SCREEN TIME POLICIES IN LOUISIANA CHILD CARE CENTERS

Amanda E. Staiano, PhD¹, Jeanette Gustat, PhD, MPH², Maranda Hyde, MPH³, Whitney Fowler, MBA⁴, Leslie Lewis, MPH, LDN, RD⁵

¹Pennington Biomedical Research Center, Baton Rouge, LA; ²Tulane University School of Public Health and Tropical Medicine, New Orleans, LA; ³Tulane University School of Public Health and Tropical Medicine, New Haven, CT; ⁴Louisiana Department of Health, Office of Public Health, Baton Rouge, LA; ⁵Louisiana Department of Health/Office of Public Health/Bureau of Family Health, New Orleans, LA

Background: Children often spend more time in front of an electronic screen than engaged in physical activity (PA). Early care and education (ECE) centers have the opportunity to reduce screen time during the preschool years and help children meet PA recommendations.

Purpose: To examine Louisiana ECE centers' compliance and perspectives regarding the Louisiana Department of Education's policies on screen time. The policies state that electronic device activities for children under age two are prohibited, and time allowed for electronic device activities for children ages two and above shall not exceed two hours per day.

Methods: In-depth telephone interviews using a structured interview protocol were conducted with 12 licensed, ECE center directors in Louisiana. Centers were randomly selected within center license type (Type I, II, or III). Interviews assessed how each of two policies were implemented, communicated, monitored, enforced and evaluated. Interviews were transcribed and coded and thematic analysis was conducted.

Results: All twelve centers implemented both screen-time policies, with eight centers (66%) implementing policies stricter than the state policies. Centers used a combination of training and verbal reminders to communicate the policies to staff and used a parent handbook to communicate the policies to parents. Daily walk-throughs were the most common method employed by the center directors for monitoring the policies. Enforcement of the policies varied by center but a majority had consequences in place for staff who failed to follow the policies. No formal evaluation was done by any center regarding the policies, but a majority (66%) had not noticed any negative results from the policies.

Conclusion: Communication changes are recommended for the Louisiana Department of Education to help inform all centers of screen time policies and available resources. Consideration should be given to creating stricter screen time policies that focus on screen time for educational purposes only.

ASSOCIATIONS WITH AFFIRMING HEALTHCARE EXPERIENCES AND SEXUAL MINORITY YOUTH'S PERSPECTIVE ON FAMILY FORMATION.

Trey Dellucci, MS¹, Emily Bettin, BA², Kathryn Macapagal, PhD², Celia Fisher, PhD³, Brian Mustanski, PhD²

¹The Graduate Center City University of New York, New York, NY; ²Northwestern University, Chicago, IL; ³Fordham University, Bronx, NY

Background: While a majority of sexual minority youth (SMY) desire to have children, they are less likely to become parents than heterosexual adults. Healthcare experiences have shown important associations with attitudes about family formation and fertility preservation in both heterosexual and SM cancer survivors. To date, no study has examined the association between interest in starting a family and healthcare experiences among non-clinical populations of SMY. The current study will fill this gap by examining the role of SM-affirming healthcare on SMY's attitudes about family formation.

Method: The current study analyses data from a larger ongoing study exploring ethical issues associated with HIV prevention among LGBTQ: the Adolescent Scientific Access Project (ASAP!). The sample was composed of 231 cisgender SMY aged 14–17 ($M=16.46$, $SD=1.05$). A majority of participants were male (55%) and 65.2% identified as youth of color. Youth answered questions on SM-affirming healthcare, interest in having children in the future, and frequency of communication about fertility with their peers, parents, and healthcare providers. Multiple regression models were used to examine differences in SMY's interest in family formation by demographics and SM-affirming healthcare experiences.

Results: 68.3% of SMY were interested in having children someday. Female youth were significantly less interested in having children compared to male participants ($OR=.54$, $CI:.31, .96$). Youth who reported their doctor as helpful with LGBQ sexual health issues were more interested in having children overall ($OR=1.67$, $CI:1.12, 2.48$) but less interested in adoption ($OR=.65$, $CI:.44, .96$). SMY with helpful providers thought more often about having biological children ($B=.21$, $CI:.04, .39$). In contrast, those who worried that their provider would not be accepting of their sexual orientation thought less often about having children ($B=-.11$, $CI:-.21, -.01$).

Discussion: The current study found showed that family formation is important to SMY. It also expanded on previous literature by demonstrating a significant association between SM-affirming healthcare providers and SMY's interest in family formation. Those with affirming healthcare providers were more likely to be interested in having children. This has important implications. Healthcare providers need training in SM issues, which can enable them to provide a safe platform for conversations about family formation.

COMMUNITY PEER MENTORING TO IMPROVE SELF-MANAGEMENT IN YOUTH WITH INFLAMMATORY BOWEL DISEASE

Zach Orlins, BS¹, Laura Mackner, PhD², Kathryn Vannatta, PhD³, Wallace V. Crandall, MD, MMM³, Joseph Rausch, PhD⁴¹Ohio University Heritage College of Osteopathic Medicine, Columbus, OH; ²Nationwide Children's Hospital/Ohio State University, Columbus, OH; ³Nationwide Children's Hospital, Columbus, OH; ⁴Research Institute at Nationwide Children's Hospital, Columbus, OH

Background: Managing inflammatory bowel disease (IBD; Crohn's disease, ulcerative colitis) is a significant challenge, not just medical management but also managing the effects of IBD on life, particularly in the areas of quality of life and daily functioning. Unpredictable and embarrassing symptoms, and the stigma that 84% of patients experience present barriers to optimal health. A community intervention such as mentoring may be well-suited for improving these areas of self-management: Peer mentors normalize the experience of IBD, reduce disease-related stigma, and engage in activities in the community, promoting generalization and independence in ways that traditional interventions do not. We worked with patients, parents, and Big Brothers Big Sisters (BBBS) to develop a multi-faceted peer mentoring program to improve self-management in youth with IBD. This pilot study assessed feasibility and preliminary outcomes.

Methods: Youth with IBD (10–17 years) were randomized into the Mentoring Program or an Enhanced Education comparison group (n=15 each). Mentors with IBD were recruited and matched with mentees. The Mentoring Program was a year-long, 1:1 mentee-mentor partnership with weekly contact (e.g., text, phone), and in-person contact 1–2 times per month, including educational group activities. The Enhanced Education group was a website with a self-management workbook and educational information from the Mentoring Program educational group activities. Participants completed assessments pre-randomization and post-intervention.

Results: Feasibility was demonstrated via mentee recruitment rate (59% of target population), mentor screening (31% rejection/withdrawal rate similar to BBBS), retention (98% over 1 year), program engagement ($M=1.6$ contacts per week; 71% attended expected group activities), and satisfaction with program (87% overall). Gender moderated preliminary outcomes: Girls in the Mentoring Program had the best outcomes post-intervention in both improved total QOL ($M_{diff}=10.01$, $p<.05$) and functional disability ($M_{diff}=4.89$, $p<.05$). In the Mentoring group, 82% achieved remission post-intervention vs. 67% in the comparison group.

Conclusions: The Peer Mentoring Program was feasible, and preliminary data suggest it improves quality of life and daily functioning. Peer mentoring may serve to extend our reach to important nonmedical areas of self-management and to stigmatized youth who may not otherwise participate in self-management interventions.

EFFECTS OF GENERAL AND DOMAIN-SPECIFIC PARENTAL MONITORING ON THE LIFESTYLE BEHAVIORS OF HISPANIC YOUTH IN A FAMILY-BASED TRIAL

Sara M. St. George, PhD¹, Tae Kyoung Lee, Ph.D², Marissa Kobayashi, BA, MHS³, Yaray Agosto, MPH², Sarah E. Messiah, PhD, MPH², Guillermo J. Prado, PhD²¹University of Miami - Miller School of Medicine, West Miami, FL; ²University of Miami Miller School of Medicine, Miami, FL; ³University of Miami - Miller School of Medicine, Coral Gables, FL

While some studies show that changing general positive parenting practices (e.g., monitoring youth whereabouts) may be sufficient to improve youth lifestyle behaviors, others indicate parents should use domain-specific strategies (e.g., monitoring youth dietary intake). To test the effects of Familias Unidas for health & wellness (FUHW), a family-based obesity prevention intervention on general and domain-specific parental monitoring and the effects of parental monitoring on lifestyle behaviors (sugar intake, fruit/vegetable intake, physical activity) at 6 months post intervention, three structural equation models were estimated (n=280 Hispanic families). Adolescents with unhealthy weight (43% overweight, 44% obese, 12% severely obese, 52% female, 13.0 ± 0.8 yrs old, 36% immigrants) and their parents (88% female, 44.9 ± 6.5 yrs old, 91% immigrants) were randomized to FUHW or community practice as usual. FUHW is a 12-week intervention that focuses on enhancing family functioning to improve adolescent diet and physical activity. A latent variable of general parental monitoring was created using parent responses on the Parental Monitoring and Parent Relationship with Peer Group Scales. Parents self-reported domain-specific monitoring using the Parent Strategies for Eating and Activity Scale, and adolescents self-reported their diet and physical activity using the NHANES Dietary Screener Questionnaire and the Physical Activity Questionnaire, respectively. Analyses were run using Mplus with Full-Information Maximum Likelihood estimation. All models controlled for parenting variables and adolescent outcomes at baseline and provided an adequate fit to the data (e.g., sugar model χ^2 (df) = 37.55 (19), $p < .05$) and general monitoring at post intervention ($b=.16-.17$, $p < .05$) positively influenced domain-specific monitoring at post intervention. Domain-specific monitoring at post intervention was negatively associated with adolescent sugar intake ($b=-.19$, $p < .05$) but not with increased fruit/vegetable intake or physical activity. These findings demonstrate the positive effects of a family-based intervention on parental monitoring of adolescent diet. More importantly, they highlight the importance of targeting domain-specific parental monitoring to successfully reduce sugar intake in a sample of Hispanic adolescents with unhealthy weight.

EMPIRICAL EVALUATION OF BEHAVIORAL HEALTH PROVIDER SERVICES IN CHILD WELFARE

Kimberlee Trudeau, Ph.D.¹, David Kraus, PhD²¹Outcome Referrals, Inc., Framingham, MA; ²Outcome Referrals, Framingham, MA

Child welfare jurisdictions employ many different types of service providers to meet the diverse behavioral health needs of children in their care. The question is: are these providers meeting the needs of these children? With behavioral outcome data from the children and placement services data, it is possible to evaluate the comparative effectiveness of providers with youth in a specific child welfare jurisdiction and identify gaps in service delivery. This project summarizes the placement data of a child welfare jurisdiction in the US. The services occurred between January 2015 and April 2017. The sample includes 530 children and adolescents for whom initial and follow up data were available. Behavioral health outcome data were collected using the Treatment Outcome Package (TOP). The TOP (e.g., Kraus et al., 2005) is an empirically validated well-being assessment that is used in behavioral health and child welfare settings. The Child TOP (for ages 3 - 13) is completed by the legal guardian and measures 13 domains. The Adolescent TOP (for ages 11 - 21) is completed by the adolescent and measures 11 domains. Additional raters who know the child well (e.g., caseworker, teacher) are also asked to complete the TOP. Both instruments assess Depression, Attention Problems, Conduct Disorders, Violence, and Suicidality. Participants endorse each item between "1=All" to "6=None of the Time" for the past two weeks. Provider evaluation scores are based on the average of all TOP scores per youth from first 30 days (initial score) and from the last 30 days (follow up score). Each youth's score is weighted to ensure that providers who work with children who have more challenges than others do not have to meet a higher threshold for a positive outcome. A review of the Provider Scorecard for this jurisdiction revealed that of the 18 providers who had served at least 10 children (range 10 - 214), less than 25% had change scores above the national average for Depression, Violence, Lack of Resiliency, Social Conflict, and Work/School Functioning. This analysis helps pinpoint specific behavioral health resources lacking in this community as well as the providers who are performing comparatively worse than others. Child welfare jurisdictions have found this to be a very valuable tool in contracting and resource allotment. Comparisons of gaps across multiple jurisdictions will be shared to highlight opportunities for behavioral health service improvement.

EXAMINING THE RELATIONSHIP BETWEEN ADOLESCENT SLEEP AND MENTAL DISTRESS IN AMERICAN INDIANS ADOLESCENTS

Matthew Frank, MPH, MSW

Albuquerque Area Indian Health Board, Inc., Albuquerque, NM

Background: During adolescence, significant changes occur in sleep patterns (e.g., decreased duration and increased sleep problems). To date, studies have not examined the relationship between sleep duration and mental distress among American Indian adolescents (AIAs).

Method: A secondary analysis of New Mexico Youth Risk and Resiliency Survey (YRRS) data (N=15,930) was used to examine the relationship between sleep duration and mental distress (i.e., feeling sad or hopeless almost every day for two weeks or more during the past 12 months) among adolescents age 14–18.

Results: AIAs, as compared to other races and ethnicities, who had < 8 hours of sleep, were significantly (AOR=1.57; CI=1.35–1.82) more likely to experience mental distress when controlling for other variables.

Implications: Existing studies demonstrate that short sleep duration is related to various negative mental health outcomes. Therefore, additional research and culturally-informed interventions are needed to fully understand this association and promote healthy sleep among AIAs.

FACTORS RELATED TO POST-TRAUMATIC GROWTH RESULTING FROM CHILDBIRTH

Christyn Dolbier, Ph.D., Meghan Sharp, M.A., Burkle Bradley, BA student

East Carolina University, Greenville, NC

Introduction: Childbirth is a challenging life event from which negative and positive psychological outcomes may emerge. Research has focused primarily on negative outcomes such as post-traumatic stress disorder (PTSD). The few studies of post-traumatic growth (PTG) document its occurrence and identify several correlates. The purpose of this research is to expand our knowledge about factors related to PTG resulting from childbirth.

Method: Participants: Women who gave birth to a living child in the past 1–3 months (N=183) were recruited from social media and message boards. Characteristics: M_{age} = 29 years; majority White, married, minimum 2-year college degree, employed full- or part-time; 64% primiparous, 51% pregnancy complications, 61% birth complications. Infants: 37% neonatal intensive care unit (NICU) admittance, 26% PTB, 27% LBW. Online survey assessed demographic, pregnancy/childbirth characteristics, childbirth appraisals, PTG (shortened PTGI), bonding (shortened PBQ), and symptoms of PTSD (PCL-5), anxiety (HADS-A) and depression (EPDS); and NICU stress (PSS: NICU) in mothers of babies in the NICU.

Results: At least moderate degrees of PTG were reported by 40% of the sample. Greater PTG for those living separately from baby's father ($M=46.36$) compared to those cohabiting ($M=35.11$), $t(158)=-2.92$, $p=.004$, and for primiparous ($M=37.41$) compared to multiparous ($M=33.27$), $t(158)=-2.02$, $p=.045$. PTG not related to NICU admittance. Childbirth appraisals: PTG not related to appraisal of childbirth as traumatic; PTG related to greater control over self ($r=.16$, $p=.040$) and support from healthcare providers ($r=.27$, $p=.001$) and family/friends ($r=.28$, $pr=.46$, $pr=.31$, p

Conclusions: These findings add non-cohabiting, NICU stress, and bonding as factors related to PTG, and further document PTG relates to first-time birth and does not relate to postpartum emotional distress. Findings conflict with prior reports of PTG negatively relating to maternal age and education, and not relating to support and control during childbirth (perhaps due to assessment being closer to birth). Surprisingly, PTG was not related to traumatic childbirth appraisal or NICU admittance. These findings can inform perinatal interventions of the potential for personal growth resulting from childbirth.

FOOD INSECURITY AND OBESITY AMONG LOW-INCOME MEXICAN ORIGIN CHILDREN: THE MODERATING ROLE OF HAIR CORTISOL.

Laura M. L. Distel, B.A.¹, Amy Bohnert, Ph.D.², Catherine DeCarlo Santiago, Ph.D.¹¹Loyola University Chicago, Chicago, IL; ²Loyola University of Chicago, Chicago, IL

Food security, the level to which food is considered stable and adequate in a home, is a growing problem in the United States, with low-income minority youth disproportionately affected. Somewhat paradoxically, research has found that some children with greater food insecurity are more likely to become overweight or obese (Dietz, 1995). Researchers have cited cheaper cost of food, adaptive overeating, and metabolic changes as possible mechanisms for this association (Casey et al., 2006). One important factor by which food insecurity influences weight may be the accumulation of chronic stress associated with food scarcity and other poverty related stressors (Alaimo, Olson & Frongillo, 2001; Drewnowski & Specter, 2004). Drawing on a low-income urban minority sample, this study aims to examine how food insecurity relates to childhood zBMI, and whether the influence of food insecurity on zBMI varies based on levels of chronic stress assessed via accumulation of hair cortisol. Participants were 50 Mexican-origin immigrant families with a child aged 6–10 years ($M=8.44$, 46% female). Anthropometric measurements were used to calculate child zBMI based on CDC growth charts (Kuczmarski et al., 2002). Hair samples were collected using thinning shears during home visits and assayed for hair cortisol levels. Primary caregivers rated 1-item measure of food insecurity utilized in the annual USDA food surveys and NHANES (Keenan, Olson, Hersey, & Parmer, 2001).

Children's zBMI scores ranged from -1.66 to 2.72 ($M = 0.87$); 12% were overweight (BMI > 85th percentile) and 34% were obese (BMI > 95th percentile). Hair cortisol levels before log transformations ranged from .53 to 369.60 pg/mg ($SD = 63.44$). Forty-four percent of primary caregivers reported not always having the kinds of food they want to eat and 8.2% reported sometimes not having enough food to eat. A multiple regression moderation analysis was conducted using PROCESS (Hayes, 2013). Hair cortisol significantly moderated the relation between food insecurity and zBMI when controlling for age and gender ($b = 0.28$, $p = .05$). Food insecurity was only associated with higher zBMI for children with the highest accumulation of hair cortisol. This finding expands upon previous research linking food insecurity to excess adipose among children, showing that hair cortisol strengthens this association. Food insecurity may only be associated with obesity for children who are exposed to prolonged chronic stress and subsequent dysregulation of the stress response system. These findings have clinical implications for the treatment of childhood obesity among low income Mexican-origin populations, including the importance of stress reduction techniques.

FORMATIVE DEVELOPMENT OF A FAMILY-BASED EHEALTH OBESITY PREVENTION INTERVENTION FOR HISPANIC PARENTS AND ADOLESCENTS

Blanca S. Noriega Esquivas, MD¹, Marissa Kobayashi, BA, MHS², Rachel Wagstaff, BSA³, David Dorcius, BS⁴, Lucia Alvarez, N/A⁵, Sara M. St. George, PhD⁶¹University of Miami - Miller School of Medicine, Miami, FL; ²University of Miami - Miller School of Medicine, Coral Gables, FL; ³University of Miami - Miller School of Medicine, Miami, FL; ⁴Florida International University Herbert Wertheim College of Medicine, Miami, FL; ⁵University of Miami - School of Nursing and Health Studies, Doral, FL; ⁶University of Miami - Miller School of Medicine, West Miami, FL

Background: Obesity disproportionately affects Hispanic populations, with 22.8% of Hispanic adolescents currently classified as obese.¹ The family system is especially important in the Hispanic community, yet there is surprisingly little research examining the effects of family-based obesity prevention programs in Hispanic adolescents. Because Hispanics (94%) are more likely than non-Hispanic whites (85%) to access the internet via a mobile device,² an innovative way to package family-based interventions for this population may be through the use of web and smartphone technology.

Aim: To engage in the initial iterative stages of user-centered design for developing a family-based eHealth obesity prevention intervention for Hispanic families by 1) exploring parents' and adolescents' perceptions and current use of technology for their health, and 2) eliciting their feedback on preliminary intervention ideas.

Methods: Hispanic adolescents ($n=20$, 13.6 ± 1.0 years old, 68% female, 32% US-born, 74% normal weight, 26% overweight) identified as at-risk for obesity (due to not meeting national recommendations for fruit/vegetable intake, physical activity, or sedentary behavior) and their parents ($n=20$, 43.7 ± 5.9 years old, 90% female, 74% married, BMI: 30.5 ± 12.4) participated in either one of two focus groups or 15 individual interviews. Transcripts were analyzed using a rapid assessment process³.

Results: Participants reported using technology for their health in limited ways (e.g., to search for medical symptoms, recipes, and workout routines on the internet). Most reported not having any health-related apps installed on their smartphones. When asked to describe features they liked about either health apps or their favorite apps more generally, parents and adolescents described the importance of interactive and social features (e.g., ability to view and/or upload photos/videos, communicate with others). Participants additionally suggested several ways to make a family-based intervention interactive (e.g., messaging between parents/adolescents, gamification/point system and competition between family members).

Conclusions: Understanding the needs and preferences of end users to inform intervention content and usability is of utmost importance in the technology development process. Input from Hispanic parents and adolescents in the present study is being used to develop intervention mock-ups for subsequent rounds of user-centered testing.

IDENTIFYING THE PREVALENCE OF PROJECT HEALTHY SCHOOLS CHILDREN AT HIGH RISK FOR CARDIOVASCULAR DISEASE AND METABOLIC SYNDROME

Anne Kalinowski, BS, Rachel Krallman, BS, Daniel Montgomery, BS, Jean DuRussel-Weston, RN, MPH, Eva Kline-Rogers, MS, RN, NP, Elizabeth A. Jackson, MD, MPH, Kim A. Eagle, MD

Michigan Medicine, Ann Arbor, MI

Introduction: Recent studies have shown that 6.8% of overweight children in the United States meet criteria for metabolic syndrome (MetS), placing these children at increased risk for developing cardiovascular disease (CVD) and other health complications. This study analyzes the prevalence of middle school students at high-risk for CVD, evaluates whether the school-based intervention Project Healthy Schools (PHS) improves CVD risk factors, and assesses if a sub-population of high-risk children also meets criteria for MetS.

Methods: PHS promotes healthy behaviors in Michigan sixth-grade students through education and environmental changes. Height, weight, blood pressure (BP), random glucose, and lipid panel data were collected between 2004–2017 from students who, with their parents, consented to physiological screening. Students were considered high-risk for CVD if they had ≥ 1 of the following criteria: BMI > 85 th percentile, total cholesterol (TC) ≥ 200 mg/dL, HDL cholesterol (HDL-C) ≤ 35 mg/dL, LDL cholesterol (LDL-C) ≥ 130 mg/dL, random glucose ≥ 140 mg/dL, systolic BP ≥ 126 mmHg or diastolic BP ≥ 80 mmHg. Program effectiveness was determined by comparing the physiological measurements of high-risk students pre- and post-PHS intervention.

High-risk students were then assessed for MetS, defined as meeting ≥ 3 of the following criteria: BMI ≥ 97 th percentile, triglycerides (TRG) ≥ 95 th percentile, HDL-C ≤ 5 th percentile, systolic BP ≥ 126 mmHg or diastolic BP ≥ 80 mmHg, random glucose ≥ 140 mg/dL.

Results: Of the 3100 consented students, 1837 (59.3%) had complete measurement data. Upon analysis, 943 (51.3%) students were considered high-risk. Post-PHS, high-risk students showed improvement in TC (159 v.157, $p < 0.001$), LDL-C (90 v.87, $p < 0.001$), random glucose (96 v.93, $p < 0.001$), systolic BP (112.7 v.111.3, $p = 0.004$), and diastolic BP (65.7 v.63.7, $p < 0.001$). Among high-risk students, 219 (23.2%) met MetS criteria. When compared to students without MetS, students with MetS had significantly higher BMI (28.3 v. 22.4, $p < 0.001$), TRG (161 v. 96, $p < 0.001$), systolic BP (118.7 v. 110.7, $p < 0.001$), and diastolic BP (70 v. 64, $p < 0.001$).

Conclusions: A large population of middle school students in Michigan is at high-risk for CVD, a significant portion of whom are also positive for MetS. Importantly, participation in PHS resulted in significant improvement of CVD risk factors in high-risk students. Future investigations should assess the long-term effects of PHS in high-risk populations.

IMPROVING ORAL CARE FOR CHILDREN WITH AUTISM

Lucía I. Floríndez, MA¹, Dominique Como, MA, OTR², Sharon Cermak, EdD, OTR/L, FAOTA², Jose Polido, MS, DDS³, Leah I. Stein Duker, PHD, OTR/L²

¹University of Southern California, Burbank, CA; ²University of Southern California, Los Angeles, CA; ³Children's Hospital Los Angeles, Los Angeles, CA

Background: Oral health, an everyday occupation of daily living, is important to both physical and psychological health. Children with autism spectrum disorders (cASD) experience significant barriers to adequate oral care, including sensory processing concerns, impairments in communication, and ineffective techniques to alleviate fear and anxiety. However, little research on efficacious interventions to improve care for this population exists.

Statement of Purpose: To gather information from parents/caregivers and dental professionals on current strategies to facilitate successful oral care encounters for cASD.

Methods: Two focus groups with parents of cASD (9 parents with children aged 5–18 years) and two focus groups with 8 dental practitioners who treat cASD were conducted. Semi-structured questions were asked about the oral care related challenges experienced by cASD and the strategies employed to address them. Each session lasted 2.5–3 hours in duration and was transcribed verbatim. Thematic analysis following a grounded theory approach was used to analyze the data by 3 independent coders.

Results: Three themes emerged from the parent focus groups. The first theme, *What Makes a Good Dentist*, focused on the dentist's knowledge, understanding, and experience. The second theme, *Tricks, Tactics, and Diversions*, described different techniques to improve dental visits. The last theme, *Preparation, Preparation, Preparation*, explored parent-implemented strategies.

In the dentist focus groups, four themes emerged. The first theme, *Parents Know Best*, described how dentists often valued parental expertise regarding care techniques. The second theme, *Preparation*, explored strategies for preparation in the home and at the dental office. The third theme, *Network of Colleagues*, referred to dentists seeking advice of other health care professionals regarding working with the ASD population, as well as mentoring new dentists. The last theme, *Flexibility*, focused on dentists doing "whatever it takes" to accommodate the needs of cASD.

Conclusions: Focus group findings provide insight into the techniques perceived by parents and dental providers to lead to successful dental care encounters for cASD. Caring for a child with ASD is a unique and challenging experience. Better understanding of these strategies can help to improve oral care for cASD, and illuminate the particularities of how cASD engage in everyday occupations. This information has the potential to improve care for this population by identifying areas for modification to create the optimal experience for cASD and their parents.

Discussion about how to facilitate better experiences for cASD in dental settings also has potential to help mitigate the health disparities faced by this marginalized population.

PARENT SUPPORT AND ADOLESCENT PERCEPTIONS OF COMMUNICATION FREQUENCY ABOUT WEIGHT-RELATED HEALTH BEHAVIORS

Lauren H. Law, MA, Dawn K. Wilson, PhD

University of South Carolina, Columbia, SC

Family Systems Theory emphasizes the role of positive parenting in promoting adolescent health, and open communication between parent and adolescent may facilitate self-regulation and behavior change. Research has shown that parents report higher frequency of these conversations than their children, yet few studies have examined factors that predict perceived frequency of these conversations in adolescents. The current study examined parenting factors associated with authoritative parenting, such as emotional and tangible support, autonomy support (providing choice), and parent frequency of health behavior communication that may be associated with adolescent perceptions of frequency of health behavior communication. Participants were African American adolescents ($N = 208$; $Age = 12.90$ years; 66% female; $MZBMI = 2.04$) and their caregivers ($Age = 43.60$ years; 94% female) enrolled in the Families Improving Together (FIT) for Weight Loss trial. Adolescent perceptions of communication frequency, parent-reported weight-related parenting behaviors, and parent-reported communication were measured using validated surveys. Adolescent zBMI was calculated from height and weight measurements and standardized using CDC growth reference curves. Regression analyses indicated that the model predicting adolescent perceived communication was significant beyond covariates (child and parent age and sex, child zBMI, and parent education; $F(11,196) = 3.52$, $p < 0.05$; $R^2 = 0.17$, $\Delta R^2 = 0.12$). Parent-reported emotional support for diet ($B = 0.28$, $SE = 0.10$, $p = 0.01$) and tangible support for PA ($B = 0.15$, $SE = 0.07$, $p = 0.03$) were positively associated with adolescent-perceived parent communication about health behaviors. Parent-reported emotional support for PA, tangible support for diet, autonomy support, and communication frequency were not significant predictors. Interestingly, adolescent- and parent-reported communication frequency were only moderately correlated within families ($r = 0.23$). Results suggest that weight-related parenting social support, especially encouragement for healthy eating and providing resources for activity, is an important predictor of youth recognition of parent conversations about health behavior change. Interventions should consider encouraging parenting skills associated with authoritative parenting style in addition to teaching parents positive communication strategies to use in health behavior change conversations in order to better support adolescents.

PEER NORMS PREDICT BENEFICIAL AND DETRIMENTAL INDICATORS OF DIET AND PHYSICAL ACTIVITY AMONG U.S. ADOLESCENTS

Elise L. Rice, PhD¹, William Klein, PhD²¹National Cancer Institute, Bethesda, MD; ²National Cancer Institute, Potomac, MD

Social norms exert notable influences on adolescents' behaviors, including those with the potential to bolster or degrade their health. Although peer influences on risky behaviors such as substance use have received greater empirical attention, prior research has documented evidence (albeit sometimes inconsistently) of social influence on adolescent dietary behaviors and physical activity. The present research extends previous work by examining associations between social norms for multiple behaviors – both beneficial and detrimental to health – in the domains of diet and physical activity and identifying moderators of those associations. Adolescent participants ($N = 1,496$; ages 12–17) from the Family Life, Activity, Sun, Health, and Eating study (FLASHE; 2014) separately reported on the extent to which their friends eat fruits and vegetables; eat junk food or drink sugary drinks; exercise; and watch TV, play on the computer, or play electronic games most days of the week. They also reported on their own attitudes and behaviors as well as their parents' corresponding attitudes and behaviors and sociodemographic characteristics. Separate adjusted regression analyses revealed that peer norms were associated with teens' own behavior for beneficial behaviors such as fruit and vegetable consumption ($\beta = 0.26$, $p < .001$) and physical activity ($\beta = 0.39$, $p < .001$) as well as detrimental behaviors such as junk food consumption ($\beta = 0.36$, $p < .001$) and sedentary habits ($\beta = 0.15$, $p < .001$). Subsequent analyses identified moderators of these associations, including attitudes about the focal behavior: liking fruits and vegetables ($b = 0.083$, $SE = 0.026$, $p = .001$) or physical activity ($b = 0.057$, $SE = 0.022$, $p = .01$) strengthened the corresponding positive associations between peer norms and teen behavior, but there were no moderation effects for detrimental behaviors. Parental norms (both descriptive and injunctive) were also associated with teen behaviors ($ps < .05$), though effects were smaller than for peer norms and not moderated by teen attitudes ($ps > .1$). Although the present results are limited by the cross-sectional nature of the data, they hold value for interventions such as social norms marketing campaigns that aim to change perceptions of peer norms for health-promoting behaviors, suggesting that optimal approaches may attempt to improve teens' attitudes about diet or physical activity in addition to their perceptions of their friends' behaviors.

PREDICTING WOMEN'S REPRODUCTIVE CARE ACCESS UNDER THE CURRENT POLITICAL ADMINISTRATION: THE ROLE OF ABORTION MISINFORMATION

Alison J. Patev, M.S., Kristina B. Hood, Ph.D.

Virginia Commonwealth University, Richmond, VA

Women's reproductive healthcare has been a divisive topic during the first year of the current political administration. Identifying influences on perceptions of women's reproductive healthcare access is crucial to better understand reproductive policy support. Conservative and religious individuals are likely to oppose abortion (Pew Research Center, 2017) and have medically inaccurate ideas about contraception (Eisenberg et al., 2004). There are also gender differences, as women access reproductive services more frequently and better understand how access to reproductive care might change under the current administration. However, individual difference factors are not the sole predictors. Abortion misinformation (AM) likely predicts perceptions of reproductive healthcare access. Those with more AM support restrictive policies such as abortion bans (Kavanaugh et al., 2013) and thus may have different perceptions about reproductive healthcare access than those with less AM. This work sought to understand the predictive power of AM on access to reproductive healthcare.

The study included 308 individuals recruited on Amazon's Mechanical Turk, with four individuals excluded due to missing data. Participants completed online items regarding self-reported conservatism, gender, and religiosity. They also completed a researcher-designed AM measure and items assessing perceptions of reproductive healthcare access under the current political administration in four areas: contraception, abortion, preventive services for women with private insurance, and preventive services for women with Medicaid. Four hierarchical regressions, controlling for conservatism, gender, and religiosity, showed that individuals endorsing more AM believe women will have easy access to reproductive health care services under the current political administration. AM was significantly related to perceptions of contraception and abortion, such that those with more AM perceive women will have easy access to contraception, $\beta = .02, p < .001$, and easy access to abortion, $\beta = .01, p = .02$. Regarding preventive care, AM was significantly related to both preventive care for women with private insurance, $\beta = .02, p < .001$, and Medicaid, $\beta = .01, p = .05$. Those with more AM perceived women with both types of insurance would be easily able to access preventive care. These findings improve understanding of perceptions of reproductive healthcare access and could be beneficial in predicting support for proposed policies.

SITTING POSTURAL CONTROL IS DIFFERENT IN INFANTS BASED ON MATERNAL PHYSICAL ACTIVITY FREQUENCY AND INTENSITY

Kailey Snyder, MS¹, Danae Dinkel, PhD², Anastasia Kyvelidou, PhD³¹University of Nebraska Omaha School of Health & Kinesiology, Omaha, NE;²University of Nebraska Omaha School of Health & Kinesiology, Omaha, NE;³Creighton University, Omaha, NE

Background: A mother's health behavior has a direct influence on the health of her child. However, the influence a mother's physical activity (PA) can have on an infant's physical development is not well understood. There is a vital need to better understand how a mother's PA can influence their infants' motor development, particularly in regards to postural control.

Purpose: The purpose of this study was to determine whether maternal PA intensity and frequency influenced infants postural control strategies at one-month post onset of sitting.

Methods: 29 infant/mother dyads were recruited as part of a larger study assessing infant physical development. Infants center of pressure (COP) was measured on an AMTI force platform approximately one month after the onset of sitting occurred. Postural control was measured via linear measures which provide information on the amount of postural sway; the root mean square value (RMS) for the center of pressure in the anterior/posterior (AP) and medial/lateral (ML) direction. PA data were collected via interview with mothers and were categorized into activity intensity (sedentary, light, moderate/vigorous activity) and frequency (Results: An ANOVA revealed significant differences in regards to PA intensity for RMS in the AP direction ($p = .034$). Infants of mothers who reported moderate/vigorous intensity PA had the lowest RMS values (mean=8.4mm). While infants whose mothers were sedentary showed the highest RMS values in the AP direction (mean=20.1mm). In regards to PA frequency, similar significant differences were seen for RMS in the AP direction ($p = .008$). Infants of mothers engaging in PA ≥ 4 days per week had the lowest RMS movement in the AP direction (mean=8.2mm) and range (22.3mm-79.6mm) and those whose mothers reported $p = .31$).

Conclusion: Maternal PA intensity and frequency appears to lead to different postural control strategies in the AP direction. Further research is needed to determine what these differences mean for future milestone achievement (i.e., onset of standing, walking). Additionally, determining causation for these differences is crucial. Further evaluating women's prenatal PA in relation to infant's motor development outcomes is needed to gain a better understanding of infant milestone attainment.

STRENGTHENING SELF-CONFIDENCE AND SOCIAL COMPETENCE: A MUSICAL CAMP FOR CHILDREN IN A YOUTH EDUCATIONAL CENTER IN GERMANY

Carina Mnich, N/A¹, Claudio Nigg, Ph.D.²¹University of Applied Sciences, Regensburg, Regensburg, Bayern, Germany; ²University of Hawaii, Honolulu, HI

Background: During childhood, it is important to gain skills to build self-confidence. At the same time, peer groups play a relevant role for developing social competence. These constructs are valuable for growing into a healthy well-adjusted adult. A musical camp promoting these constructs was implemented at a Youth Educational Center in Germany.

Purpose: To evaluate a children's musical camp on self-confidence and social competence outcomes.

Methods: In this camp, participating children could choose between three different workshops: dance; theater; or choir; or a combination thereof. Mixed throughout the 6 day camp were social spare-time activities like a campfire, a night hike, and a team training course. Participants presented their musical performance on the last day. Post-test surveys using a scale from 1–4 (1: agree; 2: agree somewhat; 3: disagree somewhat; 4: disagree) were administered to all camp participants. Additionally, participants could indicate what they liked best and what should be improved.

Results: There were 22 participants (86% female; age $M=11.9$ [$SD=1.2$] years). The positively evaluated processes (% agree or somewhat agree) were: 86.4% endorsed that ambition is an essential part for presenting a musical ($M=1.3$, $SD=0.6$); 90.9% felt comfortable in the group ($M=1.3$; $SD=0.6$); and 81.9% felt that they could bring up their own ideas ($M=1.7$; $SD=0.8$). In terms of outcomes, 86.2% reported improved their self-confidence ($M=1.6$; $SD=0.8$) and 77.3% improved their social competence ($M=1.8$; $SD=0.8$) due to the camp. Thematic qualitative data analysis revealed that many of the children highlighted the workshops, the variety of workshops, the free time activities, as well as the solidarity of the group. Most of the participants agreed that they'd like to come back the next year and the most frequent improvement was keeping everything the same.

Conclusions: The results indicate that the camp had a positive effect on self-confidence and social competence of the children. This indicates that the program is suitable to strengthen self-confidence and social competence among the participants while they can discover and develop their own life skills. Further evaluation of the camp using a more rigorous research design is recommended. In addition, longitudinal follow-up of the participants should be done to investigate long-term impacts.

Acknowledgement: We appreciate the Youth Educational Center in Waldmuenchen in Bavaria, Germany, who provided the data set.

THE RELATIONSHIP BETWEEN BREASTFEEDING PRACTICES AND POSTPARTUM DEPRESSIVE SYMPTOMS IN APPALACHIAN WOMEN

Rose A. Stephens, AS¹, Andrea D. Clements, PhD², Valerie M. Hoots, MA³, Beth A. Bailey, PhD⁴¹Department of Psychology, East Tennessee State University, Unicoi, TN; ²Department of Psychology, East Tennessee State University, Johnson City, TN; ³Department of Psychology, East Tennessee State University, Weaverville, NC; ⁴Department of Family Medicine, East Tennessee State University, Johnson City, TN

Introduction: Postpartum Depression and postpartum depressive symptoms have been found to have a strong association with breastfeeding duration in a significant portion of women across a variety of geographical locations. The aim of this study was to explore the correlation between postpartum depressive symptoms at 6 months postpartum and total duration of breastfeeding measured at 15 months postpartum in Appalachian women.

Methods: A longitudinal study was conducted in which 1,063 mostly low socioeconomic status women were recruited across 6 prenatal practices in Appalachia. At 6 weeks, 6 months, and 15 months postpartum, depressive symptoms were measured using the Edinburgh Postnatal Depression Scale (EPDS). From the original sample, 134 completed a self-report measure of breastfeeding initiation and duration at 15 months postpartum.

Results: EPDS score did not predict whether or not women breastfed, but did predict their duration of breastfeeding. Women who scored in the clinically significant range (13 or higher) on the EPDS at 6 months postpartum breastfed a significantly shorter length of time (Mean = 1.75 months, $SD = 2.70$) than women who scored below 13 on the EPDS (Mean = 4.48 months, $SD 5.22$; $t(133) = 3.61$, $p = .001$).

Conclusion: Clinically significant Edinburgh Postnatal Depression Scale scores were predictive of shorter duration of breastfeeding.

THE RELATIONSHIP OF CONSCIENTIOUSNESS TO ADOLESCENT HEALTH AND HEALTH-RELATED BEHAVIORS

Jeremy Burrus, PhD¹, Krista Mattern, PhD¹, Lucas Carr, PhD²¹ACT, Iowa City, IA; ²University of Iowa, Iowa City, IA

Background: Several meta-analyses have demonstrated the power of personality traits in predicting important life outcomes. Conscientiousness is consistently shown to be the most predictive of these traits, with conscientiousness predicting a range of outcomes, including health-related outcomes. While much research on conscientiousness and health-related behaviors has been conducted on adult populations, less has been conducted on adolescents.

Objective: To examine the relationship of conscientiousness and health-related behaviors, and subjective and objective measures of health in adolescents.

Methods: In April 2017, a national sample of 2,962 9th-12th grade students reported their height, weight, conscientiousness, and several health-related behavior questions taken from the 2017 Youth Risk Behavior Survey targeting physical activity, sedentary behavior, sleep and dietary intake. They also completed a 2-item subjective health measure ((2 items measuring how healthy students felt they were compared to their peers).

Results: Adolescent conscientiousness was significantly ($p<0.001$) associated with a host of health-related behaviors, including physical activity ($r = .14$), participation in sports teams ($r = .32$), weekday and weekend TV time ($r = -.10$ and $-.08$), time spent playing video games ($r = -.23$), weekday sleep time ($r = .12$), soda consumption ($r = -.09$), fruit and vegetable consumption ($r = .10$ and $.09$), and eating breakfast ($r = .17$). Conscientiousness was also related to subjective measures of health ($r = .18$). Interestingly, conscientiousness was not related to BMI ($r = -.04$).

Conclusions: Conscientiousness is associated with several important health-related behaviors. Although personality was previously thought to be “set in plaster” at an early age, emerging research suggests that personality is more malleable than previously thought. This suggests that interventions designed to improve conscientiousness may also lead to improved adolescent health.

A CHURCH-BASED WEIGHT LOSS INTERVENTION UTILIZING TEXT MESSAGES: THE LIFESTYLE CHANGES THROUGH EXERCISE AND NUTRITION (LEAN)

Leah A. Carter, M.Ed.¹, Robert L. Newton, Jr., Ph.D.¹, Melissa Harris, MS, BS², Sandra Larrivee, M.S.¹, Betty Kennedy, Ph.D.¹, William Johnson, Ph.D.¹

¹Pennington Biomedical Research Center, Baton Rouge, LA; ²Pennington Biomedical Research Center/Louisiana State University, Baton Rouge, LA

Introduction: Church-based weight loss programs have been shown to result in significant weight loss and improved physiological parameters in African American adults. Few have taken advantage of recent mobile health (mHealth) technologies that may enhance outcomes. The current study is designed to assess the feasibility and efficacy of a church-based weight loss intervention that incorporated mHealth technology.

Methods: A 6-month cluster randomized trial design was utilized. Eight churches were randomized to the immediate intervention group (IIG; n = 5) or the delayed intervention group (DIG; n = 3). Community health coaches were volunteer congregation members who were trained to deliver the intervention to their respective churches. The intervention was based on the Diabetes Prevention Program (DPP). Participants in the IIG received 5 text messages per week related to the intervention content. Participants in the DIG received 2–3 text messages per week consisting of general health related topics specific to African American adults. Measures included body composition, physiological parameters, quality of life, and treatment satisfaction.

Results: The participants had a mean age of 56.0 (10.3), 91.8% were female, and the mean BMI was 38.6 (6.4). The average attendance was 55%. There were 97 African American adults enrolled across the IIG (n = 68) and DIG (n = 29). There was a significant between group difference in percent weight loss (p = 0.030) in that the IIG participants lost -1.4 ± 0.4 kg and DIG participants gained 0.17 ± 0.6 kg. There was a marginally significant difference in percent body fat (p = 0.067) in that the IIG participants lost $-0.4 \pm 0.8\%$ and DIG participants gained $1.4 \pm 0.5\%$. Greater than 80% of IIG participants reported that the text messages helped them to eat and exercise more and were satisfied with the number of text messages received. Approximately 43% of participants responded to the automated text messages.

Conclusions: This DPP translation study resulted in small but significant weight loss. The text messages were feasible to deliver to African Americans in a faith-based setting and was well-received. In the future, more advanced technology such as mobile apps, physical activity monitoring devices, bluetooth weight scales could be used to provide a more comprehensive intervention while also decreasing burden on the community health coaches and participants.

A PILOT RCT TESTING EFFECTS OF STEAM-ROOM USAGE AFTER EXERCISE ON CARDIOVASCULAR FUNCTIONING AMONG PRE-HYPERTENSIVE ADULTS

Sean P. Mullen, PhD¹, Jason Cohen, B.S.², Daniel Palac, MA³, Tiffany Bullard, B.S.¹, Madhura Phansikar, M.A.¹, Jonathan North, B.S.⁴, Brett J. Wong, Ph.D.⁵, Kenneth Wilund, PhD¹

¹University of Illinois at Urbana-Champaign, Urbana, IL; ²University of Illinois at Urbana Champaign, Champaign, IL; ³University of Illinois at Urbana-Champaign, Champaign, IL; ⁴University of Illinois Urbana-Champaign, Monticello, IL; ⁵Georgia State University, Atlanta, GA

Evidence of benefits from thermotherapy (e.g., traditional Finnish sauna, infrared sauna, thermal baths) exists but few studies have evaluated them systematically in randomized controlled trials (RCTs). The effects of exogenous heat treatments appear to parallel those associated with exercise and combining interventions may result in lowered coronary risk. The primary purpose of this pilot RCT was to test the potential additive effects of supervised heat therapy with exercise (vs. exercise alone) on vascular functioning in a sample of adults with untreated, confirmed pre-hypertension (120 to 139 mmHg systolic / 80 to 89 mmHg diastolic blood pressure [BP]). Participants received 14 weeks of supervised aerobic exercise (E dose=3x/week, 50 minutes, 50–75% max heart rate) followed by our experimental manipulation consisting of either quiet, seated rest in a lobby for 10–20 minutes (n=20) or time-matched sessions in a ~90° F steam-room (n=21). At baseline and 4-month follow-up, automated SBP and DBP were assessed along with demographics, history of cardiovascular disease (CVD) and smoking status, and a battery of physical, cognitive and psychosocial measures. Our sample consisted of mostly non-Hispanic White (73.2%) middle-aged adult (M=46.66) women (58.5%) who were married with 1 to 4 children (78%) and working full-time (87.8%). Every participant received a paid gym membership for 4 months and they were further encouraged to meet public health physical activity guidelines plus AHA guidelines for reducing blood pressure. Overall compliance with sessions was 80% and the difference in attendance between steam and rest conditions was not statistically significant (30.62 sessions [SD=14.40] and 4 dropouts vs. 36.60 [SD=6.05] and 2 dropouts, respectively, p=.09). Two adverse events were reported (1 from each group) and both were attributed to existing chronic health conditions. In line with intention-to-treat, we analyzed data using plausible values generated by well-established multiple imputation procedures for missing follow-up (n=7) data. In support of our primary hypothesis, a significant group effect was found in a 2 (E+Steam, E+Rest) x 2 (SBP, DBP) MANOVA adjusting for baseline SBP and DBP and multiple comparisons (Wilks λ = .865, F=2.81, η^2 = .14). Univariate analyses revealed SBP reduction in favor of E+Steam (7.84 vs. 1.95 mmHg, η^2 = .11), even after adjusting for dose (total sessions attended) and known covariates including family history of CVD, smoking status, and living alone (p < .05, η^2 = .10). DBP change was not statistically different between groups, although improvement was observed across the intervention (3.37 mmHg vs. 2.13 mmHg). The findings support our prior studies and together they offer evidence of a promising non-pharmacological treatment for reducing BP among pre-hypertensive middle-aged adults.

AN EXPLORATION OF WHETHER RELIGIOUSNESS PREDICTS EATING BEHAVIORS, WEIGHT CONCERNS, OR WEIGHT GAIN IN PREGNANCY

Brittney Stubbs¹, Andrea D. Clements, PhD², Beth A. Bailey, PhD³¹East Tennessee State University, Johnson City, TN; ²Department of Psychology, East Tennessee State University, Johnson City, TN; ³Department of Family Medicine, East Tennessee State University, Johnson City, TN

Measures of religiousness, diet, weight gain, and eating disordered thinking were assessed in a sample of 182 (age 15 to 42 years) mostly low-income pregnant women in Southeastern Appalachia. Data were taken from a larger, longitudinal pregnancy smoking cessation study conducted from 2007 to 2013. Women completed the Brief Multidimensional Measure of Religiousness/Spirituality (BMMRS), The EAT-26, and the Adult Eating Patterns Scale during a prenatal interview for which they received \$20. Pre-pregnancy BMI and total pregnancy weight change were taken from prenatal charts. Final pregnancy weight change ranged from losing 20 pounds to gaining 92 pounds. Weight change was significantly predicted by pre-pregnancy BMI, with heavier women gaining less weight as would be recommended by healthcare providers. Religiousness was not predictive of pre-pregnancy BMI or weight change, which conflicts with some previous reports that religiousness predicts higher weight; however, pregnancy is a unique time with regard to weight and weight change. Religiousness was also unrelated to self-reported eating behaviors reported on the Adult Eating Patterns Scale, which measures intake of fats, sugars, vegetables, and lean meats. Religiousness was related to EAT_26 scores, with women scoring as more religious on the BMMRS having higher EAT_26 scores, indicating more weight concerns. Pre-pregnancy BMI was also positively related to EAT_26 scores, indicating heavier women were more concerned about their weight. Entering both pre-pregnancy BMI and BMMRS total score in a multiple regression model with EAT_26 scores as dependent variable, pre-pregnancy BMI ($b = .15, p = .04$) and BMMRS ($b = .16, p = .03$) significantly predicted weight concerns ($DR^2 = .024, F(180,2) = 3.96, p = .02$), although accounted for a very small proportion of the total variance in EAT_26 scores. Nine of the women scored above 20 points on the EAT_26, which is considered to be the cutoff for possible eating disordered thinking. Women above and below the cutoff point did not have significantly different mean BMMRS total scores ($t(181) = 0.53, p = .60$). In summary, religiousness does not seem to be a strong predictor of eating patterns or eating disordered thinking in pregnant women in this small sample in this population.

COMPLEMENTARY EFFECTS OF EXERCISE AND HEAT THERAPY ON MINDFULNESS AND COGNITION

Madhura Phansikar, M.A.¹, Daniel Palac, MA², Jason Cohen, B.S.³, Tiffany Bullard, B.S.¹, Jonathan North, B.S.⁴, Kenneth Wilund, PhD¹, Brett J. Wong, Ph.D.⁵, Sean P. Mullen, PhD¹¹University of Illinois at Urbana-Champaign, Urbana, IL; ²University of Illinois at Urbana-Champaign, Champaign, IL; ³University of Illinois at Urbana Champaign, Champaign, IL; ⁴University of Illinois Urbana-Champaign, Monticello, IL; ⁵Georgia State University, Atlanta, GA

Heat therapy is used in many cultures, yet little is known about its potential immediate and long-term cognitive benefits, especially when combined with exercise. However, effects of aerobic exercise on cognition are well-established. We hypothesized that the combination of exercise and adjuvant heat therapy would improve mindfulness and cognitive functioning. Participants received 14 weeks of supervised, regular (3x/week) moderate intensity aerobic activity (50–75% max HR, 50 mins) followed by experimental manipulation consisting of 10–20 min sessions in a ~90° F steam-room (steam group; n=21) or time-matched quiet, seated rest in a lobby (n=20). A battery of assessments including demographics, verbal vocabulary, *Mindfulness Attention Awareness Scale* (MAAS), Flanker (% cost in reaction time) and Digit Symbol Substitution Test (DSST; # correct responses) were measured at baseline and post-intervention (Month 4). Focus of attention (FoA; external=0, internal=10), Ratings of Perceived Exertion (RPE; 1=no exertion, 11=max exertion), and perceived mental fatigue (PMF; 1=low, 5=high) were measured within each session (post exercise and post manipulation, at every session). To test the immediate effect of heat, we averaged data across the first 3 sessions. The sample consisted of middle-aged adults (Female=59%, $M_{age} = 47$) who were pre-hypertensive and screened for depression and cognitive impairment. Overall compliance with sessions was 80%. To comply with intent-to-treat analysis (dropout=6), missing data were imputed via multiple imputation procedures. Results of a 2 (Steam vs. Rest) x 4 (MAAS, FoA, RPE, PMF) MANOVA, revealed a significant effect for group (Wilks $\lambda = .458, F_{(4)} = 9.46, p < .01, \eta^2 = .54$). There were no group differences in MAAS change over the 14-week intervention. However, univariate analyses revealed Steam had more internal FoA ($M_s = 6.22$ vs $3.51, \eta^2 = .37$), higher RPE ($M_s = 4.71$ vs $1.63, \eta^2 = .42$) and lower PMF ($M_s = 1.99$ vs $2.04, \eta^2 = .12$). In a separate 2 (Steam vs. Rest) x 2 (Flanker, DSST) MANOVA, a significant group effect was also found. Follow-up analyses showed that participants in the Steam condition performed significantly better on Flanker (9.45 vs $13.44, \eta^2 = .13$), even after adjusting for age, education, verbal vocabulary, and baseline Fitbit steps. A non-significant trend in processing speed favored steam (DSST=91 vs. 87, $p = .11, \eta^2 = .07$). Interestingly, upon adding dose (# of sessions attended), group differences in inhibition were attenuated ($p = .32, \eta^2 = .03$) whereas differences in processing speed were strengthened ($p = .04, \eta^2 = .12$). In conclusion, exercise and steam-room usage results in more favorable immediate change in psychological profile and longer-term change in cognitive functioning. Together, adjuvant heat therapy appears to complement the effects of aerobic exercise in pre-hypertensive adults.

INDIVIDUAL DIFFERENCES IN RELIGIOSITY INFLUENCE THE ACCEPTABILITY OF AND RESPONSE TO MINDFULNESS-BASED INTERVENTIONS

Roman Palitsky, MA, MDIV, Deanna M. Kaplan, M.A., Daniel Sullivan, PhD, Matthias R. Mehl, Ph.D.

University of Arizona, Tucson, AZ

Mindfulness-based interventions (MBIs) are in increasingly widespread use, and research on MBIs is burgeoning. However, religiosity may present an implementation challenge for interventionists, in the uncertainty about the role of spirituality in intervention design, and for participants, due to perceived conflicts between participants' spiritual commitments and the religious valence of interventions. We conducted two studies, one cross-sectional (Study 1: $n = 450$) and one experiment (Study 2: $n = 715$), to examine the extent to which religiosity influences preference for and response to mindfulness-based interventions. In Study 1, indices of conservative religiosity (Religious Schemas Scale: RSS) correlated positively with willingness to try *spiritually* valenced mindfulness ($r=0.45$) and mindfulness from one's own tradition ($r=0.49$), and negatively with *secularly* valenced ($r=-0.31$) and *Buddhist* ($r=-0.17$) mindfulness. Indices of religious flexibility (Existential Quest: EQ), on the other hand, correlated positively with willingness to try most kinds of mindfulness, including Buddhist and Secular mindfulness, exhibiting a different pattern from RSS. Study 2 examined the impact of religiosity on the experience of a brief online mindfulness intervention. This experiment presented participants with one of three religiously valenced (Secular, Spiritual, and Buddhist) guided mindfulness practices, and examined the relationships between participant religiosity (RSS; EQ), condition, and outcome variables that capture (a) acceptability and (b) pre-post affective change. This experiment featured a predominantly secular sample, and found a significant interaction of Quest and condition on acceptability of the mindfulness practice, but no significant interaction effects on pre-post affective change. However, EQ significantly predicted increased pre-post self-reported happiness ($r = 0.10$) and relaxation ($r = 0.13$), decreased stress ($r = -0.17$) and depression ($r = -0.17$), and was positively associated with acceptability ($r = 0.18$). These initial studies suggest that individual differences in religiosity impact the acceptability of MBIs, and may also influence participants' response to these interventions. We offer a series of recommendations for addressing the potential challenges to implementation and dissemination posed by religiosity, and additionally provide direction for future research.

MIND-BODY-SPIRITUAL MANTRAM VERSUS TRAUMA COPING SKILLS FOR PTSD IN VETERANS: A NATURALISTIC STUDY

Jill E. Bormann, PhD, RN, FAAN¹, Lois V. Krawczyk, PhD², Danielle Beck, MPH, CCRC¹, Pia Heppner, PhD¹

¹VA San Diego Healthcare System, San Diego, CA; ²Edith Nourse Rogers Memorial Veterans Hospital, Bedford, MA

Objectives: Prior randomized trials on outcomes of the Mantram Repetition Program (MRP) in Veterans with posttraumatic stress disorder (PTSD) have shown significant posttreatment reductions in PTSD symptom severity. A mantra(m) is a sacred word or phrase repeated silently throughout the day for mindfulness and self-regulation. This study compared the MRP versus Trauma Coping Skills (TCS) in a natural setting where Veterans with PTSD self-selected their treatments.

Methods: Using a non-randomized, naturalistic design, 66 Veterans with PTSD self-selected either 8-weeks (1 hour/week) of group MRP ($n=35$) or group TCS ($n=31$). Both interventions included education about PTSD but differed in the type of skills to manage symptoms. Clinician-Administered-PTSD Scale-version-4 (CAPS), PTSD Checklist-version 4 (PCL) and Mindfulness Attention Awareness Scale (MAAS) were administered at pre- and posttreatment. Data were analyzed using repeated measures ANOVA.

Results: There were no significant differences between groups on demographic or clinical measures at baseline. Participants' average age was $57 + 11.33$ ranging from 23 to 73 years old. Sixty-eight percent ($n=40$) were White, 92% ($n=61$) male, and 82% ($n=54$) unemployed. There were significant group by time interaction effects for CAPS, $F(1,59)=7.37, p=.01$, and PCL, $F(1,61)=6.81, p=.01$, indicating the MRP group had significantly greater decreases in PTSD symptoms at post-treatment. There was also a significant improvement in mindfulness in the MRP group, $F(2,60)=7.55, p=.01$ at posttreatment than the TCS group.

Conclusions: The MRP, a complementary and spiritual based program for PTSD coping, demonstrated significant improvements in PTSD symptom severity and mindfulness compared to the TCS group in a naturalistic, real-world setting. This study provides additional support for the therapeutic effects of the MRP among Veterans with PTSD.

MINDFULNESS-BASED SMOKING CESSATION AMONG PREDOMINANTLY LOW-INCOME, AFRICAN AMERICAN SMOKERS

Claire A. Spears, Ph.D.¹, Mark A. Dannenfelser, MA, LPC², Sharrill A. Bell, B.A.¹, Brittani P. Carter, MPH³, Charlayne A. Scarlett, B.S.¹, David W. Wetter, Ph.D.⁴¹Georgia State University School of Public Health, Atlanta, GA; ²Mindfulness Center of Atlanta, Atlanta, GA; ³Division of HIV/AIDS Prevention, Centers for Disease Control and Prevention, Atlanta, GA; ⁴University of Utah/Huntsman Cancer Institute, Salt Lake City, UT

Recent studies support the efficacy of mindfulness-based smoking cessation interventions. However, more research is needed to examine the acceptability, feasibility, and effectiveness of these programs, as well as any necessary cultural adaptations, among underserved populations (e.g., low-income African American smokers, who experience profound tobacco-related disparities). This mixed-methods feasibility study examined experiences with mindfulness-based smoking cessation treatment among 53 African American smokers (49% female), most of whom (69%) reported total annual family income < \$24,000. Participants were enrolled in Mindfulness-Based Addiction Treatment (MBAT), which consisted of eight weekly 2-hour group sessions. MBAT taught both formal (e.g., sitting meditation, body scan, yoga) and informal (e.g., awareness of breath) mindfulness practices, in addition to specific strategies for quitting smoking. Participants completed program evaluations to indicate whether they would recommend MBAT to others (1=would not recommend, 10=would definitely recommend); their confidence for continuing to practice mindfulness (1=not at all confident, 10=extremely confident); what they liked and did not like about MBAT; and recommendations for improvement. Of the 37 who have now completed the final evaluation (data collection to be complete in the next month), the mean rating of the extent to which participants would recommend the program was 9.3 ($SD=1.5$). Mean confidence ratings for continued formal and informal mindfulness practice were 7.6 ($SD=2.9$) and 7.5 ($SD=3.0$), respectively. Participants noted that the social support of the group, the meditation practice, learning to focus on the present, and learning to recognize triggers without automatically reacting were helpful. When asked what they disliked and suggestions for improvement, most participants responded “N/A” or “nothing.” Of those who provided feedback, some indicated logistical difficulties with the timing of group sessions. Participants commonly noted plans to practice formal sitting meditation and body scan in addition to more informal mindfulness of breathing, walking, stretching, and eating. Some also noted plans to practice mindfulness in the context of prayer. Example quotations from qualitative data will be presented and discussed. Overall, results provide support for acceptability and provide suggestions for offering mindfulness-based smoking cessation among low-income African American smokers.

PRELIM OUTCOME AND PROCESS RESULTS OF A RANDOMIZED WEIGHT LOSS MAINTENANCE TRIAL IN RURAL AFRICAN AMERICANS OF FAITH: THE WORD

Karen HK. Yeary, PhD

University of Arkansas for Medical Sciences, Little Rock, AR

Despite multidisciplinary efforts to control the nation's obesity epidemic, obesity has persisted as one of the U.S.'s top public health problems, particularly among African Americans. Innovative approaches to address obesity that are sensitive to the unique issues of African Americans and easily translatable to “real-world” settings are critical. RE-AIM is a useful framework for assessing key aspects of an intervention for translation into real-world practice. However, few obesity trials for African Americans measuring RE-AIM aspects have been conducted. Thus preliminary effectiveness, reach, and adoption of a lay-led weight loss maintenance intervention for rural adults of faith were assessed.

The WORD is a lay-led cluster randomized trial (425 participants in 30 churches) designed to reduce and maintain weight loss in African-American adults of faith in the Arkansas Delta region. All participants received the Diabetes Prevention Program (DPP) adapted core weight loss program from baseline to 6 months, and then were randomized to a maintenance treatment or control. The intervention's preliminary effectiveness in weight loss, reach, and adoption was assessed at baseline and 6 months.

Participants' mean weight loss was 2.3% ($SE=0.4$) from baseline to 6-month follow-up; participants who attended at least half of the intervention sessions lost 3.6% ($SE=0.6$). Most recruited churches were Baptist, 2/3 had 150 or fewer active members, and about 1/3 had operating budgets of \$15,000-\$50,000. Most lay leaders were female (89.3%), in married/committed relationships (65.5%), and employed (64.2%), with household incomes of

PROCESS EVALUATION OF A FAITH-BASED INTERVENTION TO INCREASE PHYSICAL ACTIVITY AMONG CHURCHGOING LATINAS IN SAN DIEGO.

Jessica Haughton, MPH, MA¹, Guadalupe X. Ayala, PhD MPH¹, Lilian G. Perez, PhD, MPH², Barbara Baquero, PhD, MPH³, Jacqueline Montañez⁴, John P. Elder, PhD, MPH¹, James F. Sallis, PhD⁵, Elva Arredondo, PhD¹¹San Diego State University, San Diego, CA; ²National Cancer Institute/ Health Behaviors Research Branch (HBRB)/Behavioral Research Program (BRP), Bethesda, MD; ³The University of Iowa, Iowa City, IA; ⁴San Diego State University/Institute for Behavioral and Community Health, San Diego, CA; ⁵UC, San Diego, La Jolla, CA

Background: Faith in Action was a faith-based randomized controlled trial to promote physical activity (PA) among churchgoing Latinas. *Promotoras* (community health workers) invited churchgoers to and led PA classes in Catholic churches (6 classes per week, 60-minutes each), conducted motivational interviewing calls, and mailed monthly health promotion handouts to intervention participants. Intervention versus attention-control participants increased moderate-to-vigorous physical activity (MVPA), reduced body mass index (BMI) and used more behavioral strategies for engaging in PA at post-intervention. This study examined factors associated with intervention implementation, including reach, dose delivered, and participant satisfaction.

Methods: A sample of adult Latinas ages 18–65 years old ($n=217$) were recruited from churches to serve on an evaluation cohort. Process evaluation surveys were administered at the 12-month follow-up to assess the impact of announcements made in church, participants' perceptions of and motivation to attend PA classes, participants' perceptions of the *promotoras*, and the motivational interviewing calls on increasing behavioral strategies for PA. Class attendance logs, motivational interviewing guides, and mailing logs were collected for the duration of the intervention. Associations between process measures and outcomes were assessed with linear regression models.

Results: At the 12-month follow-up, participants were more likely to report using behavioral strategies for engaging in PA if they attended more walking groups ($\beta=.31$, p

Conclusion: Findings suggest that individual factors (improving health) and intervention factors (PA classes and motivational interviewing calls) helped promote behavioral strategies to engage in PA. The PA classes provided opportunities to learn behavioral strategies for PA from the *promotoras* and other participants. The motivational interviewing calls were opportunities to discuss possible strategies to overcome barriers to PA and to motivate participants to be active. The results suggest that offering PA classes and motivational interviewing may increase behavioral strategies for PA. These findings help researchers better understand the mechanisms of change and inform dissemination and implementation research involving community-based samples in the promotion of PA.

PROJECT UPLIFT: A DISTANCE DELIVERED MINDFULNESS-BASED INTERVENTION TO ADDRESS DEPRESSION AMONG DIVERSE POPULATIONS

Ann M. DiGirolamo, PhD, MPH¹, Rakale C. Quarells, PhD², Nancy J. Thompson, PhD, MPH³¹Andrew Young School of Policy Studies, Georgia State University, Atlanta, GA; ²Morehouse School of Medicine, Atlanta, GA; ³Rollins School of Public Health, Emory University, Atlanta, GA

Project UPLIFT is a mental health skills program that was originally designed to address depression among people with co-morbid chronic disease such as epilepsy who could not get out to attend psychotherapy. People with epilepsy suffer neurological impairment, and also encounter medical, economic, and social hardships as a result of their disability. In addition, depression is a common co-morbid psychiatric disorder among people with epilepsy that often goes unrecognized and under-treated among these individuals. The UPLIFT program's eight sessions are largely based upon mindfulness-based cognitive therapy and designed to be distance-delivered to groups of 7 participants. In two randomized clinical trials among people with epilepsy, Project UPLIFT has been demonstrated to be effective in preventing the onset of Major Depressive Disorder, significantly reducing symptoms of depression, and improving satisfaction with life. Project UPLIFT has also been used, and adapted when necessary, with caregivers of people with epilepsy, African Americans with epilepsy, Hispanics with epilepsy, adults with cystic fibrosis, youth with cystic fibrosis, rural pregnant women, and women with cardiovascular disease. The presentation will share results from the clinical trials among people with epilepsy, and from studies conducted to assess the cultural appropriateness of the intervention for minority populations.

THE FAITH, ACTIVITY, AND NUTRITION (FAN) DISSEMINATION AND IMPLEMENTATION (D&I) STUDY: RESULTS OF COUNTYWIDE IMPLEMENTATION

Sara Wilcox, PhD¹, Ruth P. Saunders, PhD¹, Danielle E. Jake-Schoffman, PhD², Brent Hutto, MSPH¹¹University of South Carolina, Columbia, SC; ²University of Massachusetts Medical School, Worcester, MA

Background: Churches in the U.S. south have great potential to reach under-resourced communities for health promotion efforts. We conducted phase 1 of the FAN D&I study in a rural and medically underserved county in South Carolina. This presentation reports intervention implementation.

Methods: Churches (n=59) were randomized to a 12-mo intervention or to a control (delayed intervention) condition. The intervention, delivered by trained community health advisors, was a one-day training (resources provided) followed by brief, monthly technical assistance calls. It focused on helping churches create opportunities, set guidelines/policies, share messages, and enlist pastor support for physical activity (PA) and healthy eating (HE). We conducted telephone interviews assessing these four domains of HE and PA church practices with church coordinators at baseline (before randomization) and 12 mos later. Church coordinators, selected by pastors, agreed to serve as the study contact and coordinate implementation efforts. We tested differences between intervention and control churches over time with repeated measures regression models, controlling for church size. We also calculated effect sizes (Cohen's d) for each variable.

Results: Coordinators from 54 churches (35 intervention, 19 control) completed interviews at both times (94% African American, 96% women, 60 ± 9 years of age; 37% college graduates; 54% obese). Intervention church coordinators reported significantly greater increases in implementation of PA opportunities; HE and PA guidelines; HE and PA messages; and pastor support for HE and PA than control coordinators (p

Conclusion: We observed high rates of implementation in intervention churches. Results paralleled the pattern of implementation reported in anonymous questionnaires of church members (results reported elsewhere) and shown in our previous effectiveness trial, demonstrating replication and consistency. The potential for even broader dissemination is great, particularly because community health advisors rather than research staff trained and supported churches.

TRANSLATING POSITIVE ACTIVITIES INTERVENTIONS FOR USE WITH MILITARY VETERANS WITH KNEE OSTEOARTHRITIS

Leslie R. M. Hausmann, PhD¹, Acacia C. Parks, PhD²¹VA Pittsburgh Healthcare System, Pittsburgh, PA; ²Happify, Hiram, OH

Knee osteoarthritis is a painful, disabling condition that disproportionately affects African Americans. Existing arthritis treatments yield small to moderate improvements in pain and have not been effective at reducing racial disparities in the management of pain. The biopsychosocial model of pain and evidence from the positive psychology literature suggest that increasing positive psychological skills (e.g., gratitude, kindness) could improve pain and functioning and reduce disparities in osteoarthritis pain management. Activities to cultivate positive psychological skills have been developed and validated; however, they have not been tested in patients with osteoarthritis and their effects on racial differences in health outcomes have not been examined. This presentation will describe the process of developing the Staying Positive with Arthritis (SPA) program, a positive psychological intervention tailored based on input from the target demographic: African American and White patients being treated for painful knee arthritis in the Veterans Affairs Healthcare System. The presenter will discuss how activities were chosen for consideration, modified based on patient input, and packaged for delivery using a combination of printed workbooks and brief telephone calls with trained interventionists. Rationale for decisions about the final program's length, content, and format will be discussed, as will potential modifications to enhance future widespread implementation of the program. Finally, the presenter will share how the effects of the program on pain, functioning, and an array of psychosocial factors are being tested in an ongoing randomized controlled trial.

ACCEPTABILITY OF CAM INTERVENTIONS FOR ADHD AMONG COLLEGE STUDENTS: IMPLICATIONS FOR TAI CHI

Sandy H. Sulzer, PhD¹, Alexander Converse, PhD², Cathleen Trueba, MA³¹Utah State University, Logan, UT; ²Center for Investigating Healthy Minds, University of Wisconsin-Madison, Madison, WI; ³University of Wisconsin-Madison, Madison, WI

Objective: Developing effective non-pharmacological therapies for ADHD is important. We gauged the likelihood that undergraduates would participate in a trial of Tai Chi, a form of moving meditation, as an intervention for ADHD. We also evaluated their attitudes towards complementary and alternative medicine (CAM).

Methods: Survey responses were collected from 47 undergraduates with ADHD and 49 controls. Survey items measured the likelihood of participating in trials of Tai Chi and other non-pharmacological therapies, symptom severity, attitudes toward CAM, and general health.

Results: Undergraduates with ADHD showed greater acceptance of CAM therapies than students without ADHD. Thirty-Two percent of students with ADHD expressed a strong willingness to participate in a Tai Chi trial, with the greatest interest among women with ADHD.

Conclusion: These results support the feasibility of performing a trial of Tai Chi as therapy for undergraduates with ADHD, and suggest this population is receptive toward CAM in general.

REDUCING STUDENTS' STRESS THROUGH A BRIEF MINDFULNESS PRACTICE

Todd Wilkinson, Ph.D.¹, Natalya Jewitt, B.S.²¹University of Wisconsin - River Falls, Minneapolis, MN; ²University of Wisconsin - River Falls, River Falls, WI

Mindfulness-Based Stress Reduction (MBSR; Kabat-Zinn, 1979) has been shown to effectively reduce stress across a variety of populations (e.g., Canby, Cameron, Calhoun & Buchanon, 2015). However, research on the amount of mindfulness practice time necessary to achieve such benefits has been equivocal (e.g., Hindman, Glass, Arnkoff & Maron, 2014). The present study examined the effects on stress of a brief mindfulness practice intervention based on MBSR. Forty-eight undergraduate college students at a moderately sized public liberal arts university in the Midwestern United States participated in the study. The participants were predominantly female (77%) and ranged in age from 18–50 (M = 21.67 years, SD = 5.48). Students were instructed to complete online measures of mindfulness, stress, mood and personality variables both before and after a three-week period. The students then attended a one-hour informational session about mindfulness, as well as instructions for practicing mindfulness both formally and informally. Participants were given instructions for ways to formally practice mindfulness including mindful walking and mindful eating (i.e. the Raisin exercise). In addition, participants were explained how mindfulness practice could be incorporated more informally during everyday activities, such as while brushing their teeth or in between classes. The participants were then instructed to practice formal and / or informal mindfulness at least once per day over the three-week period. The participants then completed the post-test measures. The study received Institutional Review Board approval prior to beginning. Students received extra credit in their undergraduate psychology course for participating in the study.

The results of the study showed that participants who practiced mindfulness during the three weeks significantly reduced their levels of stress, $F(1,94) = 9.17$, $p = .002$. In addition, the students practiced on average 17.5 minutes per day. These findings demonstrate the value of this brief mindfulness practice with a population who reports experiencing significant stress (e.g., Hindman et al., 2014). Furthermore, the activities in this study did not require a substantial period of time to practice. In addition, it can be argued that this practice of mindfulness while engaged in everyday activities such as those in this study may actually require little or no additional time for practice each day. Further research is needed to replicate these findings across different samples; however, these results represent a promising approach to helping undergraduates with stress management.

RELATIONSHIP BETWEEN RESILIENCE AND TRAIT MINDFULNESS IN OLDER ADULTS WITH HYPERTENSION

Laura Redwine, PhD¹, Meredith A. Pung, PhD², Kathleen Wilson, MS², Suzi Hong, PhD³¹University of South Florida, Tampa, FL; ²University of California, San Diego, San Diego, CA; ³University of California San Diego, San Diego, CA

Resilience, the capacity to bounce back from the diverse challenges that can occur in life (Campbell-Sills & Stein, 2007), is linked with increased well-being among older adults. However, psychological traits that may enhance resilience, and in turn may reduce anxiety are not well understood in this population.

Methods: Baseline data were examined from older adults with hypertension ($n = 62$; 64.5% female, mean age = 73.5 years, $SD = 8.54$) participating in a behavioral intervention study for hypertension. Psychological factors assessed included: resilience measured with the Connor-Davidson Resilience Scale (CDRS), anxiety symptoms measured with the 8-item PROMIS Anxiety questionnaire, mindfulness measured with Mindfulness Attention Awareness Scale (MAAS), and awareness of bodily signals, aka interoceptive awareness (particular aspects of mindfulness) as measured with the Multidimensional Assessment of Interoceptive Awareness (MAIA). Independent linear regression analyses, adjusting for age and sex were performed to determine if increased mindfulness and aspects of interoceptive awareness were related to heightened resilience, and whether enhanced resilience was associated with reduced symptoms of anxiety.

Results: CDRS was positively associated with MAAS ($\text{delta}R^2 = .288$, $p < .001$), and subscales of MAIA, including attention regulation ($\text{delta}R^2 = .171$, $p = .002$), not-worrying ($\text{delta}R^2 = .163$, $p = .002$), and self-regulation ($\text{delta}R^2 = .402$, $p < .001$). Conversely, CDRS was negatively associated with PROMIS Anxiety scores ($\text{delta}R^2 = .123$, $p = 015$). In conclusion: greater levels of trait mindfulness, and aspects of interoceptive awareness were associated with increased resilience. In turn, greater resilience was related to lower anxiety levels in older adults with hypertension. Thus, interventions that enhance mindfulness may improve resilience in older adults and potentially have the additional benefit of reducing anxiety symptoms, thus improving quality of life and well-being.

A REVIEW OF LATINO/LATINX PARTICIPANTS IN MINDFULNESS-BASED INTERVENTION RESEARCH

Elizabeth W. Cotter, PhD¹, Naya Armendarez Jones, PhD²¹American University, Washington, DC; ²University of Texas at Austin, Austin, TX

Mindfulness-based interventions (MBIs) have proven efficacy in reducing stress and improving a variety of health outcomes. Recent studies consider the usefulness of MBIs for youth and adults from historically-underserved and -marginalized populations (Jee et al., 2015; Sobczack & West, 2013; Woods-Giscombe & Gaylord, 2013; Woods-Giscombe & Gaylord, 2014; Watson et al., 2016); however, the use of MBIs for Latinx populations is not well understood. This review examined the feasibility and efficacy of MBIs in peer-reviewed studies wherein the largest proportion of participants identified as either Latino or Hispanic. To practice inclusivity beyond male/female binaries, we use the term “Latinx” here. A systematic literature search across 4 databases yielded 17 articles eligible for inclusion. Generally, the existing research suggests that MBIs are feasible and acceptable in Latinx populations, and yield positive changes in a variety of psychosocial and health-related outcomes, including mental health symptomatology (e.g., depression), health behaviors (e.g., HIV transmission-related behaviors), and physical health indicators (e.g., BMI). Effect sizes ranged from small to large with stronger effects typically seen for mental-health related outcomes. Limitations of the existing research include small sample sizes, a lack of rigor in intervention design, and limited description of how interventions might be culturally or socially adapted. From an interdisciplinary perspective we describe recommendations for future research, including suggestions for culturally relevant adaptations to MBIs (e.g., congruent emotion regulation techniques, analogies, and/or visualizations) and anti-oppression practices for practitioners (e.g., understanding race-based trauma and deep listening).

CHILDHOOD EXPERIENCES AND BODY/MIND/SPIRIT HEALTH IN ADULTS

Linda C. Mefford, PhD, RN¹, Kenneth D. Phillips, PhD, RN², Misook L. Chung, PhD, RN³¹Bellarmine University, Louisville, KY; ²East Tennessee State University, Johnson City, TN; ³University of Kentucky, Lexington, KY

Background: Negative childhood experiences, such as loss of parents, abuse, and dysfunctional family relationships, affect health in adults. Less is known about how adaptive strategies could improve life satisfaction. The purpose of this study was to examine the predictability of adverse childhood experiences, chronic sorrow, religious/spiritual (R/S) practices and hope on life satisfaction in adults.

Methods: This cross-sectional study was a convenience sample of 132 adults (mean age = 33.8 ± 15.2, 82% female) recruited primarily during a health fair in the Southeastern United States. The Adverse Childhood Experiences scale and Kendall Chronic Sorrow Instrument measured negative childhood experiences. Eight subscales of the Brief Multidimensional Measure of Religiousness/Spirituality (BMMRS) assessed R/S practices (Daily Spiritual Experiences, Values, Forgiveness, Private Religious Practices, R/S Coping, Religious Support, Organizational Religiousness, Overall R/S.) The Herth Hope Index and Satisfaction with Life scale were also used. Two hierarchical multiple regressions were used to predict effects of adverse childhood experiences and chronic sorrow on life satisfaction, then to examine the additional predictive influence of R/S and hope while controlling for previous effects.

Results: Adverse childhood experiences predicted poor life satisfaction ($\beta = -.278$, $p = .016$), remaining significant through all regression steps. Forgiveness was the only significant R/S practice, predicting better life satisfaction ($\beta = .340$, $p = .037$). The addition of hope strongly predicted higher life satisfaction ($\beta = .596$, $p < .001$), with forgiveness becoming nonsignificant. Religion as coping emerged as a significant predictor of poor life satisfaction at this step ($\beta = -.331$, $p = .036$) apparently related to use of negative religious coping. In the second regression, chronic sorrow predicted poor life satisfaction ($\beta = -.240$, $p = .030$), becoming nonsignificant with the addition of R/S variables (forgiveness again emerging as a positive predictor, $\beta = .389$, $p = .02$). Adding hope to the model again produced a strong positive effect on life satisfaction ($\beta = .560$, $p < .001$), reducing the effect of forgiveness to nonsignificance.

Conclusion: Negative childhood experiences predict poor life satisfaction during adulthood. Interventions to promote hope and forgiveness and reduce negative religious coping hold promise to improve life satisfaction in adults who experienced adverse experiences or loss during childhood.

COGNITIVE FUSION PREDICTS PHYSICAL FUNCTIONING IN COLLEGE STUDENTS

Jamie S. Bodenlos, Ph.D.¹, Sarah Burstein, N/A², Kelsey Arroyo, N/A³, Elizabeth Hawes, N/A²¹Hobart and William Smith Colleges, Baldwinsville, NY; ²Hobart and William Smith Colleges, Geneva, NY; ³Hobart and William Smith Colleges, Batavia, NY

Cognitive fusion refers to the failure to distinguish ourselves and our experiences from our thoughts. It's the tendency to act on our thoughts as if they were "reality" instead of seeing them as merely cognitive events. Fusion with thoughts can result in behavior that is overly dominated by cognition and less influenced by direct experience in one's environment. Cognitive fusion and its counterpart, cognitive defusion, are important processes in the psychological flexibility model that underlies Acceptance and Commitment Therapy (ACT). Higher levels of cognitive fusion have been associated with greater levels of distress and perceptions of physical pain in both older and younger adults. It is likely that the inability to defuse from one's thoughts can have a variety of physical and emotional consequences for college students but little is known about this relationship. Therefore, the purpose of this study was to explore how cognitive fusion predicted physical functioning in college students while controlling for other related variables. Participants were 353 college students from a small liberal arts college in upstate New York. After informed consent was obtained, participants completed the following questionnaires: SF-36, Cognitive Fusion Questionnaire, Perceived Stress Scale (PSS-14), Luben Social Network Scale-Revised (LSNS), and Five Facets of Mindfulness Questionnaire (FFMQ). Participants also answered questions about sleep duration and quality on weekdays and weekends. Using Hierarchical linear regression analyses, we found that after controlling for sleep, social support, mindfulness, and stress, cognitive fusion ($\beta = -.18$, $t = -2.34$, $p = 0.02$) was the only significant predictor of physical functioning in college students. The model was able to account for 8% of the variance in physical functioning, $F(1,253) = 5.47$, $p < .001$, $R^2 = .08$. Although a small amount of variance was accounted for by cognitive fusion, it was the only variable significant for health in this sample of college students. As it is the first study to provide evidence for cognitive fusion in health, more work is needed to understand how thoughts play a role in physical health among young adults.

DIFFERENCES BETWEEN MINDFULNESS MEDITATION AND MINDFUL YOGA AS MEASURED BY THE FIVE FACET MINDFULNESS QUESTIONNAIRE

Shaun M. Jones, BA¹, William Kazanis, MS², Kristen Rosen, PhD, MPH³, Megan Curtis, MA⁴, Jennifer Sharpe Potter, PhD, MPH²

¹The University of Texas Health Science Center at Houston (UTHealth) School of Public Health in San Antonio, San Antonio, TX, San Antonio, TX;

²University of Texas Health Science Center, San Antonio, TX, San Antonio, TX;

³Northwestern University, Chicago, IL, san antonio, TX; ⁴University of Texas at San Antonio, San Antonio, TX

Objective: To measure differences between experienced seated mindfulness meditation practitioners (meditators), experienced mindful yoga practitioners (yogis), and practitioners who practice both meditation and yoga (mixed group) as measured by the Five Facet Mindfulness Questionnaire (FFMQ).

Methods: Participants (N=398) were recruited through social media and classified into 3 groups: meditators (n=52), yogis (n=68), or mixed group (n=33). Data from participants who failed to meet these qualifications (n=245) were not analyzed. Total mindfulness scores and scores in the 5 sub components of the FFMQ (observing, describing, acting with awareness, non-judging, and non-reacting) were compared between groups using a two-way ANOVA and Tukey's HSD tests.

Results: Participants were mostly female (78.60%; n=313), white (76.50%; n=304), and college educated (76.00%; n=302), consistent with mindfulness practitioners as reported by the 2012 National Health Interview Survey. The mean age was 40.49 (SD=1.08) years. On average, meditators reported practicing meditation 144.34 (SD=15.19) minutes per week (m/wk), yogis, 341.83 (SD=21.20) m/wk, and mixed group 546.97 (50.54) m/wk. A two-way ANOVA yielded a significant difference in total mindfulness, $F(2, 193) = 6.91, p < 0.001$, observing, $F(2, 193) = 4.16, p < 0.02$, describing, $F(2, 193) = 4.38, p < 0.01$, acting with awareness, $F(2, 193) = 4.14, p < 0.02$, and non-reacting, $F(2, 193) = 5.66, p < 0.01$. Tukey's HSD revealed the mixed group showed significantly greater scores than meditators in total mindfulness ($p < 0.001$), observing ($p < 0.03$), describing ($p < 0.01$), acting with awareness ($p < 0.02$), and non-reacting ($p < 0.01$). No significant differences between meditators and yogis, and between mixed group and yogis were found.

Conclusions: Findings from this pilot study support no difference between meditators and yogis, but differences between mixed group and meditators suggest that increased time spent practicing mindfulness will result in greater mindfulness outcomes. Limitations of this study include participants with different practice types and minutes per week within groups. Future research may include experimental design to measure differences between seated meditation and yoga, controlling for frequency, duration, and type of practice. Work in this line of research can be used to develop mindfulness interventions that are both effective and sustainable in peoples' daily lives.

EFFECTS OF DANCE MOVEMENT INTERVENTION ON ELDERLY WITH EARLY DEMENTIA: PRELIMINARY RESULTS OF A RANDOMIZED CONTROLLED TRIAL

Rainbow T. H. Ho, Prof¹, Tiffany Hon, Ms², Wai Chi Chan, Clinical Associate Professor³, Joseph SK. Kwan, Associate Professor⁴, Patrick Ka Chun Chiu, Honorary Clinical Associate Professor⁵, Linda Chiu Wa Lam, Professor⁶

¹Centre on Behavioral Health, The University of Hong Kong, Hong Kong, N/A, Hong Kong; ²Centre on Behavioral Health, The University of Hong Kong, Hong Kong, Hong Kong, N/A, Hong Kong; ³Department of Psychiatry, The University of Hong Kong, Hong Kong, Hong Kong, N/A, Hong Kong; ⁴The University of Hong Kong, Hong Kong, N/A, Hong Kong; ⁵Department of Medicine, The University of Hong Kong, Hong Kong, Hong Kong, N/A, Hong Kong; ⁶Department of Psychiatry, The Chinese University of Hong Kong, Hong Kong, Hong Kong, N/A, Hong Kong

Background: Dementia describes a clinical syndrome that encompasses difficulties in memory, language, and impairments in daily activities, often accompanied by anxiety and depression symptoms. The primary objective of non-pharmacological interventions is to minimize psychosocial disturbances and slow disease progression. This study aims to examine the effects of dance movement intervention which combines psychotherapeutic elements with the well-established benefits of physical activity on elderly with early dementia.

Methods: A total of 204 Chinese elderly with early dementia, defined as individuals aged 65 or above with clinical dementia rating (CDR) of 0.5 to 1, were randomised into dance-movement therapy (DMT), physical exercises (EX) and waitlist control (Control). Both DMT and EX groups received a 12-week semi-weekly intervention, with each session lasting for one hour. Cognitive functioning was measured via cognitive tests (Digit Span Test, Fuld Object Memory Evaluation and Trail Making Test) whereas psychosocial well-being and daily functioning were measured using self-reported scales (Abbreviated Geriatric Depression Scale, de Jong Gierveld Loneliness Scale, Visual Analogue Scale, and Lawton Instrumental Activities of Daily Living). Neuropsychiatric symptoms were measured via an informant reported scale (Neuropsychiatric Inventory). Assessments were performed before randomization, post-intervention (3-month), at 6-month, and at 12-month. Preliminary data from baseline and 3-month were analysed using linear mixed-model (LMM), to preserve intention-to-treat principle using maximum likelihood estimation.

Results: The mean age of the sample was 79.1 years old and the majority of them were female (82%), widowed (54%), with no formal education (36%). Using a linear mixed model with Subjects as random effects, significant Group X Time effects were found in depressive symptoms [$F(2, 195) = 3.76, p = .025$], loneliness [$F(2, 196) = 6.28, p = .002$], daily functioning [$F(2, 197) = 4.39, p = .014$], and negative mood [$F(2, 196) = 3.18, p = .044$]. Pairwise comparisons using Bonferroni test set at $p < .016$ showed significant improvements in depressive symptoms, loneliness and daily functioning but not negative mood in the DMT group compared to the Control group. The improvement in loneliness of the DMT group was also significantly greater than the EX group. None of the changes of the EX group were significantly different from the Control group. No significant Group X Time effects were found in cognitive functioning.

Discussion: The preliminary findings suggested that DMT may have therapeutic effects in elderly with dementia in comparison to Control, particularly on psychosocial well-being and daily functioning. This study is still ongoing. Follow-up data will be collected from the participants to study the long-term effects of DMT and EX on the progression of dementia.

MIND-BODY INTERVENTIONS AMONG CAREGIVERS OF PATIENTS WITH CANCER: RESEARCH SYNTHESIS AND STATE OF THE SCIENCE

Pinky Shani, PhD, ARNP

Texas Woman's University, College of Nursing, Houston, TX

Background: An estimated 2.8 million Americans provide care to a cancer survivor with the average duration of caregiving being seven years¹. Caring for a cancer survivor results in psychological distress that is often greater than the distress experienced by the survivors, leading to marked reductions in caregiver health and quality of life (QOL).²⁻⁴ Consequently, interventions aimed at improving overall QOL in caregivers are warranted.⁵ Tai Chi/Qigong (TCQ) are popular multi-modal mind-body exercises that show great promise in addressing a broad range of biopsychosocial factors central to supportive cancer care. The purpose of this review is to explore the efficacy of mind-body interventions on QOL outcomes among caregivers of patients with cancer.

Methods: Articles were retrieved from Pubmed and ScienceDirect using *caregiver*, *cancer*, *mind-body*, *yoga*, *tai chi*, and *qigong* as key search terms. Inclusion criteria: 1) quantitative articles published during or prior to 2017; 2) adult patients with cancer and their caregivers; 3) mind-body as the main intervention; and 4) quality of life as outcome. Exclusion criteria: 1) qualitative studies; 2) reviews or meta-analysis; and 3) dissertations.

Results: Five articles were eligible with four studies completed among patient-caregiver dyads and one study specific to caregivers. All studies were single-arm pilot studies with four studies and one study using yoga and mindfulness based stress reduction, respectively. No studies were found with TCQ. Studies reported improvements in caregiver QOL and physical function with two studies reporting a decrease in sleep disturbances.

Discussion: Most studies evaluated caregivers have included mind-body interventions delivered in dyads. While this approach has merit, receiving mind-body alongside the patient could both decrease the needed 'downtime' from burdensome responsibilities of caregivers, and also prevent training that more directly addresses unique psychological and physical needs of caregivers. Additional research is needed specific to the needs of caregivers using TCQ as the intervention.

PRACTICE CHARACTERISTICS OF MINDFULNESS MEDITATION PRACTITIONERS

Sujata G. Ayala, MPH¹, Ken A. Wallston, PhD², Gurjeet S. Birdee, MD, MPH³

¹Institute of Medicine and Public Health, Vanderbilt University Medical Center, Nashville, TN; ²Vanderbilt University, Nashville, TN; ³General Internal Medicine and Public Health, Vanderbilt University Medical Center, Nashville, TN

Background: Mindfulness meditation has recently gained popularity in the Western world. However, we know little about who is practicing and how they practice. We collected survey information on practice characteristics of 203 mindfulness meditation practitioners while validating the Mindfulness Self-Efficacy Scale. Weekly practice adherence has been shown to affect positive health outcomes. We performed a secondary analysis to determine practice characteristics among mindfulness meditation practitioners in an attempt to determine what characteristics contribute towards higher frequency of weekly practice.

Methods: In addition to weekly practice adherence, we examined data on age, gender, length of practice, instructor status, if they had participated in a mindfulness-based stress reduction (MBSR) program, and if they had attended a silent meditation retreat (SMR). Spearman's correlations for weekly practice adherence versus the other variables were calculated. We then ran a linear regression model with weekly practice adherence as the dependent variable and the other variables as predictors.

Results: Most of our study participants were female (n=147) and middle aged (M= 50 years, SD= 14). A majority of study participants (53%) had meditated for at least 4 years; practiced at least 4 times a week (58%); participated in MBSR (57%); attended a SMR (64%); and were not instructors (68%). Weekly practice adherence was significantly correlated with age ($\rho = 0.15, p < 0.05$), being an instructor ($\rho = 0.16, p < 0.05$), with *not* participating in MBSR ($\rho = -0.15, p < 0.05$). The linear regression model significantly predicted the variance in weekly practice adherence ($R^2 = 0.32, F(8, 160) = 2.2, p < 0.05$), with only instructor status and MBSR non-participation being significant unique contributors to the model.

Conclusions: Understanding what characteristics of mindfulness meditation practitioners enable them to practice frequently is useful in guiding newer adopters of this mind-body practice to practice more often. While our results demonstrated that older participants practiced more, age did not significantly contribute to the regression model. Mindfulness teachers practiced more often, a relationship that makes intuitive sense; however, those who had participated in an MBSR program tended to practice less often during the week. Intensive training programs may need to evaluate methods to increase long-term practice frequency.

PRAYER IN COLLEGE STUDENTS IN THE WAKE OF HURRICANES KATRINA AND RITA: PREDICTING POST-TRAUMATIC STRESS

Stephanie Grace Prost, PhD¹, Hoa Appel, PhD², Amy L. Ai, Ph.D³, Catherine M. Lemieux, Ph.D⁴¹University of Louisville, La Grange, KY; ²University of Washington-Bothell, Bothell, WA; ³Florida State University, Tallahassee, FL; ⁴Louisiana State University, Baton Rouge, LA

Risks to physical and mental health in the wake of hurricanes are numerous and previous research has pointed toward increased spirituality and religiousness as related to decreased psychological stress in post-disaster settings. Importantly, post-traumatic stress (PTS) is particularly problematic for African-Americans due to pre-disaster health disparities. Recent news coverage of Hurricanes Harvey and Irma publicized the plight of hundreds of college students stranded in the midst of flooding and power outages scrambling to evacuate dorms and campus buildings. College students face limited support in post-disaster settings as many live far from family, friends, and their spiritual centers. In light of the protective role of spirituality and religiousness and vulnerability of students removed from support networks, scholars must examine the unique contribution of prayer in post-disaster settings to support these and other vulnerable individuals and communities. This study examined relationships among prayer, other coping strategies, and student-reported PTS following Hurricanes Katrina and Rita between African-American ($n=233$) and White ($n=124$) college student groups. We anticipated that as use of prayer increased, PTS would decrease for both groups, and that a stronger relationship would emerge for African-American students.

Results from a secondary data analysis revealed that African-American students more often used prayer ($t=7.18$, $pd=0.76$) and active coping strategies ($t=2.02$; $pd=0.23$) than did their White peers. Correlational analyses did not reveal a statistically significant relationship between prayer and PTS as hypothesized. Using multiple hierarchical regression, avoidant coping strategies accounted for the largest variation in PTS for both groups as would be expected, though the relationship was stronger for African-American students. It remains important that health professionals operating within higher education settings educate and support students in the management of PTS to avoid long-term, adverse health effects. Sampling, survey methods, and PTS measures limit generalizability and temper findings. Directions for future research include use of PTS measures that account for severity and cultural context, enhanced measures of religion and spirituality, comprehensive psychometric examination of coping measures, and longitudinal data collection of health-related variables in post-disaster settings.

PREDICTORS OF RESPONSE TO A BRIEF MINDFULNESS INTERVENTION AMONG PROBLEMATIC ALCOHOL USERS

Christine Vinci, Ph.D.¹, Claire A. Spears, Ph.D.², Amy Copeland, PhD³¹Moffitt Cancer Center, Tampa, FL; ²Georgia State University School of Public Health, Atlanta, GA; ³Louisiana State University Department of Psychology, Baton Rouge, LA

Understanding characteristics of individuals who respond to mindfulness-based interventions (MBIs) can provide insight into who may be best suited for these types of interventions. Such research is consistent with the precision medicine initiative. The current study recruited problematic college student drinkers who were randomized to receive one of three brief (10 minute) interventions: mindfulness, relaxation, or control. The mindfulness and relaxation groups listened to an audio recording of either a mindfulness meditation or relaxation exercise; the control group completed a word search puzzle. Trait mindfulness (Five Facet Mindfulness Questionnaire; FFMQ), state mindfulness (Toronto Mindfulness Scale; TMS), affect (Positive and Negative Affect Schedule; PANAS), and urge to drink (single-item Likert scale) were collected at baseline. Participants completed measures of state mindfulness, affect, and urge again after the intervention. Participants ($N=207$; 76.3% female) had a mean Alcohol Use Disorders Identification Test (AUDIT) score of 10.03 ($SD=4.28$). Regression analyses predicted post-intervention outcomes (TMS subscales, PANAS-negative affect [NA] and positive affect [PA], urge) from baseline FFMQ and AUDIT scores, controlling for baseline levels of each dependent variable and stratified by condition. Significant models are reported here (all $ps<.05$). For those who received the mindfulness intervention, higher FFMQ Acting with Awareness predicted decreased NA and urge to drink; higher FFMQ Describe predicted decreased TMS Decentering; and higher FFMQ Observe predicted increased urge. For those in the relaxation intervention, higher FFMQ Nonreactivity predicted increased NA, and higher AUDIT predicted increased urge. For the control group, higher AUDIT predicted increased NA and urge, and decreased PA. Given that Acting with Awareness predicted both decreased NA and urge to drink in the mindfulness condition, individuals high on this subscale may respond particularly well to brief mindfulness interventions. Those with high levels of Nonreactivity and high AUDIT scores may not be the best candidates for a brief relaxation intervention. Results provide some insight into who may respond best to a brief mindfulness vs relaxation intervention. Future research should explore these variables with lengthier MBIs and over a follow-up period.

PROBLEMATIC INTERNET USE AND PHYSICAL HEALTH: THE ROLE OF MINDFULNESS

Jamie S. Bodenlos, Ph.D.¹, Juliana Heffern, B.S. Psychology², Kathryn Lyle, BA³, Sarah Burstein, N/A³¹Hobart and William Smith Colleges, Baldwinsville, NY; ²Hobart and William Smith Colleges, Carversville, PA; ³Hobart and William Smith Colleges, Geneva, NY

Problematic patterns of internet use (PIU) are increasing exponentially and are associated with several negative psychological and social consequences. The effect that these behavioral patterns have on physical health is less established. Mindfulness has been negatively associated with problematic internet use and positively associated with health. The current study sought to examine the relationship between problematic internet use and multiple domains of health. The primary aim was determine if mindfulness was a mediator in the relationship between problematic internet use and overall health. Participants were 353 undergraduate students from a college in the Northeast. Participants completed several self-report questionnaires including: the Five Facet Mindfulness Questionnaire, the Internet Addiction Scale (IAT), the Perceived Stress Scale (PSS-14), and the SF-36. There were significant negative correlations between the IAT and domains of health ($r=-.24$). Higher scores on the FFMQ were negatively correlated with the IAT ($r=-.34$) and positively associated with better health via the SF-36 ($r=.32$). Using the Kenny and Baron approach, we found that our model did support mindfulness as a partial mediator between PIU and health. In terms of facets of mindfulness and PIU, the IAT was significantly negatively correlated with two of the facets of mindfulness, acting with awareness ($r=-.46$) and nonjudging of experience ($r=-.33$). Addictive behaviors such as problematic internet use may lead individuals to be less mindful in their environments and be one pathway to poorer health. Mindfulness based programs have been efficacious with individuals diagnosed with internet gaming addictions and should be examined for use with individuals with PIU to help buffer negative health and psychosocial consequences.

SELF-COMPASSION AND MINDFULNESS BEHAVIORAL PRACTICES: RELATIONSHIPS WITH WELL-BEING

Tia Rich, PhD, MSW, MA¹, Sandra J. Winter, PhD, MHA¹, Rajani Kaimal, MS², Haley Hedlin, PhD³, Catherine Heaney, PhD, MPH⁴¹Stanford University School of Medicine, Palo Alto, CA; ²Quantitative Sciences Unit (QSU), Stanford Department of Medicine, Palo Alto, CA; ³Stanford University, Palo Alto, CA; ⁴Stanford, Stanford, CA

Background: The association between mindfulness practice and well-being is well documented. Less well researched are the association between self-compassion practice and wellbeing and the interaction of self-compassion and mindfulness practices in relation to wellbeing. This study examined these relationships. It was posited that self-compassion may strengthen the association between mindfulness and well-being.

Methods: Participants ($n=616$, median age=46 years, women=74%, married=44%, working=64%, non-hispanic white=66%, 16 years of education=51%, in good to excellent health=86%) completed Stanford's Well for Life Scale, an on-line survey measuring demographics and 10 domains of wellbeing: social connectedness, lifestyle behaviors (including diet, PA, and sleep), physical health, stress/resilience, emotional health, purpose and meaning, sense of self, finances, spirituality/religiosity, creativity. Overall wellbeing was calculated by summing the domain scores.

Multiple linear regression models were run to assess associations between mindfulness and self-compassion practices and well-being. Mindfulness was measured by embodied-observing practices (breathing deeply, gently stretching, noticing your senses) and by non-reactive practices (observing emotions and thoughts as they arise rather than being caught up in them). Self-compassion was measured by practices of supportive, loving kindness toward oneself.

A Wald test examined the interaction of self-compassion with mindfulness embodied-observing and mindfulness non-reactive. Models were adjusted for age, gender, education, marital and employment status.

Results: At the rate of sometimes to very often, 72% of participants practiced embodied-observing mindfulness, 56% practiced non-reactive mindfulness, and 61% practiced self-compassion. Results indicate that frequent practice of self-compassion, embodied-observing and non-reactive mindfulness were each associated with higher well-being ($p<0.005$), with the magnitude of association of self-compassion greater than the associations of the two measures of mindfulness with well-being. Unexpectedly, self-compassion did not modify the association between either measure of mindfulness and well-being.

Conclusion: Self-compassion and mindfulness practices are each strongly associated with well-being. The finding that self-compassion did not modify mindfulness with respect to wellbeing leaves questions about mechanisms of the relationships among mindfulness, self-compassion and wellbeing.

SHEDDING LIGHT ON THE RELATIONAL INFLUENCES OF YOGA ON AND OFF THE MAT THROUGH QUALITATIVE AND QUANTITATIVE METHODS

Moé Kishida, MS¹, Steriani Elavsky, PhD²¹The Pennsylvania State University, State College, PA; ²University of Ostrava, Ostrava, N/A, Czech Republic

Throughout the last few decades, the mind-body practice of yoga has seen an unprecedented rise in popularity both from the general population and the scientific community. Despite the wide-array of salutary health benefits that have been demonstrated, a clear void is present in the yoga literature investigating the ways in which yoga impacts connections with oneself and social relationships (which are invaluable to one's health and wellbeing). The overarching aim of the present study was to utilize both qualitative and quantitative methods to better understand the influences of yoga on the largely neglected "relational" (intra- and interpersonal) outcomes.

Participants were community-dwelling yoga practitioners ($N=107$), engaging in yoga at least once a week recruited for a prospective 21-day daily diary study to examine the associations between yoga and relational outcomes. First, open-ended questions ($n=107$) and in-depth interviews ($n=12$) were analyzed for emergent themes using a content analysis and constant comparison approach. Four emerging themes were identified (i.e., yoga generates calm states, mindfulness, (self-)compassion, and social connectedness) culminating in the development of a conceptual model of how yoga may work to bring about relational benefits. This line of inquiry was then extended to intensive longitudinal data to investigate the associations of daily yoga practice with mindfulness, (self-)compassion, and social connectedness, to better understand how relational benefits would manifest in regular practitioners of yoga ($n=104$) in a real world setting. Multi-level analyses indicated that on days when an individual practiced more yoga than their usual, greater mindfulness ($b=2.93$, $SE=0.39$, $p<.05$) and self-compassion ($b=1.45$, $SE=0.46$, $p<.05$) were reported. 1-1-1 multilevel mediation models demonstrated yoga had an indirect effect on both compassion and social connectedness through increases in mindfulness at the within- and between-person levels. In models testing self-compassion as the mediator, the indirect effect of daily yoga practice on compassion was significant, although limited to the within-person level.

Collectively, findings demonstrate relational benefits are: (1) perceived and experienced through daily yoga practice across diverse yoga styles and experiences, and (2) "dynamic" phenomena varying substantially within-persons over time and in sync with daily yoga practice. While further prospective and experimental research is warranted to corroborate these preliminary findings, a routine yoga practice appears to hold promise in having a positive impact (on and off the mat) on preserving and strengthening the intra- and interpersonal connections which constitute the building blocks of our day-to-day lives.

SYMPTOMS OF DEPRESSION, ASPECTS OF MINDFULNESS AND PARASYMPATHETIC ACTIVITY IN PATIENTS WITH HEART FAILURE

Laura Redwine, PhD

University of South Florida, Tampa, FL

Research shows that elevated depression symptoms are associated with reduced parasympathetic activity, which is related to increased morbidity and mortality in patients with cardiovascular disease. In contrast, trait mindfulness is associated with increased parasympathetic activity. During exertion, sympathetic discharge is increased and parasympathetic stimulation is withdrawn, resulting in increased heart rate. Vagal reactivation is an important cardiac deceleration mechanism after exercise, and indicative of parasympathetic responsiveness. Heart rate recovery (HRR) following exercise is a tool used to assess parasympathetic activity. There is limited information on trait mindfulness and parasympathetic activity in patients with Stage C symptomatic heart failure (HF). By discovering the relationships among depression symptoms, specific facets of trait mindfulness, and autonomic activity, more focused treatments may be developed for patients with HF.

Methods: 70 Stage C patients with HF (HF with preserved ($n = 33$) and reserved ($n = 37$) ejection fraction) (mean age = 65.69 +/- 8.23) were examined for depression symptoms using the Beck Depression Inventory (BDI), facets of mindfulness using the Five Facets of Mindfulness Scale (FFMS). Parasympathetic activity was assessed by examining HRR in response to Bruce protocol bicycle ergometry. Linear multiple regression analyses were performed to examine independent relationships among facets of mindfulness, depression symptoms, and HRR.

Results: Depression scores were negatively associated with HRR (delta $R = .058$, Beta = .252, $p = .044$), whereas non-reactivity to inner experience was positively related to HRR (delta $R = 0.085$, Beta = -.290, $p = .015$). Depression Symptoms were negatively related to non-reactivity (delta $R = .11$, Beta = -.353, $p = .004$). In conclusion, our findings suggest that interventions that enhance facets of mindfulness such as, non-reactivity to inner experience may reduce depression in HF patients and may improve cardiac function. However, this was a cross-sectional study and prospective research is needed to confirm whether facets of mindfulness can mediate changes in depression symptoms and parasympathetic activity.

THE ASSOCIATION BETWEEN RELIGIOSITY AND 30-DAY UNSCHEDULED RE-ADMISSIONS IN HOSPITAL SURVIVORS OF AN ACUTE CORONARY SYNDROME

Hawa O. Abu, MBBS; MPH¹, Catarina Kiefe, PhD MD², Robert J. Goldberg, PhD³, Kate L. Lapane, PhD³, Molly E. Waring, PhD³

¹University of Massachusetts Medical School, Shrewsbury, MA; ²University of Massachusetts Medical School, Worcester, MA; ³University of Massachusetts Medical School, Department of Quantitative Health Sciences, Worcester, MA

Background: Predictors of early readmission after discharge for an Acute Coronary Syndrome (ACS) have mainly included sociodemographic, clinical and psychosocial variables, but the association between religiosity and unscheduled 30-day readmissions among survivors of an ACS is unknown.

Methods: We used data from 1,929 patients hospitalized for an ACS at six medical centers in Central Massachusetts and Georgia (2011–2013). Strength and comfort from religion, patients praying for their health (petition prayers) and awareness of others praying for their health (intercessory prayers) were self-reported at the time of hospital enrollment. Thirty-day unscheduled all-cause readmissions were validated from hospital records. Modified Poisson regression analyses estimated relative risks (RR) for unscheduled readmissions adjusting for baseline characteristics.

Results: Patients were on average 61.1 years old, 33.2% were women and 81.2% were non-Hispanic Whites. Approximately 86% reported strength and comfort from religion, 61% prayed for their health and 89% were aware of others praying for their health. Overall, the risk of an unscheduled 30-day readmission was 10.4%. A great deal of strength and comfort from religion was not associated with early unplanned readmission (aRR: 1.01; 95% CI: 0.67–1.53), nor were reports of intercessory prayers (aRR: 0.82; 95% CI: 0.56–1.21). Petition prayers was associated with a higher risk of early readmission after adjusting for several sociodemographic and clinical characteristics (aRR: 1.37; 95% CI: 1.02–1.84), but this association was attenuated after accounting for a number of psychosocial characteristics (aRR: 1.28; 95% CI: 0.95–1.72).

Conclusion: A majority of survivors of an ACS reported religious engagement. Patients who prayed for their personal health had a higher risk of an early unplanned readmission compared with those who did not pray for their health. Identifying and addressing the religious needs of patients may help facilitate their recovery process from acute illness.

THE EFFECT OF YOGA PRACTICE ON PHYSIOLOGICAL STRESS AND WELL-BEING IN DIABETES PATIENTS

Maricarmen Vizcaino, PhD¹, Kristin Gosseink, PhD²¹Arizona State University, Phoenix, AZ; ²University of Texas at El Paso, El Paso, TX

Objective: The present study explored if improvements in self-reported stress and well-being occur concurrently with a reduction in the physiological stress response in adults with type 2 diabetes mellitus (T2DM) after an holistic yoga program. Previous studies have found significant improvements in different dimensions of mental health following yoga practice in T2DM patients, but no study has examined the link between psychological and physiological stress in this population.

Methods: A quasi-experimental design was used to evaluate pre- vs. post-test self-reports of stress and well-being in 7 post-menopausal women aged 50–65 with no previous yoga experience. These women completed an 8wk yoga program and were instructed to collect saliva samples so that diurnal curves of cortisol and dehydroepiandrosterone (DHEA) could be observed. Paired t-tests were used to assess pre- and post-intervention differences, with Pearson correlation to determine associations among variables. Significance was set at $p \leq 0.05$.

Results: Participants showed blunted morning cortisol levels and higher than normal DHEA values. After yoga intervention, the diurnal curves of both cortisol and DHEA showed a trend toward improvement with reduced DHEA and increased cortisol upon waking. Interestingly, morning cortisol levels were significantly correlated with perceived stress ($r = -0.77$, $p = 0.03$) and positive emotions ($r = 0.80$, $p = 0.02$). Morning DHEA significantly correlated with positive emotions ($r = -0.81$, $p = 0.04$), while DHEA levels at noon correlated with perceived stress ($r = 0.87$, $p = 0.02$) and positive and negative emotions ($r = -0.94$, $p = 0.005$, and $r = 0.90$, $p = 0.01$, respectively).

Conclusion: Although absolute changes in stress hormones were not statistically significant, a trend toward a return to normal values following yoga was observed along with significant correlations between physiological indicators of stress and perceived well-being. These data suggest a relationship between mental health and physiological stress in T2DM, and identify a need for future studies to investigate the implications of these findings for the overall physical health of T2DM patients.

THE IMPACT OF RELIGIOUSNESS/SPIRITUALITY ON PREPAREDNESS FOR END-OF-LIFE CARE AMONG FAMILY CAREGIVERS: A QUALITATIVE STUDY

Allen C. Sherman, Ph.D.¹, Stephanie Simonton-Atchley, Ph.D.¹, Kendra M. Anderson, PhD², Cindy Mikeal, PhD¹, Sarah E. Harrington, MD³, Issam Makhoul, MD⁴, Fade Mahmoud, MD⁴, Natasa Milojkovic, MD⁴, Konstantinos Arnaoutakis, MD⁴, Suen Y. James, MD⁵, Laura F. Hutchins, MD⁴

¹Behavioral Medicine, Winthrop P. Rockefeller Cancer Institute, University of Arkansas for Medical Sciences, Little Rock, AR; ²Department of Neurology, University of Texas Health Science Center-Houston, Houston, TX; ³Palliative Care, Winthrop P. Rockefeller Cancer Institute, University of Arkansas for Medical Sciences, Little Rock, AR; ⁴Medical Oncology, Winthrop P. Rockefeller Cancer Institute, University of Arkansas for Medical Sciences, Little Rock, AR; ⁵Otolaryngology, Winthrop P. Rockefeller Cancer Institute, University of Arkansas for Medical Sciences, Little Rock, AR

End-of-life (EOL) care presents family caregivers with daunting challenges, including the burdens of day-to-day care, the complexities of EOL decisions, and the grief associated with terminal illness. Growing interest has focused on the concept of “preparedness” for managing these tasks. This study explored whether caregivers’ sense of preparedness might be influenced by religious or spiritual (R/S) factors. Using qualitative methodology, we examined some of the practical functions that R/S involvement might serve in promoting or diminishing perceived readiness for EOL care. Individual, in-depth interviews were conducted with family members caring for cancer patients with terminal disease, at a large southern US oncology center. The majority of caregivers were spouses (64%), most were white (72.7%), and they were coping with a range of disease sites. Three investigators rated transcribed transcripts using thematic analysis. Data were coded using NVivo 11 software. Recruitment progressed until data saturation. Participants identified several ways in which their sense of preparedness was enhanced by R/S involvement. These major themes included provision of (1) emotional comfort; (2) perceptions of divine control; (3) support from clergy; and (4) accommodation of uncertainty or anger. Less common themes included the role of R/S factors in solidifying family cohesion, and in strengthening communication with the medical team. These results provide an important platform to support further work in this area of palliative care. They suggest that R/S involvement may enhance a sense of preparedness for EOL care among some family caregivers. Emotional comfort, a restored sense of control, and social support may be especially significant in promoting perceived readiness. As might be expected, these effects centered mainly on emotional and interpersonal aspects of EOL care. We found few indications that R/S might influence preparedness for other EOL domains, such as making challenging treatment decisions (e.g., advance directives, hospice) or managing financial tasks (e.g., estate planning). These would be useful to explore in further research.

VINYASA FLOW; METABOLIC COSTS AND LAB-BASED ESTIMATES WITH HIP-BASED AND WRIST-WORN WEARABLE SENSORS

Jeni Matthews, MS, Jennifer Huberty, PhD, Meynard John L. Toledo, MS, Lindsay Hand, BS, Matthew P. Buman, PhD

Arizona State University, Phoenix, AZ

Background: Vinyasa flow yoga, a faster paced yoga class, is a popular form of exercise in the United States. However, the energy expenditure (EE) is unknown. Though the Oxycon Mobile is a gold standard for the measurement of EE, its use presents a challenge as it interferes with yoga practice due to the equipment required (e.g., leads, cords, mask). There is a need to test more portable devices to measure EE during yoga. The hip-worn Actigraph GT3X+ (AG) and wrist-worn GENEActiv (GA) are small portable devices that measure EE and have not yet been validated for EE in yoga. The purpose of this study is to determine the EE of a vinyasa flow yoga class and validate the AG and GA for measuring EE in a vinyasa flow yoga class.

Methods: Participants were fitted to a mask attached to the Oxycon Mobile (placed in a backpack). An AG was placed on the left hip and a GA was placed on the non-dominant wrist. A Polar heart rate monitor and strap was worn around the chest, which fed instantaneous heart rate into the Oxycon program. Participants were randomized to an initial resting activity (sitting or lying down) before completing the vinyasa flow yoga video (30 minutes). The AG data was scored using the Freedson VM3 (2011) and the Freedson Adult (1998) algorithms in the Actilife software platform. EE from GA were derived using cut points from Esliger et. al. (2011). Date and time filters were added corresponding to the time stamps recorded by the tablet video files of each yoga session. Kcals and METs expended by each participant were calculated using the participants reported bodyweights. Data was analyzed using SPSS. A dependent samples t-test, an intraclass correlation coefficient (ICC), and mean absolute difference were used to determine agreement between variables.

Results: After data screening, 22 subjects (5 male, 17 female) were included in the final data sample. According to the Oxycon, participation in vinyasa flow required energy expenditure of 3.2 ± 0.4 METs. There was no relationship between the Oxycon, AG [ICC -0.01 95% CI (-0.03, 0.05)], or GA [ICC -0.03 95% CI (-0.08, 0.01)]. The mean difference in METs for the AG was -2.1 ± 0.6 and GA was -1.4 ± 0.6 (all $p < .01$).

Conclusion: According to the Oxycon, participation in a vinyasa flow yoga class met the criteria for moderate-intensity physical activity. The AG and GA consistently underestimated EE. More research is needed to determine an accurate measurement for EE during yoga using a wearable device.

ASSOCIATION OF OMEGA-3 POLY-UNSATURATED FATTY ACIDS AND DEPRESSIVE SYMPTOMS

Esther J. Holmes, MPH, CHES[®]1, Kadam Patel, MPH², Leslie Allsopp, MSN, MPH², Subhash Arayl, PhD²¹UNT Health Science Center, School of Public Health, Fort Worth, TX; ²UNT Health Science Center, Fort Worth, TX

Background: Dietary omega-3 poly-unsaturated fatty acids (n-3 PUFAs), including EPA and DHA, are primarily consumed through fish intake and have been associated with decreased depressive symptoms in some studies. Results from randomized controlled trials indicate that n-3 PUFAs can be an effective treatment for those who are depressed, but the results from individual studies vary and may not represent the general population. In addition, observational studies do not show a clear relationship between fish intake and depressive symptoms, and few studies have been conducted among a nationally representative sample of United States residents.

Methods: This study analyzed the relationship between n-3 PUFAs and depressive symptoms among 10,907 adults from the 2011–2014 National Health and Nutrition Examination Survey. Depressive symptoms were measured by the Patient Health Questionnaire and categorized based on severity. Fish consumption was measured by the 30-day food frequency questionnaires, and EPA and DHA consumption was measured by the 24-hour dietary recalls. Fish consumption was categorized based on the total number of meals within four groups: all fish, non-breaded fish, breaded fish, and shellfish. The covariates included age, gender, race, education, marital status, smoking status, health status, antidepressant use, and fish oil supplementation. The baseline category logit model was used to assess the relationship between fish meal consumption and EPA+DHA with depressive symptoms.

Results: In the adjusted analysis, those in the highest quartile of EPA+DHA consumption had a significantly lower odds of being in the highest depression category compared with the lowest depression category (OR =0.373, 95% CI: 0.172, 0.809). Those who consumed any shellfish had a significantly reduced odds of being in the highest depression category compared with the lowest depression category (OR = 0.709, 95% CI: 0.55, 0.92). Any fish, breaded fish, and non-breaded fish consumption were not significantly associated with the severity of depressive symptoms.

Conclusion: Consuming shellfish or a higher amount of EPA+DHA may be associated with a reduced odds of having severe depressive symptoms among United States residents. Further research should be conducted among longitudinal studies to confirm these results.

COMPARISONS OF FOODSERVICE STAFF AND PARENT PERCEPTIONS OF THE NUTRITIONAL QUALITY OF SCHOOL BREAKFAST

Lori Spruance, PhD, CHES¹, Amanda Haines, BS¹, Adrian Glover¹, Jordan Esplin¹, Marti Woolford, MS², Nathan Stokes, PhD¹¹Brigham Young University, Provo, UT; ²Utahns Against Hunger, Salt Lake City, UT

Purpose: Parent perception of the quality of school meals has been identified as a predictor of participation in school lunch. Although some parents have negative perceptions of school lunch, foodservice staff (FSS) perceive the quality of school lunches positively, suggesting differences in perception between parents and FSS. This study examines differences between parent and FSS perspectives of the nutritional quality of school breakfast in a rural area using visual examples of breakfast food currently served in (blinded state) public schools.

Methods: Data were collected via a cross-sectional survey of 282 parents of children in grades K-12 and 22 FSS in rural areas. Respondents were shown 12 pictures of food served as part of the school breakfast program in (blinded state). Respondents identified if they believed the pictured meal to be “healthy” or “unhealthy” and gave a short justification for their response. A content analysis was conducted for the response justifications.

Results: For nine of the 12 pictures, a higher percentage of FSS perceived school breakfast pictures as healthy compared to parents. Content analysis identified three emergent themes among responses: overall appearance (portion size, appearance or appeal of meals, whether meals were fresh or processed), nutritional component of breakfast (meal described as complete or incomplete, discussion of specific nutrients or sugar content), and specific foods to be or not to be served (respondents described a specific food rather than a broader nutrient or food category).

Conclusions: Results indicated differences between parent and FSS perceptions of the healthiness of school breakfast and identified parent concerns regarding the quality of school breakfast. Results from content analysis suggests that parents have concerns with processed foods, as well as foods and beverages high in sugar. Findings show FSS generally perceive most school breakfasts as healthy and indicate a potential disconnect between FSS and parent conceptions of “healthy”.

DESIGNING A PATIENT-CENTERED CLINICAL TRIAL FOR PROMOTING FLUID CONSUMPTION AMONG PATIENTS WITH NEPHROLITHIASIS

Ashley B. Sanders, M.S.¹, Alexandra Dubnansky², Necole Streeper, MD³, David E. Conroy, Ph.D.⁴¹The Pennsylvania State University, State College, PA; ²The Pennsylvania State University, Chadds Ford, PA; ³Penn State Health Milton S. Hershey Medical Center, Hershey, PA; ⁴The Pennsylvania State University, University Park, PA

Background: Nephrolithiasis impacts nearly 10% of the U.S. population, with the five-year recurrence rate ranging between 30–50%. Fluid consumption is critical for preventing a recurrence yet many patients fail to meet fluid consumption guidelines. This study sought to identify patient perspectives on barriers to fluid consumption and intervention elements that would facilitate recruitment and retention in a clinical trial.

Methods: Patients (*N*=19) with a history of kidney stones were recruited from medical clinics and an online advertisement. A researcher led groups of 3–5 patients in a semi-structured discussion that was digitally recorded and transcribed. Data were reduced to meaning units and analyzed using inductive content analysis.

Results: Patient-reported barriers to increasing fluid consumption involved concerns about the volume required, dissatisfaction with flavor and mineral content, and the disruptive impact of frequent bathroom trips. Patients recommended recruiting for clinical trials via clinicians, targeting patients with a history of stones and advertising on social media. They indicated that recruitment should emphasize education or personal gain as incentives. Patients also identified several retention strategies, including successful prevention of stones, education, and monetary incentives. The most important outcomes for patients involved preventing a recurrence of stones, or reducing the pain, emotional distress, inconvenience, and duration of future episodes of stones. Patients varied in how quickly they needed to see fluid consumption changes to be convinced an intervention was effective, ranging from days to years.

Conclusions: Despite some apprehension about increasing fluid consumption, patients expressed interest in interventions to prevent recurrence of kidney stones and provided insights for designing patient-centered clinical trials to evaluate candidate interventions.

DIFFERENCES IN FOOD SELECTION CRITERIA, NUTRITION LABEL USE, AND EATING BEHAVIORS AMONG YOUNG WOMEN AND MEN

Ashlie Johnson, B.S., B.A.,¹ Nina Wickens-Bhowmik, B.A.,² Silvia Canetto, Ph.D.¹, Daniel Graham, Ph.D.¹¹Colorado State University, Fort Collins, CO; ²Colorado School of Public Health, Fort Collins, CO

Women and men exhibit substantial differences in eating behaviors and rates of morbidity and mortality related to eating. An eating behavior with major differences by sex is weight-loss driven dieting. A behavior early in the sequence of weight-loss driven dieting behaviors is food selection, encompassing specific food shopping and nutrition label use at time of food purchase. Research on food selection and nutrition label use has only inconsistently examined data by sex. As a result, relatively little is known regarding women's and men's food selection criteria and nutrition-label use in relation to dieting and views of health. This study examined food selection criteria and nutrition label use in relation to weight-loss behaviors and views of health of 132 undergraduate students (53% female). Participants completed a survey assessing factors driving food shopping and nutrition-label use, as well as eating behaviors and views of health. Women reported significantly higher perceptions than men of the importance of eating healthy foods (*p*=.037). They were also more likely than men to report looking at calories, saturated fats, sodium, and vitamins when purchasing foods (*p*=.008, .008, .008, and .022, respectively). When asked about factors considered in food purchases, women gave significantly higher importance than men to calories, sugar, and brand (*p*=.009, .011, .042, respectively). Self-reported nutrition label use was associated with different factors. Among women, but not men, current dieting status significantly predicted food label use (*p*=.015). Among men, but not women, weight was a significant predictor of label use (*p*=.010). Consistent with prior findings, women and men also differed in dieting behaviors. Women were significantly more likely than men to report that they were currently trying to lose weight (54.3% vs 24.2%, respectively, *p*<.001). Women were also shown to have significantly higher rates of restrained eating behaviors compared to men (*p*=.001,) such as deliberately taking smaller portions to control weight (*p*<.001) or counting calories to consciously monitor weight (*p*=.004). Moreover, attempts at weight loss were shown to be related to different factors between men and women. In women but not men, health consciousness, nutrition label use, and the perceived importance of consuming healthy food were significantly related to trying to lose weight at the time of the survey (*p*<.001, .01, .032, respectively). These results suggest that weight loss might be related to different motivations and methods among young women and men. This study's findings have implications for the primary prevention of dysfunctional eating behaviors in women and men. Findings point to the importance of using female- and male-specific educational interventions given the different criteria women and men use in their food shopping and their differences in eating behaviors.

EFFECT OF AGRICULTURE AND NUTRITION AWARENESS ON EATING BEHAVIOR: ANALYSES OF FRUITS AND VEGETABLES CONSUMPTION IN RURAL INDIA

Yun-Hsuan Wu, PhD

McGill Centre for the Convergence of Health and Economics, Montreal, PQ, Canada

In India, the progress against a consistently low consumption of fruits and vegetables has been slow. Eating behavior has been recognized as a key factor for health improvement and disease prevention, with major efforts having been deployed around the world for its promotion. Although enhanced agriculture potentially leads to improved nutrient and health through eating behavioral pathway, there is scant empirical evidence. This aim of the research is to examine the single and combined effects of agricultural practice and nutrition awareness on fruits and vegetable consumption in rural India and whether nutrition awareness can have a reinforcing impact. The survey included questions on the household characteristics, farming activities, and consumption. A total of 427 households located across 32 villages and four districts in the state of Odish participated in the study. The influence of homegrown consumption and nutrition awareness on fruits and vegetables consumption was evaluated by a linear regression model analyses and the Poisson regression model analyses if there was a skew distribution for the outcome. All models adjusted household characteristics, food insecurity, marketing perception indicators and fruit and vegetable consumption reasons. Analyses were conducted for overall consumption and separately for fruits and vegetable. Results showed that higher homegrown consumption was associated with higher consumption on all outcome measures: fruits and vegetables ($\beta = 0.64$, $SE = 0.10$, $p = 0.008$); vegetables ($\beta = 0.56$, $SE = 0.11$, $p = 0.02$); fruits ($\beta = 0.62$, $SE = 0.06$, $p < 0.05$). Stratified analysis on Low- and High-awareness subgroups revealed that the positive effect of homegrown consumption on overall and vegetable consumption was twice stronger in the Low-awareness group compared to High. In contrast, for fruit consumption, that the influence of homegrown consumption was stronger among the High-Awareness group, although with a difference of lesser magnitude. Results are discussed in terms of the distinct contributions to healthy eating behavior stemming from the improved physical accessibility and higher income that accrue from farming practice. Future research and insights for promotion of fruit and vegetable consumption in rural and urban contexts in both developing and industrialized countries are discussed.

EXAMINING DISPARITIES IN DIET QUALITY BETWEEN SNAP PARTICIPANTS AND NON-PARTICIPANTS USING OAXACA-BLINDER DECOMPOSITION

Chelsea R. Singleton, PhD, MPH¹, Sabrina Young, MA¹, Nicollette Kessee¹, Sparkle E. Springfield, PhD², Bisakha Sen, PhD³¹University of Illinois at Chicago, Chicago, IL; ²Stanford Prevention Research Center, Stanford, CA; ³University of Alabama at Birmingham, Birmingham, AL

Background: Several studies have reported that participants of the Special Supplemental Nutrition Assistance Program (SNAP – formerly titled the Food Stamps Program) have poorer diet quality than non-participants. This research aimed to quantify how much of this disparity is explained by demographic, household, and health-related factors using Oaxaca-Blinder decomposition analysis.

Methods: Cross-sectional data on 13,589 participants of the National Health and Nutrition Examination Survey (NHANES) years 2009 – 2014 were analyzed. To measure diet quality, Healthy Eating Index (HEI) 2015 total and component scores were calculated using each subject's 24-hour dietary recall data. Oaxaca-Blinder decomposition analysis was used to examine how much of disparity in HEI-2015 total score is explained by demographic (e.g., age, sex, race/ethnicity, education, marital status), household (e.g., household size, food security status, prepared meal purchasing), and health-related measures (e.g., BMI, smoking status). Current SNAP participants were compared to both SNAP-eligible non-participants and ineligible non-participants.

Results: The total gap in HEI-2015 total score between SNAP participants and ineligible non-participants was calculated to be 6.14. Selected measures explained 91% of this disparity. On the other hand, the total gap in HEI-2015 total score between SNAP participants and SNAP-eligible non-participants was calculated to be 3.10. Selected measures explained 78% of the disparity between these two groups.

Conclusions: A significant disparity in diet quality existed between SNAP participants and non-participants in the sample. Demographic, household, and health-related factors explained a significant amount of the disparity that existed between SNAP participants and in-eligible non-participants; however, they explained less of the disparity between SNAP participants and SNAP-eligible non-participants.

EXAMINING THE RELATIONSHIP BETWEEN AGE AND DIET QUALITY IN BLACK WOMEN: A CROSS-SECTIONAL ANALYSIS OF NHANES DATA 2007–2012

Sparkle E. Springfield, PhD¹, Chelsea R. Singleton, PhD, MPH²¹Stanford Prevention Research Center, Stanford, CA; ²University of Illinois at Chicago, Chicago, IL

Background: Age is an established predictor of diet quality in the general population; however the relationship is not as clear among black women within different socioeconomic subgroups. The purpose of the present study is to assess the relationship between age and diet quality among Non-Hispanic black women within varying groups of educational attainment. This data may be used to identify demographic subgroups of black women that are more likely to have poor diet quality.

Methods: Cross-sectional data on 1,739 participants of the National Health and Nutrition Examination Survey (NHANES) 2007–2012 who self-identified themselves as Non-Hispanic black women were analyzed. Twenty-four-hour dietary recall data were used to assess diet quality via the Healthy Eating Index 2010 (HEI-2010). Multivariable-adjusted linear regression models were used to examine the association between age group (20–29, 30–39, 40–49 (reference), 50–59, 60–69, 70 and above) and HEI-2010 total score. Regression models were stratified by education group (< high school, high school or GED, some college, college degree or above).

Results: Approximately 16.7% of women in the sample had a college degree, and mean HEI-2010 total score was calculated to be 47.8 (± 0.6). Overall, women aged 20–29 had a significantly lower HEI-2010 total score compared to women aged 40–49 while women over age 70 had a significantly higher score. These findings were observed among women who reported they had some college education. No significant differences in HEI-2010 total score were found among the age groups in women with less than a high school diploma and women with a college degree.

Conclusions: Our findings suggest age has a significant and positive association with diet quality among black women with some college education. However, this association was not observed in all educational groups.

IMPACT OF PERSONAL HEALTH BEHAVIORS ON PARTNER TRAIT PREFERENCE

Christina Lawrence, MA¹, Briana V. McCoy, MA¹, Jamie Humphrey¹, Stephanie Spaulding, N/A², Brittany Canady, PhD¹¹Marshall University, Huntington, WV; ²Marshall University, Hurricane, WV

Introduction: Desired traits of a potential partner heavily influence the process of mate selection. Evolutionary psychology research suggests that women prefer more dominant, aggressive, and resource rich mates (Puts, 2010). Personality traits and gender roles have also been found to influence partner preferences, such that women of more traditional gender roles tend to value social prestige more and kindness less than egalitarian females (Rempala et al., 2014). However, research has not focused on how one's own health behaviors impact partner preference. The current study is aimed at investigating the association between personal health behaviors and preference for 14 partner traits.

Method: Participants were 137 single females ranging in age from 19 to 74 recruited via Amazon Mechanical Turk. Participants completed an online survey regarding engagement in health behaviors including alcohol use, tobacco use, tanning, exercise, and eating habits, following which they rated how desirable they perceived 14 characteristics in a potential romantic partner.

Results: Results indicate that of the characteristics assessed, loyalty/honesty were rated as most important across all participants. Inversely, religiosity/spirituality were the least preferred. Results suggest that participants' health behaviors influence preferences for partner traits. Partner trait preference was not significantly different between smokers and nonsmokers, nor for individuals who exercise frequently compared with individuals who report little to no exercise. However, a significant main effect emerged of diet on partner preference ($F(14,105) = 2.79, p < .01$). When partner traits were considered separately, it appears that individuals who eat healthier foods preferred their partners healthy and fit ($M = 12.77$) more so than did individuals who did not consume a healthy diet ($M = 9.49$). Further, results demonstrate that those individuals who consumed healthier foods more often took into account body type and height ($M = 11.20$) more so than did those whose diets were less healthy ($M = 9.02$).

Conclusion: This study indicates that an individual's health behaviors influence perceived desirability of partner characteristics. Individuals who report eating healthier foods prefer healthy and fit partners and may put more emphasis on physical characteristics such as height and body type. Previous research has demonstrated that partners influence health behaviors; if matching of health behaviors occurs during the partner selection process, it may limit the extent to which partners can influence health behavior change. Future studies may examine specifically the extent to which matching of health behaviors occurs, and its impact on engagement in health behaviors.

THE ASSOCIATION BETWEEN PERCEIVED DISCRIMINATION AND SERUM ANTIOXIDANTS: RESULTS FROM THE MIDLIFE IN THE UNITED STATES STUDY

Alvin Tran, MPH, Heather Mattei, PhD

Harvard T.H. Chan School of Public Health, Boston, MA

Objective: Discrimination – the unfair treatment towards an individual because of his, her or their race, ethnicity or other identifying characteristic – is a common occurrence in the United States. Research over the past two decades has examined the association between perceived discrimination and various health outcomes. For example, prior studies have linked the social stressor to elevated blood pressure and hypertension. The relationship between perceived discrimination and antioxidants – micronutrients that help the body ward off the harmful effects of oxidizing free radicals – remains unclear. Thus, using objective, biological data from the Midlife in the United States Study (MIDUS), we investigated the association between perceived discrimination and serum antioxidants.

Methods: We conducted a cross-sectional analysis assessing the association between self-reported perceived discrimination and serum antioxidant concentrations among 990 participants in the MIDUS Biomarker Project. Perceived discrimination was measured using participants' self-reported responses to nine items belonging to the interpersonal discrimination scale. Serum concentrations of nine antioxidants (carotenoids and Vitamin E) were collected via fasting blood samples. We conducted regression analyses to assess the relationship between perceived discrimination and antioxidant concentrations using age-adjusted and additionally adjusted models (adjusting for demographics and health status).

Results: The association between perceived discrimination and individual antioxidants varied. Individuals with greater perceived discrimination were significantly more likely to have lower concentrations of 13-cis- β -Carotene and α -Carotene – two carotenoids that can be converted to retinol (Vitamin A). Specifically, for every standard deviation increase in discrimination, age-adjusted concentrations for 13-cis- β -Carotene and α -Carotene decreased by 6% and 9%, respectively. These associations remained significant in additionally adjusted models. Perceived discrimination was not significantly associated with any other carotenoid in additionally adjusted models.

Conclusions: Perceived discrimination was significantly associated with decreased concentrations of serum 13-cis- β -Carotene and α -Carotene. This study adds to the sparse literature assessing the relationship between perceived discrimination and antioxidants. Given the cross-sectional design of this study, further research is needed to explore the relevant pathways, particularly health behaviors, between perceived discrimination and serum antioxidants.

THE GENERALIZABILITY OF THE SCOFF: A SYSTEMATIC REVIEW OF THE VALIDITY OF A WIDELY USED EATING DISORDER SCREEN

Amanda Kutz, Ph.D.¹, Shira Maguen, Ph.D.², Kathryn Min, MA, NCSP³, Alison Marsh, B.A.⁴, Robin M. Masheb, Ph.D.⁵

¹Prime Center, VA Connecticut, West Haven, CT; ²San Francisco VA Medical Center, San Francisco, CA; ³Veterans Administration, VA CT, Westport, DC; ⁴VA Connecticut Healthcare System, West Haven, CT; ⁵PRIME Center, VA Connecticut, West Haven, CT

Background. Current screening tools for eating disorders were developed to screen for anorexia nervosa (AN) and bulimia nervosa (BN) in young women. In recent years, awareness of disordered eating outside of AN and BN has increased. For instance, Binge eating disorder (BED), which is more prevalent than BN and AN, is now recognized as a distinct diagnosis in DSM-5. A much higher proportion of individuals with BED are older, overweight and male compared to individuals with AN and BN who are more likely to be younger, underweight to normal weight and female. One of the most widely used screening tools for eating disorders is the 5-item SCOFF questionnaire. The SCOFF was developed using a clinical sample of females with AN and BN. Indicative of its wide use, there are a number of validation studies which have been conducted on the SCOFF. There has not been a recent comprehensive review of these validation studies to assess evidence that the SCOFF is an adequate screening tool for eating disorders in populations outside of young, underweight to normal weight females who have AN or BN.

Methods. A PubMed search was conducted for the years of 1999 to 2017 for articles using the search term "SCOFF." Twenty of 106 articles provided some validation (e.g., sensitivity) and demographic information (e.g., age). These 20 articles were summarized in detail following PRISMA guidelines.

Results. The SCOFF tended to have higher sensitivity and specificity in studies using female samples with AN and BN. Several studies demonstrated lower sensitivity and specificity of the SCOFF in screening men, older women and individuals who are overweight, and for eating disorders other than AN and BN. Of the 20 studies, only two provided psychometric detail for BED. No studies provided psychometric detail for other newly specified DSM-5 eating disorders (i.e., atypical anorexia, low frequency or limited duration BN and BED, purging disorder, night eating disorder.).

Conclusions. This review of validation studies on the SCOFF demonstrates that the strong psychometric properties that have been used to justify its wide use have not been replicated among men, older women, racially diverse individuals, individuals who are overweight, and individuals with eating disorders other than AN and BN. Given the high rates of BED, and the newly specified eating disorders in DSM-5, a screening tool which is able to screen for a wider range of eating disorders in a variety of populations is needed.

USING PROXIMITY & PRODUCT PLACEMENT MANIPULATIONS TO INFLUENCE SNACK SELECTION IN A FOOD PURCHASING SIMULATION

Elizabeth Anderson Steeves, PhD, RD, Adeline M. Grier-Welch, BS, Ruth Z. Wooten, BS, Mikaela McIver, BS, Marleah Payne, BS

University of Tennessee, Knoxville, TN

Purpose: Small retail food outlets, like convenience stores, often provide a limited selection of healthy food options, possibly promoting less healthy food selection behaviors among customers. Interventions to promote healthier food choices in convenience stores have been conducted, but the most effective intervention strategies remain unknown and novel methods for improving consumer food selection are needed.

Methods: This study was conducted at rural county fairs in the Southeastern United States. The study implemented a food purchasing simulation with three different conditions. For the simulation, all participants were presented with 20 different individually packaged snack items mimicking the product mix typically found in convenience stores (20% healthier and 80% less healthy items). Participants were given \$5 cash to “purchase” as many or as few snacks as they desired. Participants in the Comparison Condition (n=27) were presented the foods on a shelf 10–12 feet away with healthier items distributed evenly throughout the shelf space. In the Shelf Placement Condition (n=27) the healthier options were placed at eye level in the center of the shelf that was 10–12 feet away. In the Proximity Condition (n=33) all of the healthier options were placed on a small shelf in close proximity to the research participant (within 1–2 feet) and all less healthy options were placed on a shelf 10–12 feet away. The Proximity condition was designed to simulate foods and beverages placed in a checkout aisle. Research condition, snack selections, and basic demographic information were recorded. A Kruskal-Wallis H Test was used to determine differences in the mean number of healthier items selected among conditions.

Results. Participants in the Comparison, Shelf Placement, and Proximity Conditions selected 0.63 ± 1.04 , 0.67 ± 1.30 , and 1.30 ± 1.24 healthier items (M \pm SD), respectively. The Kruskal-Wallis H test showed that there was a statistically significant difference in healthy food selection among the groups, $\chi^2(2) = 8.35$, $p = 0.015$.

Conclusions. Manipulating the foods and beverages in close proximity to customers, such as placing healthier options near the entrance to a store or near the register may be a helpful strategy for increasing the healthfulness of convenience store purchases.

ASSOCIATION BETWEEN FOOD INSECURITY AND CVD RISK FACTORS IS MODERATED BY INTAKE OF FRUITS AND VEGETABLES IN LATINOS

Andrea Lopez-Cepero, M.S.¹, Stephenie Lemon, Ph.D.², Milagros C. Rosal, MS, PhD¹

¹University of Massachusetts Medical School, Worcester, MA; ²UMass Worcester Prevention Research Center, Worcester, MA

Background: Food insecurity has been consistently associated with CVD risk factors (i.e., obesity, type 2 diabetes, hypertension and hypercholesterolemia). Consumption of fruits and vegetables may reduce CVD risk factors among food insecure Latinos.

Objective: To examine the potential moderating effect of fruit and vegetable intake in the association between food insecurity and CVD risk factors in a sample of Latino men and women in the northeast U.S.

Methods: A representative community sample of Latino individuals was recruited from a community health center in Lawrence, MA. Food insecurity was measured with the 6-item USDA Household Food Security Scale. Fruit and vegetable intake, was measured with Block's Fruit and Vegetable Screener. CVD risk factors examined included: obesity assessed by body mass index (BMI), and diagnoses of type 2 diabetes, hypertension and hyperlipidemia abstracted from electronic health records. Covariates considered included: age, gender, education and BMI (except in the obesity model). Statistical analyses included multivariable logistic regression testing for interaction between food insecurity and diet.

Results: Overall, 51% of the sample were women and most self-identified as Dominicans (73%). Thirty-one percent of the sample experienced food insecurity and 79% consumed less than 5 servings of fruits and vegetables per day. Twenty percent of food secure participants and 23% of food insecure individuals consumed 5 servings or more of fruits and vegetables per day ($p=0.439$). In adjusted models, food insecurity was positively associated with type 2 diabetes in individuals consuming less than 5 servings of fruits and vegetables per day (OR=1.79; 95% CI=1.11–2.89) but not in individuals consuming 5 servings or more of fruits and vegetables per day. Interaction analyses showed that these estimates were significantly different from each other ($p=0.04$).

Conclusion: Among those who were food insecure, low consumption of fruits and vegetables, was associated with type 2 diabetes in this Latino sample. Studies are needed to confirm our findings. Further, longitudinal studies are needed to understand a potential causal relationship. Interventions to increase availability of fruits and vegetables among food insecure Latinos may help alleviate diabetes disparities in this vulnerable group.

DO HIGHER PHYSICAL ACTIVITY LEVELS PRODUCE BETTER DIET QUALITY IN ADOLESCENTS?

Anita Bancroft, Student¹, Daniel Graham, Ph.D.²¹Colorado State University, Longmont, CO; ²Colorado State University, Fort Collins, CO

Consuming a well-balanced diet and engaging in regular physical activity are two important factors in maintaining a healthy weight, and in preventing a wide variety of chronic illness. The relationship between dietary intake and physical activity levels has previously been studied in adults and a moderate positive correlation was observed. (i.e., physical activity was higher at each increasing level of dietary healthfulness). This study aims to investigate whether the relationship between diet and activity seen among adults is similar or different among adolescents; specifically, the present study examines how moderate-to-vigorous physical activity (MVPA) relates to diet in adolescents by utilizing 2015 – 2020 Dietary Guidelines for Americans (DGA), 2010 Healthy Eating Index (HEI), and 2008 Physical Activity Guidelines for Americans (PAG). Data were provided by 86 healthy adolescents from the Fort Collins, Colorado area. Participants had an age range of 14 – 21 years with a mean age of 18.1 ± 2.1 years. An omnidirectional accelerometer (Actiwatch, Philips) was worn for one week to track physical activity levels. A self-reported dietary recall (ASA24®) was completed for two 24 hour periods to measure dietary intake. It was hypothesized that adolescents who spent more time engaging in MVPA would eat healthier diets (i.e., would score higher on the HEI and would meet more of the dietary guidelines). Participants had a mean caloric intake of 1885 ± 869 calories. Based on the HEI-2010 scoring guidelines, total HEI scores ranged from 23.64 – 92.75 and these adolescents had a mean HEI total score of 52.28 ± 1.80 . Only 8.1% of participants had a diet classified by the HEI as “good”, while 45.3% had a diet that “needs improvement”, and 46.5% had a “poor” diet. Only 16.3% of all participants met the PAG recommendation of at least 60 minutes per day of mostly MVPA. Of the participants who met the PAG, just 14.3% consumed a “good” diet according to the HEI. Most of the participants, 83.7%, engaged in 30 minutes or less MVPA per day. Contrary to the hypothesis, diet quality was not higher among those with increased activity levels; indeed, there were very few participants who are healthy diet or met PA recommendations. These data suggest that interventions aimed to improve both healthful diets and increased physical activity among adolescents are warranted.

EXECUTIVE FUNCTION MODERATES THE RELATION BETWEEN MOMENTARY AFFECTIVE AND PHYSICAL STATES AND SUBSEQUENT DIETARY LAPSES

Rebecca Crochiere, B.A., Stephanie Manasse, PhD, Meghan Butryn, Ph.D., Evan Forman, Ph.D.

Drexel University, Philadelphia, PA

Failure to adhere to a dietary regimen (i.e., dietary lapse) impedes weight loss. While studies using ecological momentary assessment (EMA; a data collection method gathering user feedback multiple times a day) have aimed to identify momentary changes in affective or physical states that trigger lapses, results have been inconsistent. Mixed results may be due in part to individual differences in executive function (EF)—or self-regulation skills such as the ability to plan and self-monitor—which may buffer the relation between negative affective or physical states and subsequent lapses. This study explored if baseline differences in EF influence the relation between intensity of affective and physical states and likelihood of subsequent lapse. We hypothesized a stronger relation between momentary elevations in boredom, tiredness, deprivation, sadness, stress, loneliness, irritation, and hunger and likelihood of lapsing among those with weaker EF.

Participants were 190 overweight adults in a behavioral weight loss treatment. Baseline EF skills, specifically planning, cognitive flexibility, and inhibitory control, were measured using the Dellsis-Kaplan EF System Tower Task, and affective or physical states and lapses were assessed in a 2-week EMA protocol at start of treatment. Generalized estimating equations demonstrated that, unexpectedly, the relation between momentary elevations in boredom and likelihood of subsequent lapsing were stronger for participants with stronger EF ($b=.03, p=.04$). By contrast, relations between momentary elevations in tiredness ($b=.02, p=.01$) and deprivation ($b=.02, p=.047$) and likelihood of subsequent lapsing were more robust for participants with weaker EF. We did not detect a moderating effect of EF on the relations between momentary elevations in sadness, stress, loneliness, irritation, and hunger and likelihood of lapsing.

Results suggesting higher EF increases likelihood of lapsing in response to boredom were unexpected; nonetheless, overweight people with stronger EF may become overweight for different reasons—such as overeating in response to boredom—than do overweight people with weaker EF. Results implying that higher EF may buffer against increased likelihood of lapsing in response to tiredness and deprivation supported our hypothesis. Those exerting EF frequently may anticipate resulting tiredness and deprivation, and thus can use their EF skills to plan meals and self-monitor hunger to avoid lapsing.

EXPLORING HOW BICULTURAL AND ASSIMILATED CHILDREN INFLUENCE THEIR LATINA MOTHERS' DIET

Sandra H. Soto, PhD, MPH, BSN¹, Elva Arredondo, PhD², Guadalupe X. Ayala, PhD MPH², Bess Marcus, PhD³, Holly Shakya, PhD³¹UNC, Chapel Hill, Chapel Hill, NC; ²San Diego State University, San Diego, CA; ³UC San Diego, La Jolla, CA

Purpose. Social and cultural factors influence dietary intake/behaviors. Research shows that mothers consume a lower quality diet when they have a child who is assimilated to the U.S. culture versus bicultural. The purpose of this study was to qualitatively compare and contrast how bicultural and assimilated children influenced their culturally traditional mothers' dietary intake/behaviors.

Methods. Separate semi-structured one-on-one interviews with 21 Mexican-origin mothers and their bicultural (n=11) or assimilated (n=10) children (10–13 years old) were conducted. We used framework analysis to reduce qualitative data to themes and subthemes. Surveys assessing mothers' daily fruit and vegetable intake, and sugary beverages, percent of calories from fat, weekly away-from-home eating, and percent of weekly grocery dollars spent on fruits and vegetables were also collected. Interview and survey data were analyzed separately and then compared between mothers of bicultural versus assimilated children.

Results. Survey data showed that mothers of bicultural children consumed a better quality diet than mothers of assimilated children. In qualitative interviews, mothers described several ways that their children's food preferences influenced their diet, cooking, food purchasing, and away-from-home eating, often differing by child's acculturation. For example, assimilated children typically preferred non-traditional foods and thus often persuaded their mothers to prepare or purchase these foods, resulting in mothers consuming these foods. Furthermore, mothers believed their children's food preferences both influenced and were influenced by their own feeding styles. Mothers of bicultural children described using more "Mexican" (i.e., authoritative) feeding styles that they believed shaped their children's palate into preferring traditional foods. Mothers of assimilated children explained that their children's preference for non-traditional foods resulted in their use of more permissive or indulgent feeding styles.

Discussion. Longitudinal research is needed to test the directionality between feeding styles and child's food preferences. Interventions may need to consider the reciprocal influences between mothers' feeding styles, children's food preferences, and how children influence their mothers' dietary intake/behaviors.

EXPLORING THE DIETARY STRATEGIES, INFLUENCES, AND RATIONALES USED BY PATIENTS PREPARING FOR OBESITY SURGERY

Ronnie Schobert, N/A, Amanda Lynch, PhD, RD

Oakland University, Rochester, MI

Introduction: Bariatric surgery promotes drastic weight loss by permanently altering the digestive system thereby restricting the amount of food one can consume. To promote health and long-term weight loss following surgery, individuals must make significant dietary and lifestyle changes. The ways in which patients prepare for bariatric surgery may impact their diet and weight management behaviors after surgery; however, little research explores patients' pre-surgery experiences. The goal of this study was to describe and explain how patients prepare for bariatric surgery.

Methods: 24 women and 6 men were recruited to participate in a two-year, mixed methods study. Data was collected in the form of diet and lifestyle questionnaires and qualitative interviews focusing on dietary behaviors, perceptions, and weight. Using a grounded theory approach, pre-surgery transcripts were coded for dietary behaviors, influences, and rationales by means of the constant comparative method. Three major themes emerged: Influences (factors that impacted patients' dietary behaviors and decisions), Strategies (tactics used to manage dietary influences), and Rationales (reasons for behaviors and decisions).

Results: Six influence categories emerged: Environmental, Psychological, Physical, Health, Circumstantial, and Surrounding People. These influences shaped participants' food related decisions and dietary strategy choices. Five strategy groups were identified: Portion Control, Substitution, Reduction, Implementation, and Elimination. Participants used between 1 and 15 techniques to ensure the successful implementation of these five strategies. They described two primary rationales for using specific strategy techniques: Health Promotion (to ensure healthy eating and weight loss) and Behavior Prevention (to avoid unwanted eating behaviors and weight gain). Due to participants' understanding that the surgery would be a "shock" to their bodies, Behavior Prevention was the more common rationale.

Conclusion: As patients prepare for bariatric surgery, they develop personalized ways of managing food and eating by employing a range of dietary strategies that promote health or prevent unwanted behaviors. Participants' contexts, experiences, and explanations for surgery influence their pre-surgery dietary behaviors and changes. Further research is needed to determine the link between pre-surgery and post-surgery dietary behaviors, strategies, and weight.

FINANCIAL HARDSHIP AND POOR DIET QUALITY: A DECOMPOSITION ANALYSIS OF NEUROBEHAVIORAL AND SOCIOECONOMIC FACTORS

Bradley Appelhans, PhD¹, Simone French, PhD², Tangney C. Christy, Ph.D.³, Melissa M. Crane, PhD¹, Michelle Li, MS RD¹, Yamin Wang, Ph.D.¹¹Rush University Medical Center, Chicago, IL; ²University of Minnesota, Minneapolis, MN; ³Rush University medical center, Chicago, IL

Socioeconomic differences in diet quality have been well-documented, but the specific drivers of these disparities are unclear. To elucidate these factors, Oaxaca-Blinder decomposition examined neurobehavioral and socioeconomic variables that account for the gap in diet quality between adults with and without financial hardship. Primary household food shoppers [N=186; 83% female; mean age=44.1; 46% African-American, 31% non-Hispanic white, 11% Hispanic, 12% other/multiracial] reported their household socioeconomic status, food security, perceived stress, and experience of financial hardship (i.e., “somewhat hard” or “very hard” to pay for basic necessities). Diet quality was quantified by applying the Healthy Eating Index-2010 scoring system to dietary intake data collected through three 24-h diet recalls. A binary choice task assessed individual differences in discounting rates for delayed monetary rewards, and an operant response task assessed the relative reinforcing value of energy-dense snacks. Researchers used a 71-item auditing tool to document the number of obesity-promoting foods in the home environment (M=20.2, SD=8.6). Body mass index (BMI; M=31.2, SD=9.2) was calculated from measured height and weight. Roughly half the sample (51%) reported financial hardship. Participants endorsing financial hardship had lower HEI-2010 scores (M=58.9, SD=12.6) than those who did not (M=66.1, SD=15.1; $p<.001$). In a decomposition analysis adjusting for age, sex, and BMI, six predictor variables collectively explained 73% of the gap in HEI-2010 scores. Discounting rates for delayed monetary rewards ($p=.02$) and food insecurity ($p=.03$) accounted for 21.1% and 17.2% of the explained diet quality gap, respectively. Obesity-promoting foods in the home accounted for 15.4% of the gap, but was not statistically significant ($p=.054$). Relative reinforcing value of energy-dense snacks ($p=.19$), perceived stress ($p=.61$), and educational attainment ($p=.23$) did not account for statistically significant portions diet quality gap. However, an interaction ($p=.01$) was observed whereby greater relative reinforcing value of energy-dense snacks was associated with decreased diet quality only in those participants who were not experiencing financial strain ($p=.001$). Neurobehavioral processes may be novel targets in efforts to improve diet quality in financially disadvantaged adults. Funded by R01HL117804. NCT02073643.

FOOD SECURITY AND GENDER MINORITY INDIVIDUALS IN THE SOUTHEAST UNITED STATES: A QUALITATIVE STUDY

Jennifer Russomanno, MPH, CHES, CMP¹, Jennifer M. Jabson, PhD, MPH², Joanne G. Patterson, MSW, MPH²¹University of Tennessee, Jefferson City, TN; ²University of Tennessee, Knoxville, TN

Background. Fourteen percent of American households are food insecure; meaning access to adequate food is limited by a lack of money and resources. Poverty, joblessness, and homelessness drive food insecurity. This problem may be especially significant for gender minority (GM) people (transgender/non-binary people). GM people are four times more likely than the national population to have annual household incomes below \$10,000, and it is estimated that joblessness and homelessness among GM people is double the national rate. GM people also face minority stressors that may contribute to drivers of food insecurity. There is little evidence describing GM people’s experiences with food insecurity. The current project investigated experiences with food insecurity among GM people living in the Southeast U.S., and how minority stress may influence food insecurity.

Methods. Semi-structured telephone interviews were conducted with 20 GM people, recruited via social media, residing in the Southeast U.S. Interviews were transcribed and coded for themes.

Results. GM people reported living in extreme poverty. They described how the conservative socio-political climate of the Southeast U.S. made it difficult to find employment and maintain a job, which were primary drivers of experienced food insecurity. Participants experienced discomfort with seeking food assistance due to explicit and passive discrimination, and for fear of reducing food availability for other, less fortunate, people. They reported being a primary caregiver for family members and prioritized the nutritional needs of others over their own. Stress from un- and underemployment, inadequate food supplies, caretaking duties, and discrimination were reported as significant contributors to their poor physical and mental health.

Conclusion. Poverty and food insecurity erodes GM people’s physical and mental health. GM people in our project faced substantial barriers—including un- and underemployment, and multi-level discrimination—that prevented them from affording adequate food. Possible public health solutions include: passing employment non-discrimination policy to protect GM people in the workplace; creating a searchable network of GM-friendly employers to assist GM people with finding employment; and building relationships between local food banks/pantries and LGBT organizations to create safe, welcoming environments to all persons in need of food assistance, regardless of gender identity.

NUTRITION LITERACY: A MEDIATOR OF HEALTHY-EATING BEHAVIOR BASED ON THE SOCIAL ECOLOGICAL FRAMEWORK

Li-Ling Liao, PhD¹, I-Ju Lai, RD, MPH, PhD², Chia-Kuei Lee, PhD³

¹Department of Health Management, I-Shou University, Kaohsiung City, Kaohsiung, Taiwan (Republic of China); ²Department of Nutrition, I-Shou University, Kaohsiung City, Kaohsiung, Taiwan (Republic of China); ³Department of Nursing, College of Medicine, National Cheng Kung University, Tainan, Tainan, Taiwan (Republic of China)

INTRODUCTION: Nutrition literacy (NL) is derived from health literacy, and which is used to elaborate individuals' health literacy regarding eating behavior. However, the link between NL and healthy-eating behavior was still unknown based on available evidence. The social ecological framework has been used widely to investigate the influencing factors of healthy-eating behavior. In this study, we expected to explore the role of NL between influencing factors and healthy-eating behavior among college students based on the social ecological framework.

METHODS: A cross-sectional and questionnaire-survey study comprising college students in Taiwan was conducted. Convenience sampling was used to select six schools: one national and one private university in each of the three regions: North, Central, and South Taiwan. In each school, 80 participants were recruited. Four-hundred twelve valid questionnaires were collected (effective response rate = 85.8%). The questionnaire used in this study was divided into four parts: self-rated NL, influencing factors of healthy-eating behavior, healthy-eating behavior, and demographic characteristics. Descriptive statistics, an independent samples t-test, a hierarchical multiple regression, and a mediation analysis were performed for data analyses.

RESULTS: College students' mean NL score was 4.32 (SD = .78, range = 1–6). In a social ecological framework, NL significantly predicted healthy-eating behavior ($\Delta R^2 = .054$, $\Delta F = 32.54$, $p < .001$), controlling for background, individual, interpersonal, environmental, and social-system factors. Among the 13 predictors across the four levels that predicted the healthy-eating behavior of college students, there were seven factors that were affected by the mediating effect of NL: social support from family (48.3%), healthy food proximity (43.1%), exposure to healthy-eating advocacy (42.4%), healthy eating attitude (41.4%), social support from peers (31.0%), healthy food preference (27.3%), and healthy-eating self-efficacy (25.9%).

DISCUSSION: This study suggests a prominent idea to improve NL and healthy-eating behavior at the same time. When improving the healthy-eating behavior of college students in the future, it is beneficial to develop the comprehensive intervention considering NL and multiple factors.

PERCEPTIONS OF NEIGHBORHOOD FOOD ENVIRONMENT ARE POSITIVELY ASSOCIATED WITH HEALTH OUTCOMES IN LOW FOOD ACCESS NEIGHBORHOOD

Keelia O'Malley, MPH¹, Revonda Darensbourg, MSW², Jeanette Gustat, PhD, MPH³, Carolyn C. Johnson, BA, MS, PhD; LPC, NCC³

¹Tulane Prevention Research Center, New Orleans, LA; ²Tulane Prevention Research Center, Tulane University School of Public Health and Tropical Medicine, New Orleans, LA; ³Tulane University School of Public Health and Tropical Medicine, New Orleans, LA

Introduction: The neighborhood food environment may either serve as a facilitator or barrier to healthy eating. The purpose of this study was to examine shopping and dietary behaviors of patrons of small food stores that traditionally do not sell many healthy food options within a low food access neighborhood.

Methods: All food outlets within one low-income predominantly African American neighborhood were identified. Trained research assistants conducted intercept interviews with individuals as they entered or left these food outlets. The interview included questions about food shopping behavior, diet and physical activity patterns, self-rated health, perceptions of their neighborhood food environment and demographic characteristics.

Results: Interviews were completed at 20 out of the 25 identified food stores in the neighborhood. A total of 214 individuals completed the intercept interviews in full (57.06% response rate). Half of the participants were 25–34 years of age, 72.90% were African American, over half (65.42%) were male and nearly half (45.79%) reported annual household incomes < \$25,000. Respondents reported shopping at the food outlet a median of twice per week (IQR = 3.85). Transport was by car by almost half and most participants (63.08%) shopped at the outlet because it was close to their residence. The majority of respondents were satisfied (56.07%) or very satisfied (27.10%) with the items available at the food outlet. Non-alcoholic beverages were purchased by the largest proportion of respondents (41.59%) followed by non-food items (35.05%), snack foods (29.91%) and alcohol (17.76%). Those who were often physically active (OR: 3.13; 95% CI: 1.62–6.02) and reported more positive perceptions of their neighborhood food environment (OR: 1.35; 95% CI: 1.02–1.79) were more likely to be in excellent or very good health compared to those in good, fair or poor health after adjustment for demographic factors. No relationship of significance was identified between perceptions of neighborhood food environment, dietary behaviors and health status.

Conclusions: Perception of the neighborhood environment may be related to health outcomes even in neighborhoods classified as having low access to healthy foods. This relationship may not be directly related to dietary behaviors but instead other pathways. Additional research may explore the identification of these pathways.

PICKY EATING PREDICTS LESS WEIGHT LOSS IN A DIET- AND LIFE-STYLE-FOCUSED PREBARIATRIC SURGERY READINESS PROGRAM

Hana F. Zickgraf, MA¹, Andrea Rigby, PsyD²¹Pennsylvania State University College of Medicine & University of Pennsylvania, Harrisburg, PA; ²Pennsylvania State University College of Medicine, Middletown, PA

Approximately 113,000 adults in the US undergo bariatric surgery each year, and this procedure is considered the gold-standard treatment for severe obesity. However, up to 25% of patients fail to lose the expected amount of excess body-weight; nonadherence to postbariatric dietary recommendations is considered the primary contributor to weight loss failure. Presurgical disordered eating, particularly binge eating, has been implicated in weight regain after surgery. However, research on the potential impact of nondisordered individual differences in appetite and food motivation in this population is lacking. In this study, we used the adult eating behavior questionnaire (AEBQ), a measure of individual differences in appetitive traits, to explore the relationships of eight food approach/avoidance-related traits with body mass index (BMI) at the beginning of the program, and weight loss/gain during the 3-6-month presurgical program. 290 consecutively enrolled prebariatric patients responded to the AEBQ. Participants were 77% female and had an average age of 42.9 (SD= 12.1). Data collection is ongoing; to date 194 have either completed the program or left without undergoing surgery. First and last weights in the program, from both program completers and drop-outs, were used to calculate weight loss during the presurgical readiness program. Confirmatory factor analysis supported the 8-factor structure identified in a community sample (RMSEA = .05, CFI = .92). Food approach scales measured eating in response to hunger, external food cues, the taste of food, and negative emotions; food avoidance scales measured responsiveness to satiety, eating slowly, undereating in response to negative emotions, and refusal to try new foods/eat nonpreferred foods (picky eating). None of the AEBQ scales was associated with weight at program entry. When all eight subscales were regressed on weight change controlling for baseline BMI, the only independent predictor was picky eating: $B = 2.7$, $p = .01$. Bariatric candidates who are selective about food and/or reluctant to try new foods may fail to lose weight through bariatric diet and lifestyle changes before surgery; whether they become able to these changes after surgery is unknown. Whereas most presurgical readiness programs focus on appetitive traits associated with overeating, individual differences in dietary flexibility may be overlooked. These differences could impact surgical candidates' ability to increase their intake of fruits and vegetables and add novel foods, such as protein supplements, to their diets.

RELATIONSHIPS AMONG DEMOGRAPHICS, STRESS AND DIETARY INTAKE BEHAVIORS AMONG LOW-INCOME OVERWEIGHT AND OBESE PREGNANT WOMEN

Mei-Wei Chang, RN¹, Alai Tan, PhD², Susan Nitzke, PhD³, Jonathan Schaffir, MD⁴¹The Ohio State University, Columbus, OH; ²Ohio State University College of Nursing, Columbus, OH; ³Univ. of Wisconsin-Madison, Cottage Grove, WI; ⁴The Ohio State University College of Medicine, Columbus, OH

Objectives. To examine relationships between demographics, stress, and dietary intakes of fat, fruit, and vegetable in low-income pregnant women.

Method. A cross-sectional pencil-and-paper survey was conducted of 353 low-income pregnant women who were overweight or obese before becoming pregnant.

Results. Women who were 35 years or older ($p = 0.006$), had a high school or less education ($p = 0.005$), or were unemployed ($p = 0.005$) were more likely to report high stress than younger women, those with at least some college education or those who were employed/homemakers. Compared to pregnant women who reported less stress, pregnant women who reported high stress were less likely to report high fruit intake (OR = 0.55, 95% CI 0.35–0.86) after adjusting for age, education, and employment status. There were no significant differences in fat and vegetable intakes between women with low and high stress.

Conclusions and implications. High stress was more prevalent among overweight or obese pregnant women who were older, had less education, or were unemployed. To help low-income overweight or obese pregnant women increase fruit intake, nutrition intervention or education may consider inclusion of stress management for those who perceive high level of stress.

THE EFFECT OF NATURALNESS ON MAKING FOOD PRODUCTS HEALTHY AND TASTY

Hajar Fatemi, PhD¹, Ji Lu, Dr.², Laurette Dube, PhD³¹McGill University, Montreal, PQ, Canada; ²Dalhousie University, Truro, NS, Canada; ³McGill University, McGill Centre for the Convergence of Health and Economics, Montreal, PQ, Canada

This paper investigates the effect of naturalness on the association between taste and health, as short-term and long-term consequences of consuming food products. Consumers generally believe that unhealthy is tasty. This belief entails that receiving short-term gratification is accompanied with long-term costs. This paper suggests that naturalness can change this belief and brings both short-term and long-term gratifications.

This paper proposes that nature is associated with balanced and holistic characteristics. This association entails balanced long-term (health) and short-term (taste) consequences for natural products. This is the opposite of common belief of unhealthy=tasty. The results of experimental study show that natural products are generally perceived to be both healthy and tasty. These products have a lower difference between their long-term and short-term consequences. This paper suggests that an increase in balanced consequences is a mechanism for the impact of naturalness on product attractiveness.

One hundred and seventy participants took part in this study on the MTurk website. The participants were randomly assigned to either the natural or the unnatural condition. Each individual answered questions regarding two food products (carrots and chocolate chips cookies). In the unnatural condition, the food products were described as being produced by industrial methods or containing preservatives and additives. In the natural condition, the food products were described as produced using organic methods or not containing preservatives and additives. Participants evaluated healthiness, taste and overall attractiveness of the product using Likert scale.

Results of this study show that naturalness decrease the difference between health and taste as the long-term and short-term consequences of food products. Food products are healthy and tasty in natural condition. Moreover, the effect of naturalness on balanced consequences is larger in products with higher immediate benefits, i.e. chocolate chips. As products with immediate benefits have higher difference between their short-term and long-term consequences, naturalness brings higher benefits to them in comparison to products with non-immediate benefits that already enjoy relatively balanced consequences. This study demonstrates that food products become more attractive when they are introduced as being natural. Balanced consequences mediate the effect of naturalness on product attractiveness.

WHO BRINGS HOME THE BACON? AN EXPLORATION OF GENDER IN HOUSEHOLD FOOD PURCHASES

Melissa M. Crane, PhD¹, Tangney C. Christy, Ph.D.², Yamin Wang, Ph.D.¹, Bradley Appelhans, PhD¹¹Rush University Medical Center, Chicago, IL; ²Rush University medical center, chicago, IL

Food purchasing behavior is an understudied precursor to eating behavior. To date, studies investigating food purchasing have focused almost exclusively on women's purchasing patterns because they are more likely than men to be the primary grocery shopper in heterosexual households. However, it is important to also study purchases made by other adults in the household in order to gain complete picture of household food environments and to identify additional points of intervention for healthy eating.

Data for this analysis come from the Study of Household Purchasing Patterns, Eating, and Recreation (SHoPPER; NCT02073643). This study included a rigorous, standardized approach to collecting and validating food purchase receipts. The primary grocery shopper in each home was trained in the collection of itemized receipts, tagging receipts and purchased foods with color coded stickers, and recording all foods purchased and consumed. Purchases made by someone other than the primary grocery shopper were also recorded. Research assistants visited homes three times over a two week period and collected and verified food purchases. The nutritional content of all foods purchased was calculated using the Nutrition Data System for Research (NDSR) and the Healthy Eating Index-2010 (HEI-2010) was calculated for purchases. All household members' demographic information recorded and heights and weights were objectively measured.

Of the primary grocery shoppers who volunteered for the study (N = 204), 17.2% (n = 35) were men. An average of 1.8 ± 0.9 adults (M ± SD) and 0.7 ± 1.1 children lived in the 204 households assessed. During the study period, 19,172 individual food items were purchased. The majority of the purchases were made by the primary grocery shopper (86.0%). For purchases made by any adult in the household, 22.8% of purchases were made by men. Men made fewer of their purchases at traditional grocery stores (51.7%) than women (70.2%; p < 0.001) however the quality of foods purchased were similar (HEI-2010: Men 57.5 ± 16.1 vs. Women 59.3 ± 16.0, p = 0.43).

Although men in this sample made significantly fewer of the overall food purchases than women, the quality of the foods were similar. Because men are more likely to purchase foods outside of traditional grocery stores, interventions targeting healthy eating among men should focus on healthier options available in these alternative locations such as carryout restaurants and fast food venues.

APPROACHES AND EFFECTIVENESS IN IMPLEMENTING THE EARLY CARE AND EDUCATION LEARNING COLLABORATIVE USING REAL-WORLD CONDITIONS

Teresa M. Smith, PhD, MS¹, Catherine Plumlee, MPH¹, Juile Shuell, MPA², Allison Gertel-Rosenberg, MS², Debbie Chang, MPH², Amy L. Yaroch, PhD¹¹Gretchen Swanson Center for Nutrition, Omaha, NE; ²Nemours Foundation, Washington, DC

Early care and education (ECE) programs are a key setting to implement strategies to improve policies and practices with regard to healthy eating and active living among young children. The National Early Care and Education Learning Collaboratives Project (ECELC) is a multi-state intervention across the United States (U.S) which is based on five strategies (self-assessment; in-person, peer-to-peer training; action planning and implementation; technical assistance; and reassessment). The ECELC has been assessed using pre and post data collected via the Nutrition and Physical Activity Self-Assessment for Child Care (NAP SACC) instrument. Results indicate that ECELC has been highly effective in implementing best practices for breastfeeding, nutrition, physical activity, and sedentary behaviors in ECE programs. However, the ECELC model is most resource intense of the models tested and therefore may not be easily spread and scaled to large numbers of ECE programs. This study compared and contrasted the full ECELC model to four alternate versions (training-only, technical assistance-only, online delivery of training, and toolkit-guided implementation of the five strategies) in an effort to test smaller, less resource-intensive forms of the model. Findings suggested that the Standard ECELC model is more effective (i.e., significant improvements from pre-assessment to post-assessment across all NAP SACC topic areas, ranging from a 10% increase in the area of Child Nutrition, which translates to about 4 more best practices on average, to a 14% increase in Infant & Child Physical Activity, which means about 3 more best practices on average) than training-only or technical assistance-only. However, adaptations to the delivery of these components (i.e., online delivery and toolkits that allow the ECELC to be implemented into existing programs and initiatives) may reduce the need for significant outside funding and may help foster and maintain sustainability of the program. Specific results will be shared during the presentation. The ECELC has been a catalyst for important changes to promote healthy eating and active living related policies and practices that may ultimately aid in childhood obesity prevention efforts throughout the U.S. While the Standard ECELC model is ultimately deemed to be the most effective, findings from the other three models described in this report show some promise for ability to implement the ECELC model into other existing frameworks.

HEALTH UTILIZATION PATTERNS AND CARE COORDINATION: LESSONS LEARNED FROM MEDICAID CLAIMS-DATA RESEARCH IN LUNG BIOPSY CASES

Darryl Somayaji, PhD, RN, Yu-Ping Chang, PhD, RN, FGSA, Sabrina Casucci, PhD, Xue Yuqing, MS, Sharon Hewner, PhD, RN

University at Buffalo, Buffalo, NY

Health utilization patterns provide opportunities for care coordination: Lessons learned from Medicaid claims-data research in lung biopsy cases.

There is great potential to support care coordination by using Medicaid claims-data to identify high need and high cost patients (super-utilizers). Claims data can identify healthcare events such as inpatient (IP), outpatient (OP), and emergency department (ED) visits along with health provider information. Identifying specific needs of patients and gaps in health services is critical to connect patients to a network of health providers, specialists, and key community resources.

The purpose of this paper is to report strengths, limitations, challenges, and strategies in using Medicaid claims-data to understand issues related to healthcare utilization and mortality in lung cancer care.

We will review: validity and methodological issues; discuss strategies for claims-based identification of an initial lung cancer diagnosis using Current Procedural Terminology (CPT) and Classification of Diseases (ICD) 9/10 codes; IP, OP, and ED utilization; and examination of factors associated with utilization and mortality. Next we will discuss strategies for strengthening the potential and benefit of using Medicaid data-sets based on lessons learned.

Finally, we will discuss research, practice, and policy implications of working with Medicaid data to improve care coordination for this vulnerable, low-income population. Research is needed to examine healthcare utilization patterns with recommended evidence-based guidelines in cancer prevention, screening, treatment, and supportive care. Coordination of appropriate and effective interventions including social and behavioral needs are key to improve quality of care. Policy changes addressing the linking of Medicaid and other clinical data sources will support and extend these efforts, ensuring the most vulnerable populations receive effective care coordination.

USING EVIDENCE TO DETERMINE PATIENT NAVIGATOR COMPETENCIES: A MIXED METHODS APPROACH

Patricia A. Valverde, PhD MPH¹, Elizabeth Calhoun, Ph.D., MEd², Kristen Wells, Ph.D.³¹Colorado School of Public Health, Aurora, CO; ²University of Arizona, Tucson, AZ; ³San Diego State University, San Diego, CA

Patient navigation is “a model of care coordination designed to reduce barriers to achieving positive health outcomes”. As an emerging field, a consensus on competencies for patient navigators has been elusive with most suggested competencies for those working along the cancer continuum and adhering to the Commission on Cancer guidelines. The remains a dearth of research on competencies for patient navigators across health conditions and different settings. The proposed presentation shares results from a mixed method study of patient navigator competencies. **The study triangulates findings from a Delphi process review of competencies, national survey of task domains, review of expert opinion, navigator focus group results, and analysis of PN competency literature. The combination of qualitative, quantitative, and ranking methodologies used provides the most comprehensive analysis of competencies for patient navigators to date.** We identify core competencies across the various sources as well as specialty competencies that are dependent on role, function, or setting of the patient navigator. The process and results provide direction for the training of patient navigator workforce that is unique from other roles including community health workers, promotoras de salud, and health educators. The establishment of core competencies and specialty competencies is an important step in the recognition of this growing field.

COLLABORATION IN THE IMPLEMENTATION OF BEHAVIORAL HEALTHCARE DELIVERY INNOVATIONS: LESSONS FROM THE CHART INVESTMENT PROGRAM

Natrina L. Johnson, MSc¹, Rani Elwy, PhD², Chris Louis, PhD³

¹Boston University School of Public Health, Boston, MA; ²Associate Professor, Department of Health Law Policy and Management, Boston University School of Public Health, Boston, MA; ³Department of Health Law, Policy and Management, Boston University School of Public Health, Boston, MA

Background: Phase 2 of the Community Hospital Acceleration, Revitalization and Transformation (CHART) program invests \$60 million into 27 community hospitals to enhance their delivery of efficient, effective care and preparing them for a value-based payment environment. Part of the evaluation focused on the implementation of each community hospital's customized innovation to reduce readmissions or emergency department revisits among vulnerable patients.

Objective: To understand whether and how hospital stakeholders and community partners collaborated to implement programs at 14 Massachusetts community hospitals that implemented behavioral health innovations.

Research Design: Key informant interviews took place from September–December 2016 with 119 hospital management, staff, and community partners. Informed by the Promoting Action on Research Implementation (PARIHS) framework and the Levels of Systemic Collaboration model, a qualitative directed content analysis approach was used to identify data corresponding to three themes: collaboration, community partnerships, and implementation success. The reliability and validity of our coding frame was assessed through joint coding by four analysts on multiple transcripts. Each coded transcript was discussed in depth until consensus was reached. Following this process, six analysts independently coded between 30–40 transcripts. Data were checked and entered into NVivo software for organization and reporting.

Results/Evaluation: Hospital staff indicated that the development of enhanced care plans through the collaboration between external community partners and the hospital was an important factor in continuing care following a hospital visit and reducing avoidable future hospital use. Implementation strategies consisting of community outreach and regular multi-disciplinary meetings that involved post-discharge providers (e.g., Skilled Nursing Facilities, community-based providers, etc.) was viewed as critical to the successful implementation of behavioral healthcare innovations, including patient tracking, telepsychiatry, and a community resource engagement platform. Hospital staff indicated that changes in emergency department operations benefitted from having more streamlined processes and collaboration with social workers and community health workers.

Conclusion: The implementation of behavioral health innovations at CHART hospitals benefitted from having collaboration across hospital stakeholders, and the integration of community partners with the healthcare team.

Future Plans: Learnings from the CHART Investment Program will help hospital stakeholders and community partners implement behavioral health care management processes critical to the success of future health care delivery improvement initiatives, including the MassHealth Medicaid ACO program.

COMPARING THE REACH OF AN EFFICACY TRIAL VS. AN EFFECTIVENESS TRIAL: WHO ARE WE REACHING?

Jodi Langley, B.Kin., Sean Locke, PhD, MA, BA, Mary Jung, PhD, MSc, BScH
University of British Columbia, Kelowna, BC, Canada

BACKGROUND: Diabetes prevention interventions targeting lifestyle behaviours have been shown to be efficacious in reducing Type 2 Diabetes (T2D) risk. Inclusion criteria for participation in such efficacy interventions has typically been highly controlled, resulting in interventions being delivered to a small, targeted sample. As such, the effectiveness of translating these programs to community-based settings has yielded inconsistent findings. Within Glasgow's RE-AIM framework, evaluating the composition and proportion of a population willing to participate in a program, *reach*, is critical for effective translation. Small Steps for Big Changes (SSBC) is a brief motivational interviewing-informed diabetes prevention program that has demonstrated efficacy when delivered in a university setting and has since been translated to a community YMCA.

PURPOSE: To compare the reach of the university-based (efficacy) and community-based (effectiveness) SSBC program utilizing the RE-AIM framework.

METHOD: The SSBC effectiveness study is run out of the YMCA in Kelowna, B.C. The efficacy study required more restrictive exclusion criteria than did the effectiveness study, however, the basic inclusion criteria for both included individuals aged 18–65 who were deemed at risk for developing T2D. All 5 dimensions of reach, in accordance to RE-AIM, including valid denominator, recruitment strategy, exclusion criteria, representativeness and qualitative measure for descriptive statistics will be used for this analyses.

RESULTS: The efficacy study employed a wider variety of recruitment strategies, whereas the effectiveness study had stronger community partnerships. In total, 235 were deemed ineligible for the efficacy study due to use of antidepressants, compared to 23 in the effectiveness study. Recruitment strategies evolved from print posters and media announcements for the efficacy trial, as compared to partnerships with the local health authority involving direct physician referral. With exclusion criteria being less stringent, 71.7% of the individuals enrolled in the effectiveness study were recruited through local health collaborations.

CONCLUSIONS: Preliminary reach evidence shows that collaborating with the local health authority for recruitment was an effective means to reach a more representative population. Although the SSBC effectiveness study is in the early stages there is strong potential to reach a larger population compared to the SSBC efficacy study.

EXTENDING OUR REACH: PRELIMINARY RESULTS DISSEMINATING MEANING-CENTERED PSYCHOTHERAPY (MCP) ACROSS SETTINGS & DISCIPLINES

Sally Reisch, BA¹, Laura C. Polacek, BA², Hayley Pessin, PhD¹, Katherine DuHamel, Ph.D.¹, William Breitbart, MD¹¹Memorial Sloan Kettering Cancer Center, New York, NY; ²Fordham University, Bronx, NY

Purpose: MCP is a brief, structured intervention for cancer patients, aimed at enhancing a sense of meaning in the face of illness. MCP Training (MCPT) is a 5-year program that aims to disseminate MCP to clinicians providing psychosocial or palliative care to people with advanced cancer using the RE-AIM framework (**R**each, **E**fficacy, **A**doption, **I**mplementation, and **M**aintenance) of implementation. The training is a 2-day intensive course comprised of interactive group exercises, lectures and small-group role plays with actors as patients. Trainees are assessed over a period of one year to determine the efficacy of MCPT.

Methods: Preliminary data from the applicant pool (n=309), the first 6 training cohorts (n=136), and 3-month follow up (T2) surveys (n=65) were analyzed. Trainees are assessed on several core competencies throughout the 2-day training, and provide feedback at the end of each day. Knowledge of MCP is assessed using a pre/post measure. Additionally, trainees are asked to complete follow-up surveys every 3 months to report implementation of MCP.

Results: 309 clinicians have applied to the MCPT program. Social workers (29.4%) and psychologists (31.1%) comprise two-thirds of applicants. The majority of applicants serve patients in academic medical centers (21.7%), comprehensive cancer centers (14.6%) or private practice (13.3%). 136 applicants have participated in the first 6 training sessions. At baseline, the majority of trainees (90.5%) self-report as new to or developing skills in MCP. Trainees improved their knowledge of MCP significantly ($t(132)=-1.99, p<0.001$) on a 10-question pre/post training assessment. 89.7% of trainees rate quality of materials highly, 4–5/5. Average trainee overall satisfaction score is 4.93/5. 47.8% of trainees completed T2 assessments, and 81.5% of those respondents report using MCP in their own clinical settings.

Conclusions: In the context of the RE-AIM model, MCPT is *reaching* the appropriate clinicians by discipline and clinical setting; it is *effective*, as most participants enter training with little MCP experience and increase their knowledge throughout the course; and it is *adopted* by 38.9% of trainees at T2. High quality of training is emphasized in trainee feedback ratings in the areas of training content and quality. Additional data is needed to identify barriers to the use of MCP and analyze MCP *implementation* and *maintenance* within this framework.

FORECASTING OF WEST NILE EPIDEMICS USING GOOGLE TRENDS: US STATE-SPECIFIC SEARCH BEHAVIOR

Cody J. Champion, B.S./M.S., Jiannong Xu, PhD

New Mexico State University, Las Cruces, NM

We extend a previously described method to forecast West Nile virus (WNV) cases, based on data obtained from Google Trends (GTs) and the CDC from 2015 to 2016. We examine the forecast accuracy of this method when applied to individual states in the USA. Previously, this method was used to forecast total WNV cases in the continental USA. Forecast accuracy is of importance to local health departments, as more precise forecasts of outbreaks can help allocate resources. Modeling was done using an autoregressive integrated moving average (ARIMA) model (0, 1, 3) including or excluding GTs data as additional regressors. Forecasting accuracy results indicate that ARIMA models using GTs data are more accurate than ARIMA models not using this data, but the location impacted this change in accuracy. Similarly, we find strong, but location dependent, correlations in many states between GTs and WNV outbreaks. ARIMA models regardless of GTs data inclusion were always much more accurate than the baseline time-series linear model. Washington, Colorado, Arizona, and New Jersey prediction models were improved significantly when GTs data was included. Differences in local population online responses to local WNV cases may be driven by different behaviors including alternative uses of social media networks or by external factors such as the availability of internet connection. Online search behaviors between states are variable and must be considered when used for forecasting WNV outbreaks. The practical application of this knowledge is that at-risk communities can be identified using real-time search data so interventions for decreasing vector exposure can be efficiently targeted.

INTEGRATING QUALITY IMPROVEMENT INTO THE WORK-LIFE OF LIFESTYLE PROGRAM COORDINATORS: LEAP PROGRAM FIRST-YEAR RESULTS

Laura Damschroder, MS, MPH, Julie Lowery, PhD, Claire Robinson, MPH, Nicholas Yankey, MPH, MSW, Michael Palmer, MSW

VA Center for Clinical Management Research, Ann Arbor, MI

Background: Quality improvement (QI) activities that are integrated into everyday work-life is a building-block skill for organizations to transform into true learning health systems. It is also an approach by which programs can be incrementally improved to more closely align with evidence-based innovations. However, learning and applying quality improvement skills is challenging for clinicians who work within a busy clinical environment. The Learn. Engage. Act. Process. (LEAP) Program is a team-level intervention, designed to empower frontline staff to implement and enhance evidence-based programs by building QI skills within the context of significant constraints on time and resources. The aim of this study was to evaluate process outcomes from a large-scale, stepped-wedge, randomized control trial of LEAP. Participants were teams responsible for leading weight management programs.

Methods: LEAP is a 21-week structured program designed to help clinicians learn and apply QI skills to their own program through weekly hands-on participation. The LEAP curriculum is delivered via an online platform. Group and individual QI coaching is provided through video conferencing calls. LEAP draws from short video clips and other resources developed by the Institute for Healthcare Improvement and HarvardX and the LEAP team. LEAP was refined based on formative feedback from three pilot teams; a total of 20 teams from 20 different medical centers, comprising 109 individuals, participated in the pilot and in the first four cohorts of teams. Measures of self-assessed QI skills and local organizational readiness for implementing change (ORIC) were administered before and after participation in LEAP.

Findings: All participants agreed that though participating in LEAP was challenging to fit into their existing work demands, LEAP was feasible to complete. All reported significant improvements across six categories of QI skills (e.g., using run charts) before versus after participation in LEAP ($p<0.01$). Lack of time was the biggest challenge, amid pressures of fulfilling other clinical responsibilities but all team leaders were committed to continuing to apply their new QI skills with ongoing support. All teams defined aims and applied acquired knowledge and skills toward achieving their aim to improve a facet of their weight management program.

Conclusions: LEAP is a scalable program with potential to empower frontline staff to engage in QI within their sphere of influence, an important foundation for learning health systems. LEAP was successful in helping frontline teams gain QI skills even with significant resource constraints.

SOCIAL-ECOLOGICAL OVERVIEW OF CHURCHES' PLANS FOR IMPLEMENTING HEALTHY ENVIRONMENT CHANGES

John A. Bernhart, MPH, CHES¹, Caroline G. Dunn, MS, RD², Sara Wilcox, PhD¹, Jessica Stucker, MSW¹¹University of South Carolina, Columbia, SC; ²USC, Columbia, SC

Purpose: Churches can provide a number of opportunities to influence member and community health. Previous interventions in churches have focused on individual-level changes, commonly offering educational sessions and/or classes, with few using an ecological approach. This study describes program plans that churches developed after they were trained to implement a faith-based, physical activity (PA) and healthy eating (HE) intervention guided by Cohen's Structural Ecological Model of Health Behavior.

Methods: Churches (N=53) attended a one-day training on strategies for creating changes to support PA and HE. All church committees wrote and submitted a program plan for implementing changes according to four adapted structural factors of Cohen's Structural Ecologic Model: 1) programs, 2) opportunities, 3) social structures and policies (not required), and 4) cultural and media messages. Plans were analyzed and coded using nVivo v.11.

Results: Plans most frequently included changes addressing PA and HE through cultural and media messages (n=468) such as encouraging pastors to discuss PA and HE from the pulpit and sharing monthly bulletin inserts. Next, churches proposed changes increasing PA and HE opportunities (n=238) such as planning time to walk after worship service and serving more fruits and vegetables at events. Plans addressing programs for PA and HE (n=75) included ideas such as starting a walking program or providing a healthy cooking class. Finally, churches addressed social structures and policy changes (n=65). Policies commonly included requiring PA breaks in church meetings lasting longer than 30 minutes and serving fruits and water instead of sweets and soda during children's Sunday School.

Conclusions: Church committees trained using an ecological approach planned a variety of activities to promote and increase PA and HE behaviors relevant to their congregation. Future studies should continue to investigate the role and influence of pastors and leaders when making healthy changes and developing policies.

CORRELATES OF SUN SAFE POLICY IMPLEMENTATION AMONG ELEMENTARY SCHOOLS

Kim D. Reynolds, PhD¹, David B. Buller, PhD², Julia Berteletti, MSW², Kim Massie, BS¹, Jeff Ashley, MD³, Mary K. Buller, MA², Richard T. Meenan, PhD⁴¹Claremont Graduate University, Claremont, CA; ²Klein Buendel, Inc., Golden, CO; ³Sun Safety for Kids, Inc., Burbank, CA; ⁴Kaiser Permanente - Center for Health Research, Portland, OR

In 2014, the U.S. Surgeon General issued a Call to Action to Prevent Skin Cancer, citing its high and increasing prevalence and cost. The Centers for Disease Control and Prevention and the Surgeon General identified sun safety in schools as a priority to reduce UV exposure and sunburns of children, with school district policy a key aspect of school-based efforts to prevent skin cancer. In this study, we explored the correlates of the implementation of sun safe practices, consistent with district board policy, among principals and teachers in public elementary schools. The sample included elementary school principals (N=118) and teachers (N=113) recruited from 40 California public school districts that had adopted Board Policy 5141.7 for sun safety and posted it online. Principals and teachers from the elementary schools reported on student sun protection policies and practices when surveyed between January 2014 and April 2016. Principals and teachers who were older (odds ratio[OR]=1.046, F=4.5, p<.04), were aware of the district board policy (OR=387.70, F=52.5, p<.0001), and could accurately recall elements of the district board policy (OR=3.5, F=50.7, p<.0001) were more likely to implement at least one school-level practice consistent with district board policy. These findings were replicated for the number of practices implemented consistent with California Senate Bill 1632 (Billy's Bill), which protects the right of students to apply sunscreen while at school without a physician note and to wear UV-protective clothing including hats on school grounds. Using the Billy's Bill outcome variable, older age (OR=1.07, F=6.1, p<.02), more years of work experience in education (OR=1.07, F=6.4, p<.02), and greater awareness (OR=98.31, F=33.41, p<.0001) and knowledge (OR=2.8, F=42.7, p<.0001) of district board policy were related to more practices implemented. The results imply that improved awareness of the existence and content of district board policy for sun safety may increase implementation of school skin cancer prevention. Districts need improved strategies for communicating these policies to principals and teachers who are responsible for implementing them to reduce UV exposure of children. Principals with greater experience might be recruited as key informants for those communications.

DID THE APPROACH USED TO RECRUIT RURAL ADULTS INTO A BEHAVIORAL INTERVENTION IMPACT RECRUITMENT, ENROLLMENT, AND ENGAGEMENT?

Kathleen Porter, PhD, RD¹, Katelynn Perzynski, BS¹, Erin Hecht, BS¹, Natalie Kruzliakova, BS², Jamie Zoellner, PhD, RD¹¹University of Virginia, Christiansburg, VA; ²Virginia Tech, Christiansburg, VA

Unsuccessful recruitment efforts have negative implications for behavioral interventions, ranging from an increased use of resources to underpowered studies. Though the evidence for how to enhance recruitment is growing, there is still much more to understand. This study seeks to expand this evidence by describing how recruitment, enrollment, and engagement indicators varied by general recruitment approach during SIP^{smart}ER's dissemination and implementation trial. SIP^{smart}ER was designed to meet the needs of low health literate individuals living in rural Appalachia. Recruitment and enrollment indicators include if a cohort delivered SIP^{smart}ER, number of screeners collected, rates of eligible individuals screened and enrolled, and health literacy of those recruited and enrolled. Engagement indicators include rates of activity completion and retention at 6-month assessment. This secondary analysis uses recruitment and implementation data, including field notes, number of surveys collected, contact logs, SSB intake, and attendance logs. Three general approaches taken to recruit cohorts were identified: community-wide (open), intact group with passive support from a group leader during recruitment and engagement (intact), and intact group with active support during recruitment and engagement (supported-intact). Data were analyzed using Chi Square tests and ANOVAs. Nineteen cohorts were approached using open (26%, n=4), intact (42%, n=8), and supported-intact (32%, n=6) approaches. Eleven (58%) enrolled enough participants to deliver SIP^{smart}ER; rates did not vary by approach. On average, more screeners were collected in open cohorts compared to intact and supported-intact cohorts (97.8 vs 43.6 and 14.5, $P=.043$). Compared to supported-intact cohorts, participants in open and intact cohorts were less likely to be eligible (84% vs 60% and 66%, $PPP=.157$), but enrolled participants in intact and supported-intact cohorts had poorer health literacy scores than those in open cohorts (5.6 and 6.3 vs. 3.5, $P=.001$). Among the five cohorts that completed SIP^{smart}ER by the summer of 2017, participants in supported-intact cohorts had higher rates of participation in intervention activities than those in open and intact cohorts (81% vs 48% and 47%, $P=.002$). Participants in intact and supported-intact cohorts were more likely to complete the 6-month assessment than those in open cohorts (100% and 92% vs 64%, $P=.012$). Though findings should be interpreted cautiously due to the small number of cohorts, this study provides evidence that targeting intact groups that have the active support of group leaders for recruitment and implementation activities can have a positive impact on recruitment, enrollment, and engagement.

EXTENDING THE REACH OF DPP INTERVENTIONS FOR WOMEN WITH PREDIABETES: TAILORING TO ENHANCE TRANSLATION IN PRIMARY CARE

Tannaz Moin, M.D., M.B.A., M.S.H.S.¹, Bevanne Bean-Mayberry, MD, MHS², Jessica L. Zuchowski, PhD, MPH³, Karen E. Dyer, PhD, MPH⁴, Alexis K. Huynh, PhD, MPH⁵, Melissa M. Farmer, PhD³, Erin Finley, PhD, MPH⁶, Alison Hamilton, PhD, MPH⁷

¹David Geffen School of Medicine at UCLA, Los Angeles, CA; ²VA Greater Los Angeles, North Hills, CA; ³VA, North Hills, CA; ⁴VA Greater Los Angeles Healthcare System, Health Services Research & Development (HSR&D), Los Angeles, CA; ⁵Veterans Health Administration, Los Angeles, CA; ⁶UT Health San Antonio/South Texas Veterans Health Care System, Boerne, TX; ⁷VA Greater Los Angeles Healthcare System, Culver City, CA

Background: Prediabetes, which now affects more than one in three US adults, increases the risk of incident diabetes for a significant portion of the population. Type 2 diabetes is a common disease, already affecting 25% of Veterans, and is associated with significant morbidity and mortality. Persistent gender disparities in quality of care for type 2 diabetes and cardiovascular (CV) risk underscore the importance of innovative approaches to target and promote diabetes prevention among women.

Methods: Women Veterans with prediabetes were invited to participate in a 12-month tailored, evidence-based intensive lifestyle intervention referred to as the diabetes prevention program (DPP). Women who met eligibility criteria were offered the choice of either a tailored peer-led, in-person DPP or an online DPP intervention. Patient and implementation outcomes were assessed using patient and provider semi-structured interviews, patient surveys and DPP participation and weight data.

Results: After screening 874 women Veterans, 541(62%) met preliminary eligibility criteria and 302 (56%) were reached by phone to confirm eligibility. Among those reached, N=216 (72%) expressed interest in DPP; 24% (N=51) chose in-person, peer-led DPP; 74% (N=160) chose online DPP and 2% (N=5) were undecided. At baseline, about 30% were aware of their previously documented prediabetes diagnosis and only 16% had previously participated in a lifestyle change program. Participation and adherence was higher with online as compared to in-person DPP (56% of online participants vs. 25% of in-person participants completed ≥ 9 sessions/modules). A total of 38 interviews were conducted (N=18 early implementation and N=20 post implementation). DPP content was well received regardless of modality but participants and providers valued having a choice between DPP modalities and agreed that offering gender-specific groups may help encourage participation.

Conclusions: Increasing prediabetes awareness and tailoring DPP intervention delivery to better meet the needs and preferences of high-risk sub-groups may help extend the reach of ongoing national efforts to prevent type 2 diabetes.

IMPLEMENTATION CHALLENGES IN INTEGRATING A PERMANENT HEALTH SURVEY AND REFERRAL SYSTEM IN THE EMERGENCY DEPARTMENT

Rachel Davis-Martin, PhD¹, Colette Houssan, MPH², Stephen Higgins, Jr., BS¹, Edwin D. Boudreaux, PhD¹¹University of Massachusetts Medical School, Worcester, MA; ²University of Massachusetts Medical School - Department of Emergency Medicine, Worcester, MA

The Computerized Health Survey (CHS) is an electronic survey designed to screen for mental health (MH) and substance use disorders (SUD) and provide referral resources based on appropriate level of care needed by the patient. The survey is patient-administered in the Emergency Department (ED) on tablet PCs installed in the treatment room. The CHS consists of brief screeners that, when positive, expand to full assessments. The screening portion of the CHS, on average, takes 4 minutes to complete with an additional 10 minutes if the patient completes the entire survey. Results from the survey are integrated into the electronic health record where ED physicians can view and save them to the chart and discuss with patients.

The CHS faced many barriers in development and implementation. Top developmental challenges included: a faulty patient wristband scanner, server communication issues, and reporting errors, which were resolved by replacing the scanner with a patient-entered name/birthdate feature, server migration, and a comprehensive review of software specifications. Delays in software updating and testing and staff concerns with hardware hindered installation into treatment rooms, prolonging full implementation. Hospital staff buy-in was particularly challenging, in part because of the volatility and stress of the ED environment. Changes in nursing staff's routine needed to be communicated well and repeatedly in order for nurses to take initiative. This barrier was addressed with informational placards, attending daily huddles multiple times per day, and demonstrating to nurses the simplicity of introducing the survey.

Since March 2016, research assistants and hospital staff have approached 2517 patients to initiate the survey. One thousand six hundred and eleven (64.0%) patients took the survey, and 563 (34.9%) screened positive, either solely or in combination, for SUD, depression, anxiety, and PTSD. Nine hundred two (35.8%) patients did not complete the CHS for reasons expected in an ED setting including: disinterest, too ill/medical interventions, and discharged during interaction. Language barriers, cognitive, visual, and auditory impairments/disabilities, technological deficits, and illiteracy prevented patients from proceeding with the survey. Our goal with full implementation of the CHS is to reach the 8000 patients who annually come into the ED with a SUD or MH issue by screening all patients at every visit.

INTEGRATION OF AN ENHANCED PSYCHOSOCIAL EVALUATION PROCESS FOR KIDNEY TRANSPLANT CANDIDATES: COUNTDOWN TO TRANSPLANT CLINIC

Erin Clifton, PhD¹, Anne Eshelman, PhD, ABPP², Dean Y. Kim, MD³, Anita Patel, MD³, Kathleen Hogan, RN BSN², Elizabeth Rubinstein, Patient Lifestyle Coach², Daisy J. Ramirez, Associates of Science³, Michelle Jesse, PhD²¹Henry Ford Health System, Ypsilanti, MI; ²Henry Ford Health System, Detroit, MI; ³Henry Ford Hospital, Detroit, MI

Background: There are approximately 100,000 patients listed and awaiting kidney transplantation with a current national average wait for a deceased donor of 3 to 5 years. Per guidelines, patients routinely undergo yearly medical re-evaluation for continued listing. However, there is a lack of standardization of continued psychosocial evaluations. As issues can (re)emerge over time, efforts to identify and reduce psychosocial risks prior to transplant have potential to improve survival and clinic outcomes. Integration of behavioral assessment into routine tertiary care is an important area of research and development.

Purpose: To describe the development and integration of an educational and evaluative clinic for listed kidney transplant patients.

Methods: The multidisciplinary kidney transplant team (including psychologists, social workers, nurses, physicians, nutritionists, and patient lifestyle coaches) collaborated to develop and integrate a clinic aimed at identifying and ameliorating risk factors for negative outcomes in patients listed and likely to receive a transplant offer in the near future (patients high on the list at a large, Midwestern transplant center). The clinic included an enhanced educational session focused on preparedness for transplant and lifestyle changes after surgery with evaluations by psychology, social work, and nephrology. Patients were required to bring two of their supports to verify adequate support for transplant.

Results: From November 2016-August 2017, 89 patients attended the clinic. Following participation, 19 patients were placed on hold, of which five holds were due in part to psychosocial factors including active substance abuse or lack of adequate support. Recommendations from the psychological assessment included; engaging in psychotherapy to address symptoms of adjustment, anxiety, or depressive disorder (n 9), mobilization of social supports (n 6), cease substance use (n 1). Strategies and resources for all recommendations were provided to the patient and communicated back to the primary team.

Conclusion: Integration of an educational and re-evaluative clinic into tertiary care can benefit patients, supports, and transplant staff by providing a way to collaborate in the identification and management of psychosocial risk factors in patients approaching transplant.

LEVERAGING PHYSICAL ACTIVITY TO PROMOTE MENTAL HEALTH IN AT RISK ADOLESCENTS: LESSONS LEARNED FROM 2 ITERATIONS OF LEADERS @ PLAY

Eduardo E. Bustamante, PhD¹, Tara G. Mehta, PhD¹, Angela Walden, PhD¹, Grace E. Cua, MSW¹, Stacy L. Frazier, PhD²¹University of Illinois at Chicago, Chicago, IL; ²Florida International University, Miami, FL

Early adolescence is characterized by sharp decreases in physical activity and out of school time (OST) programs. Nationally, 20% of middle school students are unsupervised after school, a time period when they are vulnerable to risky behaviors (e.g., sexual experimentation; drug and alcohol use; gang involvement). Leaders @ Play was developed through university-community partnership as an OST program to prepare at-risk adolescents to serve as Jr. Counselors at neighborhood parks. It focused on instilling common elements of adolescent prevention programs (i.e., effective communication, problem solving, and emotion regulation) through didactic and recreation activities, and was offered at 3 parks (N = 46 middle-school youth, 100% African-American, 100% low-income, 59% female, M = 13.09 years), 90-min/day, 2 days/week, for 10 weeks (Frazier et al., 2014). The original iteration was designed to be co-facilitated by a Physical Instructor and Social Work Intern but both co-facilitation (park staff only co-facilitated 51% of sessions) and attendance (M = 6.3 youth/session) emerged as challenges. Following the Clinic/Community Intervention Development Model (Burns & Hoagwood, 2002) we engaged in an iterative process of continuing refinement and pilot testing of the protocol to ensure that the model reflected the evolving capacity and needs of the setting. After analysis and extensive consultation with our community partner, a second iteration, Leaders @ Play 2.0, was implemented as a 1–2 hour biweekly component of a 6-week Teen Leadership Summer Camp at 5 parks (N=38 middle-school youth, 31% Hispanic, 26% African-American, 55% low-income, 43% female, M=13.2 years-old). Leaders @ Play 2.0 adapted the original intervention by simplifying the agenda and emphasizing sport and physical activity, which aligned better with park strengths. Restrictions on co-facilitator eligibility were removed to improve feasibility and scalability, and Park Recreation Leaders and University staff without extensive mental health training co-facilitated sessions with weekly supervision meetings with investigators. Physical activities were designed to directly challenge identified social skills, small group discussions were systematically conducted prior to and following each activity, and staff were trained to capitalize on teachable moments by Modeling, Observing, Reinforcing, and Encouraging (MORE) skills. Implementation was successful with a 94% park co-facilitation rate, M=9.0 youth attending each session, youth engagement from 90–100% across activities, and 81% of agenda items completed. Findings suggest that ongoing refinement of an intervention based on stakeholder feedback and data, and leveraging of existing resources, can facilitate implementation of OST physical activity programming to simultaneously promote physical and mental health among at-risk adolescents.

MOTIVATIONAL INTERVIEWING IMPLEMENTATION TO IMPROVE LINKAGE TO CARE FOR YOUTH LIVING WITH HIV: THE MINORITY AIDS INITIATIVE

Amy Pennar, PhD¹, Bo Wang, PhD², Sylvie Naar, PhD³, J. Dennis Fortenberry, MD MS⁴, Kathryn Brogan-Hartlieb, PhD, RD⁵¹Wayne State University School of Medicine, Detroit, MI; ²University of Massachusetts Medical School, Worcester, MA; ³Florida State University, Royal Oak, MI; ⁴Indiana University School of Medicine, Indianapolis, IN; ⁵College of Medicine, Florida International University, Miami, FL

Implementation fidelity is critical for achieving the benefits of evidence based interventions; however, it remains unclear how to implement evidence based practices in HIV settings utilizing paraprofessionals to deliver comprehensive services to youth living with HIV. The goal of this study was to evaluate paraprofessionals implementation fidelity following randomization to a motivational interviewing intervention to determine: 1) implementation fidelity trajectories across time, 2) optimal intervention dosing based on educators' implementation trajectories, and 3) educators' perceived barriers and facilitators for implementation. Longitudinal data were collected from 17 HIV health service organizations. Implementation fidelity was assessed at baseline and up to 15 times over two years. Random coefficient models were utilized to examine time trajectories of motivational interviewing fidelity scores and the impact of the intervention on motivational interviewing trajectories. Semi-structured interviews were conducted to determine barriers and facilitators for implementation. Motivational interviewing competency scores of the intervention group significantly increased; however, competency scores of the control group significantly decreased over time. Further analysis of the intervention group demonstrated a significant quadratic effect. Competency significantly increased during the first three months after training and then plateaued for the duration of the study (24 months). High rates of implementation adherence were evidenced. Qualitative interviews revealed insufficient time and competing priorities as perceived barriers. Intensive training and integration into routine practices were perceived facilitators. Findings support teaching paraprofessional health educators behavior change techniques to enhance linkage to care services offered to youth in HIV clinical settings. Attunement to competing demands and priorities facing paraprofessionals is critical for considering intervention implementation practices; however, continued education and emphasis on the benefits of implementation may help to overcome perceived implementation barriers. Finally, the results suggest optimization of intervention dosing occurred after three months. Future studies should determine whether more tailored training after the first three months leads to continued growth in individual implementation fidelity over time.

MOTIVATIONAL INTERVIEWING SIMULATOR: AN EXPERIENTIAL ONLINE TRAINING TOOL

Jeffrey Olivet, MA¹, Ferreira Kathleen, Ph.D.¹, Catriona Wilkey, M.S.W., M.P.H.¹, Molly Richard, B.A.¹, Svetlana Yampolskaya, Ph.D.², Andrew Northrop, B.A.³, Ken Kraybill, MSW¹

¹Center for Social Innovation, Needham, MA; ²Department of Child & Family Studies, College of Behavioral and Community Sciences, University of South Florida, Tampa, FL; ³Forio, San Francisco, CA

Motivational Interviewing (MI) is a widely researched evidence-based practice that uses collaborative conversation to support and guide people through a process of behavior change. When used with fidelity, MI has proven effective with a range of populations with outcomes of decreased substance use, increased medication adherence, reduced psychiatric symptoms, improved housing stability, and reduced high-risk sex and drug-related behaviors.

MI training typically requires intensive two-day onsite workshops. A decline in skills and knowledge following onsite training is well documented, and opportunities and funding for follow-up learning are limited. A lag time in adopting technological innovations for professional development slows the translation of research to practice, leaving providers ill-equipped to provide the best quality care.

With a Small Business Innovation Research (SBIR) Phase II grant from the National Institute of Mental Health, the Center for Social Innovation (C4) developed and evaluated the *Motivational Interviewing Simulator: An Experiential Online Training Tool*. The “*Sim*” brings together MI training approaches with online simulation technology to guide users through case-based scenarios that strengthen and reinforce MI skills. Learners play alone or with others, respond to storylines and characters with MI skills, and receive expert feedback.

C4 recruited 180 practitioners from 20 programs working with individuals living in supportive housing (many of whom have histories of mental illness, drug and alcohol addiction, and homelessness) to test the *Sim*. After receiving in-person MI training, programs were randomized into one of three conditions: 1) MI Sim; 2) eBook (a passive online version of MI information); and 3) no ongoing support. Measures of MI confidence, knowledge, and application of skills were collected at four time points. Assessment interviews were conducted at two time points using the Motivational Interviewing Treatment Integrity code. Semi-structured interviews and focus groups were conducted with clients, administrators, and practitioners. Client-level data provided insight on clinical outcomes. Findings from this study will be illustrated and discussed within the context of the human service training landscape.

PROMOTING PROGRAMS FOR DIABETES PREVENTION: A RANDOMIZED TRIAL TO DESIGN THEORY-BASED OUTREACH STRATEGIES

Susan D. Brown, PhD¹, Omid Fotuhi, PhD², Christina Grijalva, MA¹, Ai-Lin Tsai, M.A., M.S.³, Geoffrey Cohen, PhD⁴, Assiamira Ferrara, MD, PhD⁵

¹Kaiser Permanente Northern California, Oakland, CA; ²University of Pittsburgh, Pittsburgh, PA; ³Kaiser Permanente, Oakland, CA; ⁴Stanford University, Stanford, CA; ⁵Kaiser Permanente Division of Research, Oakland, CA

Two-fifths of Americans may develop diabetes, yet high-risk patients may dismiss outreach promoting preventive programs. Novel strategies are therefore needed to increase patients' uptake of preventive programs in health system settings. Self-affirmation, or writing about personal values, can minimize defensive avoidance of health-promoting information; however, implementation in health systems is scarce. Among women at high risk for type 2 diabetes in an integrated healthcare delivery system, we conducted 1) a mixed methods study to embed streamlined affirmations, without the typical writing component, in outreach messages promoting preventive programs (2015); and 2) a parallel three-group RCT comparing the streamlined affirmations to an attention-only control group (2016). In the trial ($N = 237$; 64% racial/ethnic minority), participants viewed an outreach message preceded by either a) a values affirmation, i.e., a two-sentence prompt encouraging reflection on any personal value; b) a parenting affirmation, i.e., a two-sentence prompt encouraging reflection on values related to caregiving; or c) no affirmation (control). Compared to control, neither affirmation increased self-integrity, a measure of the degree to which participants were affirmed. However, the values affirmation increased interest in prevention (68.0% vs. 51.3%; adjusted odds ratio [AOR], 95% CI: 2.1, 1.1–4.0), a composite signifying a positive response on ≥ 2 of 3 individual indicators: information seeking about diabetes prevention (whether to receive a National Diabetes Education Program website link; 73.4% vs. 59.0%; AOR 2.0, 1.0–3.9); information seeking about a health system-based lifestyle program (whether to receive a link; 70.9% vs. 59.0%; AOR 1.7, 0.9–3.4); and intention to join a program (30.4% vs. 25.6%; AOR 1.4, 0.7–2.9). Results indicate that self-affirmation can be adapted for large-scale implementation. Despite limited observed impact on self-integrity, a streamlined values affirmation may promote preventive programs among women at high risk for type 2 diabetes.

THE ROLE OF STAKEHOLDER BUY-IN AND CHAMPIONS IN IMPLEMENTING A COMPUTERIZED HEALTH SURVEY IN THE EMERGENCY DEPARTMENT

Stephen Higgins, Jr., BS, Rachel Davis-Martin, PhD, Edwin D. Boudreaux, PhD
University of Massachusetts Medical School, Worcester, MA

Smartphone and tablet PC technology are becoming common tools to improve patient care in many healthcare settings. At the University of Massachusetts Medical School, we have installed tablet PCs equipped with a computerized health survey (CHS), internet access, and educational materials about common behavioral health issues into all Emergency Department (ED) treatment rooms. The goal of the CHS is to improve patient care through medical and behavioral health screening. The CHS is designed to be self-sufficient and sustained through minimal effort as part of the nursing staff's patient care routine. This minor change in staff routine required significant stakeholder buy-in for implementation success.

To increase stakeholder buy-in of the CHS, ED physicians and nurses were actively involved in the planning process of survey items, appearance of results in the chart, and tablet installation. Additionally, ED staff were educated at monthly meetings about the goals of CHS installation for 5 months prior to tablet installation. At these meetings, a champion was identified for each hospital shift. Each champion was sent a notification email the week before tablets were ready for use and was responsible for distribution of the email to the rest of the staff. Instructions cards on how to open the survey and contact information for any questions or problems encountered were given to all champions.

To ease the burden of change to staff routine, we utilized a 3-phase rollout to implement the survey in the ED. Phase 1 lasted 1 month and started in a smaller, 12-hour, 11-room treatment area, which allowed us to contain our patient population, while utilizing the high-turnover rate. Phase 2 lasted 1 month and consisted of a 24-hour, 9-room treatment area, which allowed us to observe and address barriers to implementation during after-hour shifts. Phase 3 expanded implementation to a 24-hour, 30-room treatment area, completing tablet installation in the entire ED.

However, the implementation of these devices into the ED posed both unexpected and expected challenges, with stakeholder buy-in posing one of the most pressing, ongoing problems. Problems we encountered that affected continued stakeholder buy-in were internet connectivity, survey results not correctly pushing to medical platforms, and patients stealing tablets. Nursing huddles served as a great medium for communication between staff members, provided an opportunity to present weekly and monthly statistics, and helped identify additional champions. Preliminary data suggests that attending nursing huddles increased survey completion rates by 13%.

WHAT WORKS IN CORRECTIONS: FRONT-LINE INSIGHTS ON COMPUTER-BASED TRAINING

Valerie H. Myers, PhD¹, Susan J. Loeb, PhD, RN, FGSA, FAAN², Erin Kitt-Lewis, PhD, RN², Tiffany Jerrod, MPH³, Sophia Strickfaden, MA³, Rachel Wion, MS, RN², Janice Penrod, PhD, RN, FGSA, FAAN²

¹Klein Buendel, Inc., Golden, CO; ²Penn State College of Nursing, University Park, PA; ³Klein Buendel, Golden, CO

The prison population is aging at a rapid rate and is expected to continue to do so into the foreseeable future. As a result, United States prisons are facing increased demands in caring for aged, chronically ill, and dying inmates. Despite advances in the free world, best practices for managing geriatric issues and life-limiting or terminal illness have not been adapted for use in corrections settings. Implementing a training program addressing the health issues related to this population could mitigate legal risks and enhance care; however, the paramount focus on security makes technological advances available in the free world inaccessible inside prison walls. Lessons learned from prior development, implementation, and evaluation research targeted at enhancing care for the aged and dying in prison led to the development of a media-rich interactive computer-based learning prototype, Enhancing Care of the Aged and Dying in Prison (ECAD-P). ECAD-P contains six modules that address end-of-life and geriatric care issues in prisons. This aim of the project focused on a small-scale evaluation of ECAD-P. Specifically, in-person usability testing was conducted at one state department of corrections and one large city jail. Participants (n=24) evaluated the user interface, ease of use, and perceived barriers of the prototype. Findings from usability testing will guide design and development decisions related to user preferences, optimizing learning experiences, and preparing for implementation. A summary evaluation of the computer-based prototype training includes the participants' impressions regarding the user interface (i.e., aesthetics) of the computer-based training modules, beliefs about ease of use of the computer-based training modules, and perceived barriers regarding use of the computer-based training modules. Findings will be used to refine the computer-based training program for large-scale usability testing targeting 12 prisons and jails across the United States. Lessons learned from this usability study and the larger scale usability study will inform future dissemination of the product. The intent of this educational product is to extend the reach to promote quality of health and health equity, as well as narrow the gap in health disparities experienced by a group that have often been described as "the least among us".

USING VOICES OF COMMUNITY STAKEHOLDERS TO EXTEND THE REACH OF A BEHAVIORAL MEDICINE INTERVENTION FOR BLACK WOMEN LIVING WITH HIV

Sannisha K. Dale, PhD, EdM¹, Jasmyn Sanders, B.S.², Sherene Saunders, MPH, BS, CCHW², Joan Porter-France, MPH, B.A.Ed³, Arnetta E. Philips, CAC², Steven Safren, Ph.D., A.B.P.P.¹

¹University of Miami, Coral Gables, FL; ²University of Miami, Miami, FL; ³Florida Department of Health, Miami-Dade County, North Port, FL

Background: A limit to many behavioral medicine interventions is that they are developed without the input of community stakeholders who are knowledgeable about the issues that communities face, which can potentially limit their acceptability. The insights of communities stakeholders may also help to extend the reach of behavioral medicine approaches to communities in need. Community stakeholders with expertise in serving and advocating for Black women living with HIV (BWLWH) were interviewed to inform the development of STEP-AD (Striving Towards Empowerment and Medication Adherence), a behavioral medicine intervention for Black women living with HIV to improve medication nonadherence and address psychosocial factors (i.e. abuse/trauma histories, racial discrimination, HIV stigma/discrimination, and prescribed traditional gender roles) that have been associated with medication nonadherence.

Method: Fifteen community stakeholders residing in the Boston area were interviewed about factors impacting the lives and health of BWLWH and strategies that may be beneficial for behavioral medicine research/interventions. Semi-structured qualitative interviews were conducted with each community stakeholder and audio-recorded. Audios were transcribed in Microsoft word verbatim and coded using grounded theory.

Results: Community stakeholders noted several common insights on how to best reach and serve BWLWH including – genuine partnerships between community members and organizations/research institutions; addressing trauma and violence against women; providing mental health services in a manner that is de-stigmatizing, affirming, safe, and integrated with other care; raising awareness about the root cause of HIV-related health disparities (e.g. poverty, racism); and providing funding/resources to offset structural barriers (e.g. finance). Stakeholders also shared helpful and unhelpful ways that BWLWH cope with HIV stigma/discrimination (e.g. owning one's status vs. nondisclosure), racial discrimination (e.g. speaking up/advocating vs. silencing), gender roles (practicing self-care vs. sacrificing for others), and trauma (e.g. speaking their truth vs. silencing).

Conclusion: Qualitative insights from community stakeholders revealed that extending the reach of behavioral medicine research (such as STEP-AD) for black women living with HIV requires strong community partnerships, addressing violence/trauma, having validating settings, staff, and approaches, and knowing the impact of structural factors such as poverty and racism.

A PROSPECTIVE COHORT STUDY OF PEDIATRIC HIV DISCLOSURE AND RESILIENCE IN ZIMBABWE

Amy Finnegan, North Carolina¹, Eve Puffer, PhD², Eric Green, PhD²

¹Duke Global Health Institute, Durham, NC; ²Duke University, Durham, NC

We recruited a population representative sample of 372 children ages 9–15 on ART (antiretroviral therapy) or pre-ART at HIV clinics in two rural districts in Zimbabwe. During a baseline survey, caregivers were asked about what, if anything, their child knows about his or her HIV status. Caregivers reported on their worries about disclosing HIV to their child and how their child might react to the disclosure. Caregivers also completed the Patient Health Questionnaire-9, Strengths and Difficulties Questionnaire, and a measure of family relationship quality. We attempted to follow-up with the subset of 123 caregivers of non-disclosed children at baseline. In follow-up surveys, we also assessed medication adherence. We compared pre- and post-disclosure outcomes. 249 children (66.9%) knew their HIV status at baseline. Caregivers of the 123 non-disclosed children were contacted at 6 and 12 months. 55.3% of these children learned their HIV status within 1 year of the baseline survey. Caregivers overestimate their child's negative reaction to learning their HIV status. Using data on time since disclosure, we find that by 5-months post-disclosure, outcome levels are indistinguishable between disclosed and non-disclosed children. Children, caregivers, and families are more resilient following pediatric HIV disclosure than caregivers often suspect. Disclosure support interventions should consider addressing caregiver fears and worries to increase caregiver readiness and efficacy to disclose.

COMORBID HIV AND MENTAL HEALTH CONCERNS: THE ROLE OF BEHAVIORAL MEDICINE IN PATIENT OUTCOMES

Afiah Hasnie, M.A.¹, Florencia Pahl, Psy.D.², Pamela Gorman, R.N., ACRN³, Ronnie Mendoza, B.S. in Business Analytics/Information Technology⁴, Peggy Neumann⁵, Kelly Gilrain, PhD⁶, Cori McMahon, Psy.D.⁷

¹Cooper University Hospital & La Salle University, Camden, NJ; ²Cooper University Hospital Department of Infectious Disease, Camden, NJ; ³Cooper University Hospital EIP, Camden, NJ; ⁴Cooper Early Intervention Program, Cinnaminson, NJ; ⁵Cooper University Hospital /Early Intervention Program, Camden, NJ; ⁶Cooper University Hospital, Division of Hospital Medicine, Camden, NJ; ⁷Cooper University Hospital, Department of Infectious Disease, Woodbury, NJ

According to the CDC, more than 1.2 million people in the US are living with HIV (PLWH), 40% of PLWH are in medical care and only 30% of PLWH have achieved viral suppression. It has been established that by receiving HIV-specific care, PLWH greatly reduce the likelihood of transmitting the virus as well as increase their total life expectancy and quality of life. It is noted that HIV and anxiety disorders often co-occur, and psychosocial issues (e.g., depression, sleep, memory) frequently serve as barriers to treatment adherence and health service engagement, as well as impact immunological response and mortality. Due to these factors, increased attention has been placed on the importance of providing a multidisciplinary approach to treatment. The purpose of the current study was to determine the number of HIV patients presenting with comorbid mental health concerns as well as review the contribution of Behavioral Medicine services to improved outcomes in an urban outpatient HIV Early Intervention Program (EIP). The EIP has an annual patient census of over 900 patients and utilizes a multidisciplinary approach to medical care, providing screenings, case management, and annual mental health assessments (MHA). Importantly, the EIP predominantly serves minorities and patients of lower SES (i.e., 44% Hispanic/Latino, 37% African American, and 17% White; 76% at or below federal poverty level) and has attained an 89% viral load suppression rate amongst its patients. Since 2015, 675 subjects were evaluated by Behavioral Medicine clinicians with an MHA. Subjects ranged in age from 18–87 years (Mean = 48). Results revealed that 57% of patients endorsed symptoms of sleep and eating concerns, 43% depression, 40% anxiety, 40% trauma, 30% substance use, 23% memory difficulty, and 8% mania. Ninety-three patients completed a follow-up MHA. Of those who endorsed any initial MHA symptoms (n=85), 22% of patients reported decreases in anxiety, 13% reported decreases in sleep/appetite difficulties, and 8% reported decreases in manic symptoms during their follow-up annual assessment. However, individuals presenting with depression, trauma, substance use, and memory difficulties showed no difference or worsening in their annual scores. Results indicate the importance and need for integrated Behavioral Medicine to regularly provide evidenced-based approaches to treatment for behavioral health risk factors, to provide health-focused education, and to complete cognitive assessments and intervention for PLWH. Recommendations for improvement in assessment and service delivery for this population will be offered.

DSM-5 SLEEP DISORDERS AND EMOTIONAL SYMPTOMS IN A PUBLIC HEALTH CLINIC SAMPLE OF PEOPLE LIVING WITH HIV/AIDS

Brooke G. Rogers, MPH¹, Tiffany R. Glynn, MS¹, Jasper S. Lee, BS¹, Noelle Mendez, BA¹, William Wohlgenuth, Ph.D.², Steven Safren, Ph.D., A.B.P.P.¹

¹University of Miami, Coral Gables, FL; ²Bruce W. Carter VA Medical Center, Miami, FL

Introduction: Sleep problems are a well-known comorbidity of HIV/AIDS and can contribute to existing mental, emotional, and immune health vulnerability. However, less is known about the presence of clinical sleep disorders in this population.

Methods: A public health clinic sample of PLWHA from traditionally underserved communities, living in Miami, an urban city with high HIV prevalence and incidence (n=69; 75.4% Black, 11.6% Hispanic, 46.4% women, 21.6% sexual minority, mean age = 50.97, SD=9.09), were recruited for an observational behavioral sleep study. Participants answered questions about their background, mental and emotional functioning, and sleep. The Duke Structured Clinical Interview for DSM-5 Sleep Diagnoses was administered to assess clinical sleep disorders.

Results: Based on DSM-5 clinical diagnostic criteria, n=57 (82.6%) met for a current sleep disorder. The majority (72.5%) met criteria for insomnia disorder. Further, 34.8% were at elevated risk for sleep apnea, 21.7% had excessive daytime sleepiness, 13.0% met criteria for restless legs syndrome, and 2.9% were at elevated risk for narcolepsy. Of the total sample, 70% reported a significant mental health history (diagnosis and/or treatment). Approximately half of the sample reported current (within the past month) depression (52.2%) and/or anxiety (47.8%).

Discussion: Our results demonstrate high numbers of clinical sleep disorders and emotional symptoms in a public health clinic sample of people living with HIV/AIDS. Given the associations between sleep and mental health issues and the well-established link between mental health and HIV medication adherence in PLWHA, our findings warrant increased attention to sleep problems in PLWHA to improve health outcomes.

EXAMINING CHALLENGING PATIENTS WITH HIV IN ARGENTINA: COPA2

Deborah L. Jones, PhD, MEd¹, Lissa Mandell, BS¹, Suat Babayigit, MEd¹, Violeta J. Rodriguez, MEd², Stephen M. Weiss, PhD, MPH¹, Diego Cecchini, MD, PhD³, Omar Sued, MD⁴

¹University of Miami Miller School of Medicine, Miami, FL; ²University of Georgia, Athens, GA; ³Helios Salud, Buenos Aires, Buenos Aires, Argentina; ⁴Fundacion Huesped, Buenos Aires, Buenos Aires, Argentina

Objectives: Effective HIV treatment results in suppressed HIV viral load and improved health status. In Argentina, HIV treatment is offered to all persons at no cost. Challenging HIV-infected patients, those not retained in treatment, are an important focus of positive tertiary prevention. This preliminary study explored the relative contribution of self-efficacy, motivation, and patient-provider relationship satisfaction to engagement, treatment adherence and health status among those lost to care in Argentina.

Methods: Participants (N = 236) were identified from 6 clinics in urban centers in Argentina. Men, women and transgender adults not retained in care (no physician visit in 12 months or 3 missed pharmacy pick-ups in 6 months and having detectable viral load following 6 months of antiretroviral (ARV) prescription) were enrolled. Self-reported adherence to ARVs, adherence to pharmacy pickup, HIV viral load, and psychosocial information was assessed.

Results: Participants' mean age was 39.36 (SD=10.94) with an average income of US\$560 per month; half (53.0) were men; 56% were attending public clinics (n = 4 clinics). Participants had been diagnosed a mean of 12.44 years (SD = 7.15), had been prescribed ARVs a mean of 10.61 years (SD = 6.73), and had a mean log viral load of 4.49 (SD = 0.87). One third (36%) self-reported taking no medication in the last month, clinic data indicated only 7% filled 3 pharmacy prescriptions in the last 3 months. One third (33%) reported depression, 19% were using drugs and 38% were abusing alcohol. Using linear regression, patient-provider relationship satisfaction was associated with viral load ($b=-0.979$, $p=0.045$); clinic type (private vs public) was associated with viral load ($b=-0.182$, $p=0.208$, $p < 0.001$). Greater self-efficacy was associated with better self-reported adherence ($b= 0.449$, $p=0.002$). There was no relationship between depression, alcohol or drug abuse, and adherence or health status.

Conclusions: Preliminary results suggest that the patient-provider relationship may play an important role in health status. Continuing contact with patients lost to care may stimulate self-efficacy and adherence, and strategies from the private setting used to maintain patient contact should be explored for their applicability in the public health setting.

Study funded by NIH/NIMH, R01MH110242.

EXTENDING THE REACH OF BIOMEDICAL HIV PREVENTION TO GAY COUPLES: A QUALITATIVE STUDY OF MOTIVATIONS AND CONCERNS

Stephen C. Bosco, BS in Psychology¹, Trey Dellucci, MS², Mark Pawson, Masters³, Jeffrey T. Parsons, PhD⁴, Tyrel J. Starks, PhD⁵

¹The Graduate Center, City University of New York, Brooklyn, NY; ²Graduate Center, City University of New York, New York, NY; ³CHEST, New York, NY; ⁴Hunter College of the City University of New York (CUNY), New York, NY; ⁵Hunter College, CUNY, Brooklyn, NY

Background: HIV rates continue to disproportionately affect men who have sex with men (MSM). Recent work has shown that young MSM (18–29) are uniquely vulnerable to HIV infection, and that main partnerships account for more than half of new HIV infections. Research suggests higher rates of infection among main partnerships are linked to low perceptions of HIV-risk and lack of motivational prevention messaging. Despite the importance of HIV prevention for young MSM in relationships, few studies have examined motivations for and barriers to PrEP uptake among these partnered men.

Methods: Data were gathered from qualitative interviews conducted during the formative phase of the Couples Health Project, whose goal is to develop a brief MI-based intervention to reduce drug use and HIV risk in same-sex male couples. The sample included 10 couples where, at least one person was HIV-negative and between the ages of 18 and 29. Recordings were transcribed and coded for references to perceived barriers of PrEP and PEP (i.e. stigma, medical-related costs); perceived benefits of PrEP and PEP (i.e. health promoting, increase relationship functioning); and dyadic motivations to enhance communication around PrEP and PEP.

Results: A majority (90%) of couples ascribed to the notion that PrEP and PEP are viable sexual health promotion strategies. Despite their acceptability, 70% of couples stated that initiating a conversation regarding PrEP and PEP may evoke concerns around relationship functioning including potential trust issues and risk of infidelity. To combat potential negative relationship outcomes, 30% of couples identified the importance of being honest and supportive of each other. Additionally, 80% of couples indicated how PrEP-related stigma discourages individuals from accessing the medication. All couples stated that a supportive social network and expansion of PrEP and PEP-based knowledge would increase medication uptake among gay male couples.

Conclusions: Tailoring biomedical HIV-prevention public health campaigns that address the unique barriers identified by partnered gay men are essential. Such campaign messages must take a relationship-positive stance. Implying that PrEP/PEP are applicable when men cannot trust their partners may diminish uptake among partnered men. Instead, emphasizing anxiety reduction and related improvements in dyadic functioning, and framing biomedical prevention as “routine” health-care may reduce relational-barriers.

GENDER MODERATES AN INDIRECT PATHWAY FROM DEPRESSION TO FUTURE HIV VIRAL SUPPRESSION AMONG PLWH

Laramie R. Smith, Ph.D., Eileen V. Pitpitan, PhD

University of California San Diego, La Jolla, CA

Background: Reduced HIV incidence and improved individual health require lifelong antiretroviral therapy (ART) adherence ($\geq 95\%$) to maintain virologic suppression. Depression is a pervasive barrier to ART adherence among persons living with HIV (PLWH). PLWH who are depressed are less likely to be virally suppressed over time. While HIV-positive women are twice as likely to be depressed as HIV-positive men, less is known about whether gender differentially affects the process through which depression impacts viral suppression among PLWH. Moderated mediation allows for the analysis of both how and for whom an effect occurs.

Purpose: Moderated mediation analysis was used to test the hypotheses that depression (IV) affects future viral suppression (DV) through ART adherence (Mediator) and that the path between depression and ART adherence differs by gender (Moderator).

Method: We recruited adult PLWH accessing HIV care in the Bronx, NY (N=101) who completed baseline measures on gender (M=1, W=0), depressive symptoms (continuous; Range 0–10) and ART adherence (dichotomous; 1=

Results: The average number of depressive symptoms was 3.74 (SD=2.27). The sample was 52% men, 63% non-adherent to ART, and 46% had a detectable viral load at 12 months. Overall, there was a marginally significant direct effect with lower baseline depression predicting a detectable viral load (i.e., not being virally suppressed) at 12 months (OR =0.83, p=.07). Moderated mediation was found such that among men, higher baseline depression was associated with poor adherence (OR=1.45, p=.01), which in turn predicted having a detectable viral load at 12 months (indirect effect OR= 1.15, p=.045). The path from depression to adherence for women was non-significant (OR1.29, p=.10), resulting in no significant indirect effect (OR=1.03, p=.071).

Conclusion: The process by which depression impacts one's ability to achieve subsequent viral suppression differed by gender in this clinical sample. Future work might examine the contributions of lifetime trauma as a factor affecting both depression and poor ART adherence among women. Identifying the processes for how depression, adherence, and other variables might impact viral suppression for both HIV-positive women and men will be critical to developing gender-responsive interventions and reducing HIV incidence.

HIV AND STI TESTING CHARACTERISTICS AMONG MEN WHO HAVE SEX WITH MEN IN A SMALL METROPOLITAN REGION OF THE SOUTHEASTERN US

James A. Griffin, Ph.D., Elizabeth D. Eldridge, Ph.D., Megan M. Loew, M.S., Lara M. Stepleman, Ph.D.

Augusta University, Augusta, GA

Background. Men who have sex with men (MSM) in the South continue to be at high risk of acquiring HIV and other STIs, with rates in Georgia and South Carolina well above the national average for most STIs (CDC, 2015a) and HIV (CDC, 2015b). Routine testing for HIV and STIs is critical for early diagnosis, treatment, and transmission prevention. Known HIV and other STI testing characteristics among MSM living in the South are exceedingly limited and warrants examination.

Methods. The present survey study examined history of HIV, anal pap smear, and other STI testing in a sample of 165 mostly White (70%), gay-identified (84%), HIV-negative (84%) adult MSM ($M_{age} = 36.16$, $SD = 13.86$) of the Central Savannah River Area (CSRA) of the South. MSM were categorized into three groups for each type of test: tested in the year prior to the study, tested beyond one year, or never tested.

Results. Descriptive analyses showed approximately three out of five MSM had been tested for HIV in the past year (60.5%), while 11.3% were tested or unsure of HIV testing history, and 28.2% having last been tested over a year prior. Just over 2 in 5 MSM had been tested for other STIs in the year prior (43.2%), 27.2% had never been tested or were unsure, and 39.6% reported last testing over a year prior. Reported anal Pap smear testing revealed one in twenty (5.0%) received one in the prior year, while 91.3% of MSM had never received one, and 3.7% received one over a year prior. Chi-square analyses revealed racial minority MSM were more likely than White MSM to have been tested in the year prior (54.5% vs. 37.4%; $\chi^2 = 7.54$, $p < .05$). MSM under 30 were more likely than older MSM to have never been tested for HIV (20.9% vs. 4.4%; $\chi^2 = 20.55$, $p < .01$). Bisexually-identified MSM were more likely than gay-identified MSM to have never been tested for HIV (26.1% vs. 7.5%, $\chi^2 = 7.40$, $p < .05$). MSM living with HIV were more likely than HIV-negative MSM to have been tested for other STIs in the year prior (66.7% vs. 38.5%; $\chi^2 = 7.29$, $p < .05$) and were also more likely than HIV-negative MSM to have ever had an anal Pap smear (25.9% vs. 5.3%; $\chi^2 = 12.00$, $p < .01$).

Conclusion. Rates of routine HIV and other STI testing should be increased among MSM in the CSRA, particularly among vulnerable groups such as young and bisexual MSM. Greater interdisciplinary outreach and prevention efforts, and LGBTQ community visibility is needed in the CSRA and similar regions to reduce the rates of HIV and other STIs.

IS TRAUMA ASSOCIATED WITH INSOMNIA SYMPTOMS IN A PUBLIC HEALTH CLINIC SAMPLE OF PEOPLE LIVING WITH HIV/AIDS?

Brooke G. Rogers, MPH, Rosana Smith, BA, Kyle Hafkey, N/A, Jacqueline Rodriguez, N/A, Steven Safren, Ph.D., A.B.P.P.

University of Miami, Coral Gables, FL

Introduction: People living with HIV/AIDS (PLWHA) are more likely than the general population to have a lifetime history of trauma and insomnia. We hypothesized that in our HIV clinic sample, insomnia would be associated with number of lifetime traumas and current post-traumatic stress symptoms.

Methods: A public health clinic sample of PLWHA living in a high-prevalence and incidence urban area, Miami (n=69; 75.4% Black, 11.6% Hispanic, 46.4% women, 21.6% sexual minority, mean age = 50.97, $SD=9.09$), were recruited for an observational behavioral sleep study and were asked questions about their history of traumatic events (Brief Trauma Interview), interpersonal violence, and post-traumatic stress symptoms (PC-PTSD Screen); and, about their insomnia symptoms (Insomnia Severity Index, ISI).

Results: In our sample, 88.4% reported significant traumatic experiences, and, on average, participants reported 3.39 traumas over their lifetime ($SD=2.40$; Range = 0–10). A history of interpersonal violence, including physical or sexual abuse was endorsed by 69% of the sample; and, 21.7% of the sample screened in for clinically significant PTSD symptoms on the PC-PTSD screen. Lifetime history of trauma was not associated with current insomnia symptoms. However, current post-traumatic stress (Unstd. $B= 4.84$, $SE= 2.13$) was significantly associated with insomnia symptoms measured by the ISI ($p=.03$).

Discussion: In this sample of diverse PLWHA from traditionally underserved communities, current post-traumatic stress, but not history of a trauma or number of traumas, was associated with insomnia symptoms. One potential explanation for this finding is that the number of traumas in the sample was too high to observe variation. Alternatively, these findings may reflect resiliency to trauma in some participants who may have experienced multiple lifetime traumas, but do not have currently have PTSD symptoms. Future research should examine the co-occurrence of these conditions, implications for self-care and physical health, and the possibility of treating them through a joint intervention to improve psychosocial functioning and health in PLWHA.

MASCULINITY'S INFLUENCE ON HIV-RELATED HEALTH BEHAVIORS AMONG HIV POSITIVE BLACK MEN WHO HAVE SEX WITH MEN

Redd Driver, BA¹, Aerielle Allen, MA², Stephanie Finneran, MA¹, Seth Kalichman, PhD¹¹University of Connecticut, Storrs, CT; ²University of Connecticut, Cromwell, CT

Black Men who have sex with men (BMSM) experience the highest rates of HIV in the US. Improved treatment options for persons living with HIV are available through antiretroviral therapies (ART), resulting in nearly normal life expectancies. Yet, engagement in care and ART adherence remains poor among a significant number of BMSM. Identifying and understanding previously unconsidered psychosocial barriers to care and ART adherence are necessary to both improve clinical outcomes among HIV positive BMSM, and reduce incidence of HIV through the use of treatment as prevention (TasP). One potential barrier to HIV-related health engagement in BMSM may be internalized interpretations of masculinity. Although limited, research concerning masculinity's influence on health has demonstrated negative associations among both heterosexual men and MSM. The present study examined the relationship between masculinity and factors related the HIV-related care among HIV positive BMSM. A sample of BMSM ($N = 302$) were surveyed during the 2017 Atlanta Black Pride Festival of which 73 were HIV positive BMSM. Anonymous surveys assessed demographics, masculinity beliefs, alcohol and drug use, health care experiences, and a measure regarding Pre-exposure prophylaxis (PrEP) use among HIV negative partners. Results from independent samples t - tests demonstrated relationships between both the endorsement of masculine ideology and conformity to aspects of masculine gender norms with HIV-related health engagement. Regarding masculine ideology, a significant difference was found among HIV positive BMSM who reported knowing their current plasma viral load ($M = 2.23$, $SD = .95$) versus those who did not ($M = 2.98$, $SD = 1.04$), $p = .03$. With respect to conforming to masculine gender norms, risk-taking (Parent, Torrey & Michaels, 2012) produced significant differences among HIV positive BMSM who reported ART adherence ($M = 1.97$, $SD = .51$) versus those who reported non-adherence ($M = 2.28$, $SD = .11$), $p = .001$. Surprisingly, risk-taking was also related to a reported willingness to encourage PrEP use to an HIV negative partner ($M = 1.95$, $SD = .52$) versus those who reported a lack of willingness to encourage PrEP use ($M = 2.30$, $SD = .31$), $p = .04$. These findings indicate that masculinity influences HIV-related health behavior engagement in HIV positive BMSM. Understanding the role of masculinity as a psychosocial barrier to care engagement is needed in order to enhance linkage to and retentions in care, and treatment adherence interventions for BMSM.

MECHANISM OF CHANGE IN COGNITIVE BEHAVIORAL THERAPY FOR BODY IMAGE ON ART ADHERENCE AMONG SEXUAL MINORITY MEN LIVING WITH HIV

Kelsey A. Nogg, B.A.¹, Kalina M. Lamb, BA¹, Steven Safren, Ph.D., A.B.P.P.², Aaron Blashill, Ph.D.¹¹San Diego State University, San Diego, CA; ²University of Miami, Coral Gables, FL

Objective: Body image disturbance is a common problem reported among sexual minority men living with HIV, and is associated with poor antiretroviral therapy (ART) adherence. Recently, a novel integrated intervention (cognitive behavioral therapy for body image and self-care; CBT-BISC) was developed and pilot tested to simultaneously improve body image and ART adherence in this population. Although CBT-BISC has demonstrated preliminary efficacy in improving ART adherence, the mechanism of change are unknown.

Method: Participants wererecruited through fliers at Fenway Health, a community health center in Boston that serves the lesbian, gay, bisexual, and transgender community, community outreach, and advertisements placed on social apps targeting sexual minority men.

A total of 44 sexual minority men living with HIV who also reported elevated appearance concerns were recruited. In the two-armed randomized controlled trial, participants were randomized to the CBT-BISC or an enhanced treatment as usual condition (ETAU).

Comparing data from the CBT-BISC condition to the ETAU condition, sequential process mediation via latent difference scores was assessed, with changes in body image disturbance entered as the mechanism between treatment condition and changes in ART adherence.

Results: Overall, the data fit the model well: $\chi^2/df = 1.17$, CFI = 0.98, TLI = 0.96, and RMSEA = 0.06. Participants assigned to CBT-BISC reported greater reductions in body image disturbance from baseline to immediate follow-up, compared to those in ETAU ($b = -14.13$, $SE = 2.43$, $t = -5.79$, $p < .0001$). Reductions in body image disturbance between baseline and immediate follow-up significantly predicted changes in ART adherence between immediate follow-up and long-term follow-up ($b = -1.41$, $SE = 0.24$, $t = -2.35$, $p = .019$). Subsequently, the indirect effect from treatment condition to changes in ART adherence through changes in body image disturbance was significant ($b = 20.01$, $SE = 9.11$, $t = 2.19$, $p = .028$).

Conclusions: One pathway in which CBT-BISC positively impacts ART adherence is through reductions in body image disturbance. Body image disturbance represents one, of likely several, mechanism that prospectively predicts ART adherence among sexual minority men living with HIV.

METABOLIC RISK FACTORS AS DIFFERENTIAL PREDICTORS OF PROFILES OF COGNITIVE IMPAIRMENT AMONG OLDER HIV+ AND HIV- AGING ADULTS.

Elizabeth Pasipanodya, Ph.D.¹, Jessica L. Montoya, PhD¹, Alexandra Rooney, N/A², Ben Gouaux, B.A.¹, David J. Moore, Ph.D.¹¹University of California, San Diego, San Diego, CA; ²UCSD HIV Neurobehavioral Research Program, San Diego, CA

Background: Neurocognitive (NC) functioning among aging persons living with HIV (PLWH) exhibits significant heterogeneity, suggesting discrete subpopulations with differing risk factors for NC impairment (NCI). Metabolic factors have been associated with NC decline; however, their relationship to profiles of NCI and their differential effects by HIV serostatus have not been examined.

Methods: Participants (200 PLWH and 143 HIV-) between 35–79 years ($M=53.8$, $SD=8.7$ years) completed a neuropsychological battery assessing 7 NC domains (verbal fluency, executive functioning, speed of processing, learning, recall, working memory, and motor functioning). Following published procedures, NCI deficit scores were calculated and participants were classified with NCI vs. no NCI both globally and in the 7 domains. Latent class analysis (LCA) was used to identify subgroups of individuals with differing NCI profiles and validity of classification was examined against the Montreal Cognitive Assessment (MoCA) and a self-report of NC decline. Multinomial regression was used to identify demographic and metabolic risk factors differentially associated with classification of PLWH and HIV- participants.

Results: LCA identified 3 subgroups: 1) a normative class with low probabilities of NCI across all domains, 2) a class with high probabilities of NCI in learning and recall, and 3) a class with high probabilities of NCI in all domains (global NCI). Relative to those in the normative class, individuals in the learning and recall NCI class had lower scores on the MoCA ($X^2(1) = 27.532$, $p<0.001$) whereas those in the global NCI class had both lower scores on the MoCA ($X^2(1) = 22.841$, $p<0.001$) and greater self-reported cognitive decline ($X^2(1) = 8.195$, $p=0.004$). HIV+ status predicted global NCI classification ($OR=4.027$, $p=0.004$). The effects of age, diagnosis of hypertension, and hyperlipidemia on classification were moderated by HIV status. Specifically, older PLWH were more likely to be classified as NCI in learning and recall ($OR=1.009$, $p=0.048$) and globally NCI ($OR=1.027$, $p=0.001$). Furthermore, PLWH who had hypertension were more likely to be classified as NCI in learning and recall ($OR=4.442$, $p=0.013$), while PLWH and hyperlipidemia were more likely to be NCI in both the learning and recall class ($OR=3.518$, $p=0.034$) and globally NCI ($OR=6.110$, $p=0.032$), compared to being in the normative class. Controlling for HIV status, a diagnosis of diabetes marginally predicted global NCI classification ($p=0.071$); however, ethnicity and BMI ≥ 30 were unrelated to classification.

Conclusion: Profiles of cognitive functioning can be identified among aging adults and metabolic risk factors confer heightened risk of NCI in the context of HIV disease. Early intervention upon metabolic factors may have implications for improving the neurocognitive outcomes of PLWH.

POSITIVE LINKS: A MOBILE HEALTH INTERVENTION FOR RETENTION IN HIV CARE AND CLINICAL OUTCOMES WITH 12 MONTHS' FOLLOW-UP

Karen Ingersoll, Ph.D.¹, Rebecca Dillingham, M.D., M.P.H.²¹University of Virginia, CROZET, VA; ²University of Virginia, Charlottesville, VA

Background: The field of HIV care is challenged to achieve the 90/90/90 goals of 90% of people living with HIV learning their status through testing for HIV, 90% of those with HIV engaging and remaining in care, and 90% of those in care achieving viral suppression—achieving these goals could end HIV transmission in the U.S. by 2030. Mobile health interventions may help People Living with HIV (PLWH) improve retention in care, associated with improved clinical outcomes. We designed and piloted Positive Links, a clinic-deployed smartphone app for PLWH, and assessed longitudinal impact on retention in care and clinical outcomes including CD4 counts and Viral Loads.

Methods: The program was based at an academic Ryan White Clinic serving a non-urban population in Central Virginia. The Positive Links app features included: educational resources; daily queries of stress, mood and medication adherence; weekly quizzes; appointment reminders; and a virtual support group. Outcomes were analyzed using McNemar's tests for HRSA-1 measures, Bowker's tests for visit constancy, and nonparametric Wilcoxon signed ranks tests for CD4 counts and viral loads. Changes in outcomes at baseline, 6 and 12 months, were analyzed using generalized estimating equations (GEE) methods to account for correlations within subjects over time.

Results: Of 77 participants, 63% were male; 49% black non-Hispanic; and 72% below the federal poverty level. Participants demonstrated sustained usage of the app over 12 months. Participants' retention in care indicated by HRSA-1 increased from 48% at baseline to 91% at 6 months and 80% at 12 months ($p < 0.001$). Visit constancy increased from 26% of participants with the highest visit constancy at baseline to 40% at 6 months and 57% at 12 months ($p < 0.001$). Participants' mean CD4 counts increased from baseline to 6 months and 12 months ($p = 0.001$). Participants' mean viral loads decreased from baseline to 6 months (p

Conclusions: These data show that long-term benefits can be achieved by adding the Positive Links program to clinical care. This is the first study to show effects for both retention in care markers and clinical outcome markers by a clinic-deployed mobile health intervention for vulnerable patients. Next steps include dissemination and implementation research in other Ryan White clinics serving different demographics of PLWH.

PREDICTORS OF DISCORDANCE BETWEEN HIV-PATIENT AND INFECTIOUS DISEASE PROVIDER ASSESSMENTS OF ART MEDICATION ADHERENCE

Nicole Gause, M.A.¹, Anthony Hitch, B.A.¹, Jennifer L. Brown, PhD², Jessica Sales, PhD³, Eve Rose, MSPH⁴, Ralph DiClemente, PhD⁵

¹University of Cincinnati, Cincinnati, OH; ²University of Cincinnati College of Medicine, Cincinnati, OH; ³Rollins School of Public Health, Emory University, Atlanta, GA; ⁴Emory University Rollins School of Public Health, Atlanta, GA; ⁵Rollins School of Public Health, Atlanta, GA

Antiretroviral therapy (ART) non-adherence among HIV-infected individuals is a barrier to disease management that must be monitored by providers. Providers consider several factors (e.g., biomarkers, patient self-report) when estimating adherence; however, discordance between patient and provider assessments of adherence may adversely affect HIV treatment outcomes. The aims of the current study were to: determine the prevalence of discordance between patient- and provider-assessed ART adherence within an HIV primary care setting, and explore predictors of discordance. 250 HIV-infected Russian women (age 19–35, $M = 30$) provided estimates of ART adherence (i.e., percentage of ART medications taken in the previous month) using an audio computer-assisted self-interview (ACASI). Infectious disease doctors ($n=11$) also provided estimates of their patients' ART adherence during the previous month. Extracted medical chart data (e.g., most recent viral load) and a self-report measure of drug use (The Drug Abuse Screening Test; DAST) were examined as potential bivariate predictors of discordance. Overall, patient- and provider-assessed adherence were not related ($p = .09$) and discordance was found in 32% of cases. Providers estimated patients' adherence as being $\geq 95\%$ in 74% of cases where patients reported $< 95\%$ adherence ($n=69$). Having a higher total DAST score ($b = 0.15$, $p < .05$), and citing side effects as the reason for ART change ($OR = 2.05$, $p < .05$), were associated with patients' estimates of adherence being lower than their providers' estimates. Providers estimated adherence as being $< 95\%$ in 17% of cases where patients reported $\geq 95\%$ adherence. Having a greater number of ART regimen changes ($b = 0.37$, $p < .05$), any ART medication interruptions ($OR = 4.33$, $p < .001$), and past ($OR = 4.56$, $p < 0.001$) and current ($OR = 18.26$, $p < 0.001$) adherence concerns noted in patient's medical chart were associated with providers' estimates of adherence being lower than patients' reports. Factors that may be salient to providers who rate patients' adherence as lower focused on ART regimen changes or interruptions along with recorded adherence concerns. Patients who experience more symptoms of substance use, and those who have experienced medication side effects may rate their adherence as lower than their providers do. Providers may optimize adherence through early detection and addressment of adherence barriers by communicating with their patients about these factors.

PSYCHOSOCIAL AND SYMPTOM ASSESSMENT IN PERSONS TREATED OR MONITORED FOR ANAL HIGH-GRADE SQUAMOUS INTRAEPITHELIAL LESIONS

Jack Burkhalter, Ph.D.¹, Thomas M. Atkinson, Ph.D.¹, Yuelin Li, Ph.D.¹, Andrew Webb, BA¹, Madeline C. Rogers, BA¹, J. Michael. Berry-Lawhorn, MD², Rebecca Levine, MD³, Timothy J. Wilkin, MD, MPH⁴, Gary Bucher, MD, FAAFP⁵, David Cella, Ph.D.⁶, Jeannette Y. Lee, Ph.D.⁷, Jeff Taylor, N/A⁸, Joel Palefsky, MD²

¹Memorial Sloan Kettering Cancer Center, New York, NY; ²University of California - San Francisco, San Francisco, CA; ³Montefiore Medical Center, Bronx, NY; ⁴Weill Cornell Medicine, New York, NY; ⁵Anal Dysplasia Clinic MidWest, Chicago, IL; ⁶Northwestern Medicine, Chicago, IL; ⁷University of Arkansas for Medical Sciences, Little Rock, AR; ⁸AIDS Malignancy Consortium, San Francisco, CA

Background– Anal cancer incidence is increasing in the United States, especially among HIV-infected men and women, and is caused by infection with human papillomavirus (HPV). Screening for and treating or monitoring anal high-grade squamous intraepithelial lesions (HSIL) may compound the psychosocial burden of this population, including new treatment-related symptoms, or anxiety related to monitoring. We established collaboration with the ANCHOR (ANal Cancer HSIL Outcomes Research) trial (AIDS Malignancy Consortium; AMC-A02, -A03) to examine the impact of treating anal HSIL versus active monitoring (AM) on psychosocial outcomes and symptom burden.

Methods– English-speaking participants from 8 ANCHOR sites completed the ANCHOR Health-Related Symptom Index (A-HRSI), along with the Functional Assessment of Cancer Therapy – General (FACT-G) and M.D. Anderson Symptom Inventory (MDASI) within 2 weeks of treatment, or randomization for AM participants. A-HRSI item scores were compared between treatment and AM groups via independent samples *t*-tests. Pearson correlations were examined between A-HRSI items and similar items from FACT-G and MDASI.

Results– 110 participants (mean age = 50.6 years, 54% undergoing treatment, 80% gender male, 70% racial minority, 7% Hispanic) completed this phase of the study. Participants in the treatment group experienced significantly higher anal pain ($t(108)=2.83$, $pt(108)=3.71$, $pt(108)=2.02$, $pp's<0.05$) with corresponding FACT-G and MDASI items (e.g., pain, anxiety, depression, mobility impact).

Discussion– Initial findings indicate that participants in the treatment group are experiencing higher acute symptom burden than those who are being actively monitored without treatment. A total of 300 ANCHOR patients will be accrued to this study. Further, we will prospectively monitor clinically meaningful differences in psychosocial outcomes and symptom burden in this participant population toward enhancing our understanding of meeting their respective needs.

‘THIS ILLNESS AIN’T GONNA KILL ME’ - A QUALITATIVE INSIGHT TO HIV AND FRAMEWORK TOWARDS THE DEVELOPMENT OF AN HIV STRESS SCALE

Stephen Ramos, MA¹, Ty S. Schepis, PhD², Aimee K. Roundtree, PhD², Kelly Haskard-Zolnierok, Ph.D.², Steve Du Bois, Ph.D.¹¹Illinois Institute of Technology, Chicago, IL; ²Texas State University, San Marcos, TX

Research on HIV and stress is not uncommon in academic literature. However, little research has been done using a qualitative approach that aims to identify specific facets of stress experienced by people living with HIV (PLH). Furthermore, there is no developed, validated self-report measure of stress specific to living with HIV that can be used in either clinical settings or research settings. This study uses Grounded Theory qualitative methodology and semi-structured interviews to assess and conceptually develop stress in PLH. Participants (n=20) were 12 PLH and 8 individuals who work primarily with clients who are living with HIV. Participants engaged in semi-structured, audio recorded interviews that were transcribed for data analysis. Identified emergent themes included Housing Strains, Engagement in Substance Use, Limited Financial Abilities, Relationship Dynamics, Internal Pressures, and Psychosocial Resiliency. Results from this study suggest that unsatisfactory housing situations, such as location, lack of choice, and intrusive environment, can foster growth of stress. Engagement in substance use can be seen as both a previously utilized and familiar method of coping with stressors as well as a rational behavior that does not cognitively register as coping with stress. Limited financial means can create a constraint cycle in which the individual cannot fund basic necessities and is thus unable to be employed; this cycle can lead to a situation of strained financial resources. Because of this cycle, necessities are often placed on a hierarchy of demand and neglect. With regard to relationships, HIV both can build and sever bonds with others, depending on how disclosure is received. Lastly, data showed an overall positive regard towards life and towards the future as HIV+ individuals progress in life. These accounts can be utilized in creating a greater understanding of stress for PLH and in developing a more comprehensive and cohesive care for PLH who are experiencing stress. Furthermore, this study was one of the first to support, via qualitative data, identified domains of stress in PLH. Further research is needed to quantitatively validate these domains; however this study now provides the framework to do so.

TO BE OR NOT TO BE RELIGIOUS: THE ASSOCIATION BETWEEN RELIGIOSITY AND SEXUAL HEALTH AMONG BLACK BISEXUAL MEN

Aerielle Allen, MA¹, Ryan Watson, PhD², Lisa Eaton, PhD², Amanda Pollitt, PhD³¹University of Connecticut, Cromwell, CT; ²University of Connecticut, Storrs, CT; ³Department of Human Development and Family Sciences, University of Texas at Austin, Austin, TX

While Black churches are central tenants within the U.S., playing an important role in the establishment of norms and defining community values, they are also major sources of conflict for Black sexual minorities (Haile, Padilla, & Parker, 2011; Smith, Simmons, & Mayer, 2005). Churches with traditional teachings may stigmatize sexual minorities which can lead to higher levels of depressive symptoms, lower psychological well-being, and sexual health risks (Barnes & Meyers, 2012). However, some research examining sexual minorities and religion has emphasized the importance of spirituality and a positive relationship with God as being associated with greater well-being (e.g., lower internalized homophobia or biphobia and beneficial mental health outcomes; Barnes & Meyers, 2012). In order to examine the association between religiosity and sexual health among Black bisexual men, the current study surveyed and conducted STI testing with 225 Black bisexual men, (*Age* = 36, *SD* = 12). Respondents self-identified as bisexual and were sampled in Atlanta, GA. Overall, results demonstrated that higher levels of religiosity were significantly associated with lower odds of HIV and Chlamydia/Gonorrhea diagnosis. Specifically, Black bisexual men who reported higher levels of religiosity had a significantly lower likelihood of being diagnosed with HIV compared to those who reported lower levels of religiosity, *OR* = 0.18 [0.05–0.27], *p* < .01. Additionally, Black bisexual men who reported higher levels of religiosity had a significantly lower likelihood of being diagnosed with Chlamydia/Gonorrhea compared to those who reported lower levels of religiosity *OR* = 0.44 [0.24–0.79], *p* < .05. These findings have implications for intervention and prevention strategies. Given that religion is a contributor to the well-being of Black individuals, tactics that promote religion and a positive relationship with God may be employed to best support Black bisexual men. Additionally, these findings suggest that further investigation is needed regarding how individuals conceptualize and engage in religion. For some, religion may be associated with more traditional behaviors such as attending strict services, while others may regard religion more in terms of spirituality and a personal relationship with God. Both religiosity and spirituality may have related but different effects on the health of Black bisexual men.

YOGA INTERVENTIONS TO ENHANCE PSYCHOLOGICAL AND PHYSICAL HEALTH FOR PEOPLE LIVING WITH HIV: A SYSTEMATIC REVIEW

Eugene M. Dunne, PhD¹, Brittany L. Balletto, BS², Marissa L. Donahue, MA², Melissa Feulner, MPH², Julie DeCosta, M.S.³, Dean G. Cruess, Ph.D.⁴, Elena Salmoirago-Blotcher, MD, PhD⁵, Rena Wing, Ph.D.⁶, Michael Carey, PhD¹, Lori A. J. Scott-Sheldon, PhD²

¹Brown University, Providence, RI; ²Centers for Behavioral and Preventive Medicine, The Miriam Hospital, Providence, RI; ³The Miriam Hospital, Providence, RI; ⁴University of Connecticut, Storrs, CT; ⁵The Miriam Hospital, Alpert Medical School of Brown University, Providence, RI; ⁶Warren Alpert Medical School of Brown University, Providence, RI

Objective: The purpose of this systematic review is to examine the use of yoga to enhance psychological and biomedical health outcomes for people living with HIV (PLWH).

Methods: Studies were included if they (a) evaluated a yoga intervention in a sample of PLWH; (b) included RCTs with a control condition or a single group with pre- and post-test measures; (c) assessed a psychological or biomedical outcome; and (d) were available through July 2017. Comprehensive electronic database searches identified 208 unique studies with relevant key terms; of these, 8 studies met our inclusion criteria.

Results: The eight studies were published between 2004 and 2017; samples included a total of 328 participants (*M* age = 44 years; 37% women; *M* years living HIV = 12). The studies were conducted in the United States (3), India (3), Canada (1), and Mexico (1). Yoga components included breathing techniques, physical movement/postures, and meditation practice. Yoga styles included Sudarshan Kriya, Hatha, Iyengar, and Asthanga Vinyasa. Six of the eight studies included a control condition; controls received standard care (3) or assessment only (3). The most common outcomes measured were stress, depression, and quality of life. Compared to controls, PLWH who received the yoga intervention reported significant reductions in depression, stress/distress, as well as improvements in quality of life. No significant changes in biomarkers of stress (i.e., cortisol) or HIV (i.e., CD4+ cell counts) were observed between- or within-groups.

Conclusion: Yoga is widely practiced and purported to offer a range of health benefits. However, few empirical studies have examined the potential health benefits of yoga practice in PLWH. Additional RCTs are needed with adequate control groups and follow-up assessments to better understand the possible effect of yoga in PLWH.

DEPRESSION AND MEDICATION NONADHERENCE FOLLOWING LUNG TRANSPLANTATION

Michael C. Chu, BS, Patrick J. Smith, PhD, MPH, Gregory L. Stonerock, PhD, James A. Blumenthal, PhD, ABPP

Department of Psychiatry and Behavioral Sciences, Duke University Medical Center, Durham, NC

Background: Adherence to lifelong immunosuppressant medications (IS) is essential for positive clinical outcomes in post-transplant patients. Depression post-transplant has been linked to increased risk for morbidity and mortality in lung transplant patients, and has been associated with medical non-adherence in a variety of patient populations. However, the relationship between IS adherence and depression and on clinical outcomes remains unknown.

Methods: We conducted a retrospective study of an initial sample of 65 lung transplant recipients at Duke University Hospital transplanted in 2014 and followed for one year. To assess depression, patients completed the Center for Epidemiological Studies Depression inventory (CES-D) 2 months following their lung transplant. IS levels and time to hospitalizations within 1 year post-transplant as well as mortality data were extracted from medical records. Individual IS target ranges were obtained at 3, 6, and, 9 months post-transplant; values were considered as out of range if they were below or above the ± 3 point window for each target IS level.

Results: The average CES-D score was 8.8; 20% of patients obtained clinically significant values ≥ 16 . 33% of the IS levels were determined to be out of range. Higher CES-D scores were associated with greater incidence of out of range values ($r = 0.27$, $P = .044$). Both depression and out of range IS levels were associated with greater mortality (HR = 1.64, $P = .01$; HR = 1.75, $P = .016$ respectively). In a multivariate model, CES-D scores remained significant (HR = 1.66, $P = .008$) while adherence was attenuated (HR = 1.59, $P = .101$).

Conclusion: Both depression and IS nonadherence were predictive of greater adverse clinical events. While depression was associated with non-adherence to IS treatment, it appeared that both depression and IS non-adherence were predictive independently of worse clinical outcomes.

PATIENT ACTIVATION, PERCEIVED STRESS, AND MEDICATION ADHERENCE IN PATIENTS WITH UNCONTROLLED HYPERTENSION: THE ACT STUDY

Caroline F. Zimmermann, MS¹, Patti L. Ephraim, MPH², Rachel L. Grover, PhD³, L. Ebony Boulware, MD, MPH⁴¹HPCS, The Graduate Center, City University of New York (CUNY), Baldwin, NY; ²Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; ³Loyola University Maryland, Baltimore, MD; ⁴Duke University School of Medicine, Durham, NC

Objective: African Americans suffer from disparately high rates of poor blood pressure control (i.e., at least two measures of systolic blood pressure ≥ 140 mmHg or diastolic blood pressure ≥ 90 mmHg) as compared to non-African Americans in the United States. Research to date has identified low medication adherence as a barrier to achieving hypertensive control in this population. Further, higher perceived stress has been linked to a decrease in the likelihood of patient adherence to medication, whereas patient activation (i.e., degree to which a patient is engaged in the treatment and management of disease) promotes better medication adherence. The main objective of this study was to elucidate the relation between perceived stress and medication adherence, and to examine the possible role of patient activation as a mediator.

Methods: The current study utilized data from the Achieving Blood Pressure Control Together Study, a randomized controlled trial that administered and evaluated behavioral interventions to increase hypertension self-management in African Americans with uncontrolled blood pressure who were prescribed anti-hypertensive medication in a primary care setting ($N=149$). Patients completed validated measures of perceived stress, patient activation, and medication adherence, among other measures, at baseline during a telephone-administered questionnaire. Correlational analyses addressed relations among study variables. Regression and bootstrapping analyses were conducted to assess the proposed mediation model.

Results: Greater perceived stress and less patient activation were associated with worse medication adherence. Perceived stress [$B = -.10, p < .001$] and patient activation [$B = .03, p = .001$] were independent predictors of medication adherence in the expected direction, accounting for 19.7% of the variance. However, patient activation did not mediate the relation between perceived stress and medication adherence. Notably, controlling for perceived discrimination, depression, and age did not change results.

Conclusions: Hypotheses were partially supported by these findings. Reduced perceived stress and greater patient activation were predictive of higher adherence to anti-hypertensive medication. Interventions targeting both perceived stress and patient activation could improve medication adherence among urban African Americans and ultimately help these patients gain blood pressure control.

THE CREATION AND UTILIZATION OF CLINICAL VIGNETTES TO INDUCE OUTCOME EXPECTANCIES IN EMERGING ADULTS

Samantha Carreon, M.S.¹, Jessica Naftaly, M.S.², Amy Lang, B.S.³, Paulina Lim, B.A.³, W. Hobart Davies, Ph.D.³, Rachel Greenley, Ph.D.²¹Rosalind Franklin University of Medicine and Science, Chicago, IL; ²Rosalind Franklin University of Medicine and Science, North Chicago, IL; ³University of Wisconsin, Milwaukee, Milwaukee, WI

Introduction: Although patient-provider communication has been documented as an important influence on patient's intentions and behaviors, little is known about whether provider communication aimed at altering patient outcome expectancies may be beneficial in enhancing adherence and behavior. Vignette designs may be an ideal method for investigating how provider communication influences patients' outcome expectancies. This study examined whether study-created clinical vignettes influenced outcome expectancies in emerging adults.

Methods: 95 emerging adults (ages 18–25) provided demographic information, completed the Beliefs About Medication Scale (BAMS), and answered two study-created questions assessing whether the manipulations were successful in altering positive outcome expectancies (POE) or negative outcome expectancies (NOE) after being randomized to listen to one of three audio vignettes. Vignettes described a hypothetical encounter between a physician and participant in which the participant was seeking treatment for strep throat and was prescribed antibiotic medication. Vignettes varied in terms of the content of provider dialogue either stressing the benefits of the medication (POE), alleviating negative concerns regarding the medication (NOE), or providing standard care communication. Factual information about the prescription and essential communication points such as: the medication, purpose, duration of use, directions, and possible adverse effects were included in all vignettes.

Results: Participants randomized to the POE and NOE vignettes indicated that POE and NOE were induced significantly when compared to the standard care condition. However, for participants randomized to the POE vignette condition, there were no significant differences in BAMS' ratings of POE ($M=111.89, SD=16.62$) or NOE ($M=118.57, SD=14.66; t(55)=-1.53, p=.13$). There were also no significant differences in ratings of POE ($M=22.45, SD=9.18$) or NOE ($M=19.82, SD=7.99$) for those randomized to the NOE vignette condition ($t(58)=1.12, p=.27$).

Conclusions: Study-created vignettes enhanced POE and NOE when compared to standard care communication. Specifically, the NOE condition enhanced POE while reducing NOE. However, outcome expectancies, as measure by the BAMS, did not differ significantly for participants randomized to each vignette condition. Future research will examine whether provider communication emphasizing POE or NOE will result in higher intent to adhere than standard communication.

ACCULTURATION, MEDICATION ADHERENCE, AND COMPLEMENTARY AND ALTERNATIVE MEDICINE USE AMONG CAMBODIAN REFUGEES AND IMMIGRANTS

Elaina Jahanfard, N/A¹, Kelly Biegler, PhD², Susan E. Sim, PhD³, Elisa Nicholas, MD, MSPH⁴, Maria Chandler, M.D., MBA⁵, Quyen Ngo-Metzger, M.D.⁶, Kittya Paigne, M.D.⁷, Sompia Paigne, PhD⁸, Dara H. Sorkin, PhD²

¹University of California, Davis, Huntington Beach, CA; ²University of California, Irvine, Irvine, CA; ³University of Toronto, Toronto, ON, Canada; ⁴The Children's Clinic, Long Beach, CA; ⁵The Children's Clinic, Serving Children and Their Families, Long Beach, CA; ⁶University of California, Irvine, Irvine, CA; ⁷University of California, Irvine, Long Beach, CA; ⁸The Community Medical Wellness Center, Long Beach, CA

Purpose: Nearly 40 years after the brutal Khmer Rouge Regime (1975–1978), and mass immigration to the US, *Cambodian* American refugees still suffer from severe physical and mental health issues. As part of their cultural tradition, complementary and alternative medicine (CAM) has been widely documented as an important and regular source of health care. Previous research indicates that the use of ethnic CAM abates as people acculturate to the customs of mainstream society. The extent to which CAM use and western medication adherence changes as a function of time in the US remains unknown in this population.

Hypothesis: This study hypothesized that Cambodian refugees (immigrated before 1994) would use less CAM and adhere more to western medication than Cambodian immigrants (immigrated after 1994).

Method: Participants (N=338) were recruited from Cambodian patients being seen in a primary care setting. Depression and PTSD were assessed using the Hopkins Symptom Checklist and Harvard Trauma Questionnaire, respectively. CAM questions, drawn from the 2001 California Health Interview Survey-CAM, examined uses of CAM providers, techniques, and supplements. Relationships between immigration status, Western medication adherence, and CAM uses were evaluated using regression analyses, controlling for depression and PTSD.

Results: Refugees have lived in the US more than three times as long as immigrants (30.7 vs 8.2 years, $p<.00$) and PTSD (means=2.0 vs 2.3, $p=.00$) compared to refugees. Despite difference in time in US and mental health status, there were no statistically significant differences between the two groups in CAM use (e.g. CAM providers, common CAM techniques in the Cambodian culture, such as cupping, and supplements) or in Western medication adherence. Generally both immigrants and refugees reported that their CAM use was usually done in addition to taking their regular medications (means=1.5 vs 1.8, $p=.34$), and was rarely practiced instead of taking their regular medication (means=4.3, $p=.42$) on a 1–5 scale (1=always; 5=never).

Discussion: The findings from this research highlight that in a sample of Cambodian American patients, acculturation may have less of an influence on health practices than previously noted. Recognizing the long-held cultural practices of Cambodian Americans is an important step for providing high quality medical care.

CAREGIVER-RELATED CORRELATES OF MEDICATION NONADHERENCE AMONG PEDIATRIC LIVER TRANSPLANT RECIPIENTS

Claire Dunphy, MA¹, Arjeta Cosai, N/A², Dominique Calandrillo, N/A², Kirk Brouwer, N/A², Ronen Arnon, MD, MHA³, Rachel Annunziato, PhD²

¹Fordham University, New York, NY; ²Fordham University, Bronx, NY; ³Mount Sinai Medical Center, New York, NY

Introduction: Nonadherence to immunosuppressant medication poses a significant challenge in the care of pediatric liver transplant recipients. Prior research has focused on adolescent populations, but this problem appears to be common among younger pediatric patients as well. Since children under twelve generally rely on caregivers in the management of their medication regimen, caregiver-related factors may provide additional insight into nonadherence among members of this younger age group. This study examined possible caregiver-related factors associated with nonadherence among child-age pediatric liver transplant recipients.

Methods: Pediatric liver transplant recipients ages 0–12 and their primary caregivers (n=34) were recruited from one pediatric transplant center. Mean (SD) age at enrollment was 6.32 (3.32) years. Caregivers completed a series of questionnaires to assess socioeconomic status, health literacy, interpersonal support, psychological distress, illness perceptions, child knowledge of and responsibility for illness management, parenting practices, and barriers to adherence. Patient medical records were reviewed over a period of six months to calculate the Medication Level Variability Index (MLVI), a measure of the variability of immunosuppressant levels (tacrolimus) in the blood. A higher MLVI indicates greater nonadherence with levels above 2 being associated with poor outcomes. Correlational analyses were conducted to determine if there were associations between sociodemographic factors, questionnaire scores and adherence.

Results: Approximately 35% of patients were classified as nonadherent (MLVI >2.5) during the study period. Mean MLVI was 1.92 (1.66) for the sample. MLVI was negatively correlated with child knowledge of and responsibility for illness management ($r=-0.45$, $p=0.03$); children with a higher degree of management over their care displayed less variability in blood medication level. There were no other significant correlates of nonadherence.

Conclusions: Medication nonadherence was identified as a concern in this child-age transplant population. The correlation between adherence and child knowledge of and responsibility for illness management suggests that self-management skills may be important even in this younger age group. Additional research is needed to better understand these findings in the context of family-level variables. Importantly, in this diverse sample, socioeconomic status was not associated with nonadherence.

IMPLICATIONS OF TREATMENT EMPOWERMENT IN PREDICTING ADHERENCE IN MULTIPLE SCLEROSIS

Chloe Tuck, Masters in Biochemistry¹, Helen Lycett, BSc MSc¹, Eva Raebel, PhD, MSc, BSc², Jordi Guitart, PhD², Manjula Halai, MRPharm¹, Tom Kenny, BM, MSc PH(HSM), MFPH, MBA³

¹Spoonful of Sugar, London, England, United Kingdom; ²Spoonful of Sugar Limited, London, England, United Kingdom; ³Spoonful Of Sugar, London, England, United Kingdom

Despite advances in Multiple Sclerosis (MS) treatment options, their capacity to improve patient outcomes is hindered when patients choose not to take them. The causes of non-adherence are complex and multifactorial but can be approached as a trade-off between necessity beliefs and concerns. The Beliefs about Medicines Questionnaire (BMQ) assesses necessity and concerns directly and has shown to accurately predict adherence in long-term conditions. A patient's decision to adhere is also likely to be influenced by their level of understanding and sense of involvement in treatment decisions through interaction with their clinician.

The aim of this study was to assess the impact of treatment empowerment on necessity beliefs and concerns about medicines in MS patients to highlight ways to improve treatment outcomes in the future.

In an international quantitative survey of 1040 participants from 9 different countries (UK, USA, Canada, Australia, Germany, France, Spain, Italy and Sweden), treatment empowerment was assessed using the Treatment Empowerment Scale (TES) and necessity beliefs and concerns around medicines, as a predictor of adherence, using the BMQ.

Treatment empowerment displayed a significant positive correlation with necessity beliefs ($r=0.1562$, $p=0.0000$) and a negative correlation with concerns ($r=-0.1027$, $p=0.0009$). The correlation with necessity beliefs was more pronounced in patients who were on treatment (necessity beliefs: $r=0.2336$, $p=0.0000$; concerns: $r=-0.1050$, $p=0.0052$). However, there was no significant correlation between concerns and treatment empowerment in patients not being treated ($p>0.05$).

When considering only patients currently on treatment in countries within Europe, the correlation between treatment empowerment and both necessity beliefs and concerns increased ($r=0.2722$, $p=0.0000$ and $r=-0.1483$, $p=0.0014$, respectively).

These findings indicate treatment empowerment impacts necessity beliefs and concerns around medicines in MS patients, increasing the likelihood to adhere. They also highlight variation in the degree of impact that treatment empowerment may have on patients currently treated and untreated, as well as in country-specific contexts.

Thus, future health policy in MS should consider the importance of treatment empowerment. Further research in understanding the contextual changes will also be key to develop country specific policies that are tailored to reflect cultural aspects affecting treatment empowerment.

MEDICATION BELIEFS AND ADHERENCE AMONG YOUNG ADULT WOMEN

Lauren Strainge, M.A., Dean G. Cruess, Ph.D.

University of Connecticut, Storrs, CT

Transition to college is associated with declines in medication adherence, and greater independence enables college students to make health-related decisions that more directly reflect their personal beliefs. Negative beliefs about medications are a risk factor for poor adherence among middle-aged and older adults, but these relationships are poorly articulated among emerging adults, particularly among young women, who are significantly more likely to take daily prescription medications compared to their male peers. The purpose of this study was to examine the relationship between medications beliefs and daily adherence among a representative sample of female college students.

Undergraduate women ($n = 183$; mean age = 19.38; 28% non-white) who were prescribed daily medication completed the eight-item Morisky Medication Adherence Scale and the Beliefs about Medicines Questionnaire. About 94% of participants endorsed at least one problem with adherence. Participants generally reported low levels of concern about their own medications (mean = 9.06), low perceived necessity of their daily prescriptions (mean = 10.87), and positive attitudes towards the use (mean = 10.84) and safety (mean = 7.95) of medications. Pearson's correlation coefficients were calculated to determine the relationships between adherence and concerns with one's own medication, perceived necessity of one's own medications, beliefs about general medication overuse, and beliefs about the harmfulness of medications. We also conducted a series of hierarchical linear regressions predicting medication adherence from each belief variable. Adherence scores were positively associated with concerns about one's own medications ($r = 0.23$, $p = 0.004$), but not with other beliefs about medicines (all p values >0.05). Concerns about one's own medications significantly predicted adherence ($\beta = 0.19$, $p = 0.014$), and accounted for significantly more of the variance in adherence than that associated with demographics alone ($F(3, 169) = 5.005$, $p = 0.002$).

Women's concerns about the long-term effects of their current medications were a significant risk factor for poor adherence in our sample. However, other negative beliefs about medication were not significantly related to adherence. These findings suggest that targeted efforts by healthcare providers to address medication-specific concerns may have a positive effect on adherence among young adult women.

MHEALTH MEDICATION REGIMEN ADHERENCE PROGRAM FOR HYPERTENSIVE HISPANIC ADULTS

Jessica Chandler, Ph.D., Vanessa Diaz, MD, John Sieverdes, PhD, Candie Mendez, HS, Jenna Gunsolley, B.S, Luke Sox, B.S, Brenda Brunner-Jackson, MPH, Sachin Patel, MSc, Frank Treiber, Ph.D.

Medical University of South Carolina, Charleston, SC

Background: Uncontrolled hypertension (HTN) and medication nonadherence (MNA) are more prominent among Hispanics compared to non-Hispanic whites and African Americans. Advances in wireless health technology enable real-time monitoring of medication adherence (MA) and blood pressure (BP), facilitating timely patient provider communication including, reinforcement/motivational feedback to patients and quicker titration changes by providers. The purpose of the current study was to conduct a 6-month smartphone enabled efficacy trial addressing medication adherence (MA) and BP control among Hispanic adults.

Methods: The research design was a 6-month, two arm efficacy trial including an experimental (Smartphone Medication Adherence Stops Hypertension - SMASH) group and a standard care (SC) group. SMASH participants utilized an electronic medication tray, Bluetooth enabled, BP monitor and the SMASH app to monitor home-based adherence to their medical regimen. The SC participants received text messages including links to PDFs and brief video clips containing healthy lifestyle tips for attention control.

Results: Participants were 54 Hispanic adults (mean age: 46.5 yrs) with uncontrolled HTN. They were randomly assigned to either SMASH (n=26) or SC group (n= 28). At baseline, no participants had controlled systolic BP (SBP). Baseline group averages for SBP did not differ (150.7 and 152.3 mmHg, $p = .53$) between the SC and SMASH groups, respectively. At the 1, 3, and 6-month time points, SBP averages were significantly lower in the SMASH versus SC groups, respectively (Month 1: 124.7 vs 141.3; Month 3: 118.8 vs 136.6, Month 6: 121.2 vs 145.7 mmHg; all p -values $< .01$). At months 3 and 6, there was a significant difference between the % of participants meeting JNC8 cutoffs for SBP control (Month 3: 37.5 vs 84.0%; Month 6: 26.3 and 72.2%, both p 's $< .01$) for SC and SMASH groups, respectively. Average medical regimen adherence, as indicated by timestamped medication intake and BP monitoring for the SMASH group was 88.5% across the 6-month trial.

Conclusion: Our findings indicate that our smartphone enabled medical regimen self-management program may be an effective solution for the promotion of MA resulting in statistically and clinically significant reductions in SBP among Hispanic adults with uncontrolled HTN.

POSITIVE AFFECT AND MEDICATION ADHERENCE IN CHRONIC CONDITIONS: A SYSTEMATIC REVIEW

Sarah M. Bassett, MA¹, Stephanie Schuette, BA², Linda C. O'Dwyer, MA, MSLIS¹

¹Northwestern University, Chicago, IL; ²Duke University, Durham, NC

Suboptimal medication adherence (MA) causes increased morbidity and mortality, and inflates the cost of healthcare in the United States by \$100 billion annually. Those suffering from chronic conditions are at increased risk of non-adherence as compared to those with acute medical conditions. Although there is ample evidence demonstrating that negative affect is associated with poor health outcomes, and there is some evidence that positive affect (PA) improves health outcomes, to date, no systematic review examining the relationship between PA and MA in those living with chronic conditions has been published. The objective of this systematic review was to characterize the relationship between PA and MA in adults with chronic medical conditions.

Searches were carried out in PsycINFO, PubMed, CENTRAL and EMBASE. There were no limits on study type, publication date, or language. Studies of participants living with chronic medical conditions and reporting a relationship between PA and MA were eligible for inclusion if PA was measured prior to or concurrently with MA, regardless of participant demographics.

Eight studies met inclusion criteria. All studies were prospective cohort or cross-sectional in nature, and examined PA and MA in people living with HIV or cardiovascular conditions. All but one study outcome, which was null, indicated a positive relationship between PA and MA in these two conditions (e.g. Pregnant HIV-positive participants who felt happy all/most of the time were more likely to report perfect MA postpartum, OR = 1.69; 95% CI = 1.14 – 2.51, $d = 0.42$, and antepartum, OR = 1.78, 95% CI = 1.24 – 2.54, $d = 0.46$) (Bardeguet et al., 2008). While the literature on the relationship between PA and MA in chronic conditions is nascent, results of this systematic review suggest a positive relationship between PA and MA in HIV and cardiovascular conditions with varying effect sizes, $d = 0.03 - d = 1.27$. As studies controlling for NA revealed small but positive results for this relationship (e.g. HIV-positive participants with PA one SD above mean at baseline were more likely to report medication persistence over 18-month follow-up, OR = 1.08, 95% CI = 1.01 – 1.16, $d = 0.04$) (Carrico & Moskowitz, 2014), the current review provides some indication that PA positively impacts MA in an independent manner.

In order to elucidate this relationship, research must examine whether the positive association seen in the current review remains directionally similar in bivariate analyses, and over chronic conditions for which there is not currently data. Should future work examine these factors, and should the relationship between PA and MA remain similar after more comprehensive assessment, healthcare providers have an opportunity to implement potentially low-cost, effective interventions to increase MA.

RELATIONSHIP BETWEEN SATISFACTION WITH INFORMATION ABOUT MEDICINES SCALE (SIMS) AND MEDICATION ADHERENCE: A NARRATIVE REVIEW

Eva Raebel, PhD, MSc, BSc¹, Amanda R. V. Butler, N/A², Amy HY. Chan, PhD³, Emilie Wildman, BSc¹, Helen Lycett, BSc MSc⁴, Tom Kenny, BM, MSc PH(HSM), MFPH, MBA²

¹Spoonful of Sugar Limited, London, England, United Kingdom; ²Spoonful Of Sugar, London, England, United Kingdom; ³University College London, London, England, United Kingdom; ⁴Spoonful of Sugar, London, England, United Kingdom

Patient satisfaction with different aspects of care can determine medication adherence but it is not known whether this relationship extends to the satisfaction with information received about medicines. This study aimed to explore the relationship between patients' satisfaction with information about medicines, as assessed by the Satisfaction with Information about Medicines Scale (SIMS), and medication adherence. SIMS is a validated scale measuring the extent to which patients feel they have received sufficient information about their medicines.

Searches using pre-determined terms, including SIMS and adherence, were performed on PubMed, EMBASE and Google Scholar. Results were screened to identify studies investigating the relationship between SIMS and medication adherence.

From 493 citations, 30 studies met the inclusion criteria. Ninety-three percent of included studies were conducted in adults and two in children. Most studies took place in the UK (40%). Participant ages ranged from 2 to 92 years. Sample sizes ranged from 43 to 523 participants, with studies lasting between 10 days to 4 years. The most common disease areas were neurological conditions (20%) and cancer (13%), though 20% of studies included more than one chronic disease. Self-reported adherence was used in 93% of studies.

Just over half (53%) of the studies showed a significant relationship between SIMS and adherence. In contrast, 47% of studies found SIMS had no effect on adherence. All significant studies reported the same direction of effect – higher SIMS scores were related to higher adherence – though the strength of the relationship varied greatly between studies. Significant studies varied in age, country, sample sizes, study duration and disease area – no single factor appeared to be associated with whether SIMS had a significant relationship, or not, with adherence.

This narrative review suggests that satisfaction with medicines information, as measured by SIMS, is not consistently associated with medication adherence. The use of self-report measures in almost all studies may have affected the reliability and validity of results. Whilst SIMS may be useful to explain adherence in certain populations, satisfaction alone does not seem to be a reliable predictor of adherence in all cases. Other factors may have a greater role in influencing adherence. For future adherence interventions to be successful, factors beyond satisfaction should be explored.

SELF-EFFICACY PREDICTS MEDICATION ADHERENCE ACROSS 18-MONTHS IN ADOLESCENTS WITH CHRONIC KIDNEY DISEASE

Cyd Eaton, PhD¹, Michelle Eakin, PhD¹, Shayna Coburn, PhD², Cozumel Pruette, MD¹, Tammy Brady, MD¹, Barbara Fivush, MD¹, Susan Mendley, MD³, Shamir Tuchman, MD², Kristin Riekert, PhD¹

¹Johns Hopkins School of Medicine, Baltimore, MD; ²Children's National Medical Center, Washington, DC; ³University of Maryland School of Medicine, Baltimore, MD

Objective: Adolescents with chronic kidney disease (CKD) often exhibit poor adherence to antihypertensive medications. Adherence is vital to slowing disease progression (i.e., need for dialysis or transplant). Findings from other illnesses suggest that modifiable factors, including barriers to adherence and self-efficacy, are associated with adherence. This study examines how barriers and self-efficacy are associated with adherence to antihypertensive medication over time in adolescents with CKD.

Methods: Participants included 93 adolescents with CKD (56% male, 44% Caucasian, 14% CKD stage 4–5, M age=15.02 years, SD =2.57, range 11–20 years). Adolescents reported on barriers to adherence (Adolescent Medication Barriers Scale) and self-efficacy for taking medications across different situations (e.g., when the adolescent is tired or in a negative mood; Medication Self-Efficacy Scale) at baseline. Adherence was assessed 4 times every 6 months for a 2 week period using MEMS cap. Linear mixed models were used to examine changes in adherence over time and longitudinal relations with barriers and self-efficacy, controlling for gender, race, and estimated glomerular filtration rate (eGFR; calculated with the Bedside Schwartz equation).

Results: Adherence was stable over time (baseline M =77.37%, SD =23.66). Male gender (B =10.75, SE =4.39, p =.02) and self-efficacy (B =3.21, SE =1.21, p =.009) were significantly associated with adherence across time. Race, eGFR, and barriers to adherence were not significantly associated with adherence. There was a random effect for participant (B =283.89, SE =58.51, p <.001) with 47.31% variability in adherence accounted for by between person variability.

Conclusions: Given that adherence was stable within person over time, poor adherence will likely continue without intervention. Male gender and higher self-efficacy were associated with higher adherence. There was no association between adherence and eGFR, race, or barriers to adherence. Adolescents' levels of self-efficacy for taking medications in potentially challenging situations appear to have greater influences on adherence longitudinally than actual barriers to adherence. Future research should evaluate interventions that target self-efficacy for taking medications in various situations with the goal of facilitating improved adherence in adolescents with CKD.

6:15 PM-7:15 PM

THE USE OF THE TREATMENT-EMPOWERMENT SCALE (TES)TM TO MEASURE THE IMPACT OF EMPOWERMENT ON ADHERENCE: A REVIEWEva Raebel, PhD, MSc, BSc¹, Helen Lycett, BSc MSc², Tom Kenny, BM, MSc PH(HSM), MFPH, MBA³¹Spoonful of Sugar Limited, London, England, United Kingdom; ²Spoonful of Sugar, London, England, United Kingdom; ³Spoonful Of Sugar, London, England, United Kingdom

Adherence guidelines recommend involving patients in treatment decisions but empowerment is not routinely measured in interventions. The Treatment-empowerment scale (TES)TM is a validated measure of patients' perceptions of empowerment and their degree of involvement with treatment. The higher the TES score, the greater perception of empowerment.

This study aimed to review studies using the TES to assess the impact of treatment empowerment on medication adherence.

Studies citing Webb et al.¹ were identified in PubMed and Google Scholar and screened for the inclusion of TES. Those including TES as a determinant of adherence were selected for review. Study characteristics and the impact of TES on adherence were extracted.

From 44 citations identified, four studies met the inclusion criteria: 3 cross-sectional studies (UK) and 1 pilot randomized controlled trial, RCT (Canada). Disease areas included HIV (n=3; sample size =132) and epilepsy (n=1; sample size=1127). Mean age ranged between 39–42.

Two studies found low adherence related to perceptions of a lack of involvement in treatment decisions and patients with high TES scores reported: epilepsy - fewer practical barriers and concerns about side-effects, stronger necessity beliefs about medication and positive attitude towards treatment; HIV - lower levels of intentional non-adherence, less likely to believe clinicians were overprescribing medication. One study found a moderate relationship between empowerment and adherence after 4 days, but not in the long-term. The RCT used TES as a measure of satisfaction with healthcare professionals, which did not explain adherence.

This review indicates that control over treatment has an impact on adherence and most studies suggest TES is a reliable predictor tool. A caveat to our findings is the small sample size, which limits the generalisability of our results but highlights the need for research on this subject to verify the properties of TES in real-life settings and in other disease areas. Measuring patients' perceptions of their degree of empowerment has scope for predicting adherence levels and potentially being able to tailor interventions within the patient group depending on their TES score.

THE UTILITY OF THE EXTENDED COMMON-SENSE MODEL (ECSM) TO EXPLAIN ANTIRETROVIRAL THERAPY (ART) INITIATION

Dora PHILLIPS, MSc¹, Helen Lycett, BSc MSc², Tom Kenny, BM, MSc PH(HSM), MFPH, MBA³, Vanessa Cooper, PhD⁴, Rob Horne, PhD Health Psychology⁵¹University College London, LONDON, England, United Kingdom; ²Spoonful of Sugar, London, England, United Kingdom; ³Spoonful Of Sugar, London, England, United Kingdom; ⁴University College London, London, England, United Kingdom; ⁵UCL School of Pharmacy, Sussex, England, United Kingdom

Antiretroviral therapy (ART) is an effective treatment for preventing the development of AIDS and reducing mortality; however, its success depends on patients initiating treatment and evidence suggests not all people living with HIV start prescribed ART. The common-sense model of self-regulation (CSM) is a dynamic framework which aims to explain the processes by which beliefs about illness impact health-related behaviour. The extended CSM (eCSM) proposes that the inclusion of general and specific beliefs about treatment increases the ability of the CSM to explain treatment-related behaviours. According to the eCSM, ART-initiation is likely to be influenced by patients' beliefs about treatment and their illness perceptions.

This study aimed to establish the utility of the eCSM to explain ART-initiation by conducting a retrospective data analysis from a prospective, longitudinal, follow-up study of HIV-positive patients attending a HIV clinic in the UK.

HIV-positive patients completed validated questionnaires measuring illness perceptions and beliefs about treatment at the time ART was recommended (baseline). ART-initiation was measured using pharmacy data. Illness perceptions and beliefs about treatment were compared between patients who started or declined ART. Patients who declined ART at baseline were followed up after 1, 6 and 12 months. Beliefs about ART were compared between baseline and ART-initiation for those who later initiated ART and between baseline and 12-month follow-up for those who continued to decline.

Of 136 patients recommended ART, 38 (27.9%) declined ART at baseline. Baseline associations between illness perceptions, pharmaceutical schema and beliefs about ART were consistent with the eCSM. Hierarchical logistic regression indicated illness perceptions, pharmaceutical schema and beliefs about ART explained 31.0% of variance in ART-initiation. Beliefs about ART and pharmaceutical schema explained 20.4% of variance in ART-initiation over and above clinical variables and illness perceptions. Subsequent ART-initiation among those who initially declined was associated with an increase in ART-necessity beliefs and a decrease in ART-concerns.

This study provides support for the utility of the eCSM in explaining ART-initiation. Findings suggest interventions may increase ART-initiation by eliciting and addressing illness perceptions and beliefs about ART.

TREATMENT BELIEFS, ADHERENCE AND OUTCOMES IN PATIENTS WITH ASTHMA: THE IMPORTANCE OF BELIEFS IN UNDERSTANDING ICS NONADHERENCE

Caroline B. Katzer, MSc¹, Amy HY. Chan, PhD¹, James Pike, B.Sc. Hons., M. Phil.², Mark Small, BSc honours², Rob Horne, PhD Health Psychology³¹University College London, London, England, United Kingdom; ²Adelphi Real World, Bollington, England, United Kingdom; ³UCL School of Pharmacy, Sussex, England, United Kingdom

Background: Non-adherence to inhaled corticosteroids (ICS) is a key modifiable factor contributing to asthma morbidity and mortality. Previous studies show that ICS nonadherence is related to patients' beliefs, particularly their perceptions of personal need for daily treatment and concerns about taking ICS. This study maps ICS necessity beliefs and concerns across six countries examining variations in beliefs and whether beliefs relate to adherence and asthma outcomes.

Methods: Patients ≥ 12 years, diagnosed with asthma, and receiving ICS alone or in combination with a long-acting β_2 -agonist, were included from a cross-sectional survey of asthma patients in Europe and the US. Clinical characteristics, such as adherence, asthma control, and healthcare utilization, were collected by self- and physician-report. Patients completed the Beliefs about Medicines Questionnaire, adapted for ICS. This is a validated measure consisting of items about treatment necessity beliefs, and concerns, measured on a 5-point Likert Scale, with higher scores indicating higher necessity and higher concerns.

Results: Data from 1337 patients (from 484 physicians) were analyzed. Patients were from Germany (25%), US (21%), France (20%), Spain (16%), Italy (10%) and UK (9%). Most patients had physician-reported mild-intermittent asthma (87%) and mean (SD) age was 40 (15.5) years. There was considerable variation in necessity beliefs ($M = 3.4$, $SD = 0.8$) and concerns ($M = 2.6$, $SD = 0.7$), with 31% of patients reporting low necessity beliefs and 27% reporting high concerns. Patients with doubts about ICS necessity and high concerns had significantly lower self-reported (necessity, $\chi^2(2) = 34.31$, $p < 0.001$; concerns $\chi^2(2) = 20.98$, $p < 0.001$) and physician-reported adherence (necessity, $\chi^2(2) = 11.70$, $p = 0.003$; concerns $\chi^2(2) = 34.45$, $p < 0.001$).

Patients with high necessity beliefs ($F(2, 483) = 3.33$, $p = 0.037$) and high concerns ($F(2, 483) = 23.46$, $p < 0.001$) reported poorer control. A higher number of physician-reported exacerbations in the last 12 months was significantly associated with higher necessity ($F(2, 481) = 4.18$, $p = 0.016$) but not concerns ($F(2, 481) = 2.66$, $p = 0.071$). Physicians reported poorer asthma control in patients with high concerns ($\chi^2(2) = 21.44$, $p < 0.001$), but there was no significant relationship with necessity ($\chi^2(2) = 0.99$, $p = 0.611$). There was no association between beliefs and healthcare utilization. Physician estimates of adherence did not correlate well with patient self-report ($\rho = 0.178$, $p < 0.001$).

Conclusion: ICS necessity beliefs and concerns were associated with self- and physician-reported adherence, asthma control and exacerbations. This has implications for intervention design to optimize ICS adherence. Longitudinal studies using objective adherence and asthma control measures are needed to further explore these relationships.

WHEN MEDICATION ADHERENCE BECOMES A "WAITING GAME"

Amanda A. Lee, MPH¹, Jean Hunleth, PhD, MPH², Sarah Humble, MS³, Miquela Ibrao, MSW/MPH⁴, Aimee S. James, PhD MPH⁵¹Washington University in St. Louis, St. Louis, MO; ²Washington University School of Medicine, Saint Louis, MO; ³Washington University in St. Louis School of Medicine, Saint Louis, MO; ⁴Washington University in St. Louis, Belleville, IL; ⁵Washington University in St. Louis, St. Louis, MO

Timely adherence to medications, screenings, and other health services is vital to improving health outcomes. However, complex barriers to adherence (e.g. unemployment, medication availability, insurance) can lead patients to wait to access healthcare. Patients make a variety of trade-offs during waiting periods; some may prioritize basic needs such as food over medication copays, while others may need to forego bill payments in order to continue getting their medications. Experiences of waiting and decisions made during waiting periods are rarely captured in regard to how they affect medication adherence. We analyzed data from a mixed-methods cost-related nonadherence study to examine the experience of waiting for healthcare by people who have difficulty affording medication. Starting in October 2016, people with one or more chronic illness for which they have been prescribed a medication were recruited for a survey ($n=205$) from newspaper ads and federally-qualified health centers. A sub-sample of participants ($n=41$) also participated in an in-depth narrative interview. Field notes and interview transcripts were searched for the word "wait" and for stories related to waiting. 86% of survey participants currently had health coverage and 40% reported having a gap in coverage in the past 12 months. 45% of participants delayed or skipped appointments at least sometimes and 46% reported delaying filling/refilling a prescription because of cost at least sometimes in the past 12 months. Three waiting-related themes emerged from the interviews. 1) People often have to wait to obtain access care, such as waiting to be approved for disability or waiting to turn 65 for Medicare. 2) People make trade-offs while waiting for access, such as delaying treatments or prioritizing some medications, leaving some people anticipating an uncertain future or with feelings of frustration. 3) In the aftermath of waiting, people often expressed relief, but also repercussions from their wait. Our findings suggest that waiting for care was a common experience, distinct from delaying care. Delayed care is often attributed to patient volition, but for many people, waiting is structural and unavoidable. Understanding how people experience and respond to waiting offers researchers, policymakers, and practitioners insight into the challenges of medication adherence. Future research might investigate methods for minimizing and reducing the impacts of wait in the healthcare system.

BASELINE DAYS WALKING RELATES TO PARENTS' 12-MONTH BIO-VERIFIED CESSATION IN A CHILDREN'S TOBACCO EXPOSURE REDUCTION TRIAL

Bradley Collins, PhD¹, Uma Nair, PhD², Samantha Davis, MPH¹, Stephen J. Lepore, Ph.D.¹¹Temple University, Philadelphia, PA; ²University of Arizona, Tucson, AZ

Promoting physical activity (PA) in smoking treatment may facilitate smoking behavior change. However, underserved smokers in low-income communities have increased challenges adopting rigorous exercise routines, thus limiting their success in PA+smoking interventions. We conducted secondary analysis of data from a trial designed to help parents protect their children from tobacco smoke, exploring whether routine walking related to long-term smoking outcomes. Trial participants were randomized to 12 weeks of experimental smoking counseling or nutrition education (control) - *neither group* received counseling designed to boost daily walking or exercise. Participants completed the International Physical Activity Questionnaire (IPAQ) at baseline (BL) and 12-month follow-up (12M). A day in which participants reported >15 minutes of walking for the purpose of exercise was considered a walking day. We hypothesized that more days of walking per week and more total time per week of walking would relate to improved 12M smoking outcomes independent of experimental condition.

The study sample (n=254 parents) included 84% females, 84% African Americans and 79% living below the poverty line. Average age = 33.2 (8.5) years old. Participants were relatively inactive at BL, with few walking days/week (M=3.12, SD=3.06); and mean walking days decreased to 12M (M=1.76, SD=2.54 days/week). However, analysis with complete case data showed that BL walking days related positively to 12M bioverified quit status (p=.03) and negatively to 12M cigarettes smoked/day (p=.002). For example, smokers who reported walking 5–7 days/week at BL had higher 12M quit rates than those walking less than 5 days/week (14.6% vs. 6.7%; p=.05). Partial correlation between 12M walking and 12M cigs/day also demonstrated a negative association (p=.015) when controlling for BL walking, treatment condition and other variables associated with smoking outcomes (e.g., nicotine dependence).

Conclusion: Results suggest that greater frequency of daily walking (a low-to-moderate intensity exercise), may be an important baseline characteristic related to long-term quit status among treatment seeking smokers in low-income racial minority communities. Because walking may be a more acceptable and adoptable exercise than higher intensity PA among underserved smokers, future studies targeting this population could examine the utility and potential efficacy of promoting daily walking goals in the context of smoking cessation treatment.

BLACK WOMEN'S KNOWLEDGE OF MATERNAL BREASTFEEDING BENEFITS FOR CANCER PREVENTION: IMPLICATIONS FOR RESEARCH & PRACTICE

Tyra Gross, PhD, MPH

Xavier University of Louisiana, New Orleans, LA

Background: Breastfeeding has numerous health benefits for both infants and their mothers. Maternal health benefits include postpartum weight loss and decreased likelihood of chronic diseases, namely breast cancer and Type 2 diabetes. Despite improved breastfeeding trends in the U.S., disparities remain, with African-American (Black) women less likely to breastfeed. Compared to their White peers, African-American women of reproductive-age are more likely to be overweight or obese, have Type 2 Diabetes and hypertension, and also more likely to develop triple negative breast cancer. Efforts to increase breastfeeding rates in this population can help improve cancer disparities. Yet, few studies have explored knowledge of cancer prevention in African-American breastfeeding women.

Study Question: How do African-American women with breastfeeding history describe the maternal benefits of breastfeeding for cancer prevention?

Methods: This study employed a secondary data analysis from two studies on breastfeeding in African-American women. For the first study, three focus groups were conducted with 23 Special Supplemental Nutrition Program for Women, Infants, and Children (WIC) breastfeeding peer counselors (12 African-American). The second study consisted of individual interviews conducted with 11 African-American mothers who: were WIC participants, had breastfed 1 child for at

Results: Participants (n=21) were ages 23–46 years, 67% were married and 43% had a college degree. Personal average duration of breastfeeding was 12.6 months, which is higher than national trends. Themes include 1) “*lessens your chance*”-cancer prevention; 2) “*get my shape back*”- postpartum weight loss; 3) “*keep your health up*”-diet & lifestyle changes (ie. exercise, alcohol use, smoking).

Conclusions: Findings indicate that African-American women participating in WIC are aware of the maternal benefits of breastfeeding, namely weight reduction and breast cancer prevention. However, there may be gaps in knowledge about the importance of breastfeeding duration for these benefits. Participants viewed breastfeeding as an opportunity to create or continue healthy behavioral change from pregnancy. Future research should consider using the postpartum and breastfeeding period as an opportunity for multiple behavior change for maternal health promotion and cancer prevention. Given the cancer disparities facing African-American women, healthcare providers should counsel women on the maternal benefits of breastfeeding and the importance of longer breastfeeding durations.

DEVELOPMENT OF A BRIEF, CULTURALLY-ANCHORED ALCOHOL-REDUCTION AND FAMILY-ENGAGEMENT INTERVENTION FOR FATHERS IN KENYA

Ali Giusto, MA¹, David Ayuku, PhD², Eve Puffer, PhD¹¹Duke University, Durham, NC; ²Moi University, Eldoret, N/A, Kenya

Background: Problem drinking disproportionately affects men with disabling consequences and a cascade of negative effects on families. These problems are often worsened in low and middle-income countries and in areas where patriarchal norms place men in positions of power.

In this study, we developed a family-focused intervention for problem drinking fathers in Kenya anchored in behavioral activation (BA) and motivational interviewing (MI) to reduce alcohol-use and increase male caregiver family involvement.

Methods: Intervention development followed a mixed-method, multi-step process: 1) qualitative data analysis of family functioning and drinking in Kenya; 2) systematic literature review of dual-target alcohol use and family interventions; 3) identification of optimal evidence-based strategies; 4) collaborative development with in-country team; 5) analysis of feasibility indicators from ongoing family therapy intervention trial in Kenya.

Results: We identified three core approaches: BA, MI, and gender transformative strategies (GTS) that we used as the foundation for a 5-session intervention designed to be delivered by community-based lay providers. The functional mechanisms of these approaches remained the same but were modified for context-specific challenges and intervention goals. The intervention begins with MI to encourage engagement and readiness to change. This is followed by BA sessions targeting positive reinforcement to reduce drinking behaviors; MI techniques are integrated throughout to maintain motivation and build efficacy. A family-focus is emphasized throughout; family-related values elicited in MI as reasons for change (e.g., don't want child to drink), and clarified in BA (e.g., be a good father), drive motivation building and activity scheduling (e.g., help child with homework). This was tailored to account for context-specific family dynamics that place importance on role fulfillment (e.g., provider). Gender transformative approaches are integrated to expand traditional conceptualizations of masculinity to include care/nurturance. This is designed to increase motivation for completing family activities and reducing drinking.

Conclusions: Evidence-based MI and BA strategies are amenable to leveraging culturally-anchored values and goals to target both alcohol use and family involvement, as well as to being streamlined for implementation by lay providers.

EFFECTS OF A 12-WEEK EXERCISE AND LIFESTYLE INTERVENTION ON BEHAVIOURAL & PSYCHOSOCIAL OUTCOMES FOR ADULTS WITH CELIAC DISEASE

A. Justine Dowd, PhD¹, Liam Kronlund, MSc(c)², Cassandra Warbeck, BSc¹, Kathryn Wytmsa-Fisher, MKIN¹, Candice Parmar, BSc¹, Guillaume Millet, PhD¹, Raylene Reimer, PhD¹, Nicole Culos-Reed, PhD³¹University of Calgary, Calgary, AB, Canada; ²University of Calgary Faculty of Kinesiology, Calgary, AB, Canada; ³Faculty of Kinesiology, University of Calgary, Calgary, AB, Canada

Background: Celiac disease is a chronic autoimmune condition that requires strict adherence to a gluten-free diet (GFD) to prevent detrimental consequences (e.g., intestinal cancers, osteoporosis¹). Following a strict GFD alone is often not sufficient to effectively manage the disease,² and can be associated with detrimental outcomes including reduced quality of life (QoL)³. Given the established psychosocial benefits of regular engagement in exercise among chronic disease populations⁴, inactive adults with celiac disease may particularly benefit from an exercise and lifestyle targeted program.

Purpose: The purpose of this pilot study was to explore the effects of a 12-week supervised progressive high intensity interval training (HIIT) and lifestyle intervention on behavioural and psychosocial outcomes among inactive adults with celiac disease.

Methods: Thirty-three inactive adults diagnosed with celiac disease ($M_{age} = 45.5$, 88% female) were randomized to intervention (HIIT; $n = 16$) or waitlist control (WLC; $n = 17$). Participants in the intervention engaged in a 12-week HIIT + lifestyle education program. HIIT was comprised of 2 workouts per week, working up to 14, 30-second intervals at 90% heart rate max followed by 2 minutes recovery at 50% heart rate max. The lifestyle component included education on the promotion of a whole foods GFD, sleep hygiene, and psychosocial coping skills (e.g., self-compassion). Assessments occurred at pre and post 12-week intervention and 3-month follow-up. WLC participants were offered a 12-week HIIT program after completing the final assessment.

Results: From pre-post intervention, participants in the intervention (HIIT + lifestyle, $M_{attendance} = 72\%$; range 58–83%) reported significant improvements in adherence to a GFD ($M_{change} = -2.25$; $t(7) = -2.35$, $p = .05$, $d = 1.03$), whereas no significant change in adherence to a GFD was reported among those in WLC ($M_{change} = -0.65$; $t(9) = -0.58$, $p = .58$). Furthermore, pre-post intervention a medium effect size improvement in self-compassion was reported for those in the intervention ($M_{change} = 0.27$; $t(7) = 1.27$, $p = .24$, $d = 0.64$) versus significant worsening of self-compassion in WLC ($M_{change} = -0.25$; $t(9) = 2.34$, $p = .04$, $d = 0.75$). Finally, QoL was maintained in the intervention group ($M_{change} = 0.02$; $t(7) = 0.06$, $p = .95$) whereas WLC reported significant worsening of QoL ($M_{change} = -0.56$; $t(9) = -2.22$, $p = .05$, $d = 0.68$) from pre-post intervention.

Conclusion: Participation in the HIIT and lifestyle intervention was associated with improvements in adherence to a GFD and self-compassion and maintenance of QoL.

Support/Funding: This study is supported by a Seed Grant provided by the Faculty of Kinesiology at the University of Calgary awarded to Drs. Culos-Reed, Reimer, Millet and Dowd

EFFECTS OF A LIFESTYLE INTERVENTION ON EXERCISE & DIETARY BEHAVIOR IN PROSTATE CANCER PATIENTS ON ANDROGEN DEPRIVATION THERAPY

Brian C. Focht, PhD¹, Alexander R. Lucas, PhD², Elizabeth Grainger, PhD¹, Christina Simpson, BS¹, Ciaran Fairman, MS¹, Jennifer Thomas-Ahner, PhD¹, Zach Chaplow, BS¹, Tori DeScenza, BS¹, Steven Clinton, MD, PhD¹

¹The Ohio State University, Columbus, OH; ²Wake Forest University, Winston-Salem, NC

Emerging evidence suggests lifestyle exercise and dietary interventions (EX+D) can attenuate, or even reverse, primary adverse effects of androgen deprivation therapy (ADT) among prostate cancer (PCa) patients. However, challenges in successfully maintaining EX+D behavior change can undermine the efficacy of lifestyle interventions in the supportive care of PCa. The purpose of the single-blind, randomized controlled Individualized Diet and Exercise Adherence-Pilot (IDEA-P) trial was to evaluate the preliminary efficacy of a lifestyle EX+D intervention, implementing a group-mediated cognitive behavioral (GMCB) approach targeting the development and practice of behavioral self-regulatory skills necessary for independent maintenance of EX+D behavior, relative to standard of care (SC) treatment among PCa patients undergoing ADT. In the current study, we evaluated the effects of the EX+D and SC interventions upon select EX+D behavior outcomes. A total of 32 PCa patients (*M* age = 65 years) on ADT were randomly assigned to EX+D (*n* = 16) or SC (*n* = 16) interventions. Measures of objectively-determined and self-reported physical activity and self-reported dietary intake were obtained at baseline and 2 and 3 month follow-up assessments. Results of intention to treat 2 (Treatment) x 2 (Time) ANCOVA analysis of residualized change scores revealed significant Treatment effects for select physical activity ($p < 0.01$) and dietary intake measures ($p < 0.05$). Post hoc analysis demonstrated the EX+D resulted in increased resistance exercise participation ($d = 1.56$), total volume of physical activity ($d = .65$), and fruit and vegetable intake ($d = 1.04$) as well as decreased consumption of refined grains ($d = .49$) and sugar-sweetened beverages ($d = .44$) relative to SC. Findings from the IDEA-P trial suggest that the GMCB EX+D intervention resulted in more favorable changes in select physical activity and dietary behavior outcomes that were independently maintained at 3 month follow-up. These results underscore the utility of promoting change in EX+D behavior in the supportive care of PCa patients undergoing ADT.

EXTENDING OUR REACH IN AFRICAN AMERICAN CHURCHES: PERCEPTIONS OF DYADIC PEER SUPPORT TO PROMOTE HEALTHY WEIGHT

Cherie Conley, RN, BSN, MHS

Duke University School of Nursing, Raleigh, NC

Background: African Americans suffer from a disproportionate burden of obesity and obesity-related chronic disease. African American churches are popular places to implement obesity prevention programs. Although programs in churches have achieved positive outcomes, gains are often small and sustainability is lacking. Multiple studies have shown the benefit of dyadic support (i.e., two people working together), in achieving weight loss. However, interventions in African American churches have not used dyadic support specifically to optimize their efforts to combat obesity.

Objectives: The aim of this preliminary study was to explore church members' and county health educators' perceptions of using dyadic support to promote healthy weight in African American churches to inform the development of a dyad support intervention to augment an existing obesity prevention intervention.

Research Design: Recruited were ten congregant members from five congregations in North Carolina and four of the nine state health education coordinators who implement obesity prevention programs. This descriptive study used semi-structured qualitative interviews (i.e., What do you think about pairing up church member as part of a wellness program?). Interviews were analyzed using conventional qualitative content analysis to identify keywords and themes across cases.

Results: Five common themes emerged from the interviews: pairing up members is natural and can help achieve health goals; members want to help and be helped by other members; attitude and motivation are the most important considerations for pairing up members; dyad activities should be structured; and dyad activities should include goal setting, meeting for exercise and checking in at least twice per week.

Conclusion: Because of strong ties and relationships, the church is fertile ground for a dyad support intervention; interviewees emphasized lack of personal motivation over structural determinants as barriers to better health and felt a partner might help overcome this challenge. Members will work well with any other member of the church "family", but ensuring similar levels of motivation may be important to assess and use as a way to pair up partners. In terms of a dyadic support intervention, before engaging in any activities, dyad partners should be assisted in setting goals and thinking of strategies to attain them; and be encouraged to communicate and interact with one another consistently and frequently. The eagerness of African American church members to engage with a partner to achieve healthy weight supports implementing a dyadic support intervention in African American churches; adding this component may ultimately improve effectiveness and sustainability of obesity prevention programs.

FACTORS ASSOCIATED WITH CLUSTERING OF HEALTH-RELATED BEHAVIORS AMONGST EMERGING ADULTS IN TAIWAN

Shu-Fang Shih, Ph.D.¹, Yu-Tso Yeh, MEd.²¹National Taiwan Normal University, Taipei, Taipei, Taiwan (Republic of China); ²National Taiwan University Hospital, Taipei, Taipei, Taiwan (Republic of China)**Objectives:** To investigate factors associated with the types of health-related behavior cluster amongst emerging adults aged 18–25 in Taiwan.**Methods:** This study used the 2009 National Health Interview Survey data, and the research subjects were emerging adults aged between 18–25 years old. A multinomial logistic regression was adopted for analyzing the association between the sociodemographic variables and the types of health-related behavior cluster, including “smoking and drinking,” “unbalanced diets,” and “health-conscious.”**Results:** Compared with the health-conscious cluster, the smoking- and drinking clusters mostly comprised of men who were married, non-students, residents of low-income regions, and those who earned a high income; by contrast, the unbalanced diet cluster mostly comprised of women who were in their late teens, residing in more affluent areas, and whose incomes ranged up to NTS20,000.**Conclusions:** Emerging adulthood is a critical turning point from adolescence to adulthood, and the health problems of these emerging adults have now become an important issue. By analyzing the factors associated with the types of health-related behavior cluster rather than with the single unhealthy behaviors, the significant factors have now provided us with the relevant evidence for designing a tailored-made health promotion program. The health promotion practitioners should be encouraged to adopt a more holistic approach to understand the underlying factors associated with the overall picture of the lifestyle of one person, rather than using a simplified approach which targets only one single unhealthy behavior, so that the effectiveness of the health promotion program could be enhanced.

FEASIBILITY AND EFFICACY OF A LIFESTYLE INTERVENTION FOR RURAL-LIVING, LATE-MIDLIFE HISPANICS WITHIN A PRIMARY CARE CONTEXT.

Stacey L. Schepens Niemiec, California¹, Jeanine Blanchard, PhD, OTR/L², Cheryl Vigen, PhD², Jenny Martínez, OTD, OTR/L, BCG², Laura Guzmán, California³, Alyssa Concha, OTD, OTR/L⁴, Michelle Fluke, MBA⁵, Hector Balcazar, MS, PhD⁶, Mike Carlson, PhD¹¹University of Southern California Chan Division of Occupational Science and Occupational Therapy, Los Angeles, CA; ²University of Southern California, Los Angeles, CA; ³University of Southern California Chan Division of Occupational Science and Occupational Therapy, La Quinta, CA; ⁴USC Chan Division of Occupational Science and Occupational Therapy, Phoenix, AZ; ⁵Antelope Valley Partners for Health, Lancaster, CA; ⁶Charles R. Drew University of Medicine and Science, Los Angeles, CADespite the comparative mortality advantage that Hispanics have over non-Hispanic whites, the prevalence of chronic health problems and early-onset disability is substantially higher in this minority group. Exacerbating these inequities, Hispanics living in rural communities are vulnerable to the consequences of limited access to healthcare services. The purpose of this study was to evaluate the feasibility of *¡Vivir Mi Vida!* (VMV), a culturally tailored lifestyle intervention co-led by community health workers (CHWs) and occupational therapists (OTs) and designed for late-midlife Hispanic patients receiving primary care services.Forty Hispanic, Spanish-speaking 50- to 64-years-old participants were recruited from a primary care clinic in the Antelope Valley of California. Pilot tested as a 4-month program, VMV was adapted for rural-based implementation and included in-home visitations with a CHW and telehealth OT consultations. The program targeted a wide array of health challenges by focusing on personally meaningful social, physical, and productive activity. Information collected from patients' electronic medical records was used to help guide treatment. Subjective health, cardiometabolic measures, and health behaviors were collected pre- and post-intervention; pre-post change scores were analyzed using paired sample *t*-tests or Wilcoxon signed rank tests. Participants and key stakeholders (e.g., interveners, clinic leadership) also participated in follow-up interviews and focus groups.Adherence averaged 77% for individual, group, and telephone check-in sessions. Of those who completed post-testing (n=37; 93%), most were female (91%), born in Mexico (65%), US residents for 20+ years (78%), not employed (76%), and non-smokers (100%). Sixty-eight percent had ≥2 comorbidities. Participants demonstrated significant pre-post improvements in impact of symptoms on daily activity ($p=.008$), systolic blood pressure ($p=.006$), sodium ($p=.0001$) and saturated fat ($pp=.02$) and social role satisfaction ($p=.001$). Physical activity engagement and weight did not change ($p>.05$). Although participants were extremely satisfied with the program, stakeholders identified a number of implementation challenges.

The findings suggest that a tailored lifestyle intervention led by CHWs and OTs is feasible and can improve health outcomes in rural-dwelling, late-midlife Hispanics, despite implementation challenges faced.

IS KNOWLEDGE REGARDING THE DANGERS OF CONTRACTING BRUCellosIS ASSOCIATED WITH RISKY BEHAVIOR AMONG ARAB ISRAELIS?

Shiran Bord, MPH, PhD¹, Samira Obeid, RN, MPH, PhD², Michal Cohen-Dar, MD³, Orna Baron-Epel, PhD MPH⁴¹University of Haifa and The Max Stern Yezreel Valley College, Haifa, N/A, Israel; ²The Max Stern Yezreel Valley College, Maker village, Hefa, Israel; ³Ministry of Health, Nazereth, HaZafon, Israel; ⁴University of Haifa, Haifa, N/A, Israel**Background:** Outbreaks of brucellosis occurred in the last few years in specific communities among Arab Israelis. This disease is caused mainly by consumption of dairy products made of non-pasteurized milk from infected animals and is common in these communities.**Objectives:** To learn from where do Arab Israelis attain their information regarding brucellosis and is this information associated with consumption of non-pasteurized milk and cheese and reported outbreaks.**Methods:** A telephone survey of 306 respondents from five Arab towns in the northern part of Israel, three towns with and two without reported outbreaks of brucellosis. The questionnaire included questions regarding knowledge, source of knowledge, patterns of purchase and consumption of non-pasteurized dairy products.**Results:** In towns that had outbreaks of brucellosis over 90% of the respondents heard of brucellosis compared to only 56% in the towns without outbreaks. The level of knowledge of the respondents was high, over 60% answered correctly 4–5 questions out of five. In all towns around 30% of respondents reported hearing about the disease from the media. In the towns with outbreaks over 60% of respondents reported hearing about the disease from their social networks, whereas in the other towns only 23% heard about it from social networks. However, knowledge was not associated with consumption of dairy products made of non-pasteurized milk.**Conclusions:** Levels of knowledge did not prevent risky consumption of dairy products. Most of the information received by the residents from the various sources seem not to have had an effect on behavior.

MULTIPLE HEALTH BEHAVIORS ENGAGEMENT AMONG AFRICAN AMERICANS: CLUSTERING PATTERNS AND CORRELATES

Dalnim Cho, PhD¹, Nga Nguyen, MS¹, David W. Wetter, Ph.D.², Lorna McNeill, PhD, MPH¹¹UT Texas MD Anderson Cancer Center, Houston, TX; ²University of Utah/Huntsman Cancer Institute, Salt Lake City, UTEngaging in multiple health behaviors (MHBs) simultaneously has health and economic advantages over engaging in single health behaviors (Levi et al., 2008; Loprinzi, 2015). However, MHBs research including racial/ethnic minorities is noticeably absent (Noble et al., 2015). We examined class clustering patterns (class membership) of four behaviors—physical activity (PA), fruit & vegetable (FV) intake, smoking, and alcohol use—in a church-based African American (AA) cohort. Guided by socio-ecological models (McLeroy, 1988), we also examined what psychosocial (e.g. stress, cancer risk perception, social support, social norms) and neighborhood factors (e.g. social cohesion, neighborhood problems) are associated with the class membership (after controlling for demographics). A total of 1,467 AA adults in a large church in the Houston metropolitan area were analyzed. Latent Class Analysis showed that a 3-class model (sBIC=10137.93) is preferable to 2-Class (sBIC=10142.74) and 4-class models (sBIC=10155.05). Class 1 is characterized as not being physically active, not eating FV, and not smoking and drinking alcohol. Class 2 is characterized as being physically active, not eating FV, having smoking history and drinking mildly. Class 3 is the healthiest group, characterized as being physically active, eating many FV, and not smoking and drinking alcohol. The probability of being included in Class 1, 2, and 3 was .33, .48, and .19, respectively. Multinomial regression analysis showed that compared to participants in Class 3, those in Class 1 reported lower PA norm (i.e. reported fewer number of significant others engage in PA; $b=-.64$, 95% CI=-.96, -.31) and higher smoking norm (i.e. reported more number of significant others smoke; $b=.50$, 95% CI=.19, .81), and lower neighborhood social cohesion ($b=-.06$, 95% CI=-.11, -.00). Compared to participants in Class 3, those in Class 2 reported higher cancer risk perception ($b=.26$, 95% CI=.12, .41), lower FV norm (i.e. reported fewer number of significant others eat FV; $b=-.29$, 95% CI=-.54, -.04), lower PA norm ($b=-.57$, 95% CI=-.87, -.28), and higher smoking norm ($b=.57$, 95% CI=.29, .85). The utilization of socio-ecological models in MHBs research is supported. As participants in the healthiest group commonly reported higher positive social norms for health behaviors compared to those in the two unhealthier groups, MHBs interventions in this population should enhance social norms. Given the synergistic impacts of MHBs on health (Loprinzi, 2015), MHBs research greatly needs to focus on AAs to reduce the known health disparities (NCHS, 2016; Siegel et al., 2016).

ASSOCIATION OF PSYCHOSOCIAL AND INFORMATION PROCESSING VARIABLES WITH WEIGHT LOSS IN A 6-MONTH BEHAVIORAL HEALTH INTERVENTION

Anthony Crimarco, MS¹, Gabrielle Turner-McGrievy, PhD MS RD¹, Sara Wilcox, PhD¹, Alycia Boutte, MPH¹, Eric Muth, PhD², Adam Hoover, PhD³

¹University of South Carolina, Columbia, SC; ²Clemson, Clemson, SC; ³Clemson University, Clemson, SC

Objective: To assess psychosocial and information processing predictors of weight loss in a 6-month, mobile health (mHealth) weight loss intervention comparing two different mobile dietary self-monitoring devices.

Methods: The DIET Mobile study was a remotely-delivered 6-month randomized weight loss trial. Participants (n=81, mean BMI=34.7 ± 5.6 kg/m²) were randomized to self-monitor their diet with either a mobile app or wearable Bite Counter device. Participants received twice weekly podcasts based on Social Cognitive Theory from the Diabetes Prevention Program.

Measurements were assessed at baseline and 6 months and included weight (digital scale) and 5 psychosocial and information processing variables (self-report questionnaires). Psychosocial measures included *self-efficacy* (assessed with the Weight Efficacy Lifestyle Questionnaire, a 20-item scale with 5 situational factors: Negative Emotions, Social Pressure, Availability, Physical Discomfort, and Positive Activities). Information processing variables included *elaboration*, which focuses on persuasion and attitude change (assessed with the Elaboration Likelihood Model Questionnaire), *user control*, which focuses on the amount of control participants felt during the study (assessed with a 3-item Likert scale), *cognitive load*, which focuses on the mental burden participants felt during the study (assessed with a 2-item Likert scale), and *novelty*, which is how new, innovative, and unusual participants found the intervention (assessed with a 2-item Likert scale). These information processing variables were used in our previous research and were significant mediators of weight loss.

Both groups from the intervention were combined and only complete cases were analyzed, resulting in (n=52) participants included in analyses. A General Linear Model that included all psychosocial/information processing variables was conducted to see which variables best predicted % weight loss at 6 months.

Results: Participants lost a mean of -5.4 ± 6.1% body weight. Positive activities related to self-efficacy (F=5.4, P=0.03) and elaboration (F=8.3, P

Conclusions: This study highlights aspects of both self-efficacy (positive activities) and information processing (elaboration) that are important to target in future mHealth weight loss interventions.

CHILD'S CORTISOL LEVEL MEDIATES RELATIONSHIP BETWEEN MOTHER'S STRESSFUL LIFE EVENTS AND CHILD'S WAIST TO HEIGHT RATIO

Christine H. Naya, BS MPH¹, Chih-Hsiang Yang, PhD², Genevieve F. Dunton, PhD, MPH³

¹University of Southern California, Pasadena, CA; ²University of Southern California, STATE COLLEGE, PA; ³University of Southern California, Los Angeles, CA

BACKGROUND: Childhood obesity in the United States continues to be a major public health concern. One such factor associated with children's obesity risk is their mothers' psychosocial stress. Past literature have proposed a possible pathway of parental stress affecting child's stress, which in turn increases the child's risk of obesity. However, limited findings on this topic are mixed, most likely due to the lack of longitudinal data and the shortcomings of subjective measures of stress. This study utilized a mediation model to examine the relationship between mothers' stressful life events (SLE), children's cortisol level, and children's waist to height ratio in a longitudinal study.

METHODS: The sample consisted of 116 mothers and their children who were enrolled in the Mothers and their Children Health (MATCH) Study between 2015 and 2017. At baseline, mothers reported their SLE that had occurred during the past 6 months. At the 6 month time point, children collected saliva samples over four days, which were used to calculate the average diurnal cortisol slope (DCS). Then at the 12 month time point, children had their height and waist circumference recorded by trained staff in the lab. Analysis investigated whether the association between mother's SLE and child's waist to height ratio (WHtR) is mediated by child's DCS, controlling for mother's education, child's age, sex, and pubertal development.

RESULTS: Results indicated that child's DCS mediated the longitudinal relationship between mother's SLE and child's WHtR. Mother's SLE was modestly associated with child's WHtR ($\beta = 0.15, p = 0.08$) and positively associated with DCS ($\beta = 0.29, p < 0.01$). Child's DCS was also positively associated with WHtR ($\beta = 0.20, p < 0.05$). Once adjusted for the mediator (child's DCS), mother's SLE was no longer significantly associated with child's WHtR ($\beta = 0.10, p = 0.27$). This mediation effect was supported by the bootstrapping confidence intervals derived from 5000 samples.

CONCLUSION: These findings illustrate the potential role of child's cortisol level in mediating the longitudinal effect of mother's life events on children's adiposity. Future studies should consider how parental stress can affect a child's biological stress response and risk of obesity.

ENGAGEMENT AND WEIGHT LOSSES AMONG EMERGING ADULTS: DO OUTCOMES VARY BY RACE?

Kristal L. Brown, MSPH, Jessica Gokee, LaRose, PhD

Virginia Commonwealth University School of Medicine, Richmond, VA

Background: More than 40% of emerging adults (EA) meet criteria for overweight (OW) or obesity (OB) with prevalence exceeding 50% among minority EA. Despite increased risk, relatively few trials have targeted this population and even fewer have enrolled a racially diverse sample of EA. Moreover, weight losses achieved by this population are poor relative to other age groups, but whether disparities in outcomes exist by race among EA is unknown. Thus, the goal of the present study was to examine engagement and weight loss outcomes by race in a sample of EA enrolled in a behavioral weight loss (BWL) intervention.

Methods: Data were drawn from an ongoing randomized controlled trial targeting EA 18–25 years of age for weight loss. Participants (N=184, 60% racial / ethnic minority, BMI=33.2, 21% student, 36% non-student working, 41% work and school) were randomized to one of three arms and received a 6-month technology mediated BWL intervention matched on contact. Objective assessments of weight and anthropometrics were completed at 0, 3 and 6 months with continuous objective capture of engagement data via Bluetooth connected scales and self-monitoring app. For the purposes of the present analysis, data were collapsed across treatment arm, with arm included as a covariate in models. Weight losses and engagement across the initial 3 months of the program were examined by race / ethnicity; race was treated as a dichotomous variable comparing non-Hispanic White (NHW) vs. minority participants.

Results: Retention at 3 months was 91% and did not vary by race / ethnicity ($p=.41$). Engagement did not differ by race / ethnicity ($p=.20$). However, weight losses at 3 months were significantly better for NHW participants compared with minority participants and variability was quite high in both groups ($-3.5 \pm 4.3\text{kg}$ vs. $-2.1 \pm 4.0\text{kg}$, $p=.02$).

Conclusion: Results suggest that similar to adults, weight loss outcomes vary by race among emerging adults, although the differences are attenuated relative to previous reports in other age groups. Of note, differences in engagement were not observed, which suggests that there might be other factors contributing to differential weight loss outcomes. Given modest weight losses and high variability among this population overall, efforts to improve outcomes are sorely needed, particularly among minority EA. Findings are discussed in terms of implications for future work.

GOHEALTHYSCI: PILOT TESTING A WEIGHT MANAGEMENT PROGRAM FOR PEOPLE WITH SPINAL CORD INJURY

Susan Robinson-Whelen, PhD¹, Stephanie Silveira, BS², Rosemary B. Hughes, PhD³, Margaret Nosek, PhD⁴, Heather Taylor, PhD⁵, Tracey LeDoux, PhD, RD, FAND⁶, Lisa Wenzel, MD¹, Lauren Diaz, MS⁷

¹TIRR Memorial Hermann / Baylor College of Medicine, Houston, TX; ²TIRR Memorial Hermann / University of Houston, Houston, TX; ³University of Montana, Missoula, MT; ⁴Baylor College of Medicine / TIRR Memorial Hermann, Houston, TX; ⁵TIRR Memorial Hermann / UT Health, Houston, TX; ⁶University of Houston, Houston, TX; ⁷TIRR Memorial Hermann, Houston, TX

People with disabilities face multiple barriers to successful weight management. With input from community advisors and building upon GoWoman, an online intervention for women with mobility limitations, we developed and pilot tested GoHealthySCI, a group, peer-facilitated weight management program adapted for people with spinal cord injury (SCI). GoHealthySCI consists of 16 weekly group sessions using video teleconferencing with monthly in-person sessions, followed by 2 months of tapered sessions. Overweight or obese individuals with SCI were randomly assigned to the intervention or a control group that received materials at the end of the study. Of the 36 initially enrolled, 27 completed the post-test (14 intervention, 13 control; 25% attrition). The sample was 78% white, 59% non-Hispanic, 63% male, and predominantly middle-aged (*Mean* age=41.85, *SD*=13.18). Most had paraplegia (59%) and had been living with their injury for many years (*Mean*=19.89 years, *SD*=15.52). Preliminary evidence supports efficacy with intervention participants losing 8.07 (7.11) pounds over 16 weeks compared to 1.35 (7.87) pounds in controls (Cohen's $d=0.90$). Intervention participants also had a greater reduction in waist circumference (WC) than controls (1.67 [2.94] versus 0.24 [2.52], Cohen's $d=.52$). Weight loss was greater among men than women in the program (10.0 [8.51] versus 5.50 [4.0], Cohen's $d=.67$) but WC reduction was greater among women (2.72 [3.77] versus .89 [2.01], Cohen's $d=.60$). In terms of engagement, 4 intervention participants dropped within the first 2 weeks due to family/work conflicts or health issues. The remaining 14 participants attended 12.93 (1.9) of the 16 sessions on average. Program ratings strongly support the acceptability of the program, with 100% rating the program as good (21%) or excellent (79%), and 100% 'definitely' recommending the program. All reported making 'important' (93%) or 'minor' (7%) positive dietary changes, and all reported making 'important' (71%) or 'minor' (29%) changes in physical activity. In addition, 43% reported meeting or exceeding their weight loss goal, with 29% reporting good progress toward their goal. Perceived support in the predominantly online program was strong, with 100% describing that they felt supported by facilitators and fellow group members and 86% describing facilitators as 'very effective.' Results provide preliminary evidence of the feasibility, acceptability, and efficacy of the GoHealthySCI program.

HEDONIC HUNGER AS POTENTIAL BARRIER TO SUCCESS IN BEHAVIORAL WEIGHT LOSS

Savannah Roberts, B.S., Psychology, Jocelyn Remmert, B.A., Alexandra Convertino, B.S., Meghan Butryn, Ph.D.

Drexel University, Philadelphia, PA

Introduction: Research has demonstrated that individuals with overweight and obese BMIs may have an increased sensitivity to high-calorie, non-nutritious food, and may experience more intense cravings than individuals with normal weight BMIs, even when the food is not readily available. This susceptibility to environmental food cues in the absence of an actual caloric deficit is called hedonic hunger, and at high levels hedonic hunger can be indicative of unhealthy eating behaviors. Little research has examined hedonic hunger as a dynamic trait to determine if hedonic hunger changes during the course of behavioral weight loss (BWL) treatment. It also is unknown how changes in hedonic hunger, eating behavior, and weight are related. The goals of this study were to 1) assess the relationship between hedonic hunger and eating behavior throughout BWL treatment, and 2) determine if changes in hedonic hunger predict weight loss.

Methods: Adults with overweight or obese BMIs ($n = 320$) enrolled in a BWL treatment and completed assessments at baseline and 6 months, which included weight measurement and the Power of Food Scale (PFS), a self-report measure of an individual's sensitivity to food cues in the environment. Additional measurements taken during treatment included participant's self-reported calorie intake, used to calculate adherence to weekly calorie goals.

Results: On average, PFS scores did not significantly change between baseline and 6 months ($p > 0.05$). However, change in PFS scores between baseline and 6 months significantly predicted percent weight loss at 6 months ($p < .05$), such that higher PFS at baseline predicted lower adherence to calorie goals throughout treatment.

Conclusions: These results provide further evidence to suggest that hedonic hunger is related to eating behavior and weight loss in important ways. Experimental research is warranted to determine if providing specific strategies for regulating hedonic hunger could result in improved treatment outcome by decreasing sensitivity to environmental food cues.

IMPACT OF WEIGHT LOSS AND WEIGHT-LOSS MAINTENANCE ON CELL AGING IN ADULTS WITH OBESITY: RESULTS FROM THE SHINE STUDY

Alison R. Hartman, BA¹, Hiba Aboussleiman, BA¹, Jue Lin, Ph.D.¹, Samantha Schleicher, BA², Jennifer Daubenmier, PhD³, Frederick Hecht, MD⁴, Elissa S. Epel, PhD⁵, Ashley E. Mason, PhD⁴

¹University of California, San Francisco, San Francisco, CA; ²University of Maryland School of Medicine, Rockville, MD; ³San Francisco State University, Berkeley, CA; ⁴University of California San Francisco, San Francisco, CA; ⁵UCSF, San Francisco, CA

Objective: Higher body mass index (BMI) has been associated with shorter leukocyte telomere length (TL), a biomarker that predicts early mortality from diseases of aging. However, no studies have examined whether behavioral weight-loss interventions can attenuate TL shortening. Here we determined the impact of a mindfulness-based weight-loss intervention on TL and the association between weight-loss maintenance and change in TL.

Methods: Adults ($N=194$) with a BMI between 30 and 45 were randomized to a 5.5-month weight-loss program that included diet-exercise guidelines. Half of the sample ($n=100$) was randomized to receive mindfulness training in addition to the weight-loss program, and half of the sample ($n=94$) was randomized to receive the weight-loss program only. We assessed TL at baseline and 3, 6, and 12 months post-baseline in immune cell populations, including peripheral blood mononuclear cells [PBMCs] and granulocytes. We defined weight-loss maintenance as having lost at least 5% or 10% (tested in separate models) of body weight from pre- to post-intervention and maintenance of this loss at 12 months. We predicted that greater weight loss and weight-loss maintenance would be associated with longer TL.

Results: There was no effect of group randomization (mindfulness versus weight-loss program only), or amount of weight loss, at any time point, on change in TL. Regardless of intervention group, at 12 months, weight-loss maintenance of at least 10% (relative to lack of such weight-loss maintenance) was associated with longer PBMC TL ($b=0.10$, 95% CI [0.00, 0.19], $p=.049$), and trended toward an association with longer granulocyte TL ($b=191.56$, 95% CI [-4.23, 387.35], $p=.055$), after accounting for baseline TL. Similarly, at 12 months, weight-loss maintenance of 5% or greater (relative to lack of such weight loss and maintenance) was associated with longer PBMC TL ($b=163.32$, 95% CI 4.00, 320.62], $p=.045$) after accounting for baseline TL.

Conclusions: Among individuals with obesity, losing and maintaining a weight-loss of 10% or greater may lead to longer TL, which may portend improved immune and metabolic function. Notably, the increased TL in this study is of unknown duration beyond 12 months, and requires further study.

OBESITY PREVENTION PROGRAM WITH FOCUS ON EATING DISORDERS: 12-MONTH IMPACT OF THE 'HEALTHY HABITS, HEALTHY GIRLS - BRAZIL'

Ana Carolina Barco Leme, Ph.D.¹, Sonia Tucunduva Philippi, Ph.D.², Debbe Thompson, Ph.D.¹, Theresa A. Nicklas, DrPH³, Tom Baranowski, PhD¹¹Children's Nutrition Research Center, Baylor College of Medicine, Houston, TX; ²School of Public Health, University of São Paulo, São Paulo, São Paulo, Brazil; ³Baylor College of Medicine, Houston, TX

Background: With the increasing prevalence of pediatric obesity, there has been a parallel increase in the prevalence of "dysfunctional eating practices", including eating disorders (ED) and unhealthy weight control behaviors. Therefore, integrated intervention strategies that address both obesity and ED may minimize these interrelated public health concerns among adolescents.

Objective: To evaluate the long-term (12-month) effects of a Brazilian school-based intervention for girls targeting shared risk factors for obesity and ED.

Methods: A total of 253 girls, mean of 15.6 (0.05) years of age, from 1st to 3rd grade in 10 high schools (i.e., 5 pairs) participated in a 6-month school-based cluster randomized controlled trial. "Healthy Habits, Healthy Girls – Brazil (H3G-Brazil)", originally developed in Australia, emphasized 10 key nutrition and physical activity (PA) messages delivered over 6 months. ED prevention procedures were added to the intervention. Body satisfaction, unhealthy weight control behaviors and social cognitive variables of diet and physical activity were assessed at baseline, 6-month, and 12-month follow-up. Intervention effects were determined by one-way analysis of covariance or logistic regression, after checking for the clustering effects of school. The significance level was set at $p \geq 0.01$.

Results: Beneficial effects were detected for PA social support ($F=6.005$, $p=0.01$) and healthy eating strategies ($F=6.08$, $p=0.01$) at 6 months and healthy eating social support ($F=14.731$, $p=0.00$) and healthy eating strategies ($F=5.812$, $p=0.01$) at 12 months. The intervention group was more likely to report unhealthy weight control behaviors ($OR=1.92$, 95%CI 1.15 to 3.21, $p=0.01$) 12 months after baseline. No other significant 6- or 12-month effects were detected.

Conclusion: H3G-Brazil demonstrated positive 12-month effects on social cognitive variables, but an adverse effect on unhealthy weight control behaviors. Further work is needed to understand why this occurred and to enhance the effectiveness of H3G-Brazil for prevention of obesity and ED among girls.

PSYCHOSOCIAL ADJUSTMENT MEDIATES EFFECTS OF CHILDHOOD MATERNAL AND PEER SUPPORT ON BMI IN ADOLESCENTS

Bin Xie, PhD¹, Xiaomeng Lei, MPH¹, Mi Lei, MPH², Zhongzheng Niu, MPH³¹Claremont Graduate University, Claremont, CA; ²Claremont Graduate University School of Community and Global Health, Claremont, CA; ³State University of New York at Buffalo, Buffalo, NY

Background/Aims: We used a secondary dataset from the National Institute of Child Health and Development Study of Early Child Care and Youth Development (SECCYD) to examine mediation effects of psychosocial adjustment on the impact of accumulative and dynamic experience of maternal and peer support throughout childhood and early adolescence (from age 1 month to 11 years old) on later body mass index (BMI) in middle adolescence (age 15).

Method: The analysis sample included 844 children and their families. Maternal and peer positive support were repeatedly assessed from child's age 1 month to grade 5. Both cumulative scores and mobility measures were created to capture the accumulative and dynamic aspects of experience of support across time, which were further used to prospectively link to child's BMI at age 15. Average scores of repeated assessments of internalizing and externalizing behavioral problems from grade 3 to grade 6 were calculated to reflect psychosocial adjustment and were used as the mediators. Mediation analyses were carried out with the PROCESS macro which enabled to generate a bias-corrected bootstrapped 95% confidence intervals for indirect effects.

Results: Significant mediations of internalizing behavioral problems were observed on pathways from accumulative and dynamic aspects of positive support from mother (mediation for accumulative aspect = -0.046, 95% CI of -0.082 - -.015; for dynamic aspect = -0.17, 95% CI of -0.35 - -.031) and peers (mediation for accumulative aspect = -0.077, 95% CI of -0.14 - -.023; for dynamic aspect = -0.14, 95% CI of -0.31 - -.019) to later BMI at age 15. Similar findings on the mediations of externalizing behavioral problems were also observed for maternal (mediation for accumulative aspect = -0.077, 95% CI of -0.12 - -.042; for dynamic aspect = -0.094, 95% CI of -0.27 - -.076) and peer positive support (mediation for accumulative aspect = -0.16, 95% CI of -0.25 - -.089; for dynamic aspect = -0.16, 95% CI of -0.33 - -.018). Moderated mediation models between genders revealed the significant mediations of either internalizing or externalizing behavioral problems were mainly sustained with pronounced magnitudes in girls but not in boys.

Conclusion: Our findings demonstrated a significant mediating role of psychosocial adjustment. Future research efforts are highly encouraged to replicate our findings and further explore this underlying mediation mechanism.

RELATIONS BETWEEN WEIGHT-BASED TEASING, SELF-COMPASSION, AND EATING PATHOLOGY IN UNDERGRADUATE WOMEN

Rebecca Yeh, M.A.¹, Erika Robbins, M.A.², Edie Goldbacher, Ph.D.²¹La Salle University, Havertown, PA; ²La Salle University, Philadelphia, PA

Weight stigma, including weight-based teasing (WBT), or negative commentary from others regarding one's weight, contributes to eating disorder (ED)-related symptoms including binge and emotional eating (EE) and compensatory behaviors, purportedly because of the effect of WBT on negative self-evaluation, internalized weight bias, and increased stress and negative emotions (Vartanian & Porter, 2016; Tomiyama, 2014). Self-compassion (SC) is inversely associated with negative self-evaluation, and reflects the capacity to extend kindness to oneself, view one's suffering as a shared human experience, and hold a balanced awareness of one's experiences (Neff, 2003). SC is inversely associated with eating pathology and positively associated with body acceptance, and it partially explains the association between evaluation-based ED risk factors (e.g., body surveillance, external shame) and ED symptoms (Ferreira et al., 2013; Liss & Erchull, 2015; Taylor, Daiss & Krietsch, 2015; Dalen et al., 2015). Given preliminary evidence for an inverse association between WBT and SC (Robbins, Yeh & Goldbacher, 2017), it is plausible that SC may help explain the association between WBT and ED symptoms.

This study used bootstrapping to test whether SC (Self Compassion Scale; Neff, 2003) mediated the relation between frequency of WBT (Perception of Teasing Scale; Thompson et al., 1995) and both a general measure of ED-related symptoms (Eating Attitudes Test-26; Garner, Olmsted, Bohr & Garfinkel, 1982) and a specific measure of EE (Emotional Eating Scale; Arnow, Kenardy & Agras, 1995) in 142 female undergraduate students (M age = 20.37(5.04) years). Results demonstrated a significant indirect effect of WBT on ED symptomatology through SC ($b = .13$, BC CI = .05, .24). The direct effect of WBT on ED symptoms remained significant ($b = .46$, $p < .001$), consistent with partial mediation. Regarding EE, WBT was inversely associated with SC ($r = -.24$, $p = .003$), and SC was negatively associated with EE ($r = -.18$, $p = .04$); however, there was no significant direct ($b = .11$, $p = .65$) or indirect effect ($b = .11$, BC CI = -.02, .26) of WBT on EE. These results suggest that SC may help explain the association between WBT and general ED symptoms in college women, and that increasing SC could be one potential way of mitigating the effects of WBT on ED pathology. Clinical implications, associations with specific dimensions of ED symptoms, and future directions will be discussed.

SMALL-CHANGE BEHAVIOURAL INTERVENTION APPROACHES TO WEIGHT LOSS: A SYSTEMATIC REVIEW

Stefanie Ciszewski, M.A.¹, Lesley Lutes, Ph.D.¹, Zachary Walsh, Ph.D.¹, Susan Holtzman, Ph.D.¹, Deborah Tate, Ph.D.²¹University of British Columbia - Okanagan, Kelowna, BC, Canada; ²University of North Carolina - Chapel Hill, Chapel Hill, NC

Rates of overweight and obesity continue to rise in North America and worldwide. Traditional behavioral interventions geared at weight loss have demonstrated success in producing initial weight loss through large changes to caloric intake and physical activity. Although these changes result in steep initial weight loss, one continued problem for researchers and individuals alike is weight loss maintenance post-treatment. A novel approach to weight loss, a small changes approach, encourages participants to make modest changes to diet and activity. Theoretically, these small changes are enough to affect overall energy balance without requiring major lifestyle changes that are overly taxing to maintain long-term. Since the initial introduction of the small changes treatment paradigm, several studies have been conducted in an attempt to develop empirical support for this approach. The objective of the present review is to map the extant literature on this novel approach to weight loss. The present review, identified 12 articles that assessed 1720 participants. Although there was noted variability across the definition and application of the small changes approach, there were several common and defining features noted. The primary focus across multiple studies was that the goals for each participant were *modest* and *self-selected*. For a majority of the reviewed articles, small changes were successfully accumulated across the intervention phase to produce initial modest weight loss. Greatest data is available for 3- and 12- month assessments. Mean weight loss across 3- and 12-month assessments were -2.5kg and -2.96kg, respectively. Findings from this review also indicate that the small changes approach has demonstrated its ability to achieve initial weight loss with no study demonstrating weight regain greater than 50% across assessments through 12 months and 24 months. However, considerable variability in the application of the intervention exists. In order to gain an accurate picture of the small changes approach, researchers and clinicians developing small change interventions should stay in keeping with common and defining features of the small changes approach. Proof of concept for a small changes approach is clearly established and research on this approach can be expanded and broadened to further enhance this intervention technique and long-term treatment outcomes.

THE CORE SYMPTOMS OF BINGE EATING AND OTHER ADDICTIVE BEHAVIORS: A NETWORK ANALYSIS

Kirstie M. Herb, B.S.¹, Karen K. Saules, Ph.D.²¹Eastern Michigan University, Ypsilanti, MI; ²Eastern Michigan University, Ypsilanti, MI

Binge eating disorder (BED) is characterized by eating large amounts of food within a discrete time period with an associated sense of loss of control. Although BED is currently categorized as a feeding and eating disorder in DSM-5, there is some evidence supporting its conceptualization as a form of an addictive disorder. Research has found several similar risk factors between BED and substance use disorders, a number of clinical and behavioral parallels, and high levels of comorbidity. The literature also supports a strong relationship between overweight/obesity and BED, however the relationships between substance use and overweight/obesity are less clear.

Network analysis represents a relatively new statistical method in psychopathology research to examine how symptoms interact, perhaps in bidirectional fashion. Using a network analytic approach, we aimed to identify which binge eating symptoms are most central in a healthy (N = 155) and overweight/obese sample (N = 150). Secondary analyses examined addictive behaviors more broadly between the two groups. College students (N = 305) completed the Recognizing Addictive Disorders Scale (RAD; Carr et al., in preparation) and the Binge Eating Scale (BES) as part of a larger questionnaire battery. The RAD is a brief screener that assesses for problematic involvement with drugs, alcohol, binge eating, smoking, video games, gambling, and sex.

An independent t-test revealed there were no statistically significant differences between group means for drugs, alcohol, binge eating, smoking, video games, gambling, or sex. Groups did differ on binge eating $F(303, 2) = 27.624, p = .002$, with the overweight/obese sample endorsing significantly more problematic use. Networks examining binge eating symptoms measured by the BES revealed different central items for healthy participants than overweight/obese participants. Items relating to restriction and preoccupation with food and eating emerged as most central in the healthy network whereas items relating to loss of control were most central to the overweight/obese network. Networks examining a broader range of addictive behaviors measured by the RAD revealed problematic involvement with drugs as the most central to both the healthy and overweight/obese networks. Gambling was also highly central to the healthy network whereas alcohol emerged as central to the overweight/obese sample. Notably, the overweight/obese network was sparser, indicating weaker relationships between the addictive behaviors. These preliminary findings suggest binge eating may be a unique construct best conceptualized from an eating disorder lens.

These findings suggest weight status relates differentially to binge eating symptoms and more broadly across addictive disorders. A better understanding of the interrelationship of symptoms of these disorders may have important implications in treatment development.

WHICH FACTORS ARE ASSOCIATED WITH AN UNDERESTIMATION OF BODY MASS INDEX?

Jessica Whiteley, PhD¹, Laura L. Hayman, PhD, MSN, FAAN², Sam Simmens, PhD³, Jamie Faro, MS⁴, Meghan Mavredes, MPH³, Melissa A. Napolitano, PhD⁵¹UMass Boston, Boston, MA; ²College of Nursing & Health Sciences, UMass Boston, Boston, MA; ³George Washington University, Washington, DC; ⁴University of Massachusetts Boston, Boston, MA; ⁵The George Washington University, Washington, DC

Purpose: Some individuals tend to underestimate their BMI. Previous studies examining factors associated with this underestimation have found that non-Hispanic white adults underestimated their BMI when compared to Hispanic and Black adults, whereas other studies showed no racial/ethnic differences. Studies have also found that women and obese individuals were more likely to underestimate their BMI when compared to men and overweight individuals respectively. The purpose of this study was to examine demographic variables associated with the underestimation of self-report BMI in a diverse sample of overweight or obese young adults in a healthy body weight clinical trial.

Methods: Overweight or obese young Black, white, and Hispanic adults (18-35yo) enrolled in a healthy body weight clinical trial (n = 284; 77.5% female, 19.0% Black, 72.9% white and 8.1% Hispanic with a mean age of 22.9 ± 4.3 years) at two urban universities provided a self-reported height and weight and completed a clinic-measured height and weight. The difference between self-report and objective BMI was calculated as the amount of underestimation in self-report BMI (BMI-UND), with higher numbers indicating larger units of BMI underestimations. BMI category was created by dichotomizing the sample into overweight (BMIs 25 to < 30) and obese (BMIs 30 - 45).

Results: The mean self-reported BMI for the total sample was 29.99 ± 3.69 compared to clinic-measured BMI of 30.72 ± 3.8 , for an average BMI-UND of 0.72 ± 1.3 BMI units. Men were significantly more likely to underestimate their BMI compared to women (1.16 ± 1.2 vs. 0.59 ± 1.3 ; $p = .011$) and obese individuals were more likely to underestimate their BMI compared to overweight individuals (1.15 ± 1.5 vs. 0.37 ± 0.87 ; $p = 1.6$ for Blacks, 0.72 ± 1.1 for whites, and 0.36 ± 1.9 for Hispanics; $p = .26$). The overall model including age, race/ethnicity, gender, and BMI category significantly predicted BMI-UND. Significant predictors include BMI category ($p < .001$), the interaction between race and BMI category ($p = .03$), and the interaction between gender and BMI category ($p = .045$).

Conclusions: Unlike other studies it was men, rather than women, who tended to underestimate their BMI. Similar to other studies, obese individuals tended to underestimate their BMI more than overweight individuals. In this study, there were no significant differences in BMI underestimations among Blacks, whites and Hispanics. In the prediction model, being obese predicted BMI underestimation and this interacted with both race and gender separately. Within these two significant interactions, obese whites and obese males had the greatest underestimation of their BMI. Intervention implications will be discussed.

A DEVELOPMENTAL CASCADE PERSPECTIVE OF PEDIATRIC OBESITY: A REVIEW OF PREVENTIVE INTERVENTIONS FROM INFANCY-LATE ADOLESCENCE

Yaray Agosto, MPH¹, Sara M. St. George, PhD², Lourdes M. Rojas, MPH³, Monica Bahamon, MPH¹, Mary Soares, MPH⁴, Guillermo J. Prado, PhD¹, Justin D. Smith, PhD⁵

¹University of Miami Miller School of Medicine, Miami, FL; ²University of Miami - Miller School of Medicine, West Miami, FL; ³University of Miami Miller School of Medicine, miami, FL; ⁴University of Miami Miller Medical School, Miami, FL; ⁵Northwestern University Feinberg School of Medicine, Chicago, IL

Pediatric obesity has immediate and long-term consequences that often carry forward across the lifespan. A developmental cascade (DC) model offers a comprehensive framework for understanding cumulative factors contributing to pediatric obesity and has major implications for prevention. The purpose of this systematic review was to 1) examine preventive interventions from infancy through late adolescence reporting effects on weight status and/or related health behaviors (physical activity, sedentary behavior, diet), and 2) provide recommendations for future interventions. Following PRISMA guidelines, an electronic search of randomized controlled trials (RCTs) published in peer-reviewed journals between 1995–2016 targeting the prenatal through late adolescence stages was conducted. Search terms included: obesity, prevention, intervention, weight, exercise, sedentary, diet. RCTs without a post-intervention follow-up period or with a post-intervention follow-up period < 6 months were excluded. Intervention strategies and outcomes were then extracted and examined. The search yielded 2,612 articles, of which 625 were screened by full text review. Sixty-two interventions were included and organized by developmental stage: infancy (n=2), early childhood (n=10), childhood (n=29), early- to mid-adolescence (n=19), and late adolescence (n=2). Infancy and early childhood trials relied on universal prevention strategies targeting early feeding practices and positive parenting skills. Half of the childhood and adolescence trials were school-based and used universal prevention approaches (e.g., curriculum changes); those classified as selected or indicated prevention tended to involve the family for more intensive lifestyle modification. While existing interventions have addressed relevant developmental constructs (e.g., parent involvement), the cascade model provides useful directions for the development of future interventions. Specifically, the model suggests well-timed interventions that target key mediating variables stand to have the greatest impact. An increased focus on interrupting negative cascades in early stages is also warranted. Positive parenting approaches show promise in early childhood, and families are more often included in selected or indicated prevention studies at later stages, highlighting the need to involve parents in obesity prevention efforts across development. Longer follow-up periods are also necessary, as are corresponding mediation and moderation analyses.

ASSOCIATIONS BETWEEN FACETS OF WEIGHT-RELATED QUALITY OF LIFE AND MALADAPTIVE BEHAVIORS BEFORE AND AFTER BARIATRIC SURGERY

Tyler Mason, Ph.D.¹, Susan Yanovski, MD², Walter Pories, MD, FACS³, Anita P. Courcoulas, MD, MPH⁴, Bruce M. Wolfe, MD, FACS, FASMB⁵, Alfons Pomp, MD⁶, Steven Belle, PhD, MScHyg⁷

¹University of Southern California, Pasadena, CA; ²NIDDK/NIH, Bethesda, MD; ³Brody School of Medicine, East Carolina University, Macclesfield, NC; ⁴University of Pittsburgh Medical Center, Pittsburgh, PA; ⁵Oregon Health and Science University, Portland, OR; ⁶Weill Cornell Medical College, New York, NY; ⁷University of Pittsburgh, Pittsburgh, PA

Bariatric surgery is one of the most effective options for weight loss for individuals with obesity. However, following bariatric surgery, there is evidence for increases in substance use problems. In addition, while binge eating generally decreases after surgery, there is evidence for onset or recurrence of binge eating post-surgery in some individuals. Given that these maladaptive behaviors may be associated with weight regain and physical and psychiatric morbidity, it is important to better understand why individuals engage in these behaviors both before and after bariatric surgery. The ways in which one's weight affects their quality of life (i.e., weight-related quality of life [WRQOL]) may be a factor that increases the likelihood of engaging in maladaptive behaviors. Therefore, the purpose of this study was to examine associations among five dimensions of WRQOL and maladaptive health behaviors (i.e., binge eating, smoking, problem alcohol use) in adults with obesity before and after bariatric surgery. As part of the Longitudinal Assessment of Bariatric Surgery (LABS) study, data were collected from 2,430 individuals who received weight loss surgery (gastric bypass or banding) at baseline, 1-year, 3-years, 5-years, and 7-years. Self-report measures of demographics, WRQOL, and behaviors were completed at each assessment. Generalized linear models and general estimating equations were calculated to examine associations between facets of WRQOL and maladaptive behaviors (i.e., binge eating, smoking, and problematic alcohol use) at baseline and post-surgery. At baseline, poorer self-esteem WRQOL was independently associated with greater likelihood of binge eating, and poorer work WRQOL was independently associated with greater likelihood of smoking. After surgery, at follow-up assessments where individuals reported poorer self-esteem WRQOL than their average level, they were more likely to report binge eating, smoking, and hazardous alcohol use. Given the results of this study, psychological treatment after bariatric surgery focusing on increasing one's self-esteem related to their weight may be an important intervention and prevention strategy for a variety of maladaptive behaviors.

BARRIERS TO BEHAVIORAL WEIGHT LOSS TREATMENT

Jennifer Selensky, B.S., Robert Carels, Ph.D., MBA

East Carolina University, Greenville, NC

Objectives: Barriers to successful weight loss are poorly understood. The current study aimed to examine barriers, depressive symptoms, and social support at four different time points to identify contributing factors to poor weight loss outcomes, attrition, and the need for stepped-care in a behavioral weight loss intervention.

Methods: Fifty-three individuals (87% female; 62% Caucasian, 34% African American, 4% Asian/Pacific Islander; $M_{BMI}=35.6$, $SD_{BMI}=6.4$) were recruited for the weight loss program. All participants began with using a self-help modified version of the Diabetes Prevention Program and a Fitbit Zip® pedometer and food tracker. Over a period of six months, participants' weight loss success and need for more intensive treatment was assessed every two months based on pre-determined weight loss goals. If weight loss goals were not met, participants received meal replacements at Step 2 and individual counseling concurrent with meal replacements at Step 3. Barriers to Weight Loss, Center for Epidemiologic Studies Depression Scale, and the Weight Management Support Inventory (WMSI) were used to assess for barriers to weight loss, barriers to program completion, and the need for more intensive treatment.

Results: Independent sample t-tests were used to assess barriers contributing to attrition and found greater social pressure barriers, greater food craving barriers, and greater reported helpfulness of informational and appraisal support to be associated with dropping out of the program. A series of one-way between-group ANOVA tests were conducted to compare differences between stepped-care need. Greater emotional support frequency and greater situational, external physical activity, stress and depression, and food craving barriers were related to higher stepped status. The relationships between total percentage of bodyweight lost from baseline to 6 months and depression, social support, and barriers scores were explored at the four time points using Pearson correlation coefficient. Weight loss was related to cost of diet barriers and frequency of information support.

Conclusions: Social pressure, food craving, stress and depression, and cost of diet barriers reported during the current intervention were related to attrition, stepped-care need, and weight loss. Interestingly, greater helpfulness and frequency of weight loss support was related to attrition, greater stepped-care need, and worse weight loss outcomes.

CHANGES IN THE PERCEPTION OF SELF-WEIGHING ACROSS WEIGHT LOSS AND WEIGHT MAINTENANCE

Margaret Fahey, Master of Arts¹, Robert Klesges, PhD², Mehmet Kocak, PhD³, Gerald Talcott, PhD⁴, Rebecca Krukowski, PhD²

¹University of Memphis, Memphis, TN; ²University of Virginia, Charlottesville, VA; ³University of Tennessee Health Science Center, Memphis, TN; ⁴University of Virginia, San Antonio, TX

Background: Despite evidence demonstrating benefit, there is often reluctance to engage in self-weighing. Changes in self-weighing perceptions over the course of obesity treatment are unknown.

Methods: Participants (n=248) who were active duty military personnel and received a counselor-initiated (CI) or self-paced (SP) 12-month program adapted from Look AHEAD intensive lifestyle intervention. Self-weighing perceptions (i.e., how “helpful”, “positive”, “frustrating”, “anxiety provoking”, and “making self-conscious”) were rated on an 8-point scale at baseline, 4 and 12 months.

Results: Using random coefficient models, overall, the perception that self-weighing is *helpful* and *positive* significantly increased during the weight loss phase (*Helpful*, Baseline: M (SD) = 5.1 (2.0); 4 month change: +2.2 (2.3); *Positive*, Baseline: 4.2 (2.0); 4 month change: +1.6 (3.1)), and then slightly, but significantly decreased during the weight maintenance phase (*Helpful*, 12 month change: -0.3 (1.5); *Positive*, 12 month change: -0.4 (1.5)). In contrast, the perception that self-weighing is *frustrating* and *makes you self-conscious* significantly decreased during weight loss (*Frustrating*, Baseline: 4.5 (2.2); 4 month change: -1.0 (3.4); *Self-conscious*, Baseline: 4.5 (2.3); 4 month change: -3.3 (2.1)) and slightly, but significantly increased during maintenance (*Frustrating*, 12 month change: +0.4 (2.0); *Self-conscious*, 12 month change: +0.6 (1.8)). Perceptions of self-weighing as *anxiety provoking* were stable. At baseline, CI and SP participants perceived self-weighing similarly. Over 12 months, CI participants began viewing self-weighing as significantly more *helpful* and *positive* as well as *making them less self-conscious* than SP participants, while their view on self-weighing as *frustrating* or *anxiety provoking* did not differ significantly.

Conclusions: Participants viewed self-weighing more positively and less negatively during the weight loss phase, yet there were small, but significant reversions to baseline values during weight maintenance. However, importantly for clinical practice, perceptions of self-weighing remained significantly more positive and less negative than at baseline. In addition, participants in a more intensive weight management program had even more positive and less negative views of self-weighing.

6:15 PM-7:15 PM

COACHING IN THE KITCHEN: A PILOT STUDY OF HOME-FOCUSED WEIGHT LOSS TREATMENT

Meghan Butryn, Ph.D.¹, Alexandra Convertino, B.S.¹, Evan Forman, Ph.D.¹, Michael Lowe, Ph.D.¹, Nancy E. Sherwood, PhD²¹Drexel University, Philadelphia, PA; ²School of Public Health, University of Minnesota, Minneapolis, MN

The home food environment (HFE), which consists of the availability, portion size, and visibility of healthy and unhealthy foods in one's household, is a potentially powerful target for change during weight loss treatment, as adults consume two-thirds of their calorie intake in the home. However, HFE-focused interventions have had only modest success to date, perhaps because they have typically been delivered in the clinic. Delivering sessions in the home might facilitate more effective engagement of the HFE, but little research is available on home-based weight loss treatment for adults. This study pilot-tested a 4-week, home-based weight loss intervention that had a primary focus on modifying the HFE. Adults ($n = 10$, M age = 49.3 years; M BMI = 31.4 kg/m²) were provided with two sessions in their homes and, to increase scalability, two virtual home visits conducted through video chat. In session, coaches surveyed the HFE, provided accountability for making and maintaining HFE changes, and conducted experiential activities that reduced the intention-behavior gap for HFE change. Assessors objectively measured all foods present in the home at pre- and post-treatment. Retention and treatment engagement were excellent, with 100% of participants completing all four treatment sessions and 100% completion of the post-treatment assessment. Technology feasibility was high, with 19 out of 20 video sessions conducted as scheduled. Pre-post weight loss averaged 2.8%, which meets expectations for a 4-week program. Clinically significant decreases were observed in the availability of obesogenic foods, including sweets ($d = 0.24$), sugar-sweetened beverages ($d = 0.32$), high-calorie prepared entrees ($d = 0.30$), and added fats ($d = 0.62$). Participants also reported increases in use of HFE management strategies, including placing low-calorie foods in visible places ($d = 1.48$) and avoiding buying tempting foods ($d = 1.45$). Qualitative feedback highlighted convenience and accountability as key benefits of home visits. These data suggest that experimental research on this approach is warranted, using a full-length treatment protocol and isolating the effects of treatment location (i.e., home vs. clinic) and content (i.e., HFE vs. standard). From a treatment impact perspective, home visits are appealing not only because of their potential to improve outcomes, but because they may expand the reach of treatment to a wider audience, as many adults report barriers to attending sessions in clinic over the long-term.

DEVELOPMENT AND VALIDATION OF A CULTURALLY-SENSITIVE WEIGHT LITERACY SCALE

Monica Wang, ScD, MS¹, Tariana V. Little, MS², Amy Borg, MPH, MEd³, Christine Frisard, MS, BA⁴, Milagros C. Rosal, MS, PhD³¹Boston University School of Public Health, Boston, MA; ²Harvard T.H. Chan School of Public Health, Boston, MA; ³University of Massachusetts Medical School, Worcester, MA; ⁴University Massachusetts Medical School, Worcester, MA**Objectives:** To develop and validate a culturally- and literacy-sensitive weight literacy scale for adults.**Methods:** The two-phase study utilized quantitative and qualitative methods. Participant recruitment and study procedures took place in community settings in central Massachusetts for both study phases. Phase 1 of the study consisted of developing an initial survey (English and Spanish versions) assessing weight literacy based on a review of the literature; conducting semi-structured interviews with content experts ($N=9$) to refine survey items; and conducting in-person cognitive interviews with 20 study participants ($N=10$ English-speaking and $N=10$ Spanish-speaking adults) for survey pre-testing. Survey items were modified based on Phase 1 findings.Phase 2 of the study consisted of administering the survey to 200 study participants ($N=100$ English-speaking and $N=100$ Spanish-speaking adults) and assessing the scale's validity and reliability. Two weeks post-survey completion, a subset of Phase 2 participants ($N=35$ English-speaking and $N=35$ Spanish-speaking) completed the scale to examine test-retest reliability and a quantitative survey assessing dietary and physical activity behaviors and sociodemographics. Participants' anthropometrics were obtained by study staff. After scoring phase 2 participants' initial weight literacy scale responses, the Kuder Richardson's Coefficient of reliability was calculated. Two rounds of factor analysis were performed to identify items for elimination. Correlations between weight literacy scale scores and related measures (body mass index and weight status, dietary behaviors, physical activity behaviors, and confidence in filling out medical forms) were examined.**Results:** The final scale included 27 items and demonstrated good internal consistency (Kuder Richardson Coefficient = 0.85) and reasonable construct validity.**Conclusion:** The weight literacy scale is a reliable and valid research instrument to assess weight literacy among English- and Spanish-speaking adults.

DIFFERENCES IN RECEIPT OF DIET ADVICE FROM HEALTHCARE PROVIDERS BETWEEN AFRICAN-AMERICANS & CAUCASIANS SEEKING MEDICAL CARE

Rashelle B. Hayes, PhD Clinical Psychology¹, Leila Islam, PhD Clinical Psychology¹, Anika A.H. Alvanzo, M.D, M.S², David Pomm, M.S¹, Steven J. Ondersma, PhD Clinical Psychology³, Gabriela Villalobos, MSW¹, Dace S. Svikis, PhD Clinical Psychology¹

¹Virginia Commonwealth University, Richmond, VA; ²Johns Hopkins University School of Medicine, Baltimore, MD; ³Merrill Palmer Institute, Detroit, MI

Funding: R01 DA026091

Background: The U.S. Preventive Task Force recommends that clinicians offer intensive lifestyle counseling for obesity since research shows that physician-delivered counseling on healthy eating and physical activity are more likely to initiate patient lifestyle changes and successful weight loss. Unfortunately, weight-loss advice, which includes diet counseling, is low (34–65% among overweight & obese populations). In the U.S. African-Americans are disproportionately impacted by obesity compared to Caucasians (e.g. 44% vs. 33%), and also have higher rates of obesity-related diseases. There are, however, mixed results in the literature regarding whether ethnicity is associated with receiving weight or diet advice. African Americans, for example, may be more or less likely than Caucasians to receive weight-related advice. The association, however, could be influenced by the patient's BMI, and other demographic, and health factors. The primary aim of this study was to examine the relationship between BMI, ethnicity, and receipt of diet advice among a predominantly African-American, low-income, and urban, patient population.

Method: Participants (N= 3212) were 69% female; 47.4% BMI ≥ 30 , age M = 46.21, SD =12.02, 71% African-American; 24% Caucasian; 32% employed full or part-time, and were approached while they waited for medical care in a large hospital outpatient waiting room in Richmond, VA. Participants completed a 15-minute anonymous computer-directed health screening survey that included demographics, health status, height, weight, & whether or not they had ever been told by a doctor, nurse, or other health professional that they should go on a diet.

Results: Overall, 47.4% of the sample endorsed ever receiving prior advice to go on a diet and there was no difference between African-Americans (47.9%) and Caucasians (45.9%) ($\chi^2(1) = 1.338$; $p > .05$). An adjusted multifactorial logistic regression controlling for age, gender, number of illnesses, heart disease, employment, education, marital status, insurance, and smoking status, however, showed that females, a greater number of illnesses, presence of heart disease, and more education, was associated with greater odds of receiving diet advice (all $ps \leq .005$). Higher BMI was associated with receipt of diet advice, but more so among Caucasians (OR = 1.26, 95% CI [.197-.268]), $p < .001$; than compared to African-Americans (OR = 1.20, 95%CI [.170-.205], $p < .001$).

Conclusions: Rates of diet advice from healthcare professionals remain low. Ethnic differences exist in receipt of diet advice, but particularly among the very obese. Discussions about weight loss, including diet, should be provided to all patients, regardless of ethnicity or level of obesity.

EXERCISE PREFERENCES AMONG YOUNG ADULTS: DO MEN AND WOMEN WANT DIFFERENT THINGS?

Jean Reading, BS, MA, Jessica Gokee, LaRose, PhD

Virginia Commonwealth University School of Medicine, Richmond, VA

Background: Young adult men are difficult to recruit and retain in lifestyle interventions. This may be in part to gender differences in exercise goals observed in men, but little is known about exercise preferences for young adults, specifically. The purpose of this study is to compare the exercise preferences of young men and women to inform future interventions in this area. We hypothesize that men will prefer strength training at higher rates than women, and that women will prefer supervised guidance at higher rates than men.

Methods: The sample included 288 young adults aged 18–25 (mean age=21.85, SD=2.2). Majority were women and within a normal BMI range (M=25.91, SD=5.3). An anonymous online survey study was completed. Participants were asked their preferred type of exercise (moderate intensity cardio, strength training, intense strength training, or a combination of cardio and strength training), and if they preferred to exercise at a clinic-based facility with supervised guidance or to exercise alone with guidance. Chi-square tests were conducted to determine if there are gender differences in preferences for exercise type and mode of delivery, accounting for BMI.

Results: Over two-third of young adults preferred a combination of moderate intensity cardio and strength training. Women and men differed significantly in their exercise preferences ($p < .001$). Less than 1% of women preferred intense strength training compared to the 15.3% of men. Women (17.4%) preferred moderate intensity cardio at higher rates than men (12.2%). However, when examining outcomes by BMI category, these results were only significantly different among individuals within a normal BMI ($p = .000$). Majority of young adults (67.7%) prefer exercising with on their own with guidance from a program. Men and women did not differ in their preference to exercise with guidance or in a clinic-based program with supervision ($p = .115$).

Conclusion: Findings suggest that young adults overall prefer a combination of strength training and cardio, conducted on their own with guidance from a program. However, young men were more likely to prefer intense strength training; this was particularly true among men in a normal BMI range. These findings may be used to inform the tailoring of recruitment messaging and lifestyle interventions targeting this high-risk population.

EXTRA-FAMILIAL SOCIAL FACTORS AND OBESITY IN THE HISPANIC COMMUNITY HEALTH STUDY/STUDY OF LATINOS YOUTH

Julia I. Bravin, B.A.

San Diego State University/University of California, San Diego Joint Doctoral Program in Clinical Psychology, San Diego, CA

The role of extra-familial social factors, e.g., influence of peers and media, in youth obesity are not well understood. We examined associations of extra-familial social influences with obesity prevalence in 1444 participants ages 8–16 years (50.3% female; 45.7% children 8–11 years) of the Study of Latino Youth (SOL Youth) and explored their variation by sex and age. The Hispanic Community Health Study/Study of Latinos (HCHS/SOL; 2008–2011) is a population-based study of Hispanic/Latinos recruited from four urban US communities. The SOL Youth ancillary study recruited youth offspring of HCHS/SOL participants and their primary caregivers between 2012–2014. Caregivers provided demographic information and youth completed measures of general social support from friends, dietary and physical activity (PA)-specific support from peers, and social attitudes towards weight (awareness/internalization of societal appearance ideals). Height and weight were measured to obtain age and sex-specific body mass index (BMI) percentiles; obesity was defined as BMI ≥ 95 percentile. Logistic regression models assessed main effects of social variables, and their interactions with age and sex, adjusting for potential confounders (e.g., family socioeconomic status, child nativity), design effects, and sample weights. Associations of social factors with obesity varied by both age and sex (p values for interaction $<.05$), and thus subsequent analyses were stratified by sex and age. For female children, higher peer social support was associated with lower odds of obesity (OR 0.60; 95% CI 0.42–0.87); however, this effect was not significant in adolescents. Among adolescent females, higher awareness/internalization of societal appearance ideals was associated with increased odds of obesity (OR 1.56; 95% CI 1.17–2.09). For males, higher awareness/internalization of societal appearance ideals was associated with increased odds of obesity in children (OR 1.94; 95% CI 1.39–2.69) and adolescents (OR 1.88; 95% CI 1.29–2.74). Diet and PA-specific support from peers was not associated with youth obesity. These findings demonstrate that extra-familial factors are related to obesity among Hispanic/Latino youth and that these associations vary by sex and age. Although the cross-sectional design prohibits assessment of causality, these findings suggest the potential role of addressing social support and attitudes about weight in the prevention and treatment of obesity in Latino youth.

FRIENDSHIP AS A SOCIAL MECHANISM INFLUENCING BODY MASS INDEX (BMI) AMONG COLLEGE FRESHMEN

Meg Bruening, PhD, MPH, RD¹, Irene van Woerden, MS², David R. Schaefer, PhD³, Daniel Hruschka, PhD mph⁴, Alexandra Brewis, PhD⁵, Corrie M. Whisner, PhD¹, Genevieve F. Dunton, PhD, MPH⁶, Michael Todd, PhD¹, Punam Ohri-Vachaspati, PhD, RD¹, Melissa Laska, PhD, RD⁷

¹Arizona State University, Phoenix, AZ; ²Arizona State University, Pocatello, ID; ³University of California, Irvine, Irvine, CA; ⁴Asu, Phoenix, AZ; ⁵Arizona State University, Tempe, AZ; ⁶University of Southern California, Los Angeles, CA; ⁷University of Minnesota, Minneapolis, MN

Background: Social relationships have been proposed as a significant factor shaping obesity risk. Methodological limitations in previous studies hamper the understanding of the mechanisms by which social factors impact weight outcomes. The freshman year of college, a period of major social, behavioral, and weight changes, provides a context ideally suited to tracking longitudinally the impact of shifting friendship dynamics on weight outcomes. This study sought to identify the mechanisms by which friends impact BMI change among a diverse group of emerging adults.

Methods: A total of 251 freshmen participants (72.1% female, 51.0% non-White) in the Social impact of Physical Activity and nutrition in College (SPARC) study provided repeated information (up to 4 times) on relationships and measured body mass index (BMI) across the 2015–2016 academic year. Stochastic actor oriented models were used to simultaneously examine change in BMI through social influence and change in friendships over time, controlling for gender, race/ethnicity, and Pell grant status.

Results: At baseline, mean BMI was 24.17 ± 4.40 kg/m². Overall, BMI tended to increase over time, while the BMIs of friends were more likely to converge relative to the BMIs of students not identified as friends ($p=0.043$). The higher a participant's BMI, the greater the likelihood that the participant's BMI would increase if their friends had a higher BMI (aOR range: 1.5–2.6). Decreases in BMI were uncommon and did not reach statistical significance for any combination of participant and friend BMI.

Conclusions: Emerging adults' BMI changes appear to be influenced by the BMI of friends. Further investigation should aim to identify specific health behaviors that increase weight during college.

INITIAL WEIGHT LOSS AND FEMALE ADOLESCENT WEIGHT LOSS PROGRAM SUCCESS

Noel Kulik, Ph.D., CHES¹, Elizabeth Towner, PhD¹, Deborah F. Tate, Ph.D.²¹Wayne State University, Detroit, MI; ²University of North Carolina at Chapel Hill, Chapel Hill, NC

Behavioral weight loss programs for adolescents involving comprehensive, structured programs addressing nutrition, physical activity and behavioral skills appear to be most efficacious. There is evidence that initial weight loss (WL) in behavioral weight loss programs for adults is a significant predictor of overall program success; the purpose of this study was to determine initial 1-month WL factors that predict overall program success among adolescents. Overweight/obese female adolescent participants from two RCT 16-week WL trials were used for the purpose of this analysis. Demographic and anthropometric data, adherence (total number of weekly dietary self-monitoring diaries completed) and attendance at face-to-face meetings were collected. Descriptive statistics were used to investigate the distributions of all variables. Initial WL was examined in three ways: absolute weight loss (pounds), change in % overweight (%OW), and rate of weight loss. Absolute value change scores subtracting the 4-week and 16-week values from baseline values were calculated for absolute weight and %OW to represent WL. A step-wise, hierarchical linear regression analysis was used to examine initial WL at 4-weeks as a predictor of change in %OW at week 16. The sample was primarily white (n=72; 70.6%), with an average age of 15.6 ± 1.2 years, and a mean baseline BMI of 32.8 ± 4.2 units. Participants (n=67) lost an average of $2.43 \text{ lbs} \pm 4.46$ from 1–4 weeks, and a total of $7.21 \text{ lbs} \pm 9.56$ from baseline to 16 weeks. The number of self-monitoring diaries submitted differed significantly by weight loss group (Welch's $F(2, 60.738) = 5.104$, $p = .009$, $\eta^2 = .057$). Games-Howell post hoc analysis revealed that the increase in self-monitoring diaries from the slow to fast weight loss category (0.556, 95% CI (0.111 to 1.001)) was statistically significant ($p = .011$), suggesting that in the first month of treatment, participants who lost weight more quickly turned in significantly more diaries than participants who lost weight slower. At 16 weeks, 36.2% (n=25) participants lost 5% of their initial body weight. The full model predicting change in %OW from baseline to 16 weeks was statistically significant, $R^2 = .669$, $F(6, 57) = 19.216$, $p < .0005$; adjusted $R^2 = .634$. The addition of age, race/ethnicity, adherence, and attendance to the prediction of WL, led to a statistically significant increase in R^2 of .374, $F(4, 58) = 8.790$, $p < .0005$, and the addition of WL loss during the first month led to a statistically significant increase in R^2 of .287, $F(1, 578) = 49.402$, $p < .0005$. In the full model, initial WL and self-monitoring diaries predicted change in %OW at 16 weeks. Understanding the factors associated with program success can identify programming components that can be strengthened in future intervention development and design.

6:15 PM-7:15 PM

MEAL REPLACEMENT USAGE AND FAVORABILITY IN A WEIGHT LOSS TRIAL

Margaret DeZelar, B.A.¹, Sara A. Hoffman, M.S.², Angela F. Pfammatter, PhD³, Bonnie Spring, PhD²¹Northwestern University, Wood Dale, IL; ²Northwestern University, Chicago, IL; ³Northwestern University Feinberg School of Medicine, Chicago, IL

A majority of United States adults are overweight or obese, and that number continues to grow (Flegal et al., 2012). Commercial meal replacements (MR) are a safe and effective strategy for weight loss (Hemmingson et al., 2012; Saris, 2001), with some interventions demonstrating weight losses of 15–25% (Tsai & Wadden, 2005). Yet, questions remain about the feasibility and acceptability of liquid MR by patients in weight loss interventions. The purpose of this study was to conduct a preliminary analysis of use, adherence, and preference for MR among adults enrolled in a 6-month behavioral weight loss intervention, where half were randomized to receive MR recommendations. Rather than provide MR throughout the trial, which was considered cost-prohibitive, participants received only a one week supply and a recommendation to continue use. Participants (N=562) had BMIs ranging from 25–40 kg/m² (M=32.51, SD=3.68). Approximately 81.64% were female. Ages ranged from 18–61 (M=37.67, SD=10.61). The majority were Not Hispanic or Latino, 86.99% and 3.57% reported their ethnicity as “Other/Unknown.” At 6 months, participants completed an exit interview that included questions about MR. Of participants who completed the exit survey (n=465), 111 expressed a preference for MR (M=1.80, SD=1.41), ranking MR a 1, 2, or 3, when asked to rank 6 potential treatment components (1= I would want this component MOST and 6= I would want this component LEAST). Among the 232 participants randomized to receive meal replacement, 106 recorded intake of a standard brand MR in the smartphone app during the 6-month intervention. About half of the participants randomized to that condition preferred the MR. Of those reporting MR intake, the number of MR entries ranged from 1 to 27 over the 6 month intervention (M=5.23, SD=6.18). When asked on an exit survey what they liked most about the study, 20 participants reported a positive experience with MR. Of the 465 completed exit surveys, 171 mentioned MR and 111 of those used positive words (e.g., easy, useful, effective) to describe MR when asked for additional comments. This preliminary analysis was limited by the predetermined MR list and does not include any custom food entries made by a participant. Overall, results suggest that MR can be enjoyed and used by participants in a weight loss trial when use is recommended and not provided.

OVERVALUATION OF SHAPE/WEIGHT AND BINGE EATING ARE ASSOCIATED WITH FOOD ADDICTION IN RACIALLY DIVERSE ADULTS WITH OBESITY

Serena D. Stevens, PhD¹, Dean Lim, MA², Gabriela Bolivar, MA², Lilit Hovsepian, MA², Sylvia Herbozo, PhD³¹Cleveland Clinic, Cleveland, OH; ²Loma Linda University, Loma Linda, CA; ³University of Illinois at Chicago, Chicago, IL

Recent research has shown that food addiction is comorbid with binge eating disorder and obesity. Poor body image has also been strongly linked to both conditions. Less is known about the relationships between body image, binge eating, and food addiction in racially diverse populations. Specifically, overvaluation of shape/weight, a cognitive feature of eating disorders described as a maladaptive form of self-evaluation, has not been studied in this context. The current study examined overvaluation of shape/weight, body dissatisfaction, and binge eating in racially diverse adults with and without food addiction who were seeking weight loss treatment. Participants were 123 adults (46.3% ethnic minority) aged 18 to 84 ($M = 50.10$, $SD = 14.83$) with a mean body mass index (BMI) of 37.27 ($SD = 7.27$). Prior to the start of treatment, participants completed a battery of self-report questionnaires. Approximately 40.7% of the participants ($n = 50$) reported overvaluation of shape/weight, 21.1% ($n = 26$) reported at least one binge episode per a week for the past month, and 22.0% ($n = 27$) met criteria for food addiction. Independent samples t -tests were conducted to examine the influence of a food addiction diagnosis on BMI, overvaluation of shape/weight, body dissatisfaction, and binge eating. Results indicated that individuals who met criteria for food addiction had significantly higher BMIs ($M = 39.67$, $SD = 8.56$) than those without food addiction ($M = 36.30$, $SD = 6.43$; $t(104) = 2.15$, $p < .05$). No differences were found in body dissatisfaction between individuals with and without food addiction ($p > .05$). However, individuals with food addiction reported significantly greater overvaluation of shape/weight ($M = 5.23$, $SD = 1.18$) than those without food addiction ($M = 3.30$, $SD = 2.114$; $t(80.26) = 5.57$, $p < .001$). Individuals who met criteria for food addiction also had more weekly binge episodes ($M = 1.83$, $SD = 1.93$) than those without food addiction ($M = 0.53$, $SD = 0.91$; $t(28.88) = 3.31$, $p < .01$). Results suggest that individuals with food addiction are more likely to have poor body image as indicated by overvaluation of shape/weight, not body dissatisfaction. These findings support research showing that overvaluation of shape/weight is distinct from body dissatisfaction and may reflect greater severity of negative body image. Consistent with previous studies, individuals with food addiction had higher weight and binge frequency. Future research should investigate the implications of overvaluation of shape/weight and food addiction for long-term weight loss in racially diverse adults seeking weight loss treatment.

PEER ATTACHMENT ORIENTATION PREDICTS ENERGY AND MACRONUTRIENT INTAKE IN CHILDREN AGE 6–12

Aida Faber, PhD¹, Laurette Dube, PhD²¹Concordia University, Montreal, PQ, Canada; ²McGill University, McGill Centre for the Convergence of Health and Economics, Montreal, PQ, Canada

Background: Food overconsumption, particularly overconsumption of high caloric foods, is a core cause of obesity. This paper assesses peer attachment (internalized patterns of caretaker availability which influence self-views and distress regulation) as a controllable factor affecting food consumption in children. We hypothesize that suboptimal peer attachment styles lead to worse eating habits.

Objectives: This abstract investigates the extent to which childhood attachment styles influence macronutrient and energy consumption in children.

Methods: 271 parents reported on various behaviors of their 6–12 year old child ($M_{age} = 9.15(1.57)$) enrolled in a cohort study during a telephonic interview. Attachment was measured using the Attachment Questionnaire-Child and macronutrient consumption using web-based Food Frequency Questionnaire.

Results: Children with higher attachment avoidance had lower caloric intake ($F(6, 225) = 5.18$; $\beta = -134.10(58.93)$, $p < .05$). Attachment security and anxiety did not affect energy intake, $p > .05$. Gender was the only predictor of carbohydrate intake—compared to girls, boys consumed more carbohydrates ($F(7, 225) = 4.27$; $\beta = 33.27(16.10)$, $p < .05$). Attachment security and avoidance negatively predicted fat consumption; specifically, children with higher attachment security ($F(10, 221) = 6.52$; $\beta = -5.52(.16)$, $p < .05$) and avoidance ($F(10, 221) = 8.79$; $\beta = -7.28(2.45)$, $p < .01$) consumed less fat. On the other hand, attachment anxiety positively predicted fat consumption ($F(10, 221) = 7.53$; $\beta = 6.04(2.20)$, $p < .01$), with more anxiously attached children consuming higher amounts of fat. We found the same pattern for fat as a percentage of total energy intake. Attachment avoidance negatively predicted protein consumption ($F(7, 225) = 5.04$; $\beta = -5.53(2.46)$, $p < .05$), with more avoidant children eating fewer proteins. Attachment style did not predict fiber consumption, $p > .05$.

Conclusion: Peer attachment influences children's food consumption, affecting the core structure of their food choices. Our findings suggest that the deactivation of the avoidant attachment system translates in lower macronutrient intake, including caloric, fat, and protein. However, the hyperactivation of the anxious attachment system translates into higher fat consumption. We also show that a secure attachment does not necessarily lead to better food consumption.

PERCEIVED BARRIERS TO PHYSICAL ACTIVITY DURING BEHAVIORAL WEIGHT LOSS: ASSOCIATION WITH ACTUAL ACTIVITY LEVELS

Christine C. Call, A.B., Leah Schumacher, MS, Jocelyn Remmert, B.A., Stephanie Kerrigan, M.S., Evan Forman, Ph.D., Meghan Butryn, Ph.D.

Drexel University, Philadelphia, PA

Most adults with overweight or obese BMIs participating in behavioral weight loss (BWL) never achieve prescribed physical activity (PA) levels. Little research has examined perceived barriers to PA in the context of BWL. This study aimed to: 1) identify associations between perceived PA barriers and demographic and psychological characteristics, 2) examine changes in perceived PA barriers during BWL, and 3) determine whether perceived PA barriers predict actual moderate to vigorous PA (MVPA).

Adults (n=283) with overweight or obese BMIs enrolled in a BWL program wore an accelerometer at baseline and 6 months and completed self-report measures including: the Barriers to Being Active Scale, which assesses seven barriers to PA, a demographic questionnaire, the Physical Activity Acceptance Questionnaire, which evaluates ability to tolerate PA discomfort, and the Weight Efficacy Lifestyle Questionnaire, which measures self-efficacy for weight control.

Compared to Black participants, White participants reported lack of willpower, time, and social influence as greater PA barriers ($p < .05$), and lack of resources ($p = .09$) as a lesser PA barrier. Younger participants reported lack of time, energy, and resources as greater PA barriers compared to older participants ($p < .05$). There were no differences in perceived PA barriers by sex. Participants with greater perceived PA barriers reported lower acceptance of PA and lower weight control self-efficacy ($p < .05$). All perceived PA barriers significantly decreased from baseline to 6 months ($p < .01$), except fear of injury ($p = .06$). All baseline perceived PA barriers except fear of injury and lack of resources were associated with less MVPA at baseline controlling for BMI ($p < .05$), but did not predict 6-month MVPA. Decreases in the time and willpower barriers predicted greater 6-month MVPA controlling for baseline MVPA ($p < .01$).

Participants with greater perceived PA barriers differed on demographic characteristics and presented with additional treatment barriers, i.e., lower self-efficacy for weight management, lower acceptance of PA discomfort, and lower baseline MVPA. Perceived PA barriers decreased during BWL and a larger decrease in two barriers (lack of time and willpower) was associated with greater MVPA at 6 months, suggesting that these may be key barriers to target. Future research should examine if PA barriers predict MVPA after intervention ends, which may have additional implications for treatment tailoring.

PERSONALITY AND WEIGHT LOSS MAINTENANCE: COMPARING CONSCIENTIOUSNESS OF SUCCESSFUL AND UNSUCCESSFUL WEIGHT LOSS MAINTAINERS

Lucas Carr, PhD¹, J. Graham Thomas, PhD², Joshua Gold, M.A.¹, Jeremy Burrus, PhD³, Kevin C. O'Leary, MS⁴, Rena Wing, Ph.D.⁵, Dale S. Bond, PhD⁶

¹University of Iowa, Iowa City, IA; ²Brown University School of Medicine & The Miriam Hospital, Providence, RI; ³ACT, Iowa City, IA; ⁴The Miriam Hospital, Providence, RI; ⁵Warren Alpert Medical School of Brown University, Providence, RI; ⁶The Miriam Hospital/Brown Alpert Medical School Weight Control and Diabetes Research Center, Providence, RI

Background: The role of personality in weight loss maintenance (WLM) is poorly understood. Higher conscientiousness, a trait that reflects the tendency to be self-disciplined and contains facets of self-control, order, virtue, industriousness, responsibility, and traditionalism, might favorably influence persistence and success in maintaining a reduced body weight. Yet, while conscientiousness is related to health-promoting behaviors in general, no study has specifically evaluated the importance of conscientiousness for WLM. We compared conscientiousness and control over healthy lifestyle behaviors (i.e. food quantity and temptations, consistent meal and sleep timing, exercise adherence, and psychosocial health and stress coping) in successful and unsuccessful weight loss maintainers.

Methods: The sample included 869 National Weight Control Registry participants (52.1 ± 13.1 yrs; Body Mass Index [BMI]= 27.0 ± 5.5 kg/m²; 70% female) who reported maintaining a ≥ 30 lb weight loss for ≥ 1 yr (maintainers) and 642 participants from Amazon's M-Turk crowdsourcing marketplace (36.2 ± 11.1 yrs; BMI= 29.9 ± 7.5 kg/m²; 60% female) who reported trying but failing to maintain weight loss for 1 yr (non-maintainers). Both groups self-reported height and weight and completed a demographics form, the Cherynshenko Conscientiousness Scale and the Healthy Lifestyle & Personal Control Questionnaire online. Analysis of Covariance compared the groups on the above outcomes, adjusting for demographics and BMI, and provided estimates of effect size (ES; Cohen's *d*).

Results: Maintainers reported higher levels of total conscientiousness (180.9 ± 15.4 vs. 172.3 ± 21.2 ; $p = 0.003$; ES=0.46), order, virtue, traditionalism, responsibility, and industriousness ($p < .05$; ES=.09-.63), but not self-control, vs. non-maintainers. Maintainers also reported greater degree of control over food quantity and temptations, consistent meal and sleep timing, and exercise adherence ($p < .001$; ES=.62-1.1 for all), but not psychosocial health and stress coping, vs. non-maintainers. In both groups, higher levels of total conscientiousness were related to greater control over healthy lifestyle behaviors ($p < .001$; $r = .37$).

Conclusions: Successful weight loss maintainers reported small-to-moderately higher levels of conscientiousness compared to non-maintainers. Given the potential importance of conscientiousness for WLM, evaluating whether it can be modified to assist with long-term weight loss success is warranted.

6:15 PM-7:15 PM

REINFORCEMENT PATHOLOGY: ASSOCIATION BETWEEN INHIBITORY CONTROL, FOOD REWARD SENSITIVITY, AND WEIGHT LOSS

Kathryn M. Ross, Ph.D. M.P.H.¹, Jason Lillis, Ph.D.², Rena Wing, Ph.D.³¹University of Florida, Gainesville, FL; ²Brown University Medical School, Roseville, CA; ³Warren Alpert Medical School of Brown University, Providence, RI

Background: Preliminary evidence from correlational and lab-based studies suggests that inhibitory control and food reward sensitivity may affect energy intake regulation and thus influence body weight. Little is known, however, regarding how these factors (and their interaction, referred to as “reinforcement pathology”) may affect attempts at weight loss and whether inhibitory control and food reward sensitivity change in response to participation in behavioral weight management intervention (which focus on improving skills related to self-regulation of energy intake).

Methods: We investigated these questions in 65 participants (mean±SD age=50.8 ± 10.7years, BMI=31.4 ± 4.7kg/m², 68%Female, 83%White) enrolled in a 12-week Internet-based behavioral weight management program who completed the Go-No-Go inhibitory control task, the self-report Power of Food Scale, and were weighed at baseline and Month 3 (post-test). Multiple regression analyses were used to examine the association of these variables with weight loss.

Results: Inhibitory control at baseline was significantly associated with percent weight loss from baseline to Month 3, $\beta=0.18$, $p=.002$, such that individuals who made more errors on the Go-No-Go at baseline lost less weight during the intervention. Individuals in the lowest quartile for errors lost $-10.6 \pm 5.9\%$ of baseline weight, compared to a $-4.6 \pm 5.5\%$ loss for those in the highest quartile, $p=.006$ (total sample weight change from baseline to Month 3 was $-7.5 \pm 5.7\%$). There were no associations, however, between percent weight loss and baseline food reward sensitivity or the hypothesized reinforcement pathology interaction, $ps>.05$. From baseline to Month 3, participants demonstrated decreases in inhibitory control errors, $p=.011$, and food reward sensitivity, $\beta=0.16$, $p=.027$. Decreases in inhibitory control errors or the hypothesized interaction, however, were not significantly associated with weight change.

Discussion: The current study represents the first investigation into the impact of inhibitory control and food reward sensitivity on weight loss in adults. Our results demonstrate that individuals with poorer inhibitory control at baseline lost less weight during a 12-week behavioral weight management intervention, that participants experienced improved inhibitory control and food reward sensitivity during the intervention, and further that greater improvements in food reward sensitivity were associated with larger weight losses. Future studies should investigate whether improvements in inhibitory control and food reward sensitivity remain after the end of treatment, and further examine the impact of these factors on weight maintenance and regain.

SELECTING FOR SIMILARITY: THE PRESENCE OF HOMOPHILY AMONG WEIGHT LOSS PARTICIPANTS AND THEIR SUPPORTERS

Sara A. Hoffman, M.S.¹, Angela F. Pfammatter, PhD², Christine Pellegrini, PhD³, Siobhan M. Phillips, PhD, MPH², Bonnie Spring, PhD¹¹Northwestern University, Chicago, IL; ²Northwestern University Feinberg School of Medicine, Chicago, IL; ³University of South Carolina, Columbia, SC

In the context of weight loss, people may choose different individuals to support them. Homophily, or the tendency of people to associate with others like them, could facilitate mutual understanding and provision of social support. This study assessed the degree of homophily that exists when participants freely choose a support person (Buddy) in a weight loss intervention. Homophily was assessed on age, gender, race/ethnicity, location, and baseline BMI. Independent-samples t-tests were performed to assess for differences between groups for continuous variables. Chi-squared tests determined whether overall demographic proportions were independent by group. A similarity (Same/Different) variable was then created within each dyad and frequencies tallied, and exact binomial tests were performed on each similarity variable to determine whether probability of selecting a homophilous Buddy was different than chance. We hypothesized participants and Buddies would exhibit homophily on race/ethnicity, gender, age, and geographic location, but would not exhibit BMI homophily. Participants (P) (n=562) and Buddies (B) (n=562) were primarily White (P=74.2%; B=73.7%), female (P=81.7%; B=66.6%), and had a BMI in the overweight-obese range (P $m=32.3(3.6)$; B $m=27.4(6.0)$). Most participants chose friends (39.2%) or spouses/partners (32%) as Buddies. At the group level, Buddies weighed less ($p<.001$) and had lower BMIs ($p<.001$) than participants, but no difference was found for age between groups. The distribution of Buddy gender to participant gender was equal at the group level; however, the distributions of Buddy race and ethnicity to participant race and ethnicity were unequal at the group level ($X^2(1)=329, p<.001$; $X^2(1)=85, p<.001$). At the dyad level, most participants selected a Buddy who lived in the same geographic location (80.2%) and was of the same race (81.1%), ethnicity (80.3%), and gender (64.8%). However, most participants (84.9%) selected a Buddy of a different BMI ($m\text{ diff}=4.9\text{kg/m}^2$), and selected Buddies who weighed less. All proportions were significantly different than what would be expected by chance ($p's<.001$). While homophily on demographic features was common, lack of BMI homophily suggests the intentional selection of Buddies who weigh less, perhaps as a weight loss model. Future studies should examine whether homophily is related to more weight loss, and determine whether increased levels of homophily improve support effectiveness.

SLEEP DURATION AND ITS RELATIONSHIP TO ANTHROPOMETRICS, BMI AND WC, AMONG BLACK WOMEN IN THE SISTERTALK II STUDY

Christina Hom, MPH, Augustine W. Kang, MSc, MA, Patricia M. Risica, DrPH
Brown University School of Public Health, Providence, RI

Background: Increasing prevalence of obesity (BMI ≥ 30 kg/m²) is observed among all ethnic groups, but especially for non-Hispanic Black women among whom 56.6% are obese (Ogden et al., 2014). Sleep duration and sleep pattern are increasingly recognized as an essential aspects of health promotion. Thus, sleep may also affect obesity-related outcomes among non-Hispanic Black women.

Methods: The baseline data from 581 adult women enrolled in the SisterTalk Adhere Study who were aged ≥ 18 years, who identified as Black, spoke and read basic English, and had a BMI ≥ 22 kg/m² were examined for the relationships of sleep duration and sleep pattern with body mass index (BMI) and waist circumference (WC). Self-reported weekday sleep duration was used to categorize participants as very short sleepers (≤ 5 hours), short sleepers (6 hours), optimal sleepers (7–9 hours), and long sleepers (≥ 10 hours). Sleep pattern was defined by self-reported weekday and weekend hours of sleep categorized as consistently short sleepers (< 7 hours for weekdays and weekends), social jetlag group (< 7 hours for weekdays and ≥ 7 hours for weekends), and consistently optimal sleepers (≥ 7 hours for weekdays and weekends or

Results: During weekdays, 25.3% of women were very short sleepers, 28.6% were short sleepers, 41.0% were optimal sleepers, and 5.2% were long sleepers. Compared to optimal sleepers, both very short sleepers (+1.78 kg/m²; $p = 0.033$) and long sleepers (+4.21 kg/m²; $p = 0.006$) had significantly higher BMI. Compared to optimal sleepers, very short sleepers and long sleepers had larger WC (+2.68 cm; $p = 0.133$ and +6.79 cm; $p = 0.038$, respectively). Sleep pattern was not associated with either BMI or WC.

Conclusions: In this sample of adult non-Hispanic Black women, a U-shaped association most consistently characterized the association of sleep duration with BMI and WC. Excess weight is associated with both inadequate and excessive sleep, but abdominal obesity associated only with excess sleep. More research will help to further describe sleep as a risk factor for or result of obesity and abdominal fat.

REAL-TIME STRESS RELATES TO TEACHING EFFECTIVENESS: A LONGITUDINAL/MOMENTARY ANALYSIS

Teresa McIntyre, Ph.D.¹, Scott McIntyre, Ph.D.², Chris Barr, Ph.D.³, David Francis, Ph.D.³

¹Houston Baptist University, Seabrook, TX; ²University of Houston Clear Lake, Houston, TX; ³University of Houston, Houston, TX

This study examines the link between middle school teachers' stress responses and their teaching effectiveness (TE) over 2 years, determining both direct and mediated effects via health outcomes (burnout and somatic complaints). Participants were 202, 6th-8th grade core teachers, and were 77% female (Mean age = 40.4). This is a prospective longitudinal study over 2 academic years: Yearly, for 3 days (fall), 1 day (winter), and 2 days (spring). The multi-method model included concurrent measures of teacher stress (survey/diary) and TE (self-reported/observed). Survey measures were a Demographic and professional Survey, Maslach Burnout Inventory for teachers (MBI-form Ed, Maslach et al., 1996), Somatization scale of the Symptom Checklist - SCL-90 R (Derogatis, 1983). Ecological momentary assessment was conducted via the "Teacher Stress Diary", a validated iPod-based diary with 61 items (Authors, 2016). Items are brief questions, on a scale of 0–100, displayed on the screen (e.g. How are you feeling?). Negative affect (NA) was the mean of 5 negative affect states (e.g. stressed, sad). Self-reported TE (in previous class period) was the mean of 6 items (e.g. "Managed student behavior"). An iPad-based Classroom Observation System was developed and validated (Authors, 2011) measuring 4 core dimensions of TE: Instructional Strategies, Classroom Management and Organization, Presentation of Subject Matter and Learning Environment. The study sought to link teacher stress to TE both directly and via mediated effects (health outcomes). To evaluate direct effects, we fit Semi-parametric Mixed Effects models (SPMEM). TE was predicted by covariates (e.g. gender, seniority), time scales (season/day/hourly), and stress responses. We found direct effects of momentary stress responses (Negative affect -NA, feeling "stressed") on concurrent diary-reported TE over 2 years. Higher NA and Stress were associated with lower TE (YX estimate = -3.16 to -1.34, respectively). The direct effects of momentary stress were replicated for each dimension of TE, although with variability across dimensions. NA seems to have a stronger relation to Classroom Climate (YX estimate = -6.42) than to Instruction (YX estimate = -2.20). The multi-method data supported the predicted direct relations of real-time teacher stress and TE, suggesting that teacher well-being does matter for TE, and relations were sustained over 2 years. Mediated effects will be presented at the conference.

A SYSTEMATIC REVIEW OF CROSS-SECTOR COLLABORATION IN BUILT ENVIRONMENT INITIATIVES FOR PHYSICAL ACTIVITY: LESSONS LEARNED

Lehua B. Choy, DrPH, Cheryl Lynn. Albright, PhD, MPH

University of Hawaii, Honolulu, HI

An evidence-based strategy to increase physical activity is improving the built environment through interventions that address transportation systems in combination with land use and environmental design components. Implementing these types of interventions requires effective cross-sector collaboration among the stakeholders who have influence over the built environment. The purpose of this systematic review was to identify essential processes and characteristics of cross-sector collaborations that resulted in changes to the built environment. Four databases (PubMed, CINAHL, Web of Science, and Academic Search Complete) were searched for key terms in November 2017. To be included, articles had to be published in peer-reviewed journals, discuss features of cross-sector collaboration in the context of built environment initiatives focused on physical activity, and be conducted in North America. The systematic review followed PRISMA guidelines and utilized EPPI-Reviewer 4 software for data management. Data were abstracted by two researchers and themes were synthesized using directed content analysis. After removing duplicates, 212 articles were screened on title/abstract, 38 were reviewed on full-text, and 31 were included in analysis. A variety of sectors were involved with built environment initiatives that modified policies, plans, and infrastructure to increase physical activity among all age groups. Key themes included the evolving composition and activities of collaborative groups, the initial need to raise awareness and knowledge of the interrelationships between health and the built environment, varied mechanisms for meaningfully involving community members, challenges encountered, and lessons learned. The public health sector—particularly departments of health—played a notable role in convening and facilitating collaborative efforts with non-traditional partners, thus extending its reach into transportation, land use, and community design spheres. As collaborative groups built capacity to address the built environment, concrete accomplishments helped to sustain the work. However, many of the included studies only described cross-sector collaboration and did not measure or report on collaboration-specific outcomes. Nevertheless, the findings of this systematic review can be applied to developing or existing cross-sector collaborative efforts that are working to ensure that the built environment promotes physical activity behaviors across the lifespan.

ENJOYMENT OF PHYSICAL ACTIVITY AS A PREDICTOR OF GREATER WEIGHT LOSS

Samantha Sininsky, B.A, Savannah Roberts, B.S., Christine C. Call, A.B., Evan Forman, Ph.D., Meghan Butryn, Ph.D.

Drexel University, Philadelphia, PA

Enjoyment of physical activity (PA) has been examined as a motivator of PA in previous research. However, little research has examined how enjoyment of PA changes among adults seeking behavioral weight loss (BWL). We hypothesized that after trying a variety of new physical activities participants would increase their PA enjoyment, which may result in greater weight loss (WL). Aim 1 of this study was to evaluate if enjoyment of moderate-to-vigorous PA (MVPA) increased during 6 months of BWL treatment; aim 2 was to examine if greater increases in PA enjoyment were associated with greater WL or MVPA at 6 months.

Adults with overweight or obese BMIs (n=320) enrolled in BWL treatment completed assessments at baseline and 6 months, including weight measurement and the self-report Physical Activity Enjoyment Scale (PACES).

As expected, participants significantly increased their MVPA during treatment ($p < .001$). Enjoyment of MVPA did not significantly differ from baseline to 6 months ($p = .93$), but there was notable variability in the sample with 32.7% of participants decreasing in PA enjoyment, 36.9% increasing in enjoyment, and 5.3% showing no change in enjoyment. Change in PACES was significantly associated with WL at 6 months ($p = .03$), such that individuals with a greater increase in PA enjoyment lost more weight throughout treatment. However, after controlling for change in MVPA from baseline to 6 months this relationship was no longer significant ($p = .14$), but MVPA significantly predicted WL ($p = .005$). Change in PACES was a significant predictor of change in MVPA ($p = .002$) in that participants whose PA enjoyment increased from baseline to 6 months had a significantly greater increase in PA during this time.

Given that BWL includes strategies to make exercise more enjoyable, it was surprising that, on average, PA enjoyment did not change over 6 months of treatment. Participants with the largest increase in MVPA enjoyment had the greatest weight losses at 6 months. Interventions may need to test novel ways of increasing MVPA enjoyment. It also is possible that MVPA enjoyment is not an especially malleable construct and that participants would benefit from skills that are designed to promote MVPA in the absence of enjoyment. Even though PA enjoyment was associated with weight loss, many participants decreased their enjoyment of PA. This may stem from participants who were told to participate in PA, rather than doing the activities on their own accord.

EXPLORING THE USE OF SPORT AS A PLATFORM FOR HEALTH PROMOTION WITH CHILDREN AND YOUTH IN AFRICA

Adam H. Hansell, B.A., Peter R. Giacobbi, Ph.D

West Virginia University, Morgantown, WV

Background: The World Health Organization (2016) highlighted sub-Saharan Africa as having the lowest average life expectancy, highest rates of child mortality, and infectious diseases such as malaria, tuberculosis, and pneumonia. Over the past fifteen years sport has been studied as a platform in Africa to educate at-risk children and youth about infectious diseases and essential health practices. Including sport in health promotion initiatives can be an effective way to recruit and engage at-risk youth in Africa. The purpose of this research was to conduct a scoping review to identify how sport is used for health promotion and education among youth in Africa.

Method: The steps for the current scoping review included the following: (a) identification of the research question; (b) identification of relevant studies; (c) study selection; (d) charting of the data; (e) and data synthesis. Citations were retrieved from 10 electronic bibliographic databases, and keywords included sport, health promotion, Africa, youth, children, adolescents, youth development, disease, community, mortality, and intervention.

Results: A total of 916 articles were screened for eligibility. One author screened titles and abstracts and ten articles met inclusion criteria. All interventions were pragmatic trials and included the use of soccer to specifically target HIV awareness and prevention ($n=7$ articles) and targeted health prevention behaviors including clean water use, nutrition, risk factors for non-communicable diseases, HIV and malaria prevention, and proper sanitation practices ($n=3$ articles). Six interventions were conducted using a theoretical framework, including Social Learning Cognitive Theory ($n=3$ articles), Achievement Goal Theory ($n=2$ articles), and Theory of Planned Behavior ($n=1$ article). Youth participants experienced statistically significant improvements in levels of health knowledge from baseline to post-intervention in nine of the ten articles included in this review.

Discussion: Results suggest that sport can be utilized as an effective platform for health promotion and education among youth in Africa. Future studies have a strong foundation of research to expand upon specifically with regard to the application of theory. Considering the concerning statistics regarding disease and child mortality in Africa, the use of sport as a platform to educate children about essential health practices may serve an important role to improve overall health conditions of at-risk communities.

RELATEDNESS, MOTIVATION, AND EXERCISE BEHAVIOR ACROSS VARIOUS EXERCISE MODALITIES

Kolbie H. Gilliland, B.A., Angela B. Duncan, Ph.D.

Washburn University, Topeka, KS

Exercise is important for maintaining mental and physical health, and prevents diseases related to a sedentary lifestyle. It is vital to examine motivation to exercise and the impact of three basic psychological needs (autonomy, competency, and relatedness) on this motivation. While competency and autonomy have consistently impacted motivation to exercise, information regarding relatedness and group cohesion is lacking. The present study examined the relationship between exercise modalities (with differing degrees of relatedness), the fulfillment of basic psychological needs, and the motivation to engage in exercise among participants ($N=102$; age $M=41.2$, $SD=14.0$; BMI $M=28.3$, $SD=6.2$; 75% Female, 87% White) from community exercise facilities in the Midwest. Participants completed surveys assessing exercise behavior, fulfillment of basic psychological needs (PNSE; Wilson, Rogers, Rogers, & Wild, 2006), degree of motivation to exercise (BREQ; Mullen, Markland, & Ingledew, 1997), relatedness to others (ROPAS; Wilson & Bengoechea, 2010), and group cohesion and integration (PAGEQ; Estabrooks & Carron, 2000). We found that the basic needs of competency ($r=.49$, $p<.01$) and relatedness ($r=.52$, $p<.01$) were positively correlated with internalized levels of motivation. Exercise frequency ($r=.34$, $p<.01$) and intensity ($r=.24$, $p<.05$) also positively correlated with internalized motivation. Relatedness to others had a moderate positive correlation with internalized motivation ($r=.38$, $p<.01$), and group cohesion also had a moderate positive correlation with internalized motivation ($r=.40$, $p<.01$). Individuals in group exercise classes, especially CrossFit, reported significantly higher levels of competency ($F(2, 99) = 3.22$, $p=.044$, $\omega=.204$), general relatedness ($F(2, 99) = 5.35$, $p=.006$, $\omega=.280$), relatedness to others in exercise ($F(2, 99) = 9.25$, $p=.000$, $\omega=.373$), group cohesion ($F(2, 99) = 3.22$, $p=.044$, $\omega=.204$), group integration ($F(2, 99) = 9.94$, $p=.000$, $\omega=.386$), frequency of exercise ($F(2, 99) = 3.12$, $p=.049$, $\omega=.200$), and intensity of exercise ($F(2, 99) = 4.811$, $p=.010$, $\omega=.264$) compared to individuals exercising alone. The findings support efforts toward group exercise promotion as a potential way to sustain exercise behavior in that perceived relatedness to others and group cohesion in community exercise facilities may increase motivation to exercise. It is imperative to capitalize on community connectedness for exercise promotion.

THE EFFECTS OF PARENTAL STRESS AND FAMILY COMMUNICATION ON LEVELS OF PHYSICAL ACTIVITY AMONG HISPANIC ADOLESCENT BOYS VS. GIRLS

Marissa Kobayashi, BA, MHS¹, Tae Kyoung Lee, Ph.D.², Rafael O. Leite, BA³, Blanca S. Noriega Esquivas, MD⁴, Guillermo J. Prado, PhD², Sarah E. Messiah, PhD, MPH², Sara StGeorge, PhD²

¹University of Miami - Miller School of Medicine, Coral Gables, FL; ²University of Miami Miller School of Medicine, Miami, FL; ³University of Miami Miller School of Medicine, Department of Public Health Sciences, Boca Raton, FL; ⁴University of Miami - Miller School of Medicine, Miami, FL

Emerging research shows a negative association between parental stress and adolescent physical activity (PA) levels. However, there is a dearth of research examining the role of family communication on this relationship. Additionally, given that previous studies show PA levels are higher among boys versus girls, it is also important to understand whether and to what extent the effects of parental stress and family communication on Hispanic adolescents' PA vary by gender. Therefore, the objective of this analysis is to examine 1) the direct effects of family communication and parental stress on adolescents' PA, 2) whether family communication moderates the relationship between parental stress and PA, and 3) determine whether the model in #2 varies by gender.

Baseline data from Hispanic adolescents (N=280, 52% female, 13.0 ± 0.8 years old, BMI=28.1 ± 6.1 kg.m²) and their parents (88% female, 44.9 ± 6.5 years old) from an ongoing obesity prevention study were analyzed. To examine the study's objectives, three models were estimated. The first model examined the direct effects of parent-reported parental stress and parent-reported family communication on adolescent reported PA. The second model added a two-way interaction between parental stress and family communication to the previous model. Finally, a multiple-group model assessing for potential gender differences was estimated. Analyses were conducted using Mplus (V8) using Full Information Maximum Likelihood Estimation.

Results from the first model show that there was a negative relationship between parental stress and adolescent PA level ($\beta = -0.042$, $t = -2.013$, $p = 0.044$) as well as a positive relationship between family communication and PA ($\beta = 0.102$, $t = 2.404$, $p = 0.016$). The second model showed that the interaction between parental stress and family communication on adolescent PA level was significant ($\beta = 0.027$, $t = 2.688$, $p = 0.007$) indicating that the association between parental stress and PA was stronger for youth with low levels of family communication. The multiple-group model showed that the interaction in model #2 was significant for boys ($\beta = 0.034$, $t = 2.138$, $p = 0.032$) but not for girls. Results here emphasize the importance of targeting family communication and reducing parental stress as it relates to Hispanic adolescent boys' physical activity.

UNPACKING THE INTENTION-BEHAVIOR GAP DURING THE INITIATION OF REGULAR EXERCISE

Bree Geary, BA, MPH, Austin S. Baldwin, PhD

Southern Methodist University, Dallas, TX

Objective: Many people intend to change health behaviors but often fail to take action on their intentions – known as the “intention-behavior gap” (Sheeran, 2002). The existence of this phenomenon is well established across health behaviors, including exercise. However, there are important aspects of the intention-behavior gap during the initiation of regular exercise that are not well understood. In this study, we addressed the following questions during the first week of regular exercise initiation: (a) How prevalent are planned but not completed (skipped) exercise sessions? (b) Do different types of motivation at initiation predict frequency of skipped sessions? (c) Are the reasons cited for skipped sessions consistent with those motivations?

Methods: Physically underactive but otherwise healthy adults (N=87) enrolled in an exercise intervention and were instructed to engage in aerobic exercise for 30 minutes per day, 5 days per week (ACSM, 2011). At baseline, participants self-reported two types of motivation: autonomous motivation (i.e., value of a behavior integrated into sense of self), and controlled motivation (i.e., engaging in a behavior for external reasons such as perceived approval from others). During the first week of the intervention, daily exercise behavior was reported. If participants did not exercise on a given day but reported an intention to exercise, this was coded as a skipped workout. Participants were then prompted to indicate the reason they did not exercise. The number of skipped sessions was regressed simultaneously on autonomous and controlled motivation (using a Poisson distribution), controlling for intervention condition.

Results: Overall, 49 participants (56%) reported at least one skipped session (range: 0–5). Both autonomous (OR = .83, 95% CI = .69, 1.00, $p = .05$) and controlled motivation (OR = 1.20, 95% CI = 1.04, 1.39, $p = .01$) significantly predicted the number of skipped workouts. Reasons individuals did not exercise as intended were as follows: too busy (33%), didn't want to exercise (17.5%), tired (15.5%), sick (10.7%), and other (23.1%).

Conclusion: Results suggest skipped exercise sessions are prevalent during the first week of regular exercise initiation, and autonomous and controlled motivation predict a decrease and an increase, respectively, in the number of skipped exercise sessions. The most frequently cited reasons for skipped sessions are consistent with lower levels of autonomous motivation.

USING COMPUTER VISION TO PROVIDE AUTOMATED ECOLOGICAL ASSESSMENT OF PHYSICAL ACTIVITY: ADVANCING DIRECT OBSERVATION

Jordan Carlson, PhD¹, Bo Liu, BS², James F. Sallis, PhD³, Jacqueline Kerr, PhD⁴, J. Aaron Hipp, PhD⁵, Vincent Staggs, PhD¹, Amy Papa, MA¹, Kelsey Dean, MS¹, Nuno Vasconcelos, PhD²

¹Children's Mercy Kansas City, Kansas City, MO; ²University of California, San Diego, La Jolla, CA; ³UC, San Diego, La Jolla, CA; ⁴UCSD, San Diego, CA; ⁵North Carolina State University, Raleigh, NC

Technological advances provide opportunities for automating direct observations of physical activity, which would require less manpower and allow for ongoing monitoring and feedback. This pilot study evaluated initial validity of computer vision algorithms for providing automated ecological assessment of physical activity. The sample comprised 110.5 minutes per camera (three cameras in total) of video capturing up to nine participants engaged in sitting, standing, walking, and jogging in an open outdoor space while wearing an ActiGraph GT3X+ accelerometer. The data were collected across different times of day on three different days. Computer vision algorithms were developed to assess the number of people sedentary and in moderate to vigorous activity (MVPA), and group-based total metabolic equivalents of tasks (MET)-minutes in the scene. Bias/difference values, standard deviations (SD) of the bias, and intraclass correlation coefficients (ICC) assessed criterion validity compared to accelerometry for each minute of time, separately for each camera. On average, minute-level estimates for the number of people sedentary were within 1.8–4.1% and in MVPA within 5.8–8.9% of the criterion. Estimates of total MET-minutes in the scene were within 9.3–17.1% of the criterion. ICCs were excellent (≥ 0.82) for the number of people sedentary and in MVPA, and good for total MET-minutes (0.68–0.79). SDs around the bias were 19.5–32.4% for the number of people sedentary and in MVPA, and 42.8–49.4% for total MET-minutes. Bias estimates did not vary across cameras by more than 7.8%, and ICCs by more than ± 0.11 . The computer vision algorithms had acceptable sample-level validity (i.e., across a sample of minutes) as indicated by small (0.60) ICCs. This small pilot study shows proof of concept for automating direct observation measures of physical activity using computer vision, but further development and testing is needed before such tools can be used in a diverse range of settings. Automated ongoing assessment of physical activity in open spaces would allow for rapid feedback to support adaptive interventions and inform practice, and be particularly advantageous when manpower to conduct direct observations is limited.

A FAITH-BASED MIND-BODY INTERVENTION TO INCREASE PHYSICAL ACTIVITY, REDUCE SEDENTARY TIME, AND REDUCE STRESS IN RURAL ADULTS

Scherezade Mama, DrPH¹, Nishat Bhuiyan, B.S.², Hannah T. Jones, N/A³, Melissa Bopp, Ph.D.⁴, Eugene J. Lengerich, Pennsylvania⁵, Joshua M. Smyth, PhD⁴

¹The Pennsylvania State University, University Park, PA; ²The Pennsylvania State University, State College, PA; ³The Pennsylvania State University, State College, PA; ⁴Pennsylvania State University, University Park, PA; ⁵Penn State Cancer Institute, Hershey, PA

The purpose of this study was to explore the feasibility and efficacy of *Harmony & Health* (HH), a culturally-adapted yoga-based mind-body intervention to increase physical activity (PA), reduce sedentary time, and reduce stress, among a diverse sample of adults in a rural/nonmetro setting. HH capitalized on an existing partnership with a predominantly African American church and the faith-based community to recruit a diverse sample of men and women who were at least 18 years old, overweight or obese ($BMI \geq 25.0 \text{ kg/m}^2$), and insufficiently active (doing $N=144$) expressed interest in HH, of which 60 (41.7%) were eligible to participate and 46 (76.7% of those eligible) completed a baseline health assessment and were enrolled in the study. Participants (M age= 49.2 ± 13.5 years) were mostly women (84.8%), non-Hispanic white (47.8%) or African American (45.7%), high socioeconomic status (65.2% completed a bachelor degree or more and 37.2% reported an annual household income $\geq \$80,000$), and obese (M $BMI=32.6 \pm 5.8 \text{ kg/m}^2$). Although there were no significant changes in PA from baseline to post-intervention, participants reported less sitting time on weekdays ($\Delta=-1.6$ hours/day, $t=-3.121$, $p=.004$) and weekends ($\Delta=-1.9$ hours/day, $t=-3.864$, $pt=-2.399$, $p=.022$), and fewer depressive symptoms ($t=-3.547$, $p=.001$) at post-intervention. Non-Hispanic white participants reported increases in moderate-intensity PA ($\Delta=907.3$ MET-minutes/week) from baseline to post-intervention compared to African American participants ($\Delta=907.3$ vs. -620.4 MET-minutes/week, respectively; $F_{2,21}=5.001$, $p=.017$). Findings suggest that HH was feasible and effective at reducing sedentary time and stress in a diverse nonmetro sample, regardless of ethnicity. HH is an innovative way to intertwine spirituality, mind-body practices, and PA in an effort to improve physical and psychological health and reduce health disparities in ethnic minority and rural populations.

6:15 PM-7:15 PM

“LITTLE EXERCISE IS BETTER THAN NO EXERCISE”: MULTIPLE MEASURES OF PHYSICAL ACTIVITY AMONG OLDER AFRICAN AMERICAN WOMEN

Idethia Shevon. Harvey, DrPH¹, Ledric Sherman, PhD², Erica Spears, PhD³, Rahma Mkuu, MPH⁴, Crystal N. Alexander, BA⁵¹Texas A & M University, College Station, TX; ²Texas A & M University, College Station, TX; ³Auburn University, Auburn, AL; ⁴Texas A&M University, College Station, TX; ⁵Texas A & M University -Health Science Center, College Station, TX

Introduction: The World Health Organization (WHO) recommends that adults aged 18–64 years old exercise at least 150 minutes of moderate-intensity aerobic physical activity (PA) throughout the week, however the WHO does not provide recommendation for adults 65 years of age or older. African Americans (AAs) are disproportionately affected by several chronic conditions (e.g., T2D, CVD, and disabilities) when compared with other racial groups. Assessment of physical activity among aging adults is of particular public health significance because there are a wide variety of fitness levels in this age group, and the presence of chronic conditions may limit participation in physical activity. This multi-methods study explored the subjective and objective influence PA among older African American women.

Methods: Multi-methods approach with a triangulation design using the convergent model was used to explicitly merge qualitative and quantitative data to examine PA among African American women. Community-dwelling females provided data on their weekly activity patterns and completed a 7-day PA diary. Semi-structured interviews were used to explore the ways the participants engaged in PA. Descriptive analysis was conducted to examine subjective and objective PA levels. Interviews were audio-taped, transcribed verbatim, and data were analyzed with narrative analysis.

Results: The mean age of the female participants was 69.6 years of age (SD = ±8.0 years) and the average number of chronic condition was 2.5. African American women participated in low level physical activity (75 ± 20 min), they were more likely to engage in PA during the morning rather than in the afternoon or evening. Housework and walking were the common form of physical activity. Most of the participants stated that they need to exercise more but “a little PA is better than no PA.”

Conclusion: The study sheds light on the complexity regarding the perception of PA among older chronically-ill African American women. The perceived quality and accessibility of the built and natural environments influenced neighborhood activity in older adults. However, the focus of PA should not be on “quantity” but “quality.” The results may have implications in designing specific supportive PA programs for older African American women residing in urban neighborhoods.

ACTIVO: RANDOMIZED TRIAL OF A PHYSICAL ACTIVITY INTERVENTION FOR LATINO MEN

Britta Larsen, PhD¹, Shira Dunsiger, PhD², Sheri J. Hartman, PhD³, Sarah Linke, PhD, MPH⁴, Dori Pekmezi, PhD⁵, Tanya J. Benitez, PhD, MSW⁶, Kevin Patrick, MD, MS¹, Bess Marcus, PhD⁴¹University of California, San Diego, San Diego, CA; ²The Miriam Hospital/Brown University, Portsmouth, RI; ³University of San Diego, California, La Jolla, CA; ⁴UC San Diego, La Jolla, CA; ⁵University of Alabama at Birmingham, Birmingham, AL; ⁶University of California San Diego, La Jolla, CA

Background: Compared to non-Latino White men, Latino men report lower engagement in physical activity (PA) and experience markedly higher rates of diabetes, obesity, and other conditions related to inactivity. Despite these disparities, Latino men have been largely absent from PA interventions. We previously showed that an individually tailored theory-based mail-delivered Spanish language PA intervention could significantly increase PA in underactive Latina women. In the current study, we modified this intervention for Latino men based on formative research and added an interactive text messaging component, then tested this multimedia intervention in a small randomized controlled trial.

Methods: Participants were 46 Latino men randomized to Intervention (n=22) vs. Control (N=24) arms. Intervention participants completed monthly questionnaires and received individually tailored PA materials through the mail and received interactive text messages. Controls received materials via mail and SMS messages on wellness topics other than PA, including healthy eating, weight control and stress management, matched for contact time. PA was measured at baseline and 6-month follow-up using ActiGraph GT3X+ accelerometers and the 7-Day Physical Activity Recall.

Results: Participants were 43 (+/-10.7) years old and 87% self-identified themselves as Mexican. The majority had at least some college level education (57%), were employed at least part time (87%), were first generation (85%) and spoke more Spanish than English in the home (70%). There were no between-group differences in demographic characteristics or baseline physical activity (p's>.05). Median objectively measured moderate-to-vigorous physical activity (MVPA) increased from 10.0 at baseline to 57.5 6 months (6m) among Intervention participants and from 21.0 to 23.0, respectively, among Controls. Quantile regression indicated a significant between-group difference in median objectively measured MVPA at 6m, b=37.5 (18.0), p=.04. At baseline, median min/week of self-reported MVPA was 10.0 for Intervention participant and 5.0 for Controls. At 6m these increased to 95.00 among Intervention participants and 52.5 among Controls. There was a trend favoring greater increases in the Intervention arm's median minutes/week of self-reported MVPA at 6m (p=0.10), with Intervention participants reporting a median 42.4 minutes/week more than Controls after adjusting for baseline. Correlations between self-reported and objectively measured MVPA were borderline significant at baseline (rho=.28, p=.07) and significant at 6m (rho=.49, p=.01).

Conclusions: The intervention showed potential efficacy for increasing PA in this underactive sample of Latino men. The next steps in this line of work are to test this intervention in a larger randomized trial and assess potential for broad dissemination.

CONFLICTING OR FACILITATING GOALS: DIFFERENCES IN ADULTS' SOCIAL COGNITIONS AND EXERCISE OVER TIME

Jocelyn E. Blouin, MSc, Nancy C. Gyurcsik, PhD

University of Saskatchewan, Saskatoon, SK, Canada

A better understanding of the self-regulation of exercise is needed since most adults do not meet the public health recommendation of 150+ minutes of moderate-vigorous exercise each week. Exercise does not occur in isolation, as adults often set multiple concurrent exercise and non-exercise goals that they wish to pursue during their leisure time. Social cognitive theory (SCT) contends that whether concurrent goals are perceived to be in conflict or facilitation with one another may affect successful exercise self-regulation; conflicting goals may be more challenging to regulate than facilitative goals. As a result, adults who hold concurrent conflicting goals may report lower adherence-related social cognitions, including self-regulatory efficacy and the likelihood and value of positive proximal outcome expectations and exercise less than those holding facilitative goals. Our prospective SCT-based study examined whether adults ($N = 191$; $M_{age} = 31 \pm 12$ years) who reported their exercise and non-exercise goals conflicted or facilitated differed in their self-regulatory efficacy to manage multiple goals at the same time, outcome expectations, and exercise. Participants completed online measures of efficacy, outcome expectations, and exercise at study onset. Exercise was assessed again one month later. Participants who perceived their goals conflicted ($n = 100$) or facilitated ($n = 91$) formed comparison groups. A between groups MANCOVA with Time 1 exercise as a covariate and social cognitions and exercise as the dependent variables was significant, ($p < .0001$; $\eta^2_{partial} = .17$). Follow-up ANOVAs revealed that the group with conflicting goals reported significantly lower self-regulatory efficacy and exercised less at Time 2 compared to the group with facilitating goals (p 's $< .05$; $\eta^2_{partial} = .14$ and $.03$). Outcome expectations did not significantly differ. Findings provide first evidence that self-regulatory efficacy is a key differentiating social cognition between those who hold conflicting or facilitating goals. If study findings are replicated, at least two intervention avenues exist. First, when individuals have conflicting goals, increasing their self-regulatory efficacy may be beneficial. Second, intervening to help adults set at least some facilitative goals (e.g., exercise and socialize at the same time) may also be beneficial. Such intervention approaches should help adults learn to better self-regulate their exercise alongside their non-exercise leisure time goals.

EXAMINING PHYSICAL ACTIVITY INFLUENCES WITHIN AFRICAN AMERICAN AND HISPANIC COMMUNITIES

Elizabeth Orsega-Smith, PhD¹, Gregory M. Dominick, Ph.D.¹, Katie E. Greenawalt, MS²¹University of Delaware, Newark, DE; ²Penn State University, Lebanon, PA

In the U.S., health disparities are most prevalent among racial/ethnic minority groups. Compared to whites, African Americans and Hispanics are more likely to be obese and are less likely to meet current physical activity (PA) guidelines. This study examined factors that influence PA levels among African American and Hispanic participants enrolled in two distinct but conceptually similar, community-based health education programs implemented through the Delaware Cooperative Extension Agency.

Methods: 112 adult participants (≥ 18 years) completed baseline and 3-month post-test measures that included height/weight. Additional questionnaires assessed demographics, PA stage of change PA self-efficacy, and Godin PA score. Weight loss over the 3 months was calculated for all participants. Subsequent analyses were conducted for those who lost weight during the program ($n=62$) by racial/ethnic group. Bivariate correlations were used to identify variables that were significantly associated with Godin PA score at the end of the program. Predictors of PA were examined with linear regression analyses.

Results: Of the 62 participants included in the analysis, 31 identified as African American and Hispanic, respectively. Participants were middle aged (52.71 ± 16.55 years) and mostly female (73.4.9%). Weight loss for the overall sample was significant (4.4 ± 6.8 lbs; $p=.002$) and there were nonsignificant changes in PA self-efficacy and PA stage of change ($p>.05$) from baseline to end program. There were no significant difference between groups in Godin PA, weight loss, BMI, or PA stage of change ($p>.05$), but a near significant difference in PA self-efficacy ($p=.052$) was found. Among Hispanics, PA self-efficacy and BMI were correlated ($p<.001$) with Godin PA score and both variables were significant predictors of Godin PA score at post-test in the linear regression model ($R^2 = .52$, $p = 0.001$). For African Americans, age and PA stage of change were significantly correlated with Godin PA scores at post-test ($p,.05$), but age was the only significant predictor of PA Godin score at post-test ($R^2 = .44$, $p = 0.05$).

Conclusion: Findings support some theoretical association between PA self-efficacy, PA stage of change and overall PA in a diverse minority population who participated in a community based program. These findings varied by racial/ethnic group suggesting a need for further tailoring of programs to effectively meet the needs of community populations.

EXERCISE CAPACITY OF ACTIVE VIDEO GAME PLAY IN HEALTHY-WEIGHT CHILDREN VS. OVERWEIGHT-OBESE CHILDREN

Jungyun Hwang, PhD¹, Andres Hoyos-Cespedes, MPH², Mie Hashimoto, MPH³, Amy Shirong Lu, PhD⁴¹Northeastern University, BOSTON, MA; ²Northeastern University, Watertown, MA; ³Northeastern University, Brookline, MA; ⁴Northeastern University, Boston, MA

Replacing sedentary screen time with active video game (AVG) play is a recent strategy to reduce children's sedentary behavior. Few studies have evaluated overweight-obese children (OOC), who may have different patterns of body movements and physiologic and metabolic responses when compared with healthy-weight children (HC) during AVG play. We aimed to measure physiologic and metabolic parameters of playing three Xbox One AVGs requiring different body movements among age- and gender-matched OOC and HC.

Thirty-one children [M=9.7y, SD=1.5 / 15 OOC (56% m); 16 HC (53% m)] played three AVGs: *Fruit Ninja* (upper-body movement, UM), *Shape Up* (lower-body movement, LM), and *Kung-Fu for Kinect* (whole-body movement, WM) for 10 min per AVG. Participants wore ActiGraph accelerometers on non-dominant wrist and waist for step count, a Polar heart rate monitor (HR, beats/min), and a face mask attached to a Cosmed metabolic cart for oxygen uptake (VO_2 , ml/kg/min), respiratory exchange ratio (RER, VCO_2/VO_2), energy expenditure (EE, kcal/10min), and metabolic equivalent (MET, $3.5 \text{ mlO}_2/\text{kg}/\text{min}$).

Across all AVGs, step counts and HR were not different between OOC and HC; however, metabolic parameters were significantly different. The data means are presented in the following order: UM, LM, WM. MET was significantly lower in OO (5.0, 6.2, 5.7) than in HC (6.5, 8.6, 7.9) during each AVG play ($p < .05$). AVG play resulted in moderate-vigorous (MV) physical activity (PA) in OOC while producing vigorous-intensity (V) PA in HC. OOC had less aerobic capacity ($p < .05$) as indicated by a lower VO_2 (17.8, 22.6, 20.4) than HC (22.8, 30.3, 28.0). RER was higher in OOC than HC during LM play (0.94 vs. 0.88, $p < .05$). OOC ($p < .05$) had more EE (48.0, 60.7, 53.8) than did HC (35.3, 47.8, 42.9). When corrected for body weight, however, OOC expended less energy expressed in kcal/kg/10min than HC ($p < .05$) when playing all AVGs (0.9, 1.07, 0.97 vs. 1.16, 1.47, 1.33). Among the three AVGs, $\text{VO}_2F=46.2$, $\text{METF}=39.3$, and $\text{EEF}=20.3$ ($p < .01$) were the highest in LM and the lowest in UM.

We found differences in metabolic parameters between OOC and HC, suggesting that OOC could have lower aerobic capacity and reach fatigue status faster, though expending less energy than HC during the same AVG play. AVGs that require upper, lower, or whole body movement could be effective for increasing total EE and achieving MVPA among overweight-obese children, thereby improving their aerobic capacity for obesity prevention.

EXPLORE EFFECTS OF FREE-LIVING PHYSICAL ACTIVITY ON NEXT 24-HR GLUCOSE PATTERNS USING MOBILE GLUCOSE MONITORS IN NON-DIABETICS

Yue Liao, MPH, PHD¹, Nidhi Desai, B.S.², Jaejoon Song, PhD³, Liang Li, PhD⁴, Qiang Shen, MD, PhD³, Carrie R. Daniel, PhD, MPH³, Scott Kopetz, MD, PhD⁴, Karen Basen-Engquist, Ph.D., M.P.H.³, Susan M. Schembre, MS, PhD, RD³¹University of Texas MD Anderson Cancer Center, Houston, TX; ²Florida State University College of Medicine, Tallahassee, FL; ³The University of Texas MD Anderson Cancer Center, Houston, TX; ⁴MD Anderson Cancer Center, Houston, TX

Background: Structured exercise (e.g., high intensity interval training) performed in controlled lab settings has been shown to decrease postprandial glucose levels in both diabetic and non-diabetic populations. Less is clear about the effects of non-structured, free-living physical activity on subsequent glucose patterns. Using an accelerometer and continuous glucose monitor (CGM), the current study aims to explore whether objectively measured physical activity level is associated with glucose patterns within the next 24-hr period in a sample of non-diabetics. This information could inform the development of future physical activity interventions using glucose as a biological marker to illustrate the acute benefits of physical activity.

Methods: Thirty participants (age=37.9 [SD=13.2] years, 73.3% female, 66.7% overweight/obese) completed a 7-day monitoring period. Blood glucose was recorded every 5 minutes using the Dexcom G4 PLATINUM CGM system. Activity level was objectively assessed using an Actigraph accelerometer that was worn on the waist during waking hours. Participants also kept a food log using MyFitnessPal. Multilevel linear regression models were used to examine the effects of moderate-to-vigorous physical activity (MVPA) on next day's morning fasting glucose and 24-hr mean amplitude of glycemic excursions (MAGE), which indicates the glucose variability from peaks to nadir. Weight status was tested as a moderator. All models additionally controlled for gender, age, and total daily carbohydrate intake.

Results: Participants on average spent 30.6 (SD=28.2) minutes in MVPA per day. Prior day MVPA minutes did not affect fasting glucose the next morning. However, participants who typically had higher MVPA minutes compared to others in the sample, had marginally lower average MAGE ($b=-.008$, $SE=.004$, $p=.06$). Further, compared to normal weight participants, overweight/obese participants who engaged in some (vs. no) MVPA the prior day, had marginally lower MAGE over the next day ($b=.66$, $SE=.39$, $p=.09$).

Discussion: The preliminary findings from this study demonstrate the feasibility of collecting continuous glucose data among free-living non-diabetics and its integration with objectively assessed physical activity data. Together, this information could be used to provide just-in-time behavioral guidance as a strategy for future physical activity interventions.

IMPROVEMENTS IN PHYSICAL FUNCTION AND FITNESS: RESULTS FROM A RURAL COMMUNITY-RANDOMIZED TRIAL

Rebecca A. Seguin, PhD, CSCS¹, Meredith L. Graham, MS¹, Sara C. Folta, PhD², David Strogatz, PhD³, Galen Eldridge, MS⁴

¹Cornell University, Ithaca, NY; ²Tufts University, Boston, MA; ³Bassett Research Institute, Cooperstown, NY; ⁴Montana State University, Boston, MT

Objective. To evaluate the effects of a six-month diet and exercise-focused heart-health lifestyle program on functional fitness and physical function among midlife and older women, and examine possible differential effects on midlife (59 years) and older women (>60 years).

Methods. Sixteen medically underserved rural towns in Montana and New York were randomized to one of two six-month intervention programs: a twice-weekly experiential-learning health behavior change program focused on diet and physical activity behaviors, *Strong Hearts, Healthy Communities (SHHC)* (n=101) or a monthly healthy lifestyle education-only, minimal intervention control program (n=93). Sedentary overweight or obese females aged 40 years or over were recruited to the study. SHHC physical activities included aerobic exercise (e.g., indoor/outdoor walking; aerobic dance)—starting low-to-moderate, transitioning to moderate-to-vigorous intensity—and progressive strength-training exercises for the upper body, lower body, and core. Progressive strength training (10–20 minutes; two sets of ten repetitions) of major muscles groups, such as squats, lunges, bicep curls, and chest press, was included in approximately two-thirds of the SHHC classes. Functional fitness tests included the arm curl, chair stand, and step test from the Senior Fitness Test (Rikli and Jones, Human Kinetics, year?) and the 10-item physical function quality of life subscale of the SF-36.

Results. SHHC participants (n=82) improved significantly compared to control participants (n=69) on the chair stand and step test, as well as physical function related quality of life scores in multivariate regression analyses that controlled for site and baseline sociodemographic characteristics. SHHC participants did not improve on the arm curl when compared to control participants. These results were the same in subset analyses that stratified women aged 59 and younger versus 60 and older, in terms of significance and magnitude.

Conclusion. The SHHC program was superior in improving physical fitness and function compared to a control program, and despite a relatively modest dose of strength training, both younger and older participants made significant improvements in the measured domains of lower body strength and aerobic fitness as well as the self-reported domain of physical function related quality of life, including lifting or carrying groceries, bending, kneeling or stooping, and moderate and vigorous activities.

PHYSICAL ACTIVITY AND THE SELF-AS-DOER IDENTITY: THE MEDIATING ROLE OF INTRINSIC MOTIVATION FOR VIGOROUS BEHAVIORS

Amanda Brouwer, Ph.D, Samantha Lee, Sydney Bendtsen, Angelika Smith, Kristen Fish

Winona State University, Winona, MN

Introduction: Physical activity (PA) reduces the risks of obesity, yet two-thirds of Americans are not meeting recommended PA levels. PA interventions often demonstrate initial changes in PA, but maintenance of that change proves challenging. Lack of motivation is often cited as a reason for not engaging in PA. As such, attempts to reduce disease risk and promote PA should consider factors that affect motivation and maintenance of behavior change. One such factor is the self-as-doer. The self-as-doer, a motivational identity which aims to describe the individual in terms of *doing* a behavior, predicts PA behaviors, but little is known about the mechanisms by which it does so. Theoretically, the self-as-doer may be changing PA levels by increasing intrinsic motivation to engage in behavior, but this has yet to be explored. Therefore, the aim of the current study was to explore whether intrinsic motivation would be a mediating factor in the relationship between the self-as-doer identity and PA.

Methods: Participants, 203 adults ages 18–49 (M=20.07, SD=3.05), completed a survey and a writing activity assessing the self-as-doer for PA. Mediation analyses using bootstrapping procedures were conducted to test the indirect effect of the self-as-doer identity on PA through intrinsic motivation.

Results: Intrinsic motivation was a significant mediator, with a small effect size, of the relationship between the self-as-doer identity and vigorous PA, (b=375.62 BaCa CI[229.85, 559.71], $R^2 = .04$), but not for moderate PA, (b=77.96 BaCa CI[-.84, 176.05], $R^2 = .01$), or walking behaviors, (b=-32.40 BaCa CI[-.08, .10], $R^2 = -.0004$).

Discussion: Results demonstrate that the self-as-doer affects PA behaviors by increasing intrinsic motivation, but only for vigorous behaviors. Although research has demonstrated that increasing one's intrinsic motivation for PA increases those behaviors, this is the first to demonstrate that a self-as-doer identity can increase intrinsic motivation which then increases PA behaviors, at least for vigorous behaviors. That is, calling oneself an “exerciser” or “walker” may be the catalyst needed to develop intrinsic motivation for vigorous behavior. That intrinsic motivation did not mediate the relationship between the self-as-doer and moderate or walking behaviors might suggest that these behaviors do not require the same degree of motivation to enact as vigorous behaviors. Future researchers should explore the causal effects of this relationship.

POST-CURRICULUM TRAINING ATTITUDES, PERCEPTIONS, & BARRIERS FOR CLASSROOM-BASED PHYSICAL ACTIVITY AMONG PRE-SCHOOL TEACHERS

Debra M. Vinci, DrPH, RDN¹, Christopher K. Wirth, PhD², Melicia Whitt-Glover, PhD³, Alexandra Venezia, MS⁴¹University of West Florida, Pensacola, FL; ²University of West Florida, Pace, FL; ³Gramercy Research Group, Winston-Salem, NC; ⁴Auburn University, Auburn, AL

Background: Overweight/obesity is increasing in U.S. preschool children. Childcare programs represent an important venue for intervening on health-related behaviors among children given that children spend approximately 30 hours/week in non-parental care. Effective strategies are needed to build capacity among preschool teachers for incorporating healthy behaviors in childcare programs.

Objective: This study evaluates preschool teachers' attitudes, perceptions, and perceived barriers for integrating classroom-based physical activity following training for the *Let's Wiggle with 5-2-1-0* curriculum.

Methods: Preschool teachers were recruited from childcare centers in NW Florida for a 2-hour *Let's Wiggle with 5-2-1-0* workshop to train teachers to integrate physical activity during classroom circle time. Pre- and post-assessment data were collected 1 week before and 6 weeks after the workshop. Assessments included teacher demographics; School Physical Activity Promotion Attitude Questionnaire (SPAPAQ); School Physical Activity Promotion Competence Questionnaire (SPAPCQ); and the Barriers to Being Active Quiz.

Results: Seventy-three participants were trained from September 2016 to April 2017. Participants were primarily white (52%) or black (30%), female (100%), employed full time (84%), had post high school education (73%), and had been employed in childcare for 14.0 ± 9.6 years. We observed post-training improvements ($p < 0.05$) in teachers: 1) understanding their role in promoting physical activity at school; 2) helping children adopt lifelong physical activity habits; and 3) improving their knowledge of physical literacy. At baseline, teachers generally self-reported that they had some/few skills in performing tasks related to physical activity. After training, teachers reported improved perceived competence in all 13 areas ($p < 0.05$). Prior to the workshop, teachers reported three barriers to physical activity: lack of will power, lack of energy, and lack of time. Following training teachers reported statistically significant decreases in lack of time, lack of social influence, lack of energy, lack of willpower, and lack of resources ($p < 0.05$).

Conclusion: The *Let's Wiggle with 5-2-0-1* training workshops positively influenced preschool teachers' attitudes, perceptions, and barriers in integrating physical activity in a classroom setting. Additional data are needed to understand if improved teacher confidence leads to increased classroom physical activity among preschool children.

PRELIMINARY TEST OF TARGETING OUTCOME EXPECTATIONS TO INCREASE EXERCISE AMONG BREAST CANCER SURVIVORS

Rachel Hirschev, PhD, RN¹, Gretchen Kimmick, MD, MS², Marilyn Hockenberry, PhD, RN, PNP-BC, FAAN³, Ryan Shaw, PhD RN³, Wei Pan, PhD¹, Christy Page, MSN, RN, AOCNP, AGPCNP-BC⁴, Isaac Lipkus, PhD³¹University of North Carolina, Chapel Hill, Chapel Hill, NC; ²Duke University Medical Center, Durham, NC; ³Duke University, Durham, NC; ⁴Duke Raleigh Outpatient Treatment Center, Raleigh, NC

Most breast cancer survivors do not exercise enough to experience the associate benefits such as decreased recurrence risk, mortality, and improved quality of life. Interventions are needed to increase levels of exercise among this population. Potentially powerful interventions may be those focused on exercise outcome expectations (OEs) (i.e., what people expect to obtain or avoid by engaging in a behavior). OE dimensions include 1) importance – value placed on the outcome(s); 2) certainty – perceived probability outcome(s) will occur; and 3) accessibility – the frequency with which outcome(s) are considered. This RCT is a preliminary test of an intervention aimed to increase exercise OEs.

Participants were recruited at a tertiary cancer center in the southeastern United States and randomized to an attention control or intervention arm. Intervention arm participants received a researcher-created exercise OE booklet containing narrative messages, writing and thinking activities intended to increase OE dimensions. Attention control participants received a similar booklet, focused on diet. OEs, self-efficacy (i.e., a theoretically significant covariate), and exercise were measured at baseline, 4-, 8-, and 12-weeks post intervention, through online surveys and an accelerometer. Multi-level models were constructed using SAS proc mixed and effect sizes were calculated for each outcome.

The sample is 74% white, 26% black, an average 58 years old and 2.5 years post cancer treatment. Intervention effects include: a 0.01 point increase of overall OEs, OE accessibility, certainty, importance and exercise intentions ($p = 0.3555$), ($p = 0.6578$), ($p = 0.5026$), ($p = 0.0002$), ($p = 0.6254$); a two minute increase in weekly exercise minutes ($p = 0.2676$); and 970 increase in weekly steps ($p = 0.0283$), every four weeks in the intervention arm compared to the control arm. All effect sizes were small ranging from 0.01 to 0.09.

This is the first study to focus solely on targeting OEs to increase exercise among breast cancer survivors. Exercise is a very difficult behavior to change, thus the modest effect sizes in this study are not surprising. All intervention effects were in the intended direction. The 970 weekly step increase, every 4 weeks in the intervention arm compared to the control arm, may be clinically significant as it may equal an increase of roughly 10 minutes or ½ mile of walking every four weeks to total an increase of 40 minutes of exercise in the intervention arm over the course of the study. Regardless of the total amount of exercise, higher activity levels are related to improved health outcomes. Overall, findings from this study support the utility of targeting OEs to increase exercise among breast cancer survivors.

PSYCHOLOGICAL AND ENVIRONMENTAL INFLUENCES ON LEVELS OF PHYSICAL ACTIVITY IN WOMEN OVER 40

Christina E. Nikitopoulos, Ed.M., Ivy K. Ho, PhD

University of Massachusetts Lowell, Lowell, MA

Participation in physical activity provides long-term health benefits by improving physical and mental health. Although women over 40 would benefit the most from physical activity, they encounter the most barriers and, as a result, are the least physically active. The present study examined psychological and environmental predictors of physical activity among a group of 10,900 women over the age of 40 from the 2015 National Health Interview Survey (NHIS).

The study hypothesized that psychological well-being and connection to one's neighborhood (environment) would positively predict engagement in physical activity. The psychological well-being scale aggregates reversely coded questions regarding participants' feelings of negative psychological well-being prior to the survey. Neighborhood connection is measured as a composite scale of connection and support to one's neighborhood. Regression models examined how each predictor was associated with 3 types of physical activity: light/moderate, vigorous, and strength. Demographic measures (age, race and marital status) were added as control variables.

For light/moderate activity, a one-unit increase in psychological well-being and in neighborhood connection predicted a 2.01% increase and a 3.35% increase in participation, respectively ($p < .001$). Widowed women are expected to participate in light/moderate exercise 11.68% less ($p < .01$) than women who are married. Black/African-American women are expected to exercise 20.5% ($p < .001$) less than White women.

For vigorous activity, a one-unit increase in psychological well-being and in neighborhood connection predicted a 6.43% increase and a 5.89% increase in participation, respectively ($p < .001$). Widowed women are expected to participate in vigorous activity 16.08% ($p < .05$) less than women who were married.

For strength activity, a one-unit increase in psychological well-being and in neighborhood connection predicted a 3.45% increase and a 5.51% increase in participation, respectively ($p < .001$).

These findings indicate that a woman's age, psychological well-being and environmental connection all significantly predict the frequency of physical activity that she participates in.

SELF-EFFICACY PREDICTS ADHERENCE TO THE FITBIT ZIP IN ETHNICALLY DIVERSE MIDDLE SCHOOL AGE GIRLS

Mary Kate Clennan, M.S., Daniella Carucci, M.S., Patrice G. Saab, Ph.D.

University of Miami, Coral Gables, FL

Introduction: Consistent with Social Cognitive Theory, studies shows that higher levels of self-efficacy are related to moderate to vigorous physical activity in children. The current study extends this research by investigating whether self-efficacy also influences adherence to monitoring physical activity with an activity-tracking device, the Fitbit Zip.

Methods: 314 middle school age ($M = 11.7$ years, $SD = .84$) girls of diverse ethnic backgrounds who completed a 3-week summer health promotion program that emphasized the importance of a healthy lifestyle served as participants. The girls received a Fitbit Zip on the 3rd day of the program and were instructed to wear it all day, every day, including weekends for a total of 17 days. On the days the Fitbit Zip was not worn or not worn for the entire day (e.g., worn for 2 hours), the distance was coded as missing/incomplete as neither was representative. Thus, in this study, adherence was quantified as the percentage of days without missing/incomplete data. Physical activity self-efficacy and covariates were assessed by self-report questionnaires at baseline.

Results: On average, girls were adherent 13.3 days (78.2% adherence rate). Girls had lower adherence on weekends, compared to program days ($t(313) = 19.45$, $p < .001$). A multiple regression model was tested, controlling for program variables, age, self-reported physical activity, maternal education, body mass index, parent marital status, ethnicity, and baseline health knowledge. Results suggest that baseline physical activity self-efficacy ($M = 10.3$, $SD = 2.5$) and covariates accounted for significant variability in Fitbit Zip adherence, adjusted $R^2 = .294$, $F(17, 281) = 8.30$, $p < .001$. Findings indicate that, controlling for covariates, baseline physical activity self-efficacy significantly predicted Fitbit Zip adherence. For every one-point increase in baseline physical activity self-efficacy, miss- ingness decreased by .28 days, 95% CI [-.43, -.13].

Conclusion: Girls with higher baseline self-efficacy were more adherent to wearing their Fitbit Zip. These findings suggest it may be of value to introduce a brief intervention to increase self-efficacy before providing participants with an activity-tracking device in a health promotion program. It is critical to ensure children are adherent to activity-tracking devices as research shows that increased usage of an activity-tracking device is related to higher levels of physical activity in children.

SELF-ESTEEM MEDIATES THE RELATION BETWEEN PHYSICAL ACTIVITY AND ANXIETY IN YOUNG ADULT MALES

Elisabeth O'Rourke, MA, Alexis Lima, BA, Joseph Bettcher, MA, Atara Siegel, BA, Anna Yeo, MA, Leslie Halpern, PhD

University at Albany, Albany, NY

Introduction. Research has shown that exercise has many physical and mental health related benefits. Increased anaerobic and aerobic exercise can improve mood, decrease symptoms of anxiety, and increase overall self-esteem (SE). However, why physically active individuals report lower anxiety than those who are inactive is not well understood. This study tested a model to determine whether SE mediates the relation between exercise and symptoms of anxiety.

Method. The participants were 137 undergraduate students at a medium-sized university, [$M(\text{age}) = 19.12$, $N(\text{males}) = 72$]. The sample was ethnically diverse, with 35% White. Participants completed the following self-report measures: a demographics survey, the State-Trait Inventory for Cognitive and Somatic Anxiety (STICSA), the Rosenberg Self-Esteem Scale, and a brief self-report of exercise behavior, including number of days and hours spent exercising per week.

Results. Males ($M = 6.99$, $SD = 6.56$) reported exercising more hours/week than females ($M = 4.63$, $SD = 3.88$; $t(134) = 2.53$, $p < .05$). Correlation analyses were run separately by gender. Higher SE was correlated with less anxiety for both females ($r(64) = -.64$, $p < .01$) and males, ($r(72) = -.53$, $p < .001$, respectively). However, for females neither the number of days nor the number of hours/week exercising was related to SE, although a trend ($p < .10$) was found such that spending more days exercising was negatively associated with SE. Conversely, for males both the number of days/week and hours/week spent exercising was correlated with higher SE ($r(72) = .35$, $p < .01$; $r(72) = .29$, $p < .05$, respectively).

This mediation analysis could not be run for females due to lack of significant associations amongst the variables. For males, the regression of number of hours of exercise on anxiety, ignoring the mediator, was significant, $b = -.29$, $t(72) = -2.66$, $p < .01$. The regression of number hours of exercise on the mediator, SE, was also significant, $b = .23$, $t(72) = 2.53$, $p < .05$. The mediator (SE), controlling for hours of exercise, was significant, $b = -.58$, $t(72) = -4.62$, $p < .001$. Controlling for the mediator (SE), hours of exercise was not a significant predictor of anxiety, $b = -.15$, $t(72) = -1.55$, $p = .12$. A Sobel test found that SE fully mediated the relationship between hours of exercise and anxiety ($z = -2.18$, $p = .03$). This model did not hold for number of days/week of exercise.

Discussion. These findings provide initial support for physical activity (PA) reducing anxiety in young men by positive influences on SE. The trend finding that females who engage in more PA actually reported decreased SE may indicate that females engage in PA as a method of coping, which is worth investigating further. It is interesting that there were no associations between PA and anxiety for females. Further investigation is needed to examine the gender difference and how to use this information for improving mental health in college students.

THE EFFECT OF EXERCISE AND WELLNESS INTERVENTIONS ON PREVENTING POSTPARTUM DEPRESSION AND STRESS: THE HEALTHY MOM II TRIAL

Beth Lewis, PhD¹, Katie Schuver, PhD², Shira Dunsiger, PhD³, Carrie Terrell, MD, FACOG¹, Joseph Ciccolo, PhD⁴, Melissa Avery, PhD, APRN, CNM, FAC-NM, FAAN¹

¹University of Minnesota, Minneapolis, MN; ²University of Minnesota, Minneapolis, MN; ³The Miriam Hospital/Brown University, Portsmouth, RI; ⁴Teachers College, Columbia University, New York, NY

Approximately 10–15% of postpartum women and one-third of women who have a history of depression prior to pregnancy report postpartum depression. There is a need for low cost interventions designed to prevent postpartum depression among women at risk. The purpose of this study was to examine the efficacy of exercise and wellness interventions on preventing postpartum depression and perceived stress. Low active participants ($n = 450$) who were less than 8 weeks postpartum and had a history of depression prior to pregnancy were recruited via print, online, and email advertisements. Participants were randomly assigned to one of three groups: (1) 6-month telephone-based exercise intervention (based on self-determination and social cognitive theories); (2) 6-month telephone-based wellness/support intervention (e.g., healthy eating, sleep, and stress); or (3) usual care. Participants were 30.7 years of age on average and a majority completed at least some college (93%), were married (75%), reported an annual income above \$50k (56%), and were currently employed (68%). The sample was predominantly Caucasian (73%) with 20% identifying as Hispanic. Results indicated significant between-group differences for baseline age ($p = .01$) and depressive symptoms ($p = .03$) and therefore, these variables were included as covariates in subsequent models. Using generalized estimating equations (for binary depression outcome) and quantile regression (for continuous primary and secondary outcomes), potential between group differences for the outcome variables were examined. Analyses were conducted on the intent to treat sample, with all randomized participants included in the analysis. Overall, 2.4% of participants were depressed (based on the Structured Clinical Interview for DSM-IV Axis I Disorders; SCID-I) at 6 months and 3.6% at 9 months with no significant differences between groups. At 6 months, median depressive symptoms (based on the Edinburgh Postnatal Depression Scale) were significantly lower among wellness participants compared to usual care ($b = -1.00$, $SE = 0.46$, $p = .03$). There were no differences between exercise and usual care and exercise and wellness at 6 or 9 months. Regarding stress, the median perceived stress score at 6 months was significantly lower among exercise vs. usual care participants ($b = -2.00$, $SE = .98$, $p = .04$) and exercise vs. wellness ($b = -2.20$, $SE = 1.11$, $p = .04$) with no differences at 9 months. The wellness intervention was efficacious for preventing depressive symptoms relative to the usual care condition; however, depression was surprisingly low in all three conditions among this at risk sample of postpartum women. Exercise may have protective effect on perceived stress levels among women at risk for postpartum depression. Additional research is needed to better understand the effect of exercise on preventing both postpartum depression and stress.

THE LONGITUDINAL EFFECTS OF SOCIAL CUES' INFLUENCE ON THE RELATIONSHIP BETWEEN GOAL-SETTING AND EXERCISE PERFORMANCE

Charles Heidrick, M.S., Ashlie Johnson, B.S., B.A., Daniel Graham, Ph.D
Colorado State University, Fort Collins, CO

Building on research conducted by Heidrick and Graham (2017), the present study tested the longitudinal impact of affirmation of one's exercise goals. Heidrick and Graham (2017) reported short-term effects of social factors including feedback type, feedback presentation (human versus electronic), and social norms on exercise-related goal-setting and performance during a single exercise session. Their research demonstrated that young adults receiving affirmation from an experimenter for their stated exercise goals were more likely to achieve or exceed those stated goals compared with young adults receiving no acknowledgment. Further exploration revealed that this performance-enhancing effect of affirmation is likely attributable to the social portion of the feedback interaction, rather than the content of the affirmation message, as these enhancing effects were not witnessed when feedback was provided by a computer. The present study sought to explore the long-term effects of affirmative feedback vs. no feedback in a setting in which young adults performed the same structured exercises during two experimental sessions spaced one week apart. Seventy-one undergraduate students were recruited to participate in a randomized controlled longitudinal experiment. A researcher demonstrated four exercises (pushups, planks, jumping jacks, and single-leg balancing), after which participants set personal goals regarding their own intended performance of these exercises. Participants were randomly assigned to one of two conditions that determined their goal-related feedback from the experimenter during the first session: 1) Goal Affirmation in which the researcher looked over the participant's goals, nodded in approval, and said, "great;" or 2) Unacknowledged Goals in which the researcher placed the participant's goals face-down on a desk immediately upon receipt from the participant and the experiment proceeded. During the second session, the participants again recorded goals and completed the same four exercises; there were no differences between the conditions during session two. Results showed between-group differences in performance change between sessions; those in the Affirmation Condition improved their plank times by 6.1% ($M = 4.38$ seconds), relative to 4.3% in the Unacknowledged Condition ($M = 3.10$ seconds). A similar effect was seen for balancing (8.46 & 5.27 seconds, respectively). These effects were approaching significance for both planks ($p = .094$) and leg-balancing ($p = .109$). These results indicate that the performance-enhancing benefits of very brief affirmative feedback on exercise goals can persist into subsequent exercise sessions.

THE WEIGH AFRICAN AMERICANS MOVE: AN ANALYSIS OF THE ASSOCIATIONS BETWEEN BODY IMAGE, STAGES OF CHANGE, AND PHYSICAL ACTIVITY.

Hannah T. Jones, N/A¹, Scherezade K. Mama, DrPH², Lorna McNeill, PhD, MPH³

¹The Pennsylvania State University, State College, PA; ²The Pennsylvania State University, University Park, PA; ³UT Texas MD Anderson Cancer Center, Houston, TX

This study explored the associations between body image, exercise and weight stages of change, and physical activity (PA) in African American men and women. African American adults ($N=204$) completed anthropometric measurements and questionnaires on body image (perceived and desired), exercise and weight stages of change (SOC), and moderate-vigorous PA (MVPA). Perceived minus measured body image scores were categorized as inaccurate or accurate, and desired minus perceived body image scores were categorized as dissatisfied or satisfied. Adjusted linear regression models were used to explore associations among body image accuracy and satisfaction, SOC for exercise and weight loss, and MVPA. Most (74.0%) participants were women (M age=48.1 years, $SD=14.8$) and obese (M BMI=31.7 kg/m², $SD=7.8$). Nearly half (43.1%) of participants had completed a bachelor's degree or more, and 41.9% reported an annual household income greater than \$80,000. Over half (53.8%) of participants reported meeting PA recommendations of ≥ 150 minutes of MVPA/week. On average, participants perceived themselves as overweight (M perceived BMI=27.7 kg/m², $SD=5.8$) and desired to be normal weight (M desired BMI=24.0 kg/m², $SD=3.9$). Most (81.8%) participants perceived their body shape and size accurately, and 71.1% were satisfied with their body image. Despite over 50% of participants reporting meeting PA recommendations, nearly half (41.2%) reported being in the preparation SOC for exercise, and only 17.2% and 25.5% reported actively engaging in regular PA or maintaining a regular exercise routine. Conversely, 70.5% of participants reported being in the action or maintenance SOC for weight loss. A greater proportion of those who perceived their body shape and size inaccurately reported being in the precontemplation (29.7%) SOC for weight loss than those who perceived their body image accurately (15.1%; $\chi^2=8.060$, $p=.045$). Linear regression models revealed a significant association between perceived BMI and MVPA after controlling for gender and SOC for weight loss ($b=-.197$, $t=-2.866$, $p=.005$). Results suggest that the relationship between perceived body image and PA is influenced by weight loss SOC but not exercise SOC. Health promotion efforts are needed to reduce inaccurate perceptions of body shape and size in an effort to increase PA among African American adults.

USING DIRECT OBSERVATION TO DETERMINE CHILDREN'S PHYSICAL ACTIVITY LEVELS IN VARIOUS OUTDOOR PLAY AREAS

Shane Warehime, M.S.¹, Kailey Snyder, MS², Tyler Patterson, BS¹, Miriam Kuhn, PhD¹, Debora Wisneski, PhD¹, Danae Dinkel, PhD³¹University of Nebraska at Omaha, Omaha, NE; ²University of Nebraska Omaha School of Health & Kinesiology, Omaha, NE; ³University of Nebraska Omaha School of Health & Kinesiology, Omaha, NE

Outdoor play areas provide key opportunities for children to be physically active, learn new skills, and interact with peers. These opportunities increase children's health and facilitate development in a way that may lead to long-lasting, healthy behaviors. Even though outdoor play areas play an important role in children's health and development, little is known about how young children (< 36 months) interact with different outdoor play areas. Thus, the present study investigated children's time spent in various outdoor play areas and the physical activity (PA) level in each area. Children ($n = 52$) ages 0–36 months were observed at two childcare centers in a Midwestern city. Observation data was gathered in 15–30 minute increments over a five day period. A modified version of the Observational System for Recording Activity in Children – Preschool Version (OSRAC-P) was used to code and analyze children's location and PA levels. Locations included open areas without equipment (e.g., grass or turf play areas), areas that promoted gross motor development (e.g., large, metal playground; swing sets), and areas that promoted fine motor development (e.g., sandbox; small, plastic playground). PA levels included stationary, stationary with limb, slow-easy, moderate, or fast movement. A one-way ANOVA was conducted to determine differences in activity levels between play areas. Across all locations, children most frequently participated in slow-easy movement (35.1%). In regard to location context, children spent the majority of the time in open areas (54.3%) compared to fine motor (30.9%) and gross motor (14.8%). There was a significant difference in PA level based on location ($p < .05$), but contradict findings of a study examining indoor play in childcare centers (< 3 years old). Additional research is needed to explore the relationship between various types of play areas and PA levels of young children.

USING ECOLOGICAL MOMENTARY ASSESSMENT TO UNDERSTAND DIFFERENCES IN ASSOCIATIONS OF EXERCISE TIME AND PSYCHOLOGICAL STRESS

Amanda L. Rebar, PhD¹, Ben Jackson, PhD², Kristie-Lee Alfrey, N/A¹, Benjamin Gardner, PhD³, Corneel Vandelanotte, PhD¹, James Dimmock, PhD²¹Central Queensland University, Rockhampton, Queensland, Australia; ²University of Western Australia, Crawley, Western Australia, Australia; ³King's College London, London, England, United Kingdom

Psychological stress puts people at risk for acute health problems (e.g., headaches, influenza), chronic illnesses (e.g., heart disease), and all-cause mortality. Evidence suggests daily exercise may help reduce stress; however, some people may benefit more from exercise than others. For example, Fly-in, Fly-out (FIFO) workers, who commute long distances to work and stay on-site for consecutive days/weeks experience different daily stressors (e.g., long-work hours, fatigue) from their partners at home (e.g., loneliness, additional childcare and domestic responsibilities), and from university students (e.g., studying, financial strains). The aim of our study was to determine if the daily exercise-stress association differs between these groups.

We conducted an ecological momentary assessment study across three cohorts: university students ($n = 103$, 52% female, age: $M=22$, $SD=3$), FIFO workers ($n = 64$, 80% male, age: $M=40$, $SD=10$), and partners of FIFO workers ($n = 42$, 100% female, age: $M=39$, $SD=9$). Participants self-reported their psychological stress, time spent exercising, and time spent in work at the end of the day for up to 7 consecutive days. Multilevel modelling was conducted to test whether there were group differences in the between- and within-person associations of daily psychological stress and exercise after accounting for time spent working.

There were significant cohort differences in the association between exercise and stress at the daily level ($\gamma = -0.22$ & -0.17 , $p's < .05$). For university students, stress was highest on days when they exercised *more* than usual ($\omega = 0.11$, $p = .03$). For FIFO workers, there was no association between stress and daily exercise ($\omega = -0.06$, $p = .21$), and for FIFO partners, stress was highest on days when they exercised *less* than usual ($\omega = -0.12$, $p < .01$).

The association between exercise and stress varies, both in magnitude and direction, depending on people's daily life contexts. Further intervention work is needed to tease a part causality of this finding, but this evidence highlights the need for consideration of people's daily stressors when promoting exercise as a means for reducing psychological stress.

WHAT ARE THE COST IMPLICATIONS OF PHYSICAL ACTIVITY PROGRAMS FOR RURAL CANCER SURVIVORS?

Whitney Smith, BS¹, Maria Pisu, PhD², Michelle Martin, PhD³, Haiyan Qu, PhD, MSHA², Robert A. Oster, PhD², Richard Shewchuk, PhD⁴, Laura Q. Rogers, MD, MPH²

¹University of South Alabama College of Medicine, Mobile, AL; ²University of Alabama at Birmingham, Birmingham, AL; ³University of Tennessee Health Science Center, Memphis, TN; ⁴University of Alabama Birmingham, Birmingham, AL

Background: Cancer survivors (CS) who exercise have better overall health and lower healthcare costs than their sedentary peers. Yet the time commitment and expense of exercise may offset these savings and cause CS to forgo exercise. In this study, we evaluate costs/expenses reported by rural CS participating in a 3-month exercise intervention (Better Exercise Adherence after Treatment for Cancer [BEAT Cancer]) that begins with supervised exercise sessions and transitions to independent exercise.

Methods: 15 female CS (post-primary cancer treatment) participating in BEAT Cancer at a rural community cancer center self-reported pre- and post-intervention frequency and average exercise duration, exercise-related travel distance and cost, exercise accessory costs, and healthcare visits and costs. Wilcoxon Signed-Rank and McNemar's tests compared pre- and post-intervention responses.

Findings: Participant mean age was 58 ± 12 years. Half (53%) were White and 47% were African-American; annual household income was $\leq \$20,000$ for 36%, $\$20,000 - \$50,000$ for 28%, and $\geq \$50,000$ for 36%. Most (66%) had breast cancer; 25% had Stage 0 - I, 58% Stage II, and 17% Stage III, 86% received surgery, 73% chemotherapy, and 67% radiation. Weekly minutes of moderate to high intensity exercise significantly increased from pre-intervention (median = 0) to post-intervention (median = 150, $p = 0.008$). A non-significant increase in monthly exercise expenses (e.g., gym fees, equipment costs, and miscellaneous exercise items) occurred from pre-intervention (median = \$0) to post-intervention (median = \$50, $p = 0.286$). The percent exercising at a gym (33% vs. 67%, $p = 0.031$) and travel miles per week dedicated to exercise significantly increased from pre- to post-intervention. A statistically significant decline in monthly self-reported physician visits occurred pre- to post-intervention (median = 3 vs. 1, $p = 0.016$) with a trend toward a decrease in monthly prescription costs from pre- to post-intervention (median = 24 vs. 20, $p = 0.099$). No significant difference in number of hospital visits was found.

Conclusions: Results suggest that in rural CS an increase in costs due to travel miles and gym attendance when participating in a facility-based exercise program may be offset by declines in healthcare expenses. Further research should examine these findings in larger studies to better understand the cost implications of such programs for survivors.

RACISM AS AN ADVERSE CHILDHOOD EXPERIENCE [ACE]: IMPLICATIONS AND FUTURE DIRECTIONS

Pamela Behrman, PhD

College of Mt. St. Vincent, New Britain, CT

According to the Southern Policy Law Center [SPLC] (2017), there are 917 active hate groups in the United States, a trend that appears to be increasing. This includes 130 KKK groups, 100 white nationalist groups, 193 Black separatist groups, 101 anti-Muslim groups, and 99 Neo-Nazi groups (SPLC, 2017). The SPLC notes that during the first ten days following the November 2016 American presidential elections, there were 867 reported bias-related incidents, including more than 300 that targeted Muslims or immigrants (Potok, 2017; SPLC, 2017). The majority of these reported incidents occurred on college campuses or in K-12 schools (Potok, 2017).

What is "racism"? How does it impact on the physical and mental health of developing children and adults? Is racism an "ACE"—an "Adverse Childhood Experience"? What are the long-term consequences of childhood exposure to racism? Are the effects intergenerational? Should race-based stress items be included in ACEs and other health-based psychosocial screenings? If yes, what are the possible consequences?

Using an ecobiodevelopmental framework (Shonkoff & Garner, 2012), and literature on ACEs, historical trauma, and epigenetics, the authors explore these topics in the context of childhood exposure to racism and discrimination. It is purported that the toxic stress of childhood exposure to racism can amplify the effects of other forms of potentially traumatic stressors, resulting in the increased likelihood of long-term and even intergenerational trauma transmission. Implications for screening for race-based stress are discussed in the context of health promotion and illness prevention.

CFS ABSTRACT 2018

Cody L. Boland, B.S.¹, Sara F. Milrad, M.S.¹, Daniel Hall, PhD², Devika R. Jugagir, PhD³, Emily Lattie, PhD⁴, Sara Czaja, PhD⁵, Dolores Perdomo, Ph.D.¹, Mary Ann Fletcher, Ph.D.⁶, Nancy Klimas, MD⁷, Michael H. Antoni, PhD⁸

¹University of Miami, Miami, FL; ²Massachusetts General Hospital Department of Psychiatry, Boston, MA; ³University of Miami Department of Psychology, Coral Gables, FL; ⁴Northwestern University, Chicago, IL; ⁵University of Miami Miller School of Medicine, Miami, FL; ⁶Nova Southeastern University, Miami, FL; ⁷Nova Southeastern University, Miami VA MedicalCenter, Miami, FL; ⁸University of Miami, Coral Gables, FL

Introduction: Symptoms such as persistent fatigue, pain and depression are highly prevalent among individuals diagnosed with Chronic Fatigue Syndrome (CFS). Previous research has shown that, compared to non-Hispanic whites (NHW), ethnic minorities diagnosed with CFS may experience more severe symptoms. As depression has been linked to somatic symptoms in chronic illnesses, the purpose of this study was to assess the associations between NHW and Hispanic (H) ethnic groups, depressive symptomatology, and the frequency, severity, and intensity of CFS-related symptoms.

Methods: Cross-sectional data were obtained from 116 ethnically diverse (NHW: n=81; H, n=35) individuals with a CFS diagnosis. All participants completed the Center for Epidemiologic Studies Depression Scale (CES-D), the CDC Symptom Inventory for CFS (CDC-CFS), and the Fatigue Symptom Inventory (FSI) as part of a longitudinal study investigating the efficacy of a remotely-delivered cognitive behavioral stress management intervention. Separate ANCOVAs explored the relationship between ethnicity, CES-D scores, and CFS-related symptomatology (via CDC-CFS and FSI) after accounting for covariates.

Results: Analyses revealed that, although there were no differences in reported CFS symptoms between ethnic groups alone, there was a significant ethnicity by CES-D score interaction with respect to multiple measures of CFS symptomatology. This suggests that there is a stronger positive relationship between depressive symptoms and CFS symptomatology among H individuals than among NHW individuals. This interaction was associated with both the symptom frequency subscale ($p < .05$) and symptom severity subscale ($p < .05$) of the CDC-CFS as well as the intensity of fatigue subscale ($p < .05$) of the FSI. No association was found in the fatigue interference subscale of the FSI. CES-D scores did not differ by ethnic group.

Discussion: Study findings demonstrate the potential differences in the impact of depression on symptom burden between NHW and H patients with CFS. With tailored interventions gaining popularity, these findings highlight a potential avenue for targeting symptom burden in specific ethnic minority groups. Further research is needed to evaluate the mechanisms behind these interactions.

RACIAL DIFFERENCES ON MMPI-2-RF PROFILES AMONG VETERANS PARTICIPATING IN A CHRONIC PAIN REHABILITATION PROGRAM

Savannah LeBarre, Psy.D.¹, Aaron M. Martin, Ph.D.¹, Melissa Echevaria Baez, Psy.D.¹, Evangelia Banou, Ph.D.¹, Stephanie N. Miller, Ph.D.²¹James A Haley VA, Tampa, FL; ²James A. Haley VA Hospital, Tampa, FL

Chronic pain (CP) affects over 50% of U.S. Veterans, contributing to significant disability and reduced quality of life. Race related health disparities require further consideration within pain management, as pain varies by race, and racial minorities may differ in terms of their appraisal of CP. Pain appraisals are informed by psychological factors that arise from lived experiences. Understanding these underpinnings, including characterological make-up and adjustment, may serve to identify treatment targets that vary by race. The Minnesota Multiphasic Personality Inventory-2 Restructured Form (MMPI-2-RF) is an objective psychological test that assesses personality and psychopathology. On the MMPI instruments, CP is generally associated with elevations on scales measuring somatic complaints, emotional dysfunction, and interpersonal dysfunction. Racial minorities have produced mean scale score differences across several scales including those reflecting somatic concerns, suspiciousness, eccentric behaviors, excessive energy, impulsivity, cynicism, aberrant experiences, and persecutory ideation. Such differences have not been explored using the MMPI-2-RF. Given the high prevalence of CP, we attempt to address this knowledge gap in the Veteran population. We hypothesized that race would be associated with CP, such that non-whites report higher pain. Additionally, we hypothesized that there would be racial differences on the MMPI-2-RF scales and that these differences would exist after controlling for pain and relevant co-variables including gender and pain. Admission data was gathered from Veterans in a 19-day, inpatient Chronic Pain Rehabilitation Program. Of the 253 participants, 151 identified as White, 63 African American/Black, 22 Hispanic/Latino, and 17 as other. In addition to the MMPI-2-RF, the Pain Outcomes Questionnaire was administered. Race was correlated with various measures of thought dysfunction, education, marital status, insomnia, duration of pain, and pain. Regression models controlling for gender and pain found race significantly related to thought dysfunction, ideas of persecution, raw aberrant experiences, multiple specific fears, psychoticism, and disconstraint. Clinical implications, limitations, and recommendations for future research will be discussed.

THE LIVED EXPERIENCE OF AFRICAN-AMERICAN INFORMAL CAREGIVERS OF FAMILY MEMBERS WITH ALZHEIMER'S DISEASE AND RELATED DEMENTIAS

Dell Mars, PhD, RN

Southeastern Louisiana University, Baton Rouge, LA

The purpose of this qualitative study was to describe the lived experience of African American informal caregivers of family members of Alzheimer's Disease and Related Dementias (ADRD) in a home environment. Using a qualitative, phenomenological approach, a purposive sample of 16 African American informal caregivers completed a 30 to 60-minute in-depth interview. Four themes emerged: sense of obligation, arduous journey, sentinel events, and faith in God. Findings indicated that by acknowledging and supporting the voices of caregivers of family members with ADRD, collaboration with healthcare teams could provide the informal caregiver with knowledge, social support, and the anticipatory guidance needed for coping with the unique challenges of caring for a family member with ADRD. Family assessment of the caregiving situation can lead to positive outcomes for the caregiver and care recipient.

VALIDATION OF A COOKING HABIT SURVEY IN AFRICAN-AMERICANS USING A COGNITIVE INTERVIEW FOCUS GROUP

Nicole Farmer, MD¹, Tiffany Powell-Wiley, MD, MPH², Kimberly Middleton, RN, MPH, MS³, Valerie Mitchell, BA⁴, Gwendolyn Wallen, RN, PhD¹¹Clinical Center/National Institutes of Health, Bethesda, MD; ²Cardiovascular Pulmonary Branch, National Heart Lung and Blood Institute/National Institutes of Health, Bethesda, MD; ³Clinical Center/National Institutes of Health, Bethesda, MD; ⁴Cardiovascular Pulmonary Branch, National Heart Lung and Blood Institute/National Institutes of Health, Bethesda, MD

Background/Purpose: Habitual cooking of healthy meals is crucial in sustaining healthy eating behaviors and preventing diet related chronic disease. African Americans reportedly cook dinner at home 4.4 times per week based on national survey data, which is lower than the overall population average of 5. Cultural or psychosocial factors may cause this disparity; however cooking survey data which would help identify barriers is limited. The purpose of this study was to utilize a cognitive interview (CI) focus group to determine content validity and cultural conversion of survey questions designed to identify motivators, barriers, and psychosocial influences on cooking habits.

Methods: Data were collected using a CI focus group with participants recruited from a faith-based community based participatory research (CBPR) study. The survey consisted of previously validated questions from other community studies. After individual survey completion, a 90-minute moderator-led focus group was conducted using group-based think aloud CI techniques. Audiotapes of the focus group were transcribed verbatim.

Results: Participants (n=11) ranged in age from 51 to 77, 30% had an annual income <\$70,000, and 54.5% were college graduates. The average frequency of cooking dinner at home was 3.3 times per week. Strategies suggested to improve the survey were 1) changing the culinary term 'knife skills' to 'chopping', as most participants did not relate to the term, 2) adding 'grandmother' and 'home economics' as sources of cooking skills development, and 3) inclusion of the term 'organic' for health food options. Participants discussed barriers to affording to eat balanced, healthy meals and how health consciousness can impact food security. Lastly, the focus group participants shared information regarding affordable healthy food sources in their community.

Conclusion: Preliminary findings from this sample suggest using CI focus group in validating surveys related to cooking habits in African-Americans. This approach allowed for development of community fostered conversations regarding cultural contributors to cooking habits. In addition, community shared resource learning can occur in the CI focus group setting which helps to promote ideas for intervention development and is the foundation of CBPR. Our survey findings were to omit culinary terms, inquire about non-parental cooking influencers, and address food security concerns in the context of health consciousness.

DIGITAL STRATEGIES TO PROMOTE ADVOCACY FOR DISPARITIES IN MENTAL HEALTH AND CHILDHOOD OBESITY AMONG LATINO CHILDREN

Rosalie Aguilar, M.S.¹, Kip Gallion, M.A.², Amanda Merck, MPH³¹Salud America!-UT Health San Antonio, San Antonio, TX; ²UT Health Science Center at San Antonio, San Antonio, TX; ³Salud America, San Antonio, TX

Latino children comprise nearly 1 in 4 of the U.S. youth population, yet disparities in obesity are widespread and use of mental health care services among this group remain low. According to a recent research review conducted by *Salud America!*, 22% of Latino kids face depressive symptoms--a rate higher than all other groups other than Native Americans. High rates of depression in this population may be the result of factors such as bullying, discrimination, poverty and additional community and family related stressors that can have detrimental effects on a Latino child's health. With 38% of Latino youth either overweight or obese, vs. 29% of non-Latino whites, Latino kids also face the risk of developing chronic illnesses such as type II diabetes.

While several interventions and public health campaigns continue to focus on individual behavioral change there is growing consensus about the need for public policy and campaigns aimed at reducing disparities. Emerging strategies to raise awareness of such disparities and policy solutions include the use of digital content curation, social media, petition campaigns and digital toolkits to spark action and change. In response to this growing demand, *Salud America!* developed a comprehensive, culturally and ethnically relevant digital campaign called #SaludWater. The campaign included a social media guide to share with partner organizations, an online petition aimed at getting hydration stations for schools, and an action toolkit available upon request to school advocates.

The campaign produced a total of 40,115 digital signatures in support of hydration stations, and garnered support from over 40 partners across the U.S. The hashtag #Salud Water was used 947 and produced 26,737 video views, 6.3 million social impressions and a reach of 1.4 million. Digital ads ranged from \$0.38-\$1.00 per click and on average contributed to 87.9% of reach for paid ads. *Salud America!* content curators followed up with 28 advocates who requested a personalized #SaludWater toolkit via email and continue to work with wellness coordinators to get hydration stations and update district wide policy to support hydration for Latino youth. A similar toolkit aimed at increasing access to mental health care services and promoting social and emotional learning is currently in development and a similar strategy to promote healthy minds will be used for the upcoming campaign.

DISCLOSURE OF SEXUAL ORIENTATION TO HEALTHCARE PROVIDERS: THE IMPORTANCE OF SEXUAL AND ETHNORACIAL IDENTITIES

Christopher W. Wheldon, PhD

National Cancer Institute, Bethesda, MD

Objectives. High-quality medical care for sexual minorities is contingent upon disclosure of sexual orientation to health care providers (HCP). Using an intersectionality framework, we assessed the degree to which sexual and ethnoracial identities are associated with disclosure among male sexual minorities.

Methods. Gay/bisexual men 18+ years who resided in the United States, Canada, or the United Kingdom were recruited via social media in 2015 (N=1,340). They completed a web-based survey that included the following outcome measures: (1) Ever disclosed sexual orientation to HCP (binary), (2) feel uncomfortable disclosing, (3) believe sexual orientation is not medically relevant, (4) received lower quality care because of sexual orientation (outcomes 2–4 are 5-point Likert scales). Linear (Beta coefficients [B]) and logistic regression (Odds ratios[OR]) were used to assess association by bisexual (vs. gay) and ethnoracial identities (Latino & black men). Alpha was set at p

Results. 61% of men had disclosed to a HCP. Bisexual men (vs. gay men) were less likely to disclose (OR=.36); whereas, black men more likely (OR=1.68). This association was attenuated after controlling for HIV-status. On average, men were *not* uncomfortable disclosing (M=2.9;SD=1.4); however, bisexual (B=.38) and Latino (B=.26) men were more uncomfortable. Relatedly, bisexuals (B=.41) believed more strongly that sexual orientation was *not* medically relevant as did Latino (B=.20) and black men (B=.22). Furthermore, black bisexual men believed this to a greater degree (B=.38). Sexual and ethnoracial identity was not associated with perceived lower quality care. Men who had previously disclosed were on average less likely to believe they've received poorer quality care because of their sexual orientation (B=-.39).

Conclusions. Bisexual and ethnoracial minorities may experience additional barriers to disclosure as multiple minority identities may carry added stigma around issues of sexuality.

ETHNIC GROUP DIFFERENCES IN FRAMINGHAM RISK SCORES

Claire T. Ing, DrPH¹, Joseph Kaholokula, PhD¹, Hyeong Jun Ahn, PhD¹, Andrew Grandinetti, PhD²

¹John A Burns School of Medicine/University of Hawaii, Honolulu, HI; ²Myron B. Thompson School of Social Work/University of Hawaii, Honolulu, HI

Cardiovascular diseases (CVD) are the leading causes of death in the United States. In Hawai'i, Filipinos and Native Hawaiians have the highest rates CVD related risk factors. No study to date has compared these ethnic groups CVD risk to other ethnic groups and non-Hispanic Whites. The Framingham Risk Score (FRS) is a gender-specific algorithm that predicts the 10-year CVD risk of an individual. Understanding ethnic differences in CVD risk can aid in developing targeted prevention programs. The purpose of this research is to examine differences in FRS across ethnic groups in Hawai'i, controlling for sociodemographic, biological, and psychological factors.

Kohala Multi-Ethnic Health Study included a two-hour clinical examination and interview. Clinical measurements were blood pressure, high-density lipoprotein, weight, and cholesterol. Demographic measures assessed: ethnicity, age, gender, education, marital status, and income. White, Japanese, and Filipino participants were categorized as such if they reported 100% blood quantum in their respective ethnic groups. Native Hawaiian participants were defined as those reporting any Native Hawaiian blood quantum. Center for Epidemiological Studies-Depression (CES-D) scale assessed depressive symptoms and current smoking status was assessed via self-report. FRS algorithm requires age, gender, total cholesterol, smoking status, high-density lipoprotein, systolic blood pressure, and hypertension treatment status.

Data from 1,146 individuals with no prior CVD event were analyzed. The participants had the following characteristics: 55.4% female, mean age of 48.8 yrs, 44.4% Native Hawaiian, 15.4% Filipino, 15.3% Japanese, 25% White, and 64.6% had a high school degree or less. Mean FRS scores were 12.87 for Native Hawaiian, 15.39 for Filipino, 17.01 for Japanese, and 12.94 for White. Four hierarchical regression models were run with the final model accounting for 61.7% of the variance in FRS (p)

A possible explanation for these results may be related to acculturation differences between younger and older age groups in the Japanese and Filipino populations. The older members of these two ethnic groups may have immigrated to Hawai'i for plantation work, have little formal education, and have maintained a more traditional lifestyle. Younger Filipinos and Japanese may have more formal education but have adopted a more western lifestyle (i.e., sedentary, poor diet, increased alcohol and tobacco consumption). Clinical and intervention implications of these results will be discussed.

6:15 PM-7:15 PM

ETHNIC IDENTITY PREDICTS WEIGHT MISPERCEPTION FOR EMERGING ADULTS CLASSIFIED WITH OVERWEIGHT/OBESITY

Courtney Maclin-Akinyemi, M.S., Kristina Decker, Masters Degree, Idia B. Thurston, Doctorate, Robin Hardin, M.A., Jessica Mandell, B.A.

University of Memphis, Memphis, TN

Background: While weight perception impacts engagement in health behaviors, weight misperception has been shown to be protective for individuals with overweight/obesity. Ethnic identity has also been identified as a protective factor associated with greater engagement in health promoting behaviors. Given that emerging adults have among the highest rates of overweight/obesity, the current study investigated whether ethnic identity predicts weight perception, while controlling for race, sex, and depressive symptoms.

Methods: Participants were 245 emerging adults 18-25-year-olds ($M_{age}=21.74$, $SD=2.30$; 53% White, 23% Black, 12% Hispanic, 6% Multiracial, 6% Other races; 69% female) enrolled through Amazon Mechanical Turk and a university subject pool. Body Mass Index (BMI, kg/m^2) ranged from 25.01–64.15 ($M_{BMI}=30.69$, $SD=6.15$) and was calculated using self-reported height and weight to classify individuals as overweight or obese. Respondents completed the Social Identities and Attitudes Scale (including the Ethnic Identification and Ethnic Stigma Consciousness subscales used in these analyses), Center for Epidemiologic Studies Depression Scale, and responded to the question - "How do you currently think of yourself in terms of weight?", with response options from Very Underweight to Very Overweight/Obese." Controlling for sex, race, and depressive symptoms, a multiple regression analysis was conducted to examine if ethnic identity predicted weight perception.

Results: The model was significant ($F(5, 240)=9.98$, $p<.001$, Adj. $R^2=.16$) with being female ($B=.40$, $SE=.08$, $p<.001$) and having higher depressive symptoms ($B=.01$, $SE=.003$, $p<.05$), associated with more accurate weight perception. Conversely, ethnic identification ($B=-.02$, $SE=.01$, $p<.05$) was inversely related to weight perception, such that emerging adults with stronger ethnic identification were less likely to perceive their weight accurately (i.e., they were more likely to misperceive their weight as lower than it was). Ethnic stigma consciousness and race were not significant predictors of weight perception.

Discussion: Findings suggest ethnic identity contributes to under-perceiving one's weight among emerging adults with overweight/obesity. Considering that weight misperception for individuals with overweight/obesity is protective against poor health outcomes, results highlight the potential benefits of harnessing ethnic identification in culturally-responsive health promotion interventions.

EXPLORING THE RELATIONSHIP BETWEEN RACE-RELATED STRESS AND PSYCHOLOGICAL DISTRESS AMONG COLLEGIATE BLACK MALE ATHLETES

Jessica Jackson, M.A.

New Mexico State University, Los Angeles, CA

Black male-student athletes constitute almost one quarter of the total National Collegiate Athletic Association (NCAA) student-athlete population. Yet, the *Mental Health Best Practices* (NCAA Mental Health Task Force, 2016) released by the NCAA Sport Science Institute in early 2016, did not emphasize cultural considerations for student-athlete mental wellness despite evidence that the psychological needs of Black male student-athletes differ from their White peers (Anshel and Sailes, 1990). Specifically, research has highlighted the significant amounts of stress that collegiate Black males experience as competitors at the college level (Melendez, 2008; Sadberry, 2013); simultaneously being valued as a representative of the university community and discriminated against as a member of a racial/ethnic minority (Engstrom & Sedlacek, 1991). Chronic exposure to discrimination based on race, racism, can result in a complex reaction conceptualized as race-related stress (Utsey, 1999). This study aims to explore the relationship between race-related stress and psychological distress among NCAA Division I, male student-athletes.

Current and former Division I Black male student-athletes were recruited nationally using snow-ball sampling. Participants completed online surveys. Those participating in the study ranged from 18 to 67 years with a mean age of 25.7 years ($SD=10.68$). Current student athletes accounted for 57.7% of the sample ($n=30$). Research participants reported seven different sports: football $n=24$ (46.2%), basketball $n=7$ (13.5%), baseball $n=2$ (3.8%), track & field $n=13$ (25%), soccer $n=3$ (5.8%), rowing $n=1$ (1.9%) and other $n=2$ (3.8%).

Preliminary results: 53 of the participants (98.1%) reported experiencing race-related stress; more than half of the participants reported experiencing high levels of race related stress.

- Almost a quarter of participants met the clinical threshold for depression (21.2%, $n=11$).
- Institutional and individual racism were positively associated with anxiety symptoms; the higher the number of instances of these specific types of racism the more symptoms of anxiety were endorsed.
- Somatization (distress caused by the perception of bodily dysfunction) was positively associated with the overall global index score on the index of race-related stress (includes all 3 subscales: individual, cultural and individual racism); the higher the number of experiences with racism the more physical symptoms were endorsed.

The preliminary results of this study suggest psychologists and other mental health professionals working with Black male student-athletes should consider how experiences of racism may influence mental health when diagnosing and treatment planning.

LATENT CLASSES OF DEPRESSIVE SYMPTOMS IN ASIAN AMERICANS AND LIFETIME CHRONIC MEDICAL DIAGNOSES

Jacqueline H. J. Kim, Ph.D.¹, Annette L. Stanton, Ph.D.², Donna K. Nagata, Ph.D.³

¹University of California, Los Angeles, Encino, CA; ²Department of Psychology, University of California, Los Angeles, Los Angeles, CA; ³University of Michigan, Ann Arbor, Ann Arbor, MI

Background: Asian Americans (AAs) face health disparities in medical conditions such as diabetes and specific cancers. It is important to explore AAs' depressive experiences in relation to health, as research documents the association of depression and chronic illness trajectories. To capture depressive experiences broadly, this study included physical symptomatology that is historically salient in Asians' psychological distress. The primary goal was to uncover constellations of depressive symptoms in AAs and their relationship to lifetime serious disease.

Methods: Data come from the 2002–2003 National Latino and Asian American Study (NLAAS). A subsample of 309 AAs ($M_{age} = 38.71$) reporting emotional distress from feeling sad/discouraged/loss of interest, for most of the day, for several days or longer, was selected for a latent class analysis of symptoms from the Composite International Diagnostic Interview. The associations of latent symptom classes with participant-reported medical diagnoses of heart disease ($n = 19$), diabetes ($n = 26$), and cancer ($n = 3$) were examined with logistic regressions.

Results: A 4-class solution was the best fit. Two classes were primarily psychiatric: 40% characterized by non-anhedonic DSM depressive symptoms, and 23% characterized by hopelessness and anxiety with highest probability for anhedonia, low self-confidence, and psychomotor retardation. Additional classes included both psychiatric and chronic physical symptoms: 23% with highest probability for various chronic pains and functional impairment and 14% characterized by guilt, suicidality, and non-DSM somatic symptoms (e.g., neurasthenic fatigue, GI problems). Age, gender, depression severity, and age at immigration did not predict class membership. Those in the hopelessness/anxiety class were significantly more likely to have received diagnoses of heart disease ($OR = 11.63, p = .002$) and diabetes ($OR = 7.14, p = .001$) compared to the non-anhedonic symptom class. No symptom classes were related to lifetime cancer diagnosis.

Conclusions: AAs' depressive experiences vary, with greater impairment when chronic physical symptoms co-occur. Only the hopelessness/anxiety symptom class was related to lifetime heart disease and diabetes, however. Future work should explore causal directions of these associations. The null finding for cancer perhaps results from its low rate in this sample, necessitating additional research.

OLDER LATINOS' PERCEIVED BENEFITS AND BARRIERS FOR TECHNOLOGY USAGE

Isabela G. Marques, BS¹, Brenda M. Munguia, N/A², David X. Marquez, PhD³¹University of Illinois at Chicago/CAPES Foundation, Chicago, IL; ²University of Illinois at Urbana-Champaign, Chicago, IL; ³University of Illinois at Chicago, Chicago, IL

The U.S. older adult population is growing rapidly, and technology is advancing exponentially. Older generations frequently do not stay updated with the progress in technology. Older Latinos face many difficulties with handling technology due to low income and education, and language and cultural barriers. Technology components are being increasingly used in health behavior interventions and are demonstrating promising outcomes, also among older adults. Identifying barriers, specifically in the older Latino population, will help to understand the factors that prevents this ethnic group from using electronic devices. The purpose of the study was to examine the perceived benefits and barriers of technology usage among older Latinos. Six focus groups were conducted with Latinos aged 55 and older who were cell phone owners. A survey on technology usage was administered before the discussion. Focus group questions were asked about their experience with technology and interest in learning a new technology, and perceived benefits and barriers to engaging in technology. Responses were audio recorded, transcribed verbatim in Spanish and translated to English. Directed content analysis was conducted. Twenty-seven participants comprised six focus groups, M age =68.07, 49% male (N=13). Participants reported making phone calls as the primary reason for cell phone usage (96%). Most participants reported being very interested in learning how to better navigate technology, mainly cell phones; however, a few participants were not interested at all in learning about new devices. Perceived benefits for technology usage were the convenience in searching for information; information exchange, mainly with family members, and assistance for navigation. The main barriers for technology usage were the lack of proper skills to use it, the need to be taught, and vulnerability. Results suggest that most older Latinos perceive technology as a useful tool; however, the lack of experience with it, and the need to be taught restrict older Latinos' usage of technology. Technology classes to promote regular learning could provide the knowledge, practice and confidence needed to overcome the barriers faced by older Latinos.

PERCEPTIONS OF CAREGIVING BURDEN AMONG OLDER LATINO CAREGIVERS

Guilherme Moraes Balbim, MS¹, Isabela G. Marques, BS², Melissa Magallanes, MS³, Judith S. Rocha, MSW, LCSW⁴, David X. Marquez, PhD¹¹University of Illinois at Chicago, Chicago, IL; ²University of Illinois at Chicago/CAPES Foundation, Chicago, IL; ³University of Illinois at Chicago, Lansing, IL; ⁴University of Illinois at Chicago, Jane Addams College of Social Work, Chicago, IL

A growing number of Latino caregivers are assuming the demanding role of caring for a relative with Alzheimer's disease and related dementia (ADRD). Latino caregivers spend more time caregiving than non-Latino White caregivers. As the ADRD progresses caregivers have to endure an ever-increasing burden of care and management of the care recipient. This has significant implications for caregivers' physical and mental health, and overall well-being. The purpose of this study was to describe Latino caregivers' perceptions of caregiving burden. Participants were 16 Latino caregivers (12 females and 4 males), aged 50 years and older, caring for a relative with ADRD for at least 4 hours per day at least during the past 6 months. A semi-structured interview guide was asked in English or Spanish consisting of questions about the perceptions of caregiver role and burden, social support, coping strategies, physical activity and health. For the purpose of this study responses on perceptions of burden were analyzed. Interviews were transcribed, translated, and directed content analysis was conducted. The results showed that the caregivers perceived caregiving burden as multidimensional. Eight categories of burden were identified: 1) Caregiving responsibilities, related to expected obligations as a primary caregiver on a daily basis; 2) the need to be ready to attend to the care recipient; 3) other responsibilities, in the sense that caregivers have other household, work-related or care obligations besides the caregiving role; 4) needing help and lack of support, related to the lack of extra help and the necessity of more involvement of other family members on caregiving obligations, 5) concerns about the future, with concern of their own and the care recipient's future, 6) financial difficulties, related to how the family's financial situation is affected by caregiving obligations, 7) caregiver's own health, how caregiving prevents them from engaging in appropriate disease/health management, leading to disease aggravation, and other health problems; and 8) difficulties with extreme climatic conditions, and how it affects the daily obligations, especially during the winter. It is concluded that older Latino caregivers have many sources of burden which affect their physical and mental health, and their ability to provide better care. Future studies should propose tailored interventions taking into consideration the mentioned sources of burden as external factors that can impact caregivers' health and their adherence to intervention programs.

RACE/ETHNICITY, RESILIENCE, AND SOCIAL SUPPORT AMONG OEF/OIF COMBAT VETERANS

Matthew Herbert, PhD¹, Desmond W. Leung, BS², Elizabeth Floto, MA¹, James Pittman, PhD³, Niloofar Afari, PhD⁴

¹VA San Diego Healthcare System, San Diego, CA; ²Baruch College & The Graduate Center, CUNY, New York, NY; ³VA San Diego Healthcare System, La Jolla, CA; ⁴VA San Diego Healthcare System / UC San Diego School of Medicine Department of Psychiatry, La Jolla, CA

Several studies have reported racial/ethnic differences in mental and physical health conditions among Operation Enduring Freedom (OEF) and Operation Iraqi Freedom (OIF) Veterans. Examining racial/ethnic differences in protective factors against mental and physical health conditions may help improve assessment and treatment of Veterans. The present study examined the relationship between race/ethnicity and psychological resilience, and the moderating role of social support in this relationship among non-Hispanic White ($n = 605$), Hispanic ($n = 107$), African American ($n = 141$), and Asian American ($n = 97$) OEF/OIF combat Veterans. Veterans were primarily male (88%) with a mean age of 31.4 ($SD = 8.35$). Psychological resilience significantly differed as a function of race/ethnicity, with Asian American Veterans reporting lower psychological resilience compared to non-Hispanic White Veterans ($p < .001$). There were no other racial/ethnic differences in psychological resilience. Linear regression analysis showed that the relationship between race/ethnicity and psychological resilience differed as a function of social support ($b = -0.43$, $SE = 0.17$, $p < 0.01$). Specifically, increased social support was related to increased psychological resilience among non-Hispanic White ($r = .43$, $p < .001$) and African American Veterans ($r = .23$, $p = .01$), but this relationship was not observed among Hispanic ($r = -.01$, $p = .91$) or Asian American Veterans ($r = -.03$, $p = .81$). Our results are consistent with past research showing Asian American Veterans exhibit lower psychological resilience compared to non-Hispanic White Veterans. This suggests Asian American Veterans may be particularly vulnerable to the mental and physical health conditions commonly associated with the OEF/OIF conflicts. Further, cultural differences in how and why individuals use social support may underlie the finding that the relationship between psychological resilience and social support was only found in non-Hispanic White and African American Veterans. Future qualitative and quantitative research is encouraged to better understand how social support relates to psychological resilience among minority OEF/OIF combat Veterans.

THE INFLUENCE OF SPIRITUALITY ON DEPRESSION-INDUCED NEUROINFLAMMATION IN A COMMUNITY SAMPLE OF AFRICAN AMERICANS

Olga M. Herren, MS¹, Silas E. Burris, MS², Shellie-Anne Levy, PhD³, Michael W. Lipscomb, PhD², Denee T. Mwendwa, PhD², Clive Callender, MD, FACS⁴, Alfonso Campbell, PhD²

¹Howard University, Germantown, MD; ²Howard University, Washington, DC; ³University of Florida, Gainesville, FL; ⁴Howard University Hospital, Washington, DC

African Americans (AAs) are disproportionately impacted by cerebrovascular pathology and more likely to suffer from premature cognitive decline. Depression is a risk factor for poorer cognitive functioning. Despite inconsistent rates of depression in the AAs, depressive symptoms adversely affect cognitive functioning, and research is needed to identify factors that serve to mitigate its effects on cognitive functioning. Studies have demonstrated positive influences of spirituality within the AA community. It is important to determine whether spirituality helps to attenuate the effects of depressive symptoms on cognitive functioning as well as determine the pathophysiological mechanisms that help explain these relationships. This study examines the influence of daily spiritual experiences on the relationship between depressive symptoms and cognitive functioning. Methods employed aim to examine how inflammatory markers help explain the association between depressive symptoms and cognitive functioning and whether spiritual experiences moderate this relationship. We examine if different types of spiritual experiences serve as more effective moderators than total spiritual experiences. A sample of 161 (mean age = 45.6) participants completed the Daily Spiritual Experience Scale (DSES), Beck Depression Inventory-II (BDI-II), Trail Making Test A and B (TMT) and Stroop Color and Word Test (Stroop). Blood samples were collected from these participants to measure inflammatory mediators (IL-6, IL-1a, TNF-a). Principal component analysis was used to identify various types of spiritual experiences. Linear regression analyses were also used. The results found higher BDI-II scores were associated with poorer psychomotor speed and visual scanning, as measured by TMT A ($B = 1.49$, $p = .01$). IL-6 explained a significant amount of variance in this relationship ($B = .24$, $CI\ 95\% [.00, .64]$). IL-6 significantly mediated the relationship between depressive symptoms and performance on the TMT B, a measure of psychomotor speed and mental flexibility ($B = .03$, $CI\ 95\% [.003, .095]$). The component that pertained to direct interaction with the Divine had significantly greater effects on depressive symptoms and performance on TMT A and TMT B. Frequent spiritual experiences among AAs may ameliorate the negative influence of depressive symptoms on cognitive functioning, and each kind of spiritual experience identified as unique to AAs may have its own particular kind of benefit.

COMMUNITY SUPPORT FOR OFFERING SEXUAL HEALTH SERVICES THROUGH SCHOOL BASED HEALTH CLINICS AFTER TWO YEARS OF AWARENESS EFFORTS

Michele J. Moore, PhD¹, Elissa Barr, PhD¹, Kristina Wilson, PhD²¹University of North Florida, Dept of Public Health, Jacksonville, FL;²Department of Health-Duval, Jacksonville, FL

Purpose: This research assessed changes in community support for sexual health services offered through school-based health clinics (SBHCs) over a two year period in a large county in the southeast. This CDC funded partnership project set goals to: 1) implement School-Based Surveillance (Youth Risk Behavior Survey; School Health Profiles) to establish priorities and increase community awareness; 2) implement Exemplary Sexual Health Education in middle and high schools; 3) increase the number of schools that provide and link students to Sexual Health Services; 4) implement Safe and Supportive Environment initiatives supporting LGBTQ students; and 5) educate decision-makers to support policies to implement these efforts. A number of initiatives were undertaken in the interim between surveys to increase community awareness of local youth sexual risk behaviors and effectiveness of sexuality education and health services, as well as adding sexual health services to 6 SBHCs. Documentation of community opinions was sought to help inform administrators in their decisions to support policies impacting youth sexual health.

Methods: The instrument was developed after review of existing surveys on support for sexuality education and health services in the schools. An expert panel reviewed the survey for readability, content and face validity. Random-digit-dialing was used to administer the survey in year 1 (T1, N=311) and year 3 (T2, N=329). Frequencies for variables on support for sexual health services and demographics were run using SPSS. Chi-square tests were used to examine differences in support from T1 to (T2).

Results: The sample had slightly more females (T1=54%, T2=55%); was mostly white (T1&T2=60%), followed by African American (T1=30%, T2=25%); and had many with at least a college degree (T1=39%, T2=44%). Most participants were supportive of offering sexual health services at both middle schools (MS) and high schools (HS) at both T1 and T2: testing for STIs/HIV (MS: T1=61%, T2=67%; HS: T1=77%, T2=85%), treatment for STIs/HIV (MS: T1=60%, T2=67%; HS: T1=75%, T2=81%), pregnancy testing (MS: T2=58%; HS: T2=71%), and provision of condoms (MS: T1=44%, T2=52%; HS: T1=63%, T2=69%). Analyses showed a significant increase in support from T1 to T2 only for STDs/HIV testing in high school.

Conclusions: Results demonstrate strong community support for offering sexual health services through SBHCs to both middle and high school students. Although there was only a significant increase in support for one of the services, increased support for all services was documented. Discussion will focus on initiatives to increase awareness of local youth sexual risk behaviors and strategies to reduce them, as well as plans to continue to increase community support for offering sexual health services through SBHCs.

DIFFERENTIAL SEXUAL RISK BEHAVIOR ASSOCIATED WITH MARIJUANA AND ALCOHOL AMONG HIV-POSITIVE YOUNG MEN WHO HAVE SEX WITH MEN

Douglas Bruce, PhD¹, Shannon Bowers, IL¹, Alida Bouris, PhD², Daniel Reirden, MD³, John Schneider, MD⁴¹DePaul University, Chicago, IL; ²University of Chicago, Chicago, IL; ³Childrens Hospital of Colorado, Aurora, CO; ⁴University of Chicago Medicine, Chicago, IL

Background: Substance use has been linked generally to sexual risk behavior among young men who have sex with men (YMSM), including YMSM living with HIV/AIDS (HIV+YMSM). Substance use has been conceptualized as a mechanism for increased sexual risk behavior among YMSM in a number of ways, including sensation seeking, coping with stressors, or reducing motivation for protective behavior, yet results have been mixed in assessing effects of substance use on sexual risk due to a range of measurement techniques across studies. While research has linked methamphetamine to event-level sexual risk behavior among HIV+ MSM, few studies have explored the sexual contexts of substance use among HIV+ YMSM with the two most prevalent substances used, alcohol and marijuana.

Methods: We conducted semi-structured interviews with 30 HIV+ YMSM (mean age=23.1, SD=1.1) recruited from adolescent HIV clinics and service sites in Denver and Chicago. Participants were asked open-ended questions regarding their marijuana and alcohol use, and use connected to their sexuality and sexual contexts. Interviews were audio-recorded and transcribed. A diverse team of analysts developed and iteratively refined a coding framework. Transcripts were coded using relevant categories and sub-categories until convergent coding was achieved across the data.

Results: Participants described marijuana use in sexual contexts in terms of arousal, relaxation, enhancement, and creativity, while alcohol use in sexual contexts was characterized by arousal, disinhibition, and impairment. Some participants considered marijuana use to be protective through cognitively imparting increased focus on risk, while alcohol use was described more commonly as risk producing through impairment and moderation of intention to reduce risk behavior.

Discussion: Alcohol and marijuana use were both characterized as agents of arousal in sexual contexts by the participants in this study. By contrast, intentions to reduce risk were maintained, and in some cases, enhanced by marijuana use, while intentions to reduce risk appear to be impaired by alcohol use. Event-level risk measurement is needed to advance understanding of substance use, sexual behavior and risk reduction strategies in this population.

HOW EARLY PARENTAL SEX DISCUSSIONS MODERATE THE INFLUENCE OF INTENTIONS ON SEX INITIATION IN DIVERSE ADOLESCENTS

Patricia Cabral, M.A.¹, Jan Wallander, PhD²¹University of California, Merced, Merced, CA; ²University of California, Merced, MERCED, CA

Objective: Parents are an important source of sexual health information for all youth. Moreover, parent-child communication about sex is associated with youth's sexual intentions, which is an important predictor of an adolescent's sexual behaviors. Yet, associations between parental communication about sex and adolescents' intentions and sex initiation may differ across race/ethnicity. Thus, we examined associations between parental communication about sex and intentions across Black, Latino, and White adolescents. Furthermore, we examined how parental communication moderated the influence of intentions on sex initiation across racial/ethnic groups.

Methods: Using data from 4,824 (50.7% female) Black (36.4%), Latino (37.6%), and White (26%) adolescent participants from the *Healthy Passages™* study, we measured racial/ethnic differences in associations between parental communication about sex at 5th grade, intentions to have sex before the end of high school at 7th grade, and sex initiation by 10th grade.

Results: A significantly greater percentage of Latino adolescents reported never discussing sex with their parents at 5th grade (54.5%), followed by Black adolescents (27.3%), compared to White adolescents (18.2%); $\chi^2 = 27.58, p < .001$. Also, a significantly greater proportion of Latino (43.8%) and Black (34.5%) adolescents reported higher intentions to have sex before the end of high school at 7th grade in comparison to White adolescents (21.7%); $\chi^2 = 174.62, p < .001$. Moreover, higher intentions predicted a greater likelihood of sex initiation by 10th grade among all groups (Black OR = 1.29, 95% CI = [1.08, 1.53], $p < .01$; Latino OR = 1.60, 95% CI = [1.28, 1.99], $p < .001$; White OR = 2.21, 95% CI = [1.50, 3.26], $p < .001$). Yet, early parental communication about sex moderated this association only among Black (OR = 1.09, 95% CI = [1.02, 1.16], $p < .05$) adolescents.

Conclusions: The role of early parental communication about sex on subsequent intentions and sex initiation is nuanced across racial/ethnic groups. Findings of this study may provide guidance for early parent-focused intervention efforts in reducing early sex initiation.

BODY IMAGE AND CONDOMLESS ANAL SEX AMONG YOUNG LATINO SEXUAL MINORITY MEN

John P. Brady, MS¹, Kelsey A. Nogg, B.A.², Kaitlin N. Rozzell, BS², Aaron Blashill, Ph.D.²¹San Diego State University, La Jolla, CA; ²San Diego State University, San Diego, CA

Objective: The association of body image and sexual risk behaviors among sexual minority men (SMM; e.g., gay, bisexual) has produced mixed results. However, body image is a multidimensional construct and it is possible that mixed findings were due to a lack of investigation into moderation effects. The current study aims to investigate the roles of appearance orientation (APPOR; cognitive/behavioral investment in appearance) and the potential moderating effects of appearance evaluation (APPEV; satisfaction of one's own appearance) in predicting condomless anal sex (CAS) among Latino SMM.

Methods: Participants were 151 Latino SMM recruited from the San Diego area who were HIV negative or were unaware of their HIV status ($M = 24.18$ years old, $SD = 3.19$). Participants completed a self-report questionnaire online in either English or Spanish, which included the MBSRQ-AS APPOR and APPEV subscales as well as items on sexual behaviors. A binary variable was created from a free response item in which participants reported the number of condomless anal sex partners they had over the previous 3 months, with 0 = "0 CAS partners" and 1 = "1 or more CAS partners"

Results: A binary logistic regression was conducted with APPOR, APPEV, and their interaction term entered as predictor variables, and the binary CAS variable entered as the criterion. APPOR was positively associated with CAS (Odds Ratio; $OR = 3.06$ [95% CI: 1.58, 8.17, $SE = 0.34, p < 0.01$). A significant interaction was also found ($OR = 0.17$ [95% CI: .04, .68, $SE = 0.71, p = 0.01$). To probe the significant interaction, simple slope analyses were performed at the mean \pm 1 SD values of APPEV. Results indicated that the strongest association between APPOR and CAS was found among men 1 SD below the mean on APPEV ($OR = 11.47$ [95% CI: 2.83, 46.53, $SE = 0.71, p < .001$).

Conclusions: Sexual minority Latino men who are highly invested in their appearance are at greater odds of engaging in CAS; however, this association becomes dramatically stronger in the context of men who are dissatisfied with their appearance. It is possible that these men seek out sexual partners as a means to redress concerns that they are unattractive, and forgo condom negotiating given the potential anxiety that may be associated with negative evaluations from their sexual partners. Thus, being highly invested in, and being dissatisfied with, one's appearance may be a significant risk factor for STI and HIV/AIDS risk in this population.

ETHNICITY MODERATES EFFECTS OF MOTIVATIONAL INTERVIEWING TARGETING RISKY SEXUAL BEHAVIOR AMONG AT-RISK ADOLESCENT FEMALES

Daniel Delaney, MA Clinical Psychology¹, Shayna Bassett, PhD², Mary Clair-Michaud, PhD³, Molly Magill, PhD⁴, Jennifer Clarke, MD⁵, Rebecca Lebeau, PhD⁶, Melanie Gold, DO, FAAP⁷, L.A.R. Stein, PhD²

¹University of Rhode Island, Providence, RI; ²University of Rhode Island, Kingston, RI; ³Rhode Island Training School, Cranston, RI; ⁴Center for Alcohol and Addiction Studies, Brown University, Providence, RI; ⁵Center for Primary Care and Prevention, Memorial Hospital of RI, Pawtucket, RI; ⁶Executive Office of Health and Human Services, Cranston, RI; ⁷Department of Pediatrics, Columbia University Medical Center, New York, NY

Motivational Interviewing (MI) has been shown to produce more optimal client outcomes across a variety of health-related behaviors. Although some studies suggest MI is more successful with ethnic minority groups, the research remains mixed. The current study investigated the impact of ethnicity on an MI intervention aimed at reducing risky sexual behavior among adolescent females. Participants (N=272) recruited from social service agencies were randomly assigned to receive two sessions of a computer-assisted motivational intervention (CAMI) or didactic educational counseling (DEC). Baseline assessments were conducted prior to the first treatment session with follow-up assessments collected at 3-, 6-, and 9-months. Participants were 17 years old on average and 44% identified as Hispanic. Generalized estimating equations (GEE) were used to model change by intervention group over time, with ethnicity as a moderator (3-way interaction), in percent of times participants reported unprotected sex with main partners and other partners. Results indicated a significant 3-way interaction effect for percent of unprotected sex for both main partners ($\beta = -.17$, $SE = .08$, $p = .027$) and other partners ($\beta = .08$, $SE = .04$, $p = .025$). Hispanic participants showed enhanced treatment effects over time, with CAMI showing a slight advantage over DEC among Hispanic participants. An overall significant main effect of ethnicity was also found on percent of unprotected sex for main partners ($\beta = -.25$, $SE = .11$, $p = .026$) and trend toward statistical significance for other partners ($\beta = -.09$, $SE = .05$, $p = .066$). Regardless of treatment condition, Hispanic participants had less unprotected sex compared to non-Hispanic youth with other partners and main partners across the 3, 6, and 9-month follow-ups. Results suggest interventions aimed at reducing risky sexual behavior are differentially efficacious for Hispanic at-risk adolescent females, with MI producing more sustained effects. These findings have important implications for adolescent health and ethnic health disparities.

INTERNAL PREDICTORS OF SILENCING THE SELF IN BLACK WOMEN

Robin Hardin, M.A., Idia B. Thurston, Doctorate, Caroline Kaufman, B.A., Courtney Maclin-Akinyemi, M.S., Jessica Mandell, B.A., Danielle Porter, High School Diploma

University of Memphis, Memphis, TN

Background: Silencing the self (i.e., putting the needs and wants of a romantic partner before one's own needs) has been associated with detrimental consequences, such as engagement in risky sexual behavior among Black women. However, less is known about factors that contribute to higher rates of silencing the self. In previous research, self-esteem, gender role beliefs, and gender ratio imbalance beliefs and behaviors (belief that the ratio of men to women in a particular setting is unequal and subsequent behaviors engaged in due to these beliefs) have been associated with risky sexual behavior. Thus, the current study investigated whether these variables were associated with silencing the self among Black female college students.

Methods: Participants included 99 female undergraduate students enrolled at a Mid-South University who self-identified as Black and heterosexual. Participants were 18–49 years old with a mean age of 22.93 ($SD = 6.21$). Regarding current relationship status, 36 (36.4%) were single, 33 (33.3%) were in a long-term relationship, 13 (13.1%) were married/living with a partner, 11 (11.1%) were in a short-term dating relationship with one person, 5 (5.1%) were dating a few different people, and 1 (1.0%) was separated. Participants completed demographics questions and the Silencing the Self Scale, Rosenberg Self-Esteem Scale, Gender Role Beliefs Scale, and Gender Ratio Imbalance Beliefs and Behaviors Scale (i.e., GRIBBS). A multiple linear regression was conducted to predict silencing the self from self-esteem, gender role beliefs, and gender ratio imbalance beliefs and behaviors.

Results: The overall regression model was significant ($F(3,95) = 17.97$, $p < .001$, $Adj. R^2 = .34$) with higher self-esteem ($B = -1.05$, $SE = .29$, $p < .001$) and GRIBBS ($B = .57$, $SE = .16$, $p = .001$) associated with greater self-silencing. Gender role beliefs was not a significant predictor of silencing the self in this sample.

Discussion: Findings suggest that Black women who believe there is an imbalance of available men to women in their environment and women who have lower self-esteem are more likely to silence themselves in relationships. Given known associations between silencing the self and risky sexual behaviors, these findings suggest a novel avenue for tailored interventions for Black women. Future longitudinal studies should explore various mechanisms by which self-silencing may lead to increased risk behavior among Black college women.

LONELINESS MEDIATES THE RELATIONSHIP BETWEEN PAIN DURING INTERCOURSE AND DEPRESSIVE SYMPTOMS AMONG YOUNG WOMEN

Madison E. Stout, B.S.¹, Samantha M. Meints, Ph.D.², Adam T. Hirsh, PhD³¹Oklahoma State University, Stillwater, OK; ²Brigham and Women's Hospital, Winthrop, MA; ³Indiana University - Purdue University Indianapolis, Indianapolis, IN

Dyspareunia, or pain during intercourse, affects 12 to 44% of women. Previous research suggests that women who experience pain during intercourse also experience higher rates of depressive symptoms, and that loneliness is one factor that might contribute to this relationship. We hypothesized that women who experience more severe and interfering pain during intercourse would report higher rates of loneliness and higher rates of depressive symptoms. Further, we hypothesized that loneliness would mediate the relationship between pain during intercourse and depressive symptoms. 104 female participants (85.6% white, 74.03% partnered, 20.9 [3.01] years old) completed an online survey including a demographic questionnaire, the 10-item PROMIS Vaginal Discomfort Measure, the 6-item PROMIS Depression Measure, and the 20-item Revised UCLA Loneliness Scale. Pearson correlations and a bootstrapped mediation analysis were conducted to elucidate the relationships among pain during intercourse, loneliness, and depressive symptoms. Pain during intercourse, loneliness, and depressive symptoms were all significantly correlated ($p < 0.5$). Results of the mediation analysis indicated that loneliness was a significant mediator of the relationship between pain during intercourse and depressive symptoms (indirect effect = 0.077; 95% CI = 0.05 to 0.19). After accounting for loneliness, pain during intercourse was not significantly related to depressive symptoms, suggesting that loneliness fully mediated the relationship between pain during intercourse and depressive symptoms. These findings are consistent with previous studies highlighting that pain during intercourse is related to depressive symptoms. The current study adds to that literature and suggests that more frequent and severe pain during intercourse leads to more loneliness, which then leads to increased depressive symptoms. Prior studies have found that women frequently conceal their pain from partners, friends, and physicians, which might be one explanation for the current results. This line of work has important implications for clinicians, as loneliness might be an important target for treatment in women who experience pain during intercourse and depressive symptoms.

MOTIVATIONAL INTERVIEWING TO REDUCE RISKY SEXUAL BEHAVIORS AMONG AT-RISK FEMALE ADOLESCENTS: A RANDOMIZED CONTROLLED TRIAL

Amy M. Moore, MS

University of Rhode Island, Kingston, RI

Background: At-risk female adolescents are disproportionately impacted by sexually transmitted infections and unplanned pregnancies. Therefore, effective interventions targeting risky sexual behaviors associated with these adverse health outcomes are essential. The current study examined the effectiveness of a computer-assisted motivational intervention (CAMI) on reducing risky sexual behaviors in at-risk female adolescents.

Methods: Participants (N=272) were recruited from social service agencies and randomly assigned to receive two sessions of CAMI or didactic educational counseling (DEC). On average, participants were 16.9 years old (SD = 1.7), 34.9% identified as White, 33.8% as Multiracial, 21.3% as Black, and 9.9% as other. Assessments were collected at baseline, 3, 6, and 9 months to assess sexual partners, condom use, and substance use during sex. Generalized estimating equations (GEE) modeled change by group over time for sex without a condom while using substances.

Results: A significant treatment by time effect was found for all partners (OR = .51, $p = .017$) and main partners (OR = .55, $p = .048$) for sex without a condom while using substances. Compared to DEC, participants who received CAMI were less likely to report sex without a condom while using substances with all partners and main partners, and this effect held across 3, 6 and 9 month follow-ups. Further, participants who received DEC reported an increase in sex without a condom while using substances with all partners and main partners at 6 and 9 month follow-ups. No significant effects were found for sex without a condom while using substances with other partners.

Conclusions: Our results indicate that CAMI reduces risky sexual behaviors in at-risk female adolescents. Given that consistent condom use is critical to the health of sexually active adolescents, CAMI could play an important role in risk reduction.

OUT OF SYNC: SOCIAL JETLAG AND SEXUAL HEALTH BEHAVIORS AMONG GAY AND BISEXUAL MEN

Brett M. Millar, PhD¹, Jeffrey T. Parsons, PhD²¹Graduate Center CUNY, New York, NY; ²Hunter College of the City University of New York (CUNY), New York, NY

Background: Social jetlag refers to the mismatch between one's chronotype (being an "early bird" vs. a "night owl") and the timing of activities—and typically, evening types experience worse outcomes, particularly in outcomes that require "being at one's peak" during the daytime (e.g., school, work, fitness). However, research has not yet considered whether sex is an activity that commonly occurs at night, and whether morning types may thus experience the difficulties with self-regulation at night that evening types often experience during the day. We explored mental and sexual health among 1113 gay and bisexual men (GBM) and the mismatch between chronotype and times of day or night when sex with casual partners occurs.

Method: We surveyed 1113 HIV-negative GBM in a national cohort study on depression, social anxiety, emotion dysregulation, sexual compulsivity, sexual transmission risk, time of most recent anal sex (with and without condoms) with a casual partner, and their usual time of feeling tired.

Results: The sample had a mean age of 42, although later chronotype was associated with younger age. Adjusting for age, having an evening chronotype was associated with greater depression (Wald $\chi^2(2)=38.9$, $p<.001$, social anxiety (Wald $\chi^2(2)=15.9$, $p<.001$), and emotion dysregulation (Wald $\chi^2(2)=24.7$, $p<.001$)—but no differences emerged on sexual compulsivity nor on odds of recent HIV risk, suggesting that evening types were not experiencing greater distress regarding sex than morning types. Of the 344 men with recent events, 49.4% reported that last sex without condoms occurred after 9pm. While evening types were more likely to report later times of sex, many morning types also reported times later than 9pm (37%). Sex without condoms tended to occur later than sex with condoms, especially among the younger men (18–29), as 52.1% reported that their last condomless sex occurred later than their usual time of feeling tired (vs. 36.5% for sex with condoms).

Conclusions: It is proposed that these findings of no chronotype differences on sexual distress or risk-taking—even though differences were observed in depression and other mental health outcomes—may be partly explained by our finding that sex was, for most participants, a night-time activity (when morning types are expected to be experiencing circadian misalignment). The finding that GBM commonly reported late-night times for sex—especially sex without condoms, among the younger men—is relevant for the consideration of social jetlag, as these men are commonly making sexual health decisions late at night. These findings have implication for HIV/STI prevention and health behavior change, as well chronobiology and sleep research.

PSYCHOSOCIAL FACTORS, PHYSICAL ACTIVITY, AND RISKY SEXUAL BEHAVIOR AMONG MSM AND TRANSGENDER WOMEN IN THE US: A CLUSTER ANALYSIS

Sanaz Nosrat, MA, CSCS¹, Nicholas J. SantaBarbara, MS, CSCS², James W. Whitworth, MA², Mark E. Louie, Ed.M.¹, Joseph Ciccolo, PhD¹¹Teachers College, Columbia University, New York, NY; ²Teachers College Columbia University, New York, NY

Background: With persistently high rates of new HIV infection among men who have sex with men (MSM) and transgender women, it is important to identify certain subgroups at higher risk for contracting HIV within this population. Poor psychosocial health (e.g., psychological distress, poor body image, high impulsivity) is known to be associated with an increased likelihood of risky sexual behavior, such as condomless receptive anal intercourse (RAI) and use of drugs/alcohol with sex. In contrast, regular physical activity (PA) is known to have positive effects on these psychosocial factors, yet the role it may play among these different factors with respect to risky sexual behavior remains unclear.

Purpose: To identify expected at-risk clusters (i.e., based on psychological distress, body image, impulsivity) while also including leisure-time PA, and explore whether or not the identified clusters differ in risky sexual behavior.

Methods: Baseline data from a longitudinal internet survey with non-PrEP-using MSM and transgender women from all major US regions were used. A total of 263 MSM including 14 transgender women completed the Godin Leisure Time Exercise Questionnaire (GLTEQ), Kessler Psychological Distress Scale (K10), Body Area Satisfaction Scale (BASS), Barratt Impulsiveness Scale (BIS-15), and questionnaires assessing drugs/alcohol use with sex, and frequency of condom use with RAI in the past month. Participants were ages 18–70 ($M_{age}=39.9 \pm 14.2$), mostly White (66.9%), and self-identified as gay (53.6%). Cluster analysis was conducted using Euclidean distance and K means. Clusters were then compared using Chi square tests and ANOVAs.

Results: Cluster analysis produced two distinct clusters: A ($N=135$; $M_{K10}=17.2 \pm 5.8$, $M_{BIS-15}=26.6 \pm 5.3$, $M_{BASS}=3.5 \pm 7$, $Median_{GLTEQ}=42$), and B ($N=128$; $M_{K10}=29.3 \pm 7.9$, $M_{BIS-15}=35.1 \pm 6.9$, $M_{BASS}=2.8 \pm 7$, $Median_{GLTEQ}=25$). Cluster B had more transgender women ($X^2=5.2$, $p=.02$), was more likely to engage in condomless RAI ($X^2=12.4$, $p<.001$), and more likely to use drugs/alcohol with sex ($X^2=9.4$, $p=.002$) in the past month. Clusters were not significantly different with respect to age, sexual orientation, and racial group.

Conclusions: These results indicate that within a national sample of non-PrEP-using MSM and transgender women, those with poor psychosocial health, high impulsivity, and lower levels of leisure-time PA engage more in risky sexual behavior and therefore are at greater risk for HIV infection. Future longitudinal research is needed to explore the relationship between levels of PA, psychosocial health, and risky sexual behavior.

SEXUAL HEALTH CARE EXPERIENCES AND NEEDS AMONG A NATIONAL SAMPLE OF TRANSGENDER MEN AND NON-BINARY INDIVIDUALS

Augustus Klein, MSW¹, Sarit A. Golub, PhD, MPH²¹Hunter College, Brooklyn, NY; ²Hunter College/Graduate Center, City University of New York, New York, NY

Background: Transmasculine (TM)-individuals have received scant attention in research and often don't receive adequate sexual health care. This may be due, in part, to biased assumptions about sexual behavior among TM, including that they are not at risk for HIV. This NIH funded national study of TM sexual health needs and preferences (led by a majority trans-identified research team) was designed to address this gap and improve sexual health care provided to TM.

Methods: From May – July 2017, 1,852 TM-individuals representing all 50 states, participated in a 45-minute online survey. Two-thirds of participants (67%) were under 30, 30% were TM of color, and 43% made under \$25k/year. Participants answered a series of questions about their sexual activity/behavior, sexual health care experiences and needs, and preferred language for provider conversations regarding their overall sexual health.

Results: Over 74% had engaged in sexual activity within the past 6 months (46% with ciswomen; 37% with cismen; 21% with transmen; 12% with transwomen). Among sexually active participants, 33% (n = 449) reported frontal receptive sex and 15% (n = 203) reported anal receptive sex with a partner with a penis. However, only 25% reported having a sexual history taken within the past 6 months; and 51% do not feel comfortable talking with a provider about their sexual health. As an opener to sexual health conversations, 66% stated it is very important for a provider ask if they are comfortable discussing their sexual health. In contrast to current wisdom about sexual history taking, the majority of participants said they want providers to use medical/anatomical terms. However, 63% of participants stated that a provider had *never* asked for preferred words to describe their body/genitalia. Lastly, participants prefer providers to ask gender neutral questions when taking a sexual history, e.g., 53% preferred "Are you sexually active?" (less than 2% preferred the commonly used question: "Do you have sex with men, women or both?").
